## **Acknowledgments**

My deepest gratitude goes firstly to my supervisor Prof. Dr. Christian Robl who excellently guided me during my study and also for his motivation, immense Knowledge and patience. His continuous support always convinced me to do my best in all of time of research and finally writing this thesis. Besides my supervisor, my appreciation also extends to my research group and my laboratory colleagues and I am so much grateful for their assistance and suggestion.

I would specially like to thank Mrs. Antje Wermann and Mrs. Christina Apfel for their generous supports. Actually I have learnt very much from them. They helped me to improve my german language skill and many other things. I am also thankful them for special instrumental analysis which is relevant to my work such as TG and XRD analysis.

My sincere thanks also go to Prof. Dr. Wolfgang Weigand because of his kind support during my Ph.D study, in particular for my scholarship (DAAD) extension.

The financial assistance from DAAD (Deutscher akademischer Austauschdienst) in the form of scholarship as research fellowship is gratefully acknowledged.

Last but not the least, I would like to thank my family: my parents, my best friends and to my brother and my little son for their love and encouragements. They supported spiritually me throughout writing this thesis and my life in general to pursue my interests. This work is simply impossible without them.

# Chapter 1

## 1. General Introduction

### 1.1. Definition of Coordination polymer

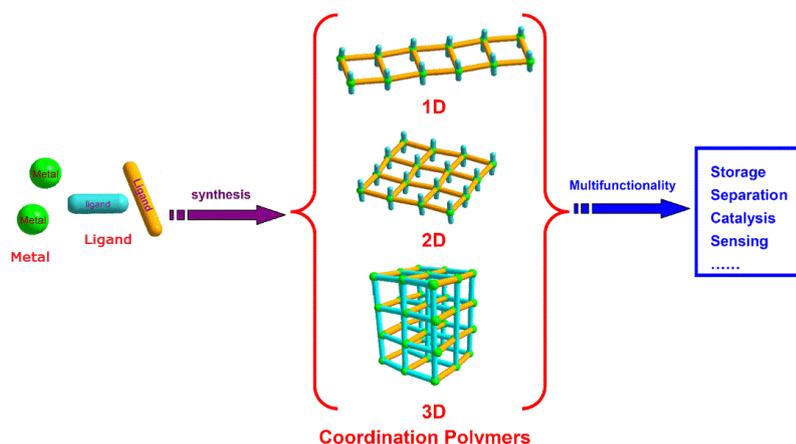

Coordination polymers (CPs) are defined as large molecules, or macromolecules, composed of several repeated metal ions and organic ligands as fundamental subunits which are linked by covalent bonds and other weak chemical bonds [1]. The research area of coordination compounds (also known as metal-organic framework (MOFs) as porous coordination polymers) has turned out as a great research area over the past two decades. Moreover, it also takes significant attention to the realm of various applications of molecular magnetism, photoluminescence, catalysis, non linear optics (NLO) materials, spin-crossover materials, micro magnets, medical applications like drug delivery and implantable devices, gas storage/adsorption and materials science [2–11]. Actually, special interest in design of coordination polymers is the search for their interesting properties and applications. The one of an early example is coordination polymers of formula  $[M(\text{Pc})\text{X}]_{\infty}$  ( $M=\text{Si, Ge; X= O}$ ), ( $\text{Pc}=\text{Phthalocyanine}$ ) which was first synthesized in the early 1960s by Joyner and Kenney [12]. Similar polymeric structures of  $M= \text{Al, Ga, Cr; X= F}$  [12] and compound  $[\text{Ga}(\text{Pc})\text{F}]_{\infty}$  had also been reported. The electrical conductivity of these coordination polymers was vastly investigated by Kenney and co-workers [12].

The luminescent effect of polymeric networks has attracted much interest because of their potential applications for photoelectronic devices or as fluorescent sensors and probes. Indeed, the coordination polymers often expose more stability (thermal- and solvent-resistant) than the pure organic ligands and may affect the emission wavelength of these organic molecules [13–16]. The further example, can be third-order non linear optical materials (NLO) in the realms of CPs and MOFs which are currently interest of many research groups since they can be used for a number of photonic applications, for example, optical signal processing, optical communication, optical computing, electrooptic modulation, optical limiting effect and etc [17]. In principle, in comparison with traditional NLO materials, the metal atom in coordination polymers introduces more sublevels into the energy hierarchy, which makes it possible to take place more allowed electronic transition, hence a larger NLO effect could be observed [18–20]. In the perspective of magnetic effect, many coordination polymers and metal-organic frameworks of transition metals have been reported in past two

decades [21–28]. For instance, the magnetic properties of lanthanide coordination polymers have been studied because many Ln(III) ions, such as Tb(III), Dy(III) or Ho(III) exhibit the strong unquenched orbital angular momentum that results in magnetic anisotropy, originating from unpaired  $4f$  electrons. Therefore, lanthanide ions have become good candidates for synthesizing single-molecule magnets (SMM) and single-chain magnets (SCM) [29–32]. Besides, many interesting properties of coordination polymers, it is worth to note that the metal organic frameworks (MOFs) have emerged as a strong potential adsorbent and being as catalysts due to their porous nature, easily tunable and tailored structures and chemical functionality which ease diffusion and interfacial contact between active sites and reagents [33–35]. As a matter of interest, one of daily usage of coordination polymer is a cathode for sodium–ion batteries. Prussian blue (PB) mesocrystals with sodium ions as the alkaline metal have been synthesized and used as cathode materials in sodium–ion batteries. The mesocrystalline structure provided PB with very different phase change behavior and electrochemical performance in contrary to PB single-crystals in cyclic voltammograms and galvanostatic discharge/charge voltage profiles of PB/Na half-cells [36]. Besides, many useful applications of coordination polymers and metal organic frameworks, it is worthy to describe the coordination polymers (CPs) and metal organic frameworks (MOFs) briefly.

The term “coordination polymer” was first used by J. C. Bailar in 1964, since he found the similarities between organic polymers with inorganic coordination compounds which can be considered as polymeric species. In comparison, he made the rules for the architecture and the required properties of new species which involved metal ions and organic ligands [1]. In addition a certain number of principal differences between CPs and polymers must be considered in order to avoid confusion: i) despite polymers usually exhibits a certain size distribution due to variable chain lengths, MOFs and CPs are usually characterized in the solid state and they possess infinite metal-ligand assemblies which extend into one-, two- or three- dimensional networks (Figure1.1) [37]; ii) a polymer is combined by many small molecules known as monomer units via covalent bonds, while a coordination polymer network is generally based on coordinative bonds. Coordinative bonds are formed into equilibrium which may be more on the side of the products and less of the starting materials. For both, weak intermolecular interactions may affect on the overall arrangement and influence the properties; iii) as a consequence, in solution, polymers may be identified by their chain length, while for MOFs or CPs the identity of polymeric structure depends on various factors. For instance, the solvent, the temperature, pH, the pressure and etc., i.e., which influence stability; iv) The polymers may own properties which cause elastomers, duroplasts,

or thermoplasts due to the connection of an immense number of monomers while the coordination polymer networks are usually in solid state and crystalline, hence they are well-ordered in the long range. The latter leads to the fact that the structure of MOFs and CPs can be usually detected. Therefore, the structure can be shown by single crystal X-ray structural analysis technique [38].

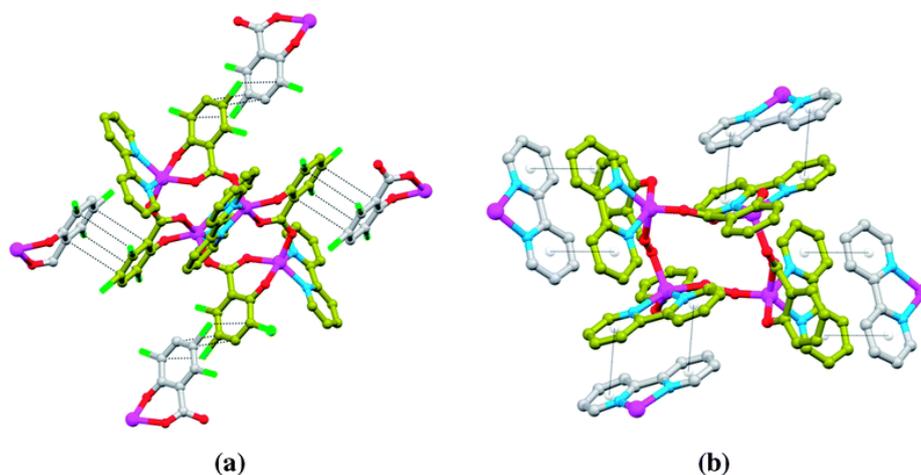

**Figure 1.1:** Schematic view of synthetic process of coordination polymers from starting materials [37]

Furthermore, there is another issue that makes CPs different from organic polymers. They are highly crystalline and cannot be processed like organic counterparts. The metal-ligand bonds can be easily broken due to the solvation, so the species existing in solution does not need be true monomers or oligomers.

## 1.2. Chemical interactions in coordination polymers

In principle, coordination polymers and metal-organic frameworks are generally defined as compounds containing backbones constructed by metal ions as “nodes” and organic ligands as linkers into an infinite array. This infinite net must be defined by coordination bonds. Weaker noncovalent interactions like hydrogen bonds or  $\pi$ - $\pi$  stacking play significant roles for packing of chains, two dimension net and three dimensions frameworks [39–40]. However, the multidimensional supramolecular structures of metal complexes which are merely constructed by hydrogen bonds are not considered as coordination polymer [41–43]. Furthermore, metallo-macrocycles, metallosupramolecular cubes, cages or capsules, [44–45], metallocatenanes, [46] coordination clusters [47] or helicates [48] which do not expose infinite metal-ligand assemblies, hence there are not considered as coordination polymers.

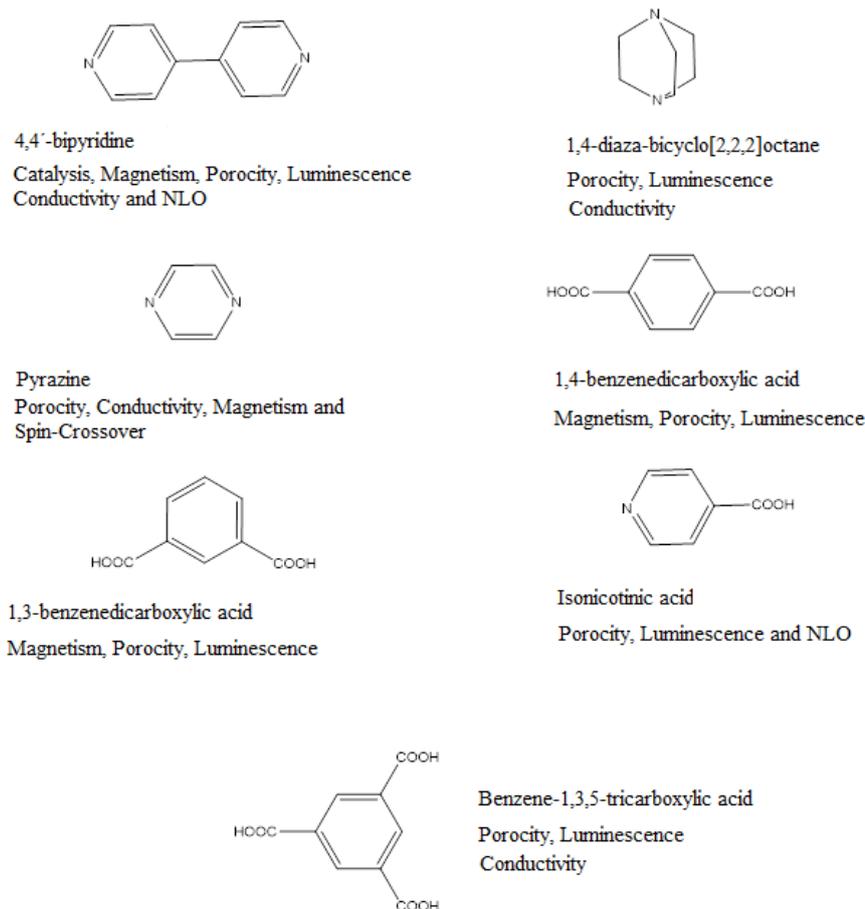

Coordination bonds are the donation of a lone electron pair of the ligand (Lewis base) to the metal cation (Lewis acid) and electrostatic attractions between the positively charged metal ion and a negatively polarized or charged donor atom of the ligand [49]. Weaker interactions also strongly influence the formation of coordination polymers such as hydrogen bond [50–53], metal–metal interaction [54], Metal-aromatic interactions [55] and  $\pi$ – $\pi$  interaction [56–57]. An example of  $\pi$ – $\pi$  stacking interaction illustrated with (Figure 1.2).

**Figure 1.2:** Crystal packing of two different side views of Zn complex and how the tetranuclear zinc complex self-assemble to generate 3D supramolecular framework with pair wise  $\pi$ – $\pi$  stacking [57]

### 1.3. The ligands in coordination polymers

The ligands are used in the construction of coordination polymers act as a bridge between metal ions. This requires usually multidentate ligands with two or more donor atoms, called di-, tri-, tetra- which depends on the number of donor atoms. Special importance is relevant to rigid bridging ligands because they induce a certain steric consequences of the assembly process. The diversity of organic components basically affects on the variety of structural topologies. Moreover, selecting the suitable organic ligands also tunes the interesting physical properties and thus, attains various applications, such as catalysis, luminescence, magnetism, nonlinear optics. Popular ligands are depicted in (Figure 1.3), for constructing coordination polymers with these kinds of properties. As it can be concluded, nitrogen and oxygen donor ligands feature highly in the construction of coordination polymers [58–64].

**Figure 1.3:** Some very famous and capable ligands and their application in the field of coordination polymers and metal-organic frameworks [64]

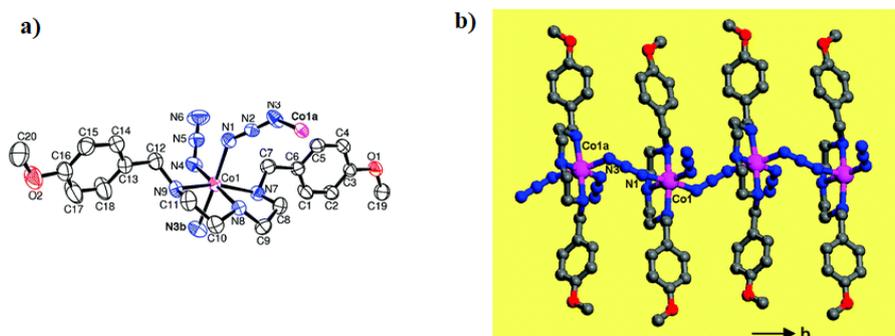

In the majority of coordination polymers, either the O-atoms of anions (carboxylates, nitrates, sulfates, phosphates, phenolates) or the N-atoms of cyanates, cyanides, amines, pyridines engage in the coordination bonds with transition metal ions. Hence, classification of ligands into inorganic and organic molecules can make it easier to investigate the ligand role in construction and properties of coordination polymers.

### 1.3.1. Inorganic Ligands

Divers metal-ligand assemblies can be formed into various inorganic bridging molecules such as halide  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$  or pseudohalide  $\text{N}_3^-$ ,  $\text{CN}^-$ ,  $\text{SCN}^-$ ,  $\text{OCN}^-$ ,  $\text{SeCN}^-$  and other small inorganic species like  $\text{H}_2\text{O}$ ,  $\text{O}^{2-}$ ,  $\text{O}_2^{2-}$ ,  $\text{OH}^-$ ,  $\text{S}^{2-}$ ,  $\text{HS}^-$ ,  $\text{Se}^{2-}$ ,  $\text{HSe}^-$ ,  $\text{Te}^{2-}$ ,  $\text{HTe}^-$ ,  $\text{TeS}_3^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{CO}_3^{2-}$ ,  $\text{CO}$  and  $\text{NH}_2^-$ . It is worth mentioning that metal clusters can also act as bridging ligand for construction coordination polymers, like large metal-oxygen clusters of polyoxometalate anions (POMs) which are either connected as guests, templates or counter

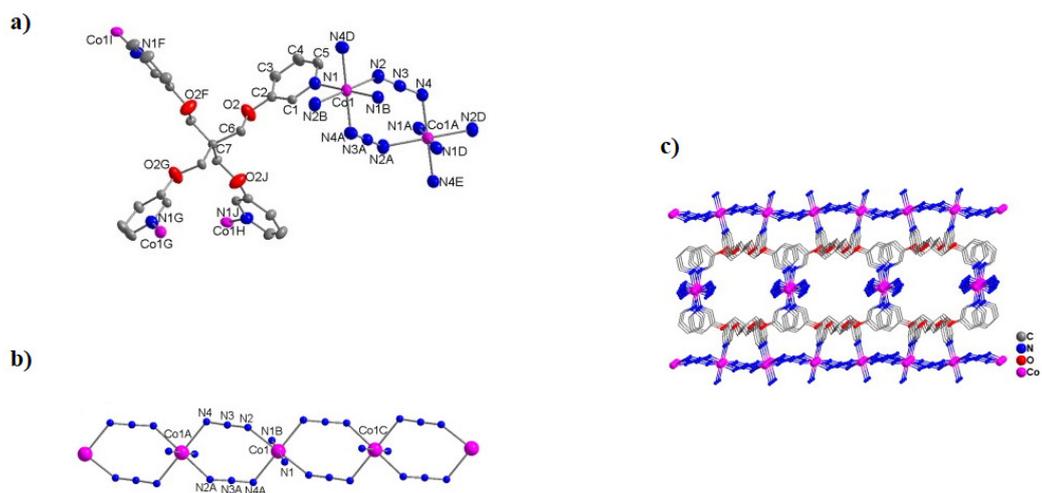

ions through noncovalent interactions (van der Waals interaction, hydrogen-bonding or ionic interactions) with the transition metal and organic moieties or coordinated to metal atoms as inorganic ligands through covalent bonds [65–68].

In between, short bridging pseudohalide ligands such as cyanides and azides have been merely used for construction coordination polymers and metal organic framework of transition metals. One of the very common examples of pseudohalide ligands is azide that exposes a number of various binding modes and has been incorporated into an array of 1D, 2D and 3D coordination polymers (Figure 1.6). As a matter of interest, the type of coordination modes can affect on the magnetic properties of coordination polymers. Normally, the end-to-end (EE) coordination mode gives antiferromagnetic coupling while the end-on (EO) causes ferromagnetic coupling [69]. An example, compound  $[\text{Co}(\text{bmdt})(\text{N}_3)_2] \cdot \text{MeCN} (1 \cdot \text{MeCN})$  [bmdt = *N,N'*-bis(4-methoxybenzyl)diethylenetriamine] exhibits 1D coordination polymer with well-isolated heterochiral chains (Figure 1.4). However, Magnetic data reveal ferromagnetic interactions between  $\text{Co}^{2+}$  ions within a chain mediated by single EE azides, which is very unusual because the EE mode mostly promotes antiferromagnetic coupling [70].

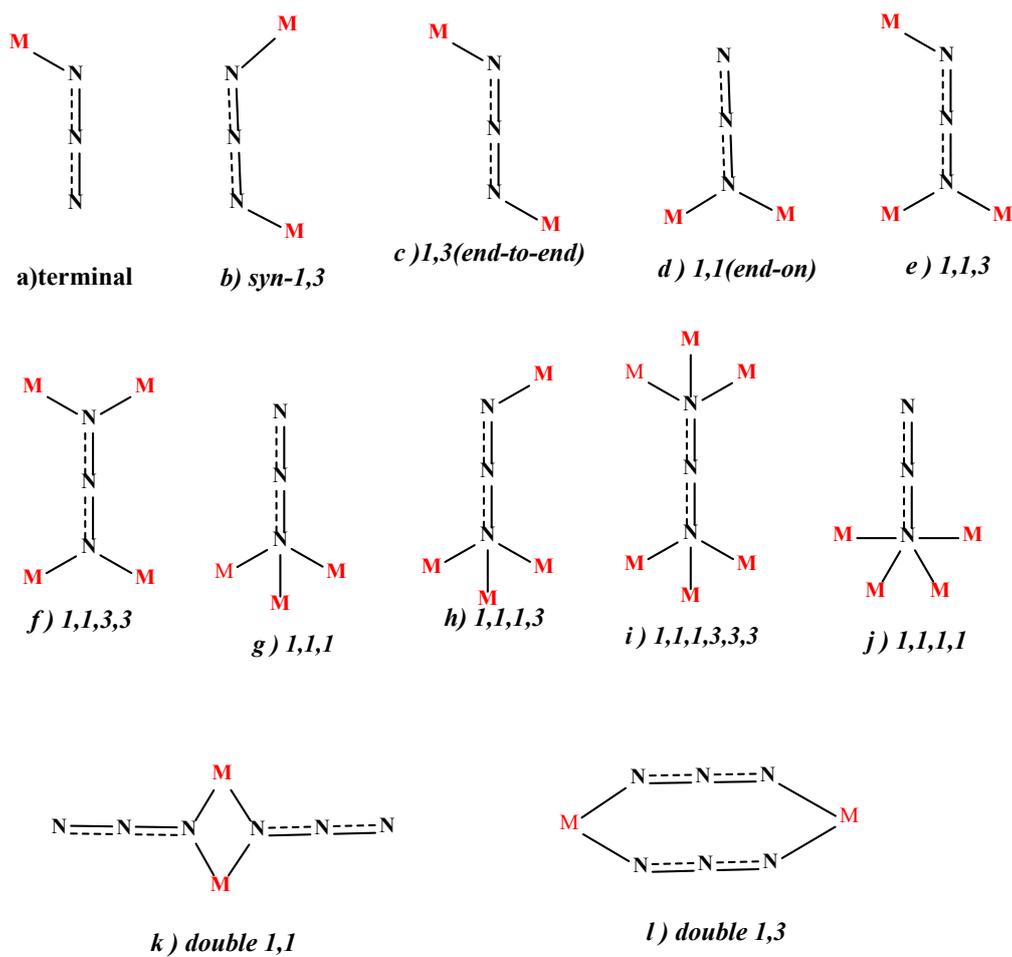

**Figure 1.4** : The material  $[\text{Co}(\text{bmdt})(\text{N}_3)_2] \cdot \text{MeCN} (1 \cdot \text{MeCN})$  shows polymeric chain with EE azide bridging ; **a)** 50% ellipsoid probability and the atom-labeling scheme; **b)** the chain structure running along the *b*-axis [70]

More example of azide EE bridging mode is in compound  $[\text{Co}_2(\text{N}_3)_4(\text{L})]_n \cdot 4n\text{H}_2\text{O}$  (L = tetrakis(3-pyridyloxymethylene) methane), the  $\text{Co}^{2+}$  chains are formed by double end-to-end (EE) azide bridges and are further linked by the tetrapyridyl ligands into a 3D network (Figure 1.5). Moreover, EE azide bridges transmit antiferromagnetic interactions along the chains within this compound [71].

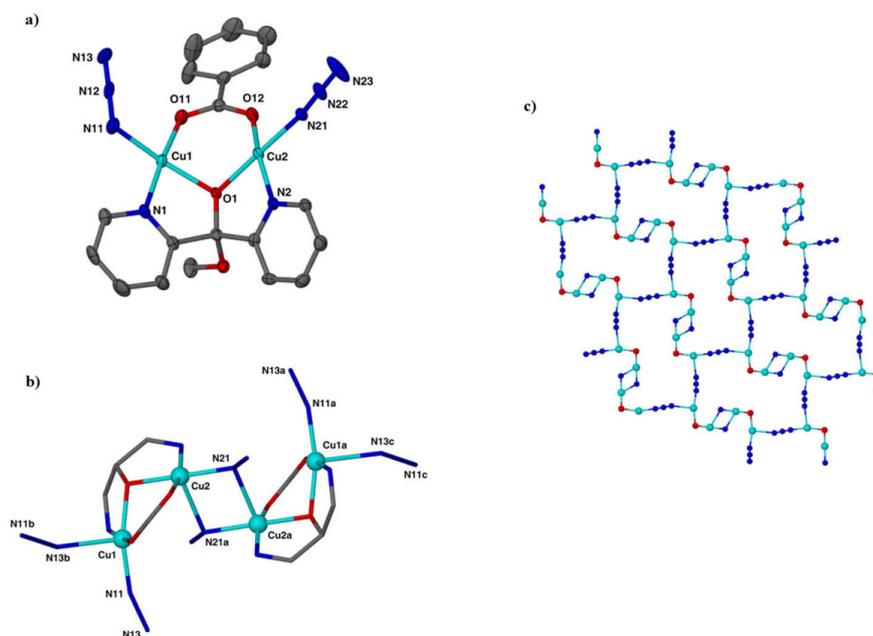

**Figure 1.5:** a) coordination environment around cobalt ions and the ligands in cobalt coordination polymer ; b) the chain along the  $c$ -axis in this compound ; c) 3D network is formed by bridging behavior of tetrapyrridyl ligands [71]

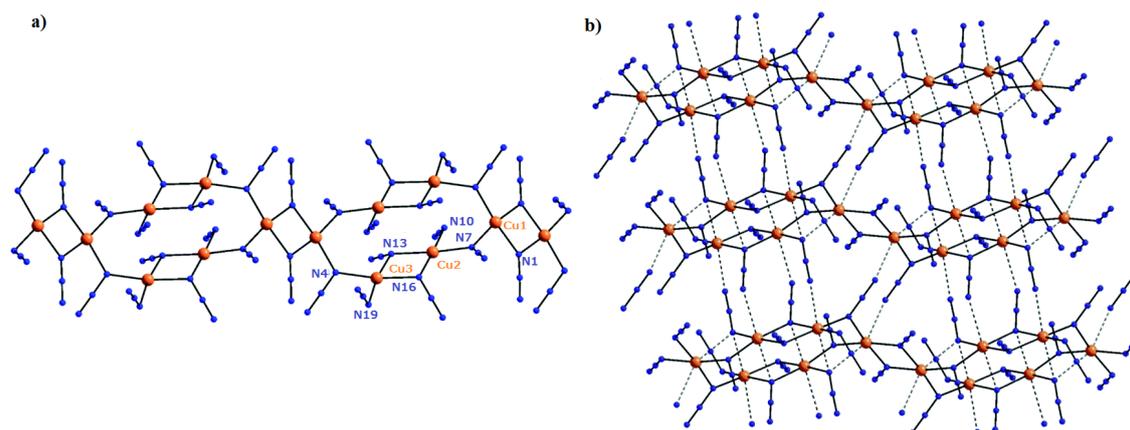

**Figure 1.6:** Different binding modes of azide ions ( $N_3^-$ )

Another example is copper coordination polymer of formula  $[\text{Cu}_2(\text{O}_2\text{CPh})(\text{N}_3)_2\{(\text{py})_2\text{C}(\text{OMe})\text{O}\}]_n$ . The dinuclear units assemble with two EO azide ligands that bridge the Cu2 atoms to form a tetranuclear unit (Figure 1.7). The latter is further linked with the Cu1 centers of four EE azide ligands to form a 2D network [72].

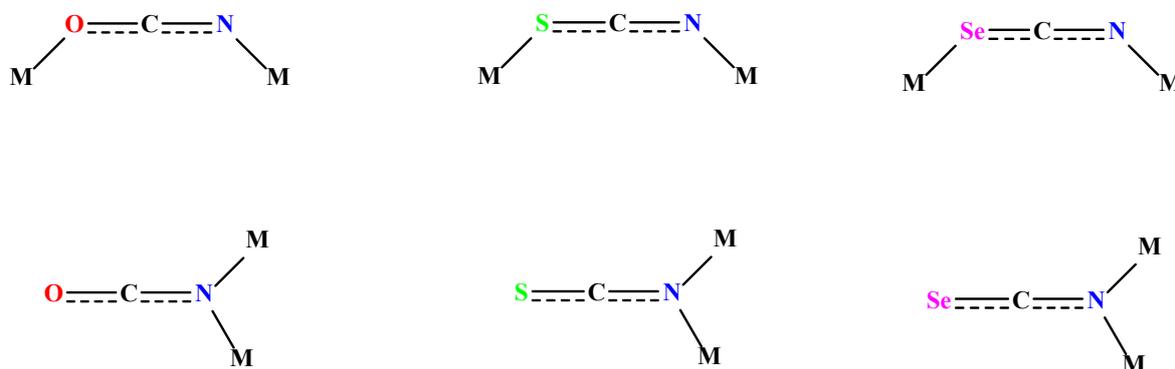

**Figure 1.7:** a) ORTEP view of the asymmetric unit; b) the assembly of two dinuclear units; c) the 2D network [72]

Further example of azide bridge in the EO fashion is an anion  $\{[\text{Cu}_3(\text{N}_3)_7]^{-}\}_n$  shows 1D polymeric structure, where EO-azide ions bridge the  $\text{Cu}^{2+}$  ions to construct an anion chain  $\{[\text{Cu}_3(\text{N}_3)_7]^{-}\}_n$ . In such structure, the three crystallography independent  $\text{Cu}^{2+}$  ions (Cu1, Cu2, and Cu3) are connected by EO-azides to form a linearly arranged  $\text{Cu}_3$  motifs and such a  $\text{Cu}_3$  motif further links with a centrosymmetrically equivalent  $\text{Cu}_3$  motif by two EO-azides at both ends, resulting in the formation of an elongated  $\text{Cu}_6$  ring as the repeating unit of the chain. Additionally, the two adjacent rings are serially connected with Cu1 ions by double EO-azides along the chain [73]. In this compound, the canted ferromagnetism is induced through the Cu–N<sub>azido</sub>–Cu super exchange pathways with lower angles (Figure 1.8) [73].

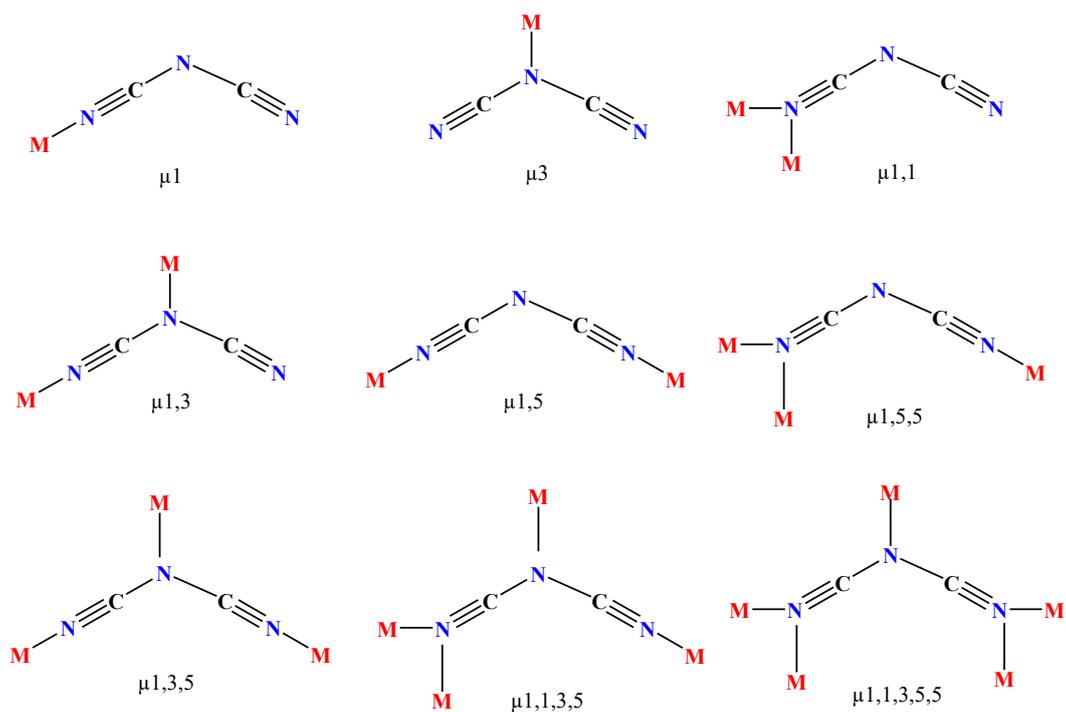

**Figure 1.8 :** a) View of the  $\{[Cu_3(N_3)_7]^{-}\}_n$  chain along the  $b$ -axis,  $Cu^{2+}$  ions are bridged by double EO azide ligands; b) View of the supramolecular  $\{[Cu_3(N_3)_7]^{-}\}_n$  layer [73]

Anionic ligands in the form of  $NCX^{-}$  (where  $X= O, S$  and  $Se$ ) can be used for constructing coordination polymers as terminal or bridging ligands. These ligands can also act like azide in both EO and EE binding modes and can have implications for magnetic materials (Figure 1.9) [74–79].

**Figure 1.9:** Coordination binding modes of  $NCX^{-}$  ligands

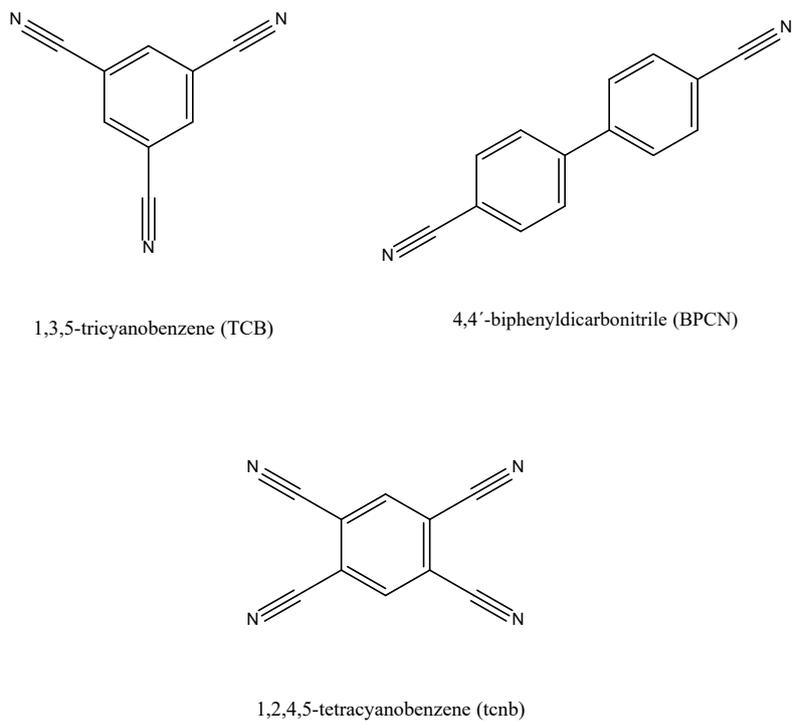

Small polynitrile ligands such as dicyanamide (dca) and tricyanomethanide (tem) are also used for the synthesis of coordination polymers with transition metals, since they exhibit a large range of binding modes (Figure 1.10).

**Figure 1.10:** Various coordination modes of dca ligand

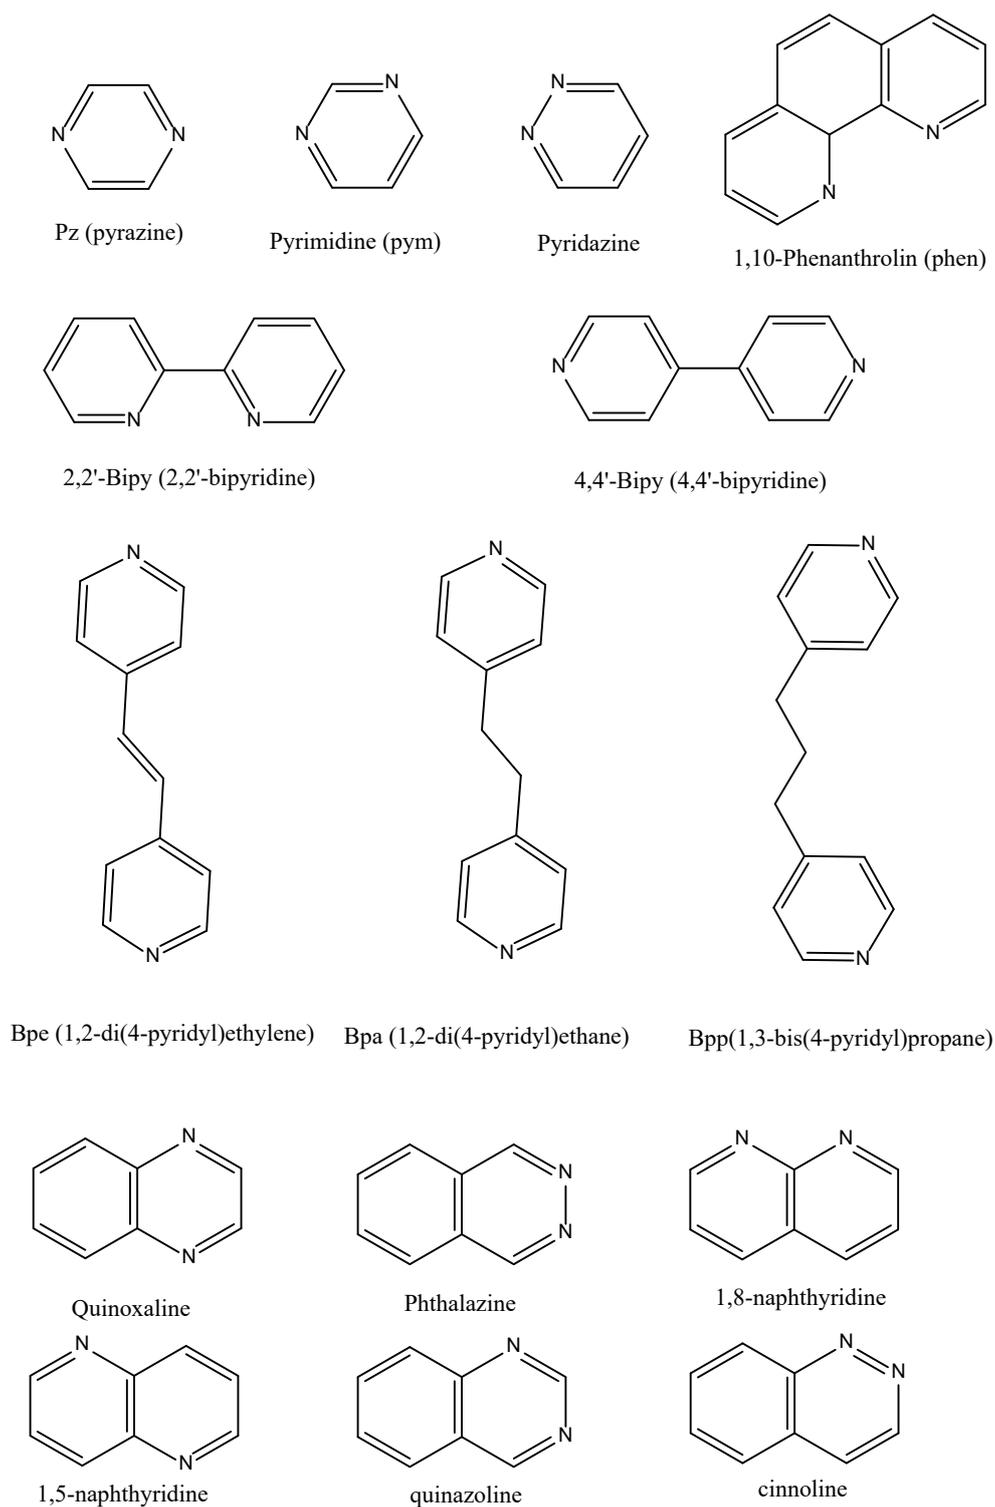

### 1.3.2. Organic molecules act as ligands in coordination polymers and metal organic framework

There are numerous reported organic compounds incorporating into coordination polymers and metal organic frameworks. Commonly used compounds include oxygen and nitrogen donor atoms, such as pyridine and its derivatives or carboxylic acids. In comparison, sulfonic acids, phosphonic acids, thiophen, furan, Schiff-bases (nitrogen- imin group) are rather less studied. Neutral polynitrile compounds are weak donor ligands and tend to bind well to soft metal ions such as  $\text{Cu}^+$  and  $\text{Ag}^+$ . For example, the the ligand 1,3,5-tricyanobenzene (TCB), 1,3,5-tris(4-ethynylbenzonitrile)benzene (TEB) and 1,3,5-tris(3-ethynylbenzonitrile)benzene (TEBB) have been already reported (Figure 1.11) [80–81].

**Figure 1.11:** 2-connecting nitrile ligand 4,4'-biphenyldicarbonitrile (BPCN), 1,3,5-tricyanobenzene (TCB) and 1,2,4,5-tetracyanobenzene (tcnb)

Pyridine and its derivative are very often used for construction of coordination polymers and are very well established in three basic classes: 2-, 3- and 4-connecting modes. Examples of higher coordination pyridyl ligands (i.e. 5- and 6-connecting) are very rare. Some of the mostly used 2-connecting pyridyl ligands are depicted in (Figure 1.12).

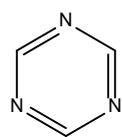

**Figure 1.12:** List of some suitable 2-connecting pyridyl ligands

One of the simplest 2-connecting pyridyl ligand is pyrazine (pyz) which provides a linear connection with transition metal ions. An example, compound  $[\text{Cu}_2(\text{pyz})_4](\text{ClO}_4)_2 \cdot \text{HBz} \cdot \text{H}_2\text{O}$  (HBz = Benzoic acid) presents a quartz-like topological net with a  $(6^4.8^2)$  point group [82]. Pyrimidine (pym) and pyridazine (pydz) perform as a bent connectors, have been used in the

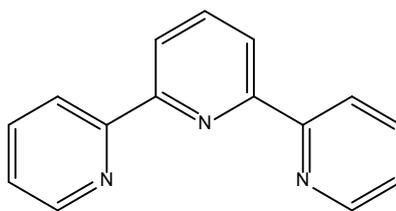

same way as pyrazine. Such ligands can also be functionalized as 2,3-pyrazinedicarboxylic acid or pyridazine-3-carboxylic acid which are very interesting for framework topologies. As longer linear 2-connecting pyridyl ligands, (4,4'-bipy) [4,4'-bipy = 4,4'-bipyridine] is a current choice to construct CPs and MFOs and has been reported in many coordination polymer articles. For example, in coordination compound  $[\text{Hg}(4,4'\text{-bipy})(\text{SCN})_2]_n$ ,  $\text{Hg}^{2+}$  ions are linked by the bridging (4,4'-bipy) ligands to yield a zigzag chain extending infinite 1D construction [83]. There are numerous coordination polymers based on 4,4'-bipy that may form frameworks with different topologies including simple 1D, 2D and 3D networks depending upon transition metal cations.

The three connecting pyridyl-based ligand, triazine (tri), 2,4,6-tris(4-pyridyl)-1,3,5-triazine (tpt) and 1,3,5-tri(4-pyridyl)-benzene (tpb) have been successfully applied for the construction of frameworks with interesting topologies as well.

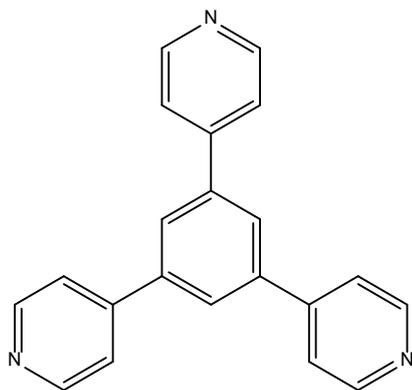

Compared to 2- and 3-connectors, there are fewer examples of 4-connecting pyridyl ligands and they have been mainly focused on porphyrin analogues, but several other ligands have been also applied (Figure 1.13). Since 4-connecting pyridyl ligands are mostly large, hence they usually produce frameworks of large cavities.

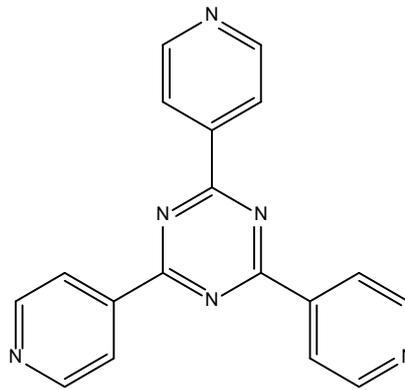

1,3,5-triazine (Tri)

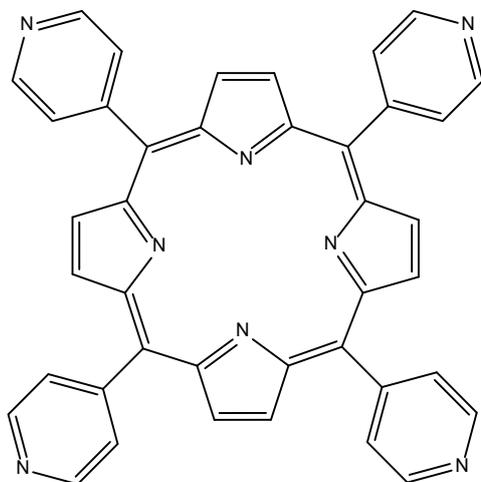

2,6-di(pyridin-2-yl)pyridine

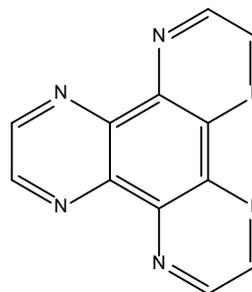

1,3,5-tri(4-pyridyl)-benzene

2,4,6-tris(4-pyridyl)-1,3,5-triazine (tpt)

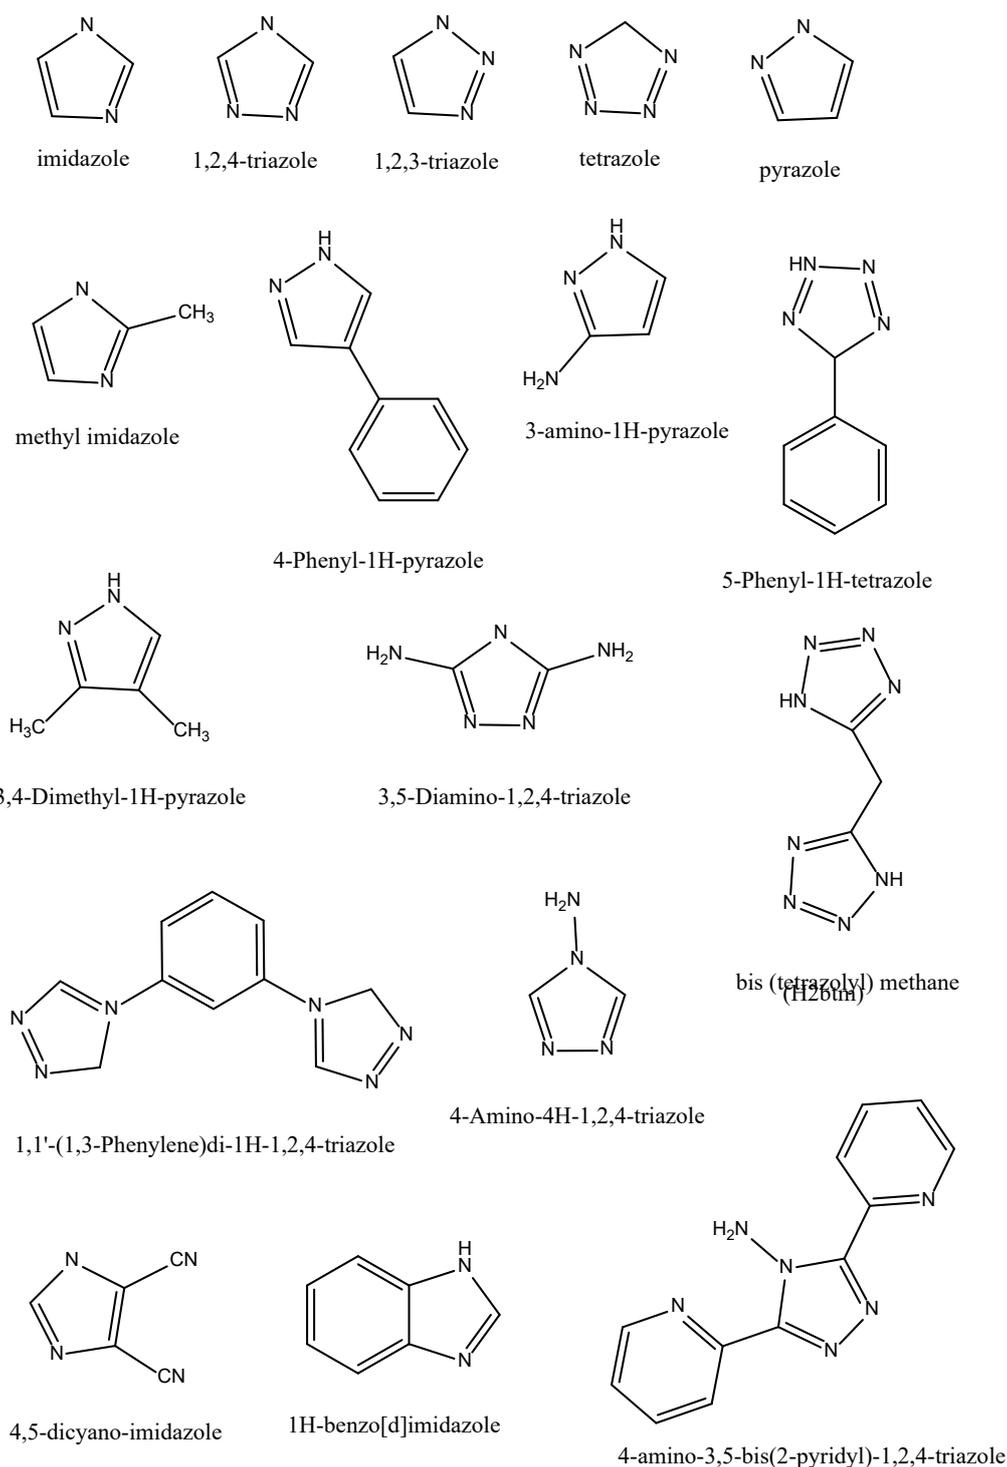

5,10,15,20-Tetra(4-pyridyl)-porphine (tpyp)

1,4,5,8,9,12-hexaazatriphenylene (HAT)

**Figure 1.13:** Some 3- and 4-connecting pyridyl ligands which have been commonly used in coordination polymer synthesis

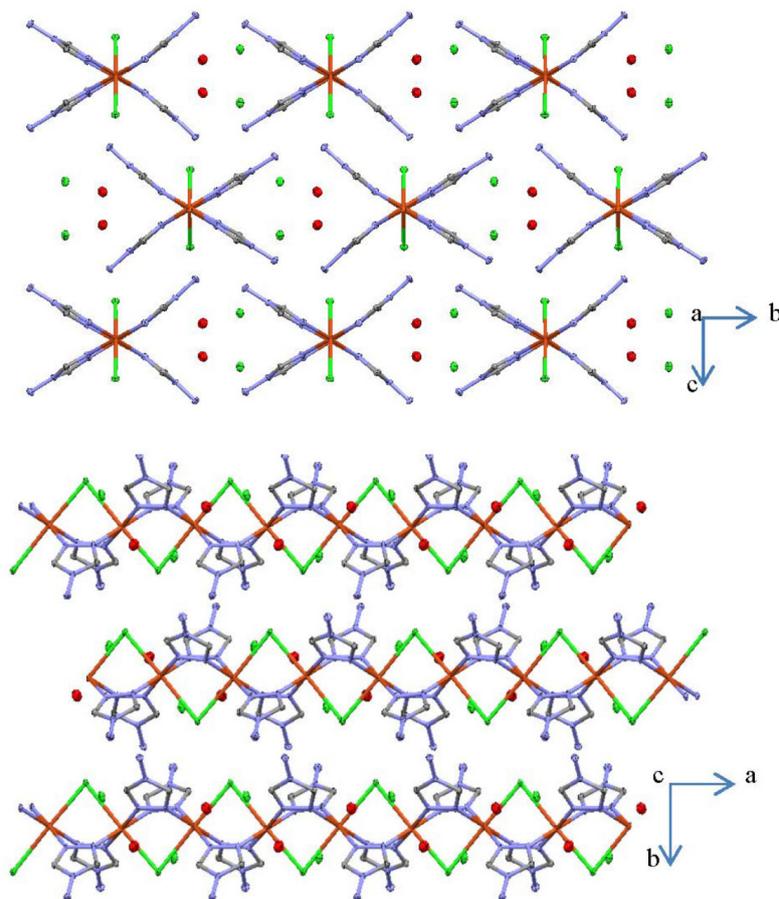

N-donor aromatic heterocyclic molecules such as imidazole, triazole and pyrazole have been used as much as pyridyl donor ligands since they coordinate to transition metal ions with a similar affinity. Moreover, greater diversity of network topologies could be obtained by these ligands. Some more usable heterocyclic nitrogen donor ligands are shown in (Figure 1.14).

**Figure 1.14:** Some interesting and common used 5-membered N-donor rings

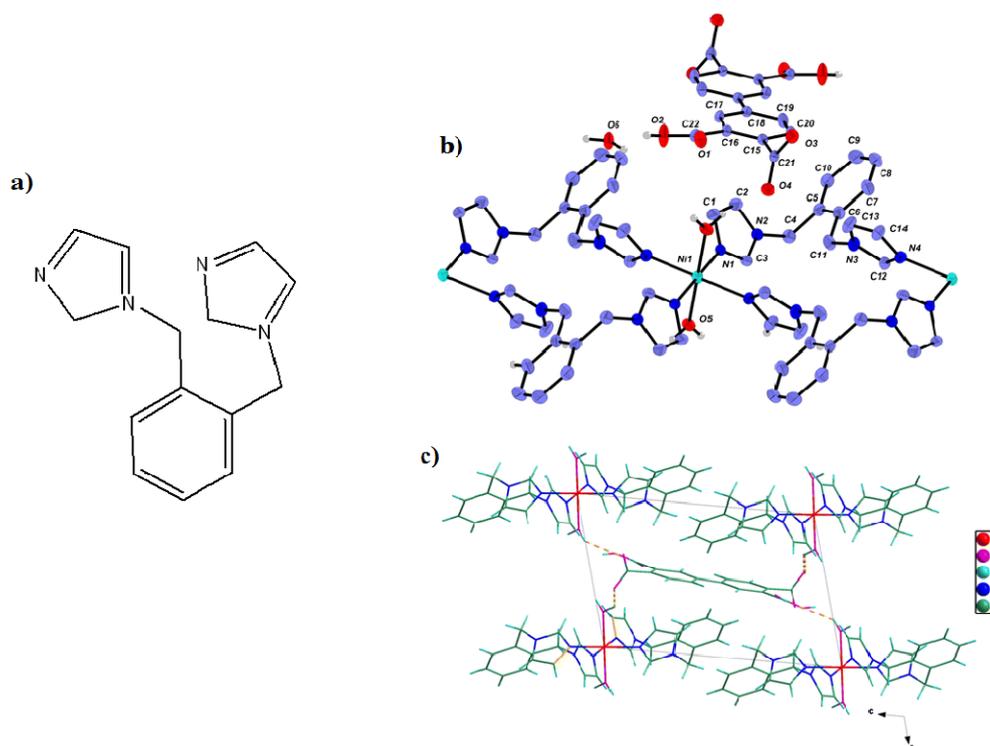

An example, triazole (trz) ring is present in chain compound  $[\text{Cu}(\mu_2\text{-NH}_2\text{trz})_2\text{Cl}]\text{Cl}\cdot\text{H}_2\text{O}$  ( $\text{NH}_2\text{trz} = 4\text{-amino-}4\text{H-}1,2,4\text{-triazole}$ ) where each  $\text{Cu}^{+2}$  ion is coordinated by two chlorine

atoms in *trans*-configuration and four nitrogen atoms arising from four different NH<sub>2</sub>trz ligands (Figure 1.15) [84]. This results the formation of a distorted 1D coordination polymer.

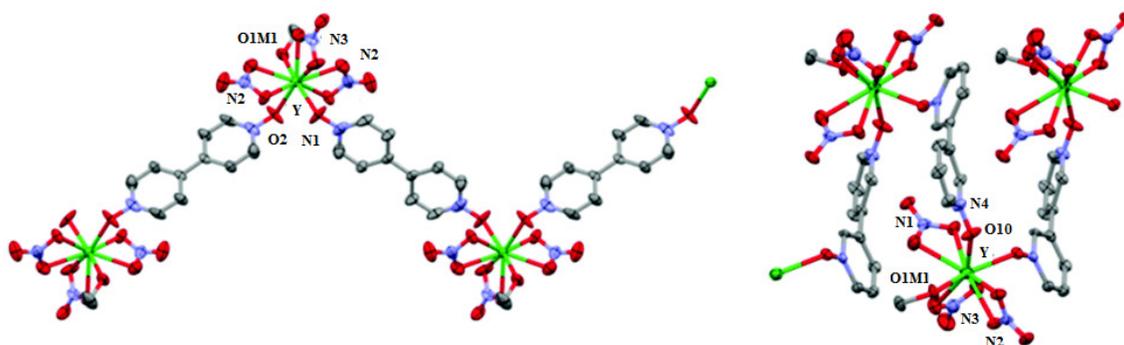

**Figure 1.15:** Thermal ellipsoid (50%) along the *a* (top) and *c*-axes (bottom). The nitrogen atoms are depicted in blue, the carbon atoms in grey, the chloride ions in green and the copper atoms in red. H-atoms were removed for clarity [84]

Another example involves ligand (bib) has been recently reported to a 2D structure of NLO properties in compound [Ni(H<sub>2</sub>O)<sub>2</sub>(bib)<sub>2</sub>].(H<sub>2</sub>BTA)·2H<sub>2</sub>O (H<sub>4</sub>BTA = biphenyl-3,3',4,4'-tetracarboxylic acid, bib= 1,2-bis(imidazole-1-yl methyl)benzene ) as depicted in (Figure 1.16) [85].

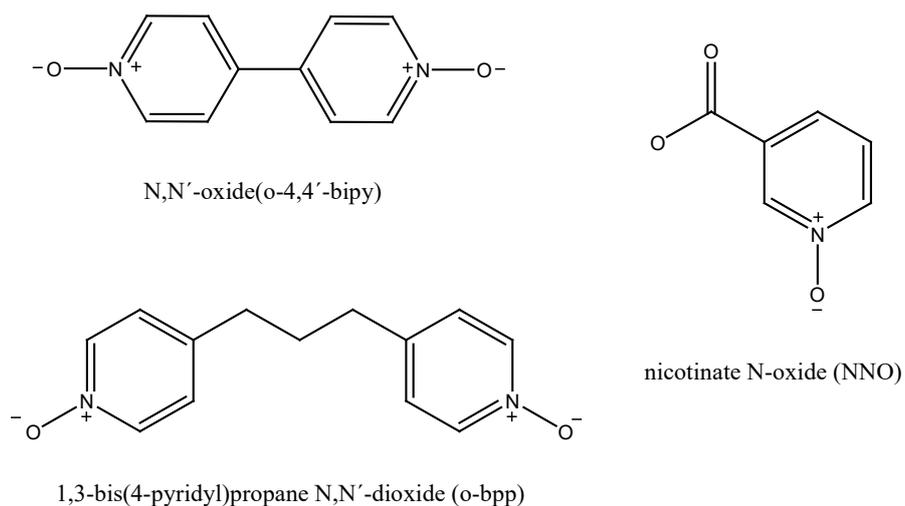

**Figure 1.16** : The structure of ligand 1,2-bis(imidazole-1-yl methyl)benzene (bib) (a); ORTEP representation of compound  $[\text{Ni}(\text{H}_2\text{O})_2(\text{bib})_2] \cdot (\text{H}_2\text{BTA}) \cdot 2\text{H}_2\text{O}$  with 40 % probability displacement ellipsoids (b); View of the structure of along the b axis (c) [85]

Apart from nitrogen donor ligand, many oxygen-donors organic compounds have been extensively used for the formation of coordination polymers and metal organic frameworks. Beside carboxylate ligands, other O-donor ligands such as N-oxides have caught considerable attention. An example is a compound  $\{[\text{Yb}(4,4'\text{-bpdo})(\text{NO}_3)_3(\text{CH}_3\text{OH})]\}_\infty$ , each metal centre is nine-coordinated with YbO<sub>9</sub> coordination sphere and resulted in 1D coordination polymer built from repeating zigzag chains of linked Yb(III) cations (Figure 1.17) [86].

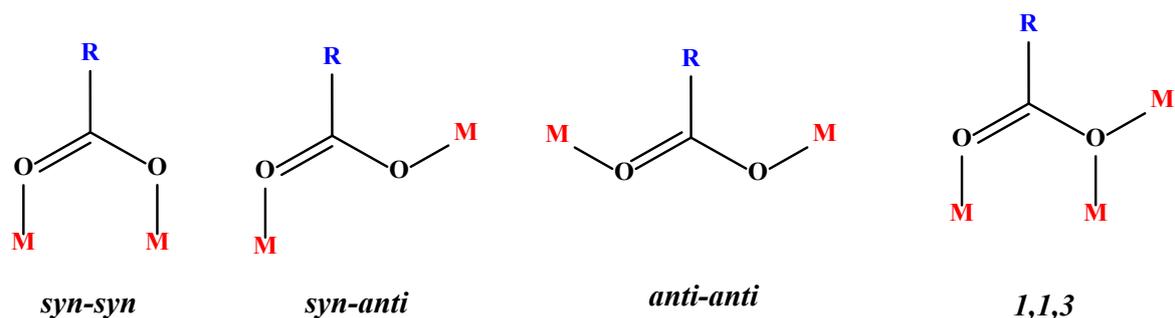

**Figure 1.17**: The structure of  $\{[\text{Yb}(4,4'\text{-bpdo})(\text{NO}_3)_3(\text{CH}_3\text{OH})]\}_\infty$  (left) and showing 1D coordination polymer chain(right) [86]

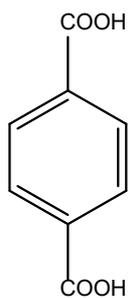

**Figure 1.18:** Structures of some very convenient *N*-oxide ligands

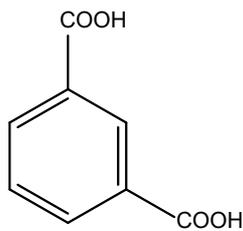

Carboxylate ligands can form strong bonds with metal ions with various binding modes in either a monodentate or bidentate. The common carboxylate coordination modes are shown in (Figure 1.19).

Indeed, 2-connecting carboxylate and 2-connecting pyridyl ligands are among the most studied types of ligands in CPs and MFOs field. For example, in the 3D coordination polymer [Cd(bdc)(bipm)] bipm = bis(4-imidazolphenoxy)methane, H<sub>2</sub>bdc = 1,4-benzenedicarboxylic acid, where the Cd<sup>2+</sup> ion adopts a highly distorted tetragonal pyramidal coordination sphere and is five-

coordinated by two nitrogen atoms from two bipm ligands and three oxygen atoms from two  $\text{bdc}^{2-}$  anions. The  $\text{bdc}^{2-}$  anion connects two  $\text{Cd}^{2+}$  ions *via* one monodentate carboxylate and one chelating carboxylate moieties (Figure 1.21) [87].

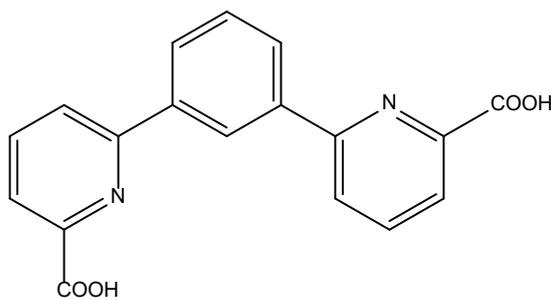

**Figure 1.21** : Coordination environment of the  $\text{Cd}^{2+}$  ion in  $[\text{Cd}(\text{bdc})(\text{bipm})]$  **(a)** ; The schematic view of the square network in Cadmium complex **(b)** ; The schematic view of the 2D  $\rightarrow$  2D parallel interpenetration of pairs of sheets **(c)**; The schematic view of the interpenetration of two sheets from adjacent layers; note the different orientations of the two sheets**(d)**; The perspective view of the 2D  $\rightarrow$  2D parallel  $\rightarrow$  3D parallel interpenetration **(e)** [87]

One of the recent reported MOFs based on a 3-connecting carboxylate ligand, benzene-1,3,5-tricarboxylic acid (btc), is a series of isorecticular lanthanide metal–organic frameworks, Ln-MOFs ( $\text{Ln} = \text{Eu}, \text{Gd}, \text{and Tb}$ ), shown in (Figure 1.22) [88]. Another example of 3-connecting carboxylate ligand is 1,3,5-tris(carboxylphenyl)benzene which is analogue of (btc) ligand.

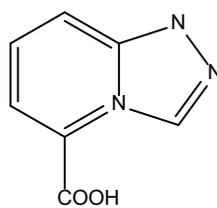

**Figure 1.22:** Schematic view for the synthesis of lanthanide metal–organic frameworks (Ln-MOFs) *via*  $\text{Eu}^{3+}$ ,  $\text{Gd}^{3+}$ , or  $\text{Tb}^{3+}$  with equimolar benzene-1,3,5-tricarboxylic acid (BTC). Secondary building units (SBUs) are formed through rigid M–O–C core clusters [88]

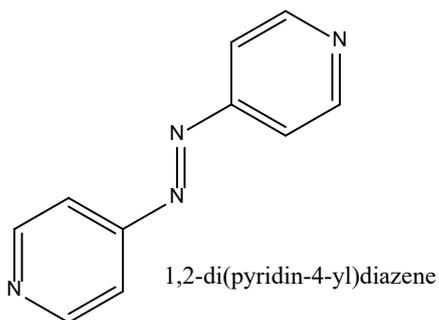

Ligands containing both pyridyl and carboxylate functional groups such as pyrazine-2-carboxylate (2-pyc) and the longer version 4-(pyridine-4-yl)pyridine-2-carboxylic acid (ppca), have been successfully utilized for the formation of coordination compounds (Figure 1.23).

**Figure 1.23:** Most interesting five-membered N-donor rings ligand structure used for coordination polymer synthesis

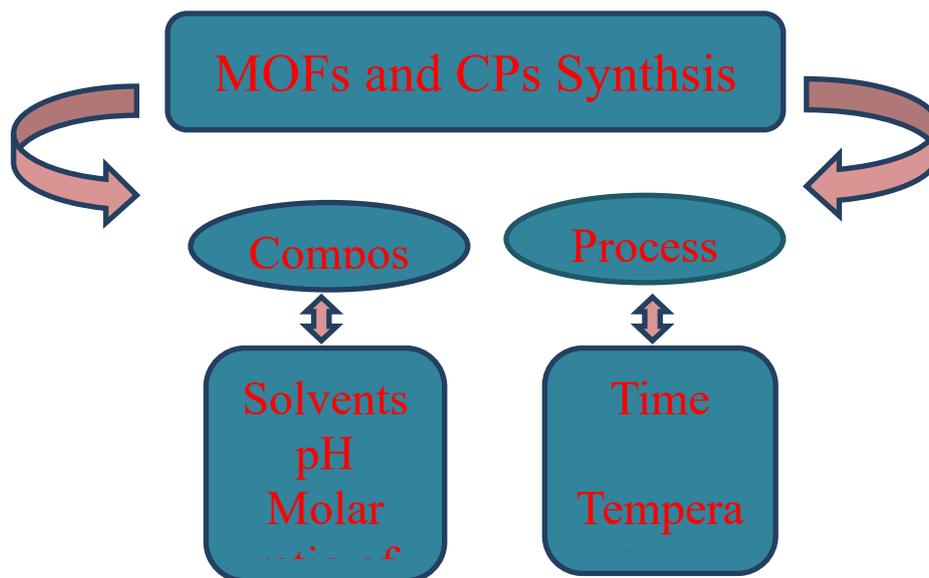

Sulfonic acids, phosphonic acids, thiophen, furan, Schiff-bases (nitrogen- imin group), large aromatic ligands such as pentacene, benzanthracene, triptycene, pyrene and perylen and metal clusters have been also used to construct very interesting coordination networks (Figure 1.24).

**Figure 1.24:** Some other convenient ligands that have been frequently use to construct coordination polymers

## 1.4. Synthesis method

As mentioned earlier, a coordination polymer is a complex of metal ions and ligand molecules extended in one, two and three dimensions and formed by self-assembly process. Self-assembly is very effective for the following reasons: (i) a wide variety of frameworks can be realized just from simple building blocks of metal ions, organic bridging ligands and counter anions; (ii) easy and rational modification of organic bridging ligands is possible; (iii) several interactions such as coordination bond, hydrogen bond, aromatic interaction, metal-metal bond and van der waals interaction are available; (iv) the reaction can be controlled by different factors such as temperature, pH, solvent, pressure, etc. For coordination polymers, the recrystallization method is not useful for obtaining high purity or large single crystals because they are insoluble in most solvents. Therefore, common techniques to synthesize pure coordination compounds are slow diffusion, hydrothermal and slow evaporation and many other methods. Moreover, a new synthetic approach has been developed as well [89]. It is well known that the crystallization, structure and morphology of MOFs and CPs do not only depend on the modules building blocks, but they are in control of many experimental conditions such as solvent type [90], pH value of reaction mixture [91], temperature [92], reagents concentration [93], time [94], molar ratios of starting materials [95], the nature of counter ions [96] and pressure [97]. These parameters are divided into two main categories including a) compositional parameters like solvent type, pH, substituent of ligands, the molar ratio of starting materials, counter ions and concentration; and b) process parameters such as pressure, time and temperature (Figure 1.25) [98]. Keeping in mind that these parameters have a deep influence on the structure of final framework and could lead to compounds with different particle sizes distributions and morphologies with different applications. In the following, some important synthetic routes will be mentioned here.

**Figure 1.25:** Schematic feature parameters which play roles in MOFs and CPs synthesis [98]

#### 1.4.1 The slow evaporation method

Slow evaporation is implied as one of the typical methods for the synthesis of MOFs and CPs. In this method, evaporating of solvents occurs at room temperature and metal salts and organic linkers are mixed together in the liquid phase with or without auxiliary ligands (Figure 1.26). Highly soluble precursors are usually required in this method which should be concentrated by slow evaporation process. The great disadvantage of this method is that it is very time-consuming compared to the other conventional synthesis methods. This problem can be sometimes overcome by using low-boiling solvents [99–102]. In point of fact, this technique needs convenient conditions:

- Crystals growth in saturated solution.
- Solubility increases by temperature and crystal can appear during cooling step.

## Slow evaporation method

- Supersaturated solution
- Constant temperature
  - Temperature stabilization
  - Rate of evaporation – few mm<sup>3</sup>/hr
- Solubility – High solubility of reagents in large amount of solvent
- Evaporation of solvent – excess amount of solute (substance) gets crystallized

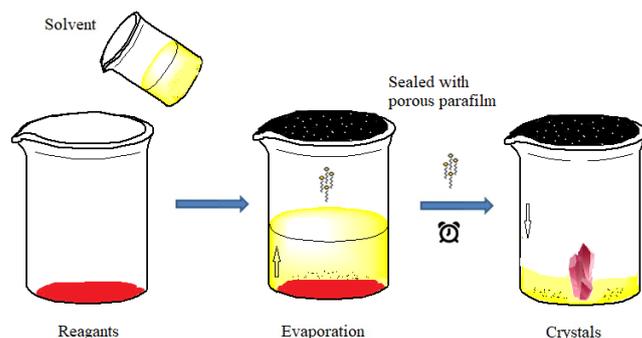

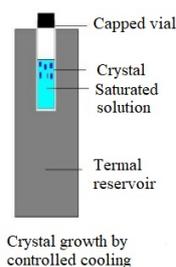

Figure 1.26: Slow evaporation method [103]

### 1.4.2 The slow diffusion method

Rapid mixing of metal ion with ligand solutions may result in microcrystal (powder) with size in the order of  $\mu\text{m}$  which is not suitable for X-ray single crystal structural analysis. To avoid precipitation, diffusion method is often used. Large single crystals suitable for X-ray structural analysis could be obtained by slow diffusion of the two above mentioned solutions [104]. Various devices, such as straight-tube (test-tube) (Figure 1.27), NMR tube, H-tube (Figure 1.28) and Y-tube glass cell have been designed for this goal. In this technique, second solvent should be added slowly and carefully on top of the first solvent hence, the two liquid layers do not mix at all. During several days or even weeks, top solvent slowly diffuses into the first solvent, decreasing the solubility of product and producing large, good quality crystals. For this reason, either narrow Schlenk flasks or NMR tubes are preferred due to their smaller surface area of the boundary [104]. This method could be utilized either for air-stable or air-sensitive compounds. This is worth to note that the Schlenk flask is normally used for air-sensitive materials.

**Liquid-Liquid Diffusion (Binary solvent system in test-tube)**

$S_1$  = Solvent 1 (the solute is either poorly or not soluble in solvent  $S_1$ )

$S_2$  = Solvent 2 (the solute is soluble in solvent  $S_2$ )

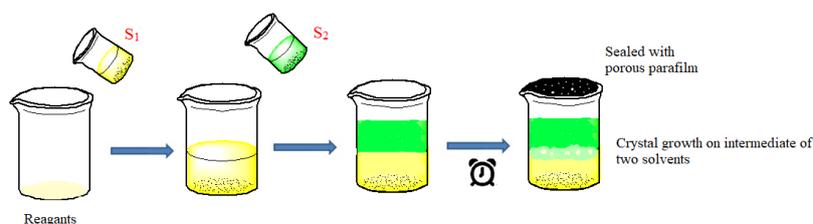

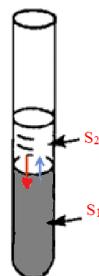

$S_1$  and  $S_2$  should form discrete layer

$\text{Et}_2\text{O}$  ( $S_1$ ) /  $\text{CH}_2\text{Cl}_2$  ( $S_2$ ): is good combination

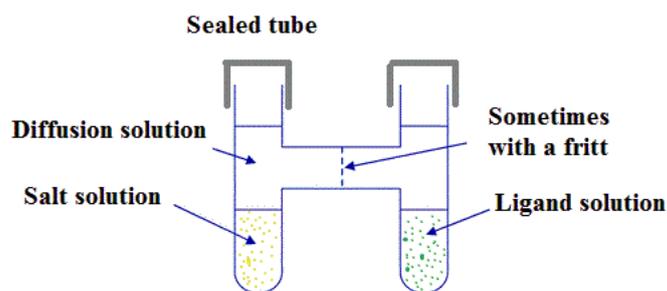

Crystal forms in intermediate of two solvents

Necessary conditions :

1.  $D_{S1} > D_{S2}$
2. Slowly pour  $S_1$  into tube (use the syringe)
3. Narrower tube (e.g., NMR tube) >>> layering tube
4. Work great for milligram amount of materials

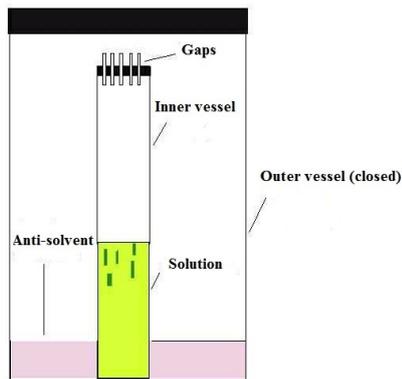

**Figure 1.27:** Slow diffusion in test-tube

**Figure 1.28 :** Slow diffusion in H-tube [105]

### 1.4.3. Vapor Diffusion Technique

This method involves the diffusion of the vapor of a volatile solvent into the solution including sample. This gradually decreases the overall solubility of the product and forces the product to crystallize (Figure 1.29) [104a, 106]. This method can be used for either air-stable or air-sensitive samples (Figure 1.30) [107].

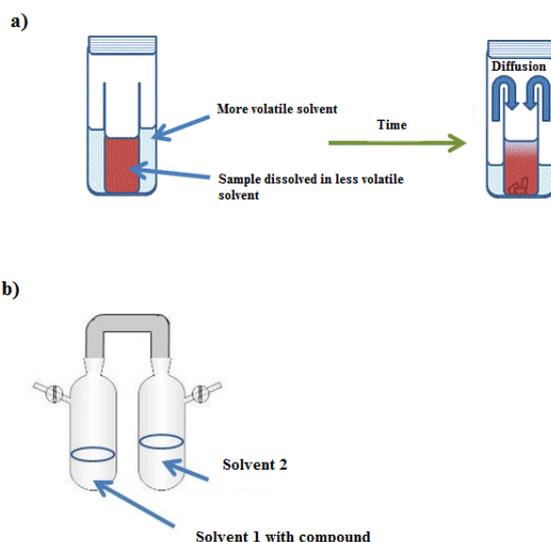

#### Vapor Diffusion

Similar to solvent diffusion but in separate vials for ( $S_1$ ) ( $S_2$ )

1. Dissolve in  $S_1$ , in smaller open vial
2. Place small vial into larger vial with  $S_2$  and cap off

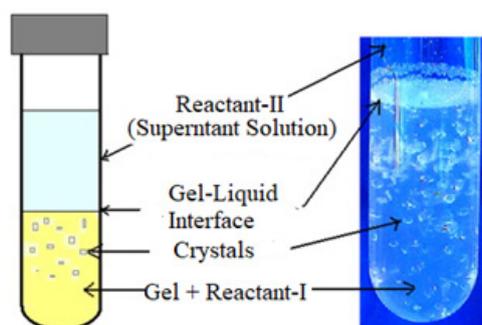

**Figure 1.29:** Vapor diffusion mechanism [106]

**Figure 1.30:** Vapor diffusion for air-stable samples (a); for air-sensitive samples (b) [107]

#### 1.4.4. Gel growth method

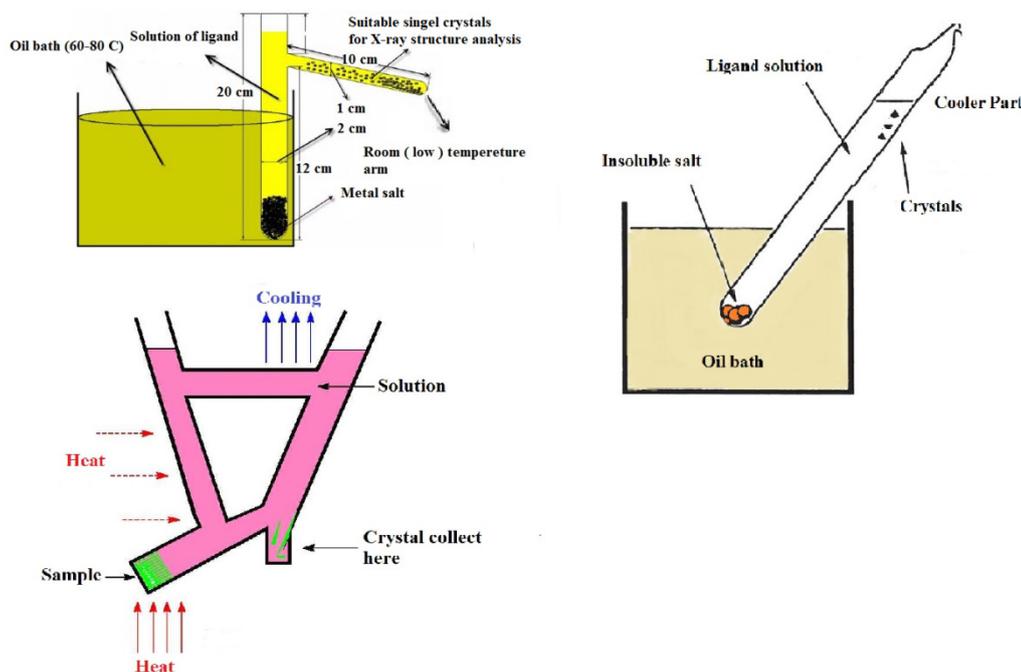

Large crystals with dimensions of several mm can be obtained via this technique within 3 to 4 weeks. Furthermore, crystals are very pure since the growth takes place at room temperature for several days and weeks. Growing crystals is usually carried out in a U-shaped Tube or test-tube as depicted in (Figure 1.31). Sodium metasilicate, also known as silica hydrogel, has been the mostly used [108–111].

**Figure 1.31:** Schematic feature of gel growth method in test-tube and real sample [111]

### 1.4.5 Temperature gradient method

Temperature gradient method is pointed as convenient way to grow large and high quality single crystal at a fixed temperature [112–115]. In this technique, a thermal gradient is obtained by local heating or cooling of a part of the tube and it causes the warmer portion of the solution is saturated more than the cooler part. In consequence, warmer solution can be transferred to the cooler part by convection currents where crystal grows. The polar solvents are normally used in this method such as water, ethanol, methanol and acetonitrile, hence the highest temperature must be adjusted up to boiling point of solvent. As a matter of fact, this method is applicable to moderate temperature, approximately up to 100 °C. Furthermore, this method is suitable for the reagents which are insoluble or slightly soluble. This method is commonly carried out in branched tube, either test tube or V-shaped tube as illustrated with (Figure 1.32).

**Figure 1.32:** Thermal gradient method via different types of vessel . Branched tube (a); test-tube (b); V-shaped tube (c) [106,116]

#### 1.4.6. Hydro (solvo)thermal methods

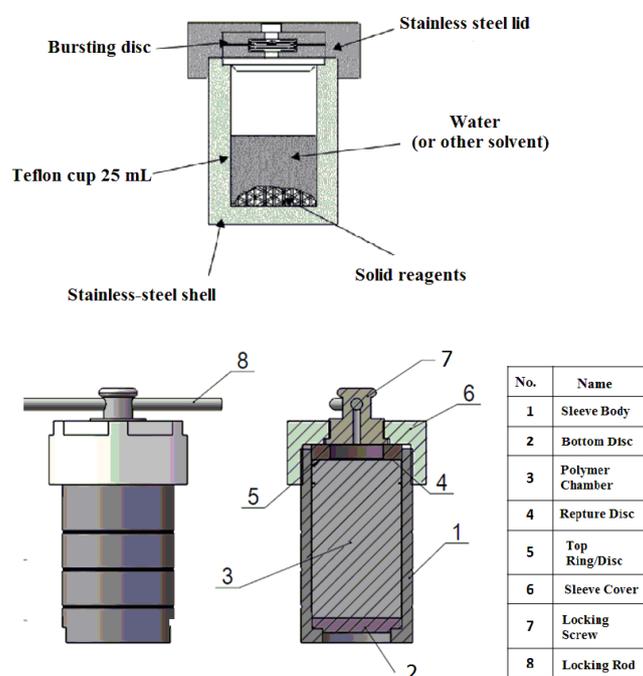

The hydrothermal technique performs as an important tool for advanced materials processing with a wide variety of technological applications such as electronics, catalysis, ceramics, magnetic data storage, biomedical, biophotonics and etc. Indeed, the hydrothermal technique is known an efficient technique for synthesizing nano-hybrid and nanocomposite compounds.

Hydrothermal processing is defined as heterogeneous reaction under high pressure and temperature between materials that are relatively insoluble under ordinary conditions to dissolve and recrystallize materials [117–118]. In this synthetic method, reactions are carried out at higher temperatures (temperature higher than 100 °C) and pressure for several hours or days into the well-sealed vessels. Usually, Teflon-lined autoclaves are used. The reactants are taken in polar and high boiling point solvents such as DMF, DEF, DMSO, H<sub>2</sub>O, acetone, acetonitrile and alcohols or sometimes a mixture of these solvents when the solubility of the starting materials are different. The major advantage of this method is that it offers high solubility of the precursors and formation of crystals with good quality suitable for structural characterization [119]. The running temperature range is commonly between 100–260 °C inside autoclave under autogenous pressure. Under these conditions, water properties undergo significant changes and its viscosity and polarity (dielectric constant) decrease, but pressure,

ion production and also the diffusion process increase. So, crystal growth of this solution is favored. As a result, hydrothermal method can be an excellent alternative to boost solubilities of starting materials (Figure 1.33, 1.34) [120]. It is worth to notice that solvothermal technique is very similar to the hydrothermal concepts. But the only difference is that the precursor solution is not aqueous.

**Figure 1.33:** Different size and shape of hydrothermal tubes which are produced via environment friendly materials [121]

**Figure 1.34:** Schematic feature of hydrothermal tube.

### 1.4.7. Solvent-free method

Solvent-free synthesis is an advantageous method, since it could explain the role of solvent molecules in template microporous structures, giving access to large scale green production processes, and even providing more convenient lab-scale preparative methods. Recently, there have been several reports on using of mechanochemical methods (grinding) to produce various coordination complexes [122–125], and three reports of the synthesis of one- and two-dimensional coordination polymers [126–128]. The 3D coordination polymer  $[\text{Cu}(\text{isonicotinate})_2]_n$ , which is an example of permanent open porosity, is produced by grinding [129]. The solvent-free method is quick and gives a quantitative yield, without the need for solvents or external heating. Clearly, it can expose higher efficiency in terms of materials, energy, and time compared to solvothermal method (Figure 1.35).

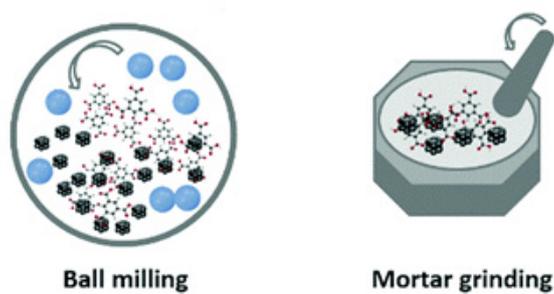

Figure 1.35: Synthesizing coordination polymer by solvent-free method [130]

## 1.5. Structural modulation by reaction condition

A polymeric metal-organic compounds and coordination polymers are usually insoluble, because coordination bonds are usually stronger and have better directionality than hydrogen bonding and other weak supramolecular interactions. However, structural diversity and uncertainty is an intrinsic problem for crystallization and construction of coordination polymers due to the coordination flexibility of the metal ions and organic ligands, as well as the presence of other chemical variable such as solvent molecules [131]. Among a number of factors that may contribute to the structures of coordination polymers, temperature, pH, solvent, counterion, and template (or additive) play an important role in the formation of products. To continue, some of them will be discussed here to illustrate their significance of modulation of the structures [131].

### **1.5.1. Temperature Effect**

Temperature plays an important role in formation of kinetic and thermodynamic product. The thermodynamically favored product that can usually be obtained at higher reaction temperature and can be even synthesized more remarkably under hydro(solvo)thermal reactions, in which metastable kinetic phases can be more controlled. Furthermore, higher temperatures can raise the solubility of reagents which might reduce the kinetics of crystal growth and lead to bigger and better quality of particles [132–133]. Moreover, selecting an appropriate reaction temperature can provide possibility to control on the evaluation of colloidal solution [134].

### **1.5.2. pH Effect**

Acid-base reactions are usually involved in the assembly of coordination polymers. It is well-known that crystallization and growth of inorganic-organic hybrid materials are highly affected by the acidity/basicity of reaction media. The deprotonation of an organic ligand and sometimes generation of an  $\text{OH}^-$  ligand in aqueous solution by changing of pH of reaction will provide connectivity of polycarboxylate ligands to metal ion based on acid-base concept. Moreover, the reaction kinetics can be influenced by altering pH conditions in some cases [135].

### **1.5.3. Solvent Effect**

Solvent molecule determines the solubilities of both reactants and products which simulates the supersaturation and kinetics of crystal formation, determining the final particle shape and dimensions. Besides their role in dissolving the reactants and products, they can also impact on the superstructures of the intermediates and final products through supramolecular interactions between the products and solvents, Therefore, solvent molecules can have effect not only on the crystallization process, but also on the configurations of the certain groups of the products, leading to different structures. They play a role of template and occupy the voids of the products and also they only serve as the crystallization environment and do not exist on the products [136–138].

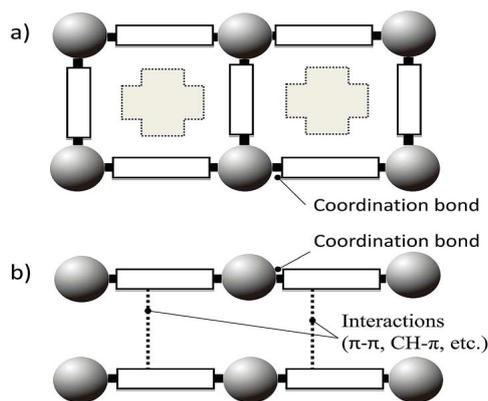

#### 1.5.4. Counter ion effect

Counterions usually are attributed as the anions that are not involved in the inner coordination sphere. But still they can affect the crystallization of coordination polymer products, leading to different coordination structures. In addition, charge is an important factor of rational construction of functional coordination polymers. Because most transition metal ions exist on a positive charge in the framework, an anionic source must be included to neutralize the overall charge. Many N-containing heterocyclic ligands are electrically neutral and, therefore, counter anions are included in the crystal. Frequently used anionic sources are inorganic anions, such as  $\text{ClO}_4^-$ ,  $\text{BF}_4^-$ ,  $\text{NO}_3^-$ ,  $\text{NCS}^-$ ,  $\text{PF}_6^-$ ,  $\text{NO}_2^-$ ,  $\text{SiF}_6^{2-}$ ,  $\text{CN}^-$ ,  $\text{CF}_3\text{SO}_3^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{N}_3^-$  and halides, which are introduced together with metal ions from the corresponding metal, sodium and potassium salts. The inorganic anions exist as (i) free guests; (ii) hydrogen-bond acceptor; and (iii) coordination unit. An important characteristic of inorganic anions is their ability to act as hydrogen-bond acceptor sites through their O and F atoms. In some cases, especially in silver (I) coordination polymers [139], the counter-ion can play a key role in formation of final supramolecular structure. Indeed, the different counter-ions have different coordination interactions with metal ions due to the different H-bonding interaction with the other components and the different influence on crystallization speed for different supramolecular products. Besides supramolecular interactions, counter anions also play important roles in the self-assembly. For example, in silver (I) coordination polymers, changing anions often alters the structural topologies, sometime even the overall physical properties of polymeric  $\text{Ag}^+$  complexes [140]. The anions can usually exist on coordinating, weakly coordinating, noncoordinating silver(I) polymeric complexes. Among the commonly used anions,  $\text{BH}_4^-$ ,  $\text{ClO}_4^-$ ,  $\text{NO}_3^-$ ,  $\text{CF}_3\text{SO}_3^-$  and  $\text{CF}_3\text{CO}_2^-$ ,  $\text{PF}_6^-$  and  $\text{SbF}_6^-$  are usually uncoordinated.

#### 1.6. Lanthanides

The lanthanides (Ln) are composed of lanthanum (La) and 14 other elements (Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, and Lu). These elements are stable in the III oxidation state and are simply characterized by the electronic structure of the 4f orbitals. Since, 4f orbitals are shielded by the outer 5s and 5p orbitals, there is a slight shift in their electronic transitions. The energy levels of the trivalent lanthanide ions are given in (Figure 1.36) [141–142].

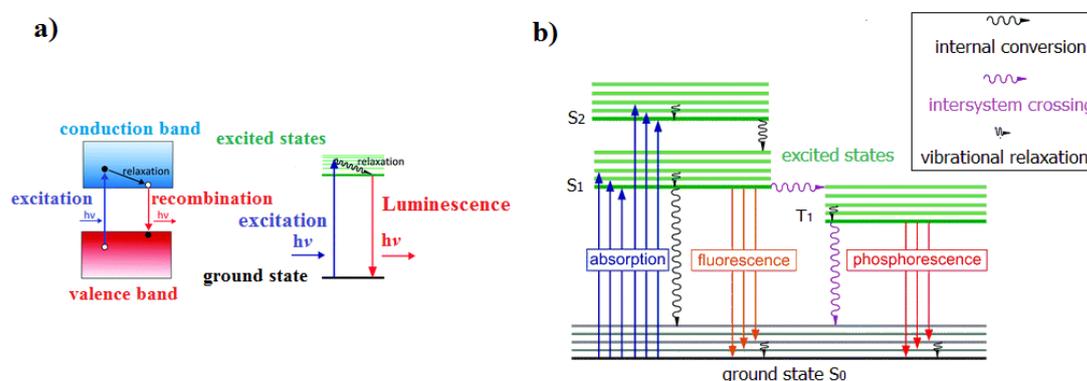

**Figure 1.37:** Structure of Ln-MOFs (a); the structure of Ln coordination polymers are constructed by metal ions and organic ligands (b) [142]

Such cavities are utilized as nanoscale sensors for metal ions and gas or organic molecules based on the host-guest chemistry. Chandler et al. described CO<sub>2</sub> gas sensors that employ luminescent Ln-MOFs [158]. Liu et al. and Pan et al. have demonstrated Ag<sup>+</sup> sensors based on Ln-MOFs [159–160]. In addition, Rocha and Carlos have provided a review on luminescent multifunctional lanthanides-based Ln-MOFs [161]. On the other hand, coordination polymers composed of lanthanide ions and organic ligands have also attracted considerable attention in the coordination chemistry, inorganic chemistry, supramolecular chemistry, polymer and material science. One-, two- and three-dimensional alternating sequences of metal ions and organic ligands (Figure 1.37) exhibit remarkable characteristics as novel organic–inorganic hybrid materials with various structures, and individual physical properties that can be prepared by the combination of lanthanide ions and organic ligands. Moreover, the characteristic network structure results in photonic applications. Luminescent lanthanide coordination polymers have characteristic network structures built of lanthanide ions and functional organic linkers. The luminescence properties depend upon the coordination structures around the lanthanide ions, causes significant photophysical properties. In next the section, photonic application, photofunctional materials, and the photophysical properties of lanthanide coordination polymers are introduced.

### 1.6.1. Luminescence in lanthanide MOFs and CPs

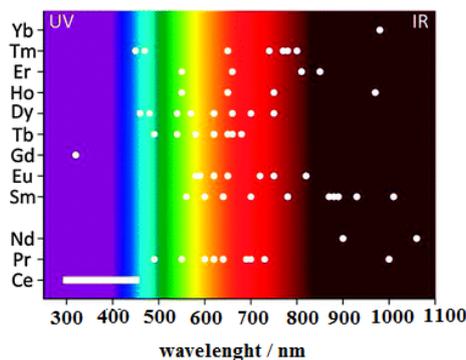

Luminescence is described as spontaneous emission of radiation stimulated by an absorption of an electronically or vibrationally energy. Although the excitation energy is frequently in form of light (photon), but it could also be achieved in number of different ways, such as electrical field, ionizing radiations, chemical or electrode reactions, within biological systems and through

mechanical forces. A general distinction between semiconductor-based luminescence and the luminescence stems from the metal ions, organic molecules or coordination complexes. The general mechanisms for these two types are depicted in (Figure 1.38a) [162–163]. Both ground and excited states evolve from the MOs of organic molecules and coordination complexes. The fundamental mechanism is similar in all cases, to excite an electron from the ground to an excited state and the consecutive return to the ground state through emitting of a photon that is with nanoparticles spanning the gap between molecules and semiconductors. Generally, a distinction can be defined between two main luminescence phenomena: fluorescence and phosphorescence which shown in (Figure 1.38b) [163].

**Figure 1.38** : Simplified mechanisms of semiconductor (electronic bands; left) and molecular based excitation/emission processes (discrete energy levels; right) (a) ; Jablonski diagram showing basic photophysical processes; S denotes singlet, T triplet states; internal conversion and intersystem crossing are nonradiative processes; intersystem crossings are accompanied by a forbidden change in the spin state (b) [163]

Lanthanide-based luminescence has proven its versatility in many areas including solid state lighting and biomedicine [164]. Different lanthanide elements in their trivalent state expose various luminescence colors and characteristics (Figure 1.39). A huge number of luminescent lanthanide materials are relevant to Tb (III) and Eu(III) which provide green or red  $4f-4f$  emissions, respectively. Furthermore, Tb (III) and Eu(III) ions identify an energy gap between their main emissive and receiving states that is large enough to avoid pronounced vibrational quenching. Lanthanide ions such as Nd(III), Er(III) or Yb(III) can provide  $4f-4f$  emissions in technologically relevant ranges such as NIR [186] or show up conversion effects where two or more NIR photons are combined into one shorter wavelength [163].

**Figure 1.39:** Wavelength of the main emissive transitions of the trivalent lanthanide coordination compounds in the near-UV to near-IR range; the relative intensities of transitions and thus the overall emission color of a lanthanide (III) compound may vary and that Ce(III) emissions are  $5d-4f$  in nature, covering the indicated range depending on the chemical environment of the cerium ion [163]

So far, lanthanides show much richer photophysics, as they are not generally restricted to MC  $4f-4f$  luminescence [165]. Evidently, Ce(III) can show  $5d-4f$  transitions due to an emission in the visible range, as the energetic level of the  $d$  states is dropped by ligand and crystal fields. These transitions exhibit a much higher dependence on the coordination environment of the metal ion than  $4f-4f$  transitions, due to participation of  $5d$  states. They cause broad absorption and emission bands that do not require an antenna effect to improve brightness, as the transitions  $f-d$  and  $d-f$  are parity allowed. This is also observed for divalent lanthanide ions like Eu(II), because they can also commit  $5d$  levels in luminescence processes. Reduction of energy of  $5d$  states depends on chemical surrounding and the crystal field dominates broad band processes that are parity allowed and as strong as for Ce (III). Hence, transitions involving  $d$  and  $f$  states significantly differ from  $4f-4f$  transitions [163].

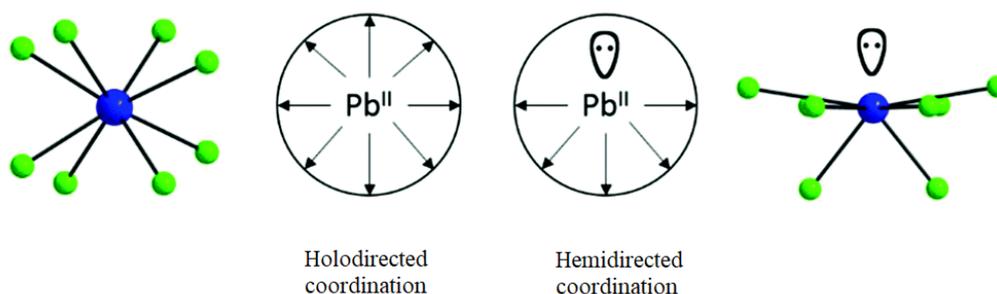

The construction of lanthanide CPs and MOFs vary in some aspects from those containing transition metals. Moreover, under different synthetic thermal conditions involving room temperature or solvothermal which leads to CP formation, the co-ordination of water or other oxygen-containing solvents often cannot be avoided. Nevertheless, lanthanide CPs mostly possess interesting and unusual topologies and often forming iso-structural series. Luminescent lanthanide CPs and MOFs represent a well-established area, which has already been developed towards applications [166–167]. Although Eu(III) and Tb(III) are often selected for luminescence studies, almost of the lanthanides exhibit photoluminescent properties. The energy levels of some commonly used lanthanides are shown in (Figure 1.39). Except Gd(III), the highest labeled energy level for each element is the level from which luminescence occurs. In fact, the lifetimes of nearly all lanthanides emissive transitions are very long, on the order of hundreds of microseconds. This

prevents their use in applications requiring fast emission, such as scintillation and displays. When the luminescence is sensitized through the antenna effect, the lifetime is even longer, usually close to a millisecond [167–168].

## 1.7. Lead coordination chemistry

According to the general rule concerning oxidation states of the p block elements, lead shows the oxidation states II and IV. However, Lead exposes oxidation state II more than IV in coordination compounds due to effect of the so-called “inert electron-pair”[169]. This property was explained by the relativistic stabilization of the 6s orbital, caused by the direct relativistic effect and the presence of the filled 4f subshell. The lead (IV) compounds are strong oxidants in aqueous systems, being spontaneously reduced to lead (II) under formation of oxygen gas.

The lead (II) displays the broad range of coordination numbers from 2 to 12. Therefore, a large variety of configurations of its complexes and compounds results [170]. According to the valence bond theory, the inert electron-pair can either occupy a hybrid orbital formed by mixing the 6s and 6p orbitals on the metal ion and as such becoming stereochemically active or be a pure  $s^2$  electron-pair and thereby stereochemically inactive. In terms of coordination number, this means that the hybrid orbital with a lone electron-pair can be considered an additional ligand in the coordination sphere normally even taking up *more* space than that of an ordinary ligand [171]. However, according to molecular orbital theory the classical conception of 6s/6p orbital hybridization on the lead (II) ion is regarded as incorrect. This is because the energy levels of these orbitals are too unsimilar and the different spatial distribution of their corresponding wave functions [172–175]. Instead, the stereochemical activity observed in lead (II) complexes should be noticed as a result of an antibonding lead 6s-ligand np (6s/np) interaction which causes structural distortions to energetically minimize these unfavorable covalent interactions [172–175]. Two general structural types of lead (II) complexes are determined, *hemidirected* and *holodirected*, as introduced by Shimoni-Livny et al (Figure 1.40) [176]. In the former, the electron distribution around the metal ion is greatly unevenly distributed, caused by antibonding metal–ligand interactions creating a visual gap in the coordination sphere [177].

**Figure 1.40:** Pb (II) complexes can be either hemidirected (right) or holodirected (left) [178]

The lead coordination sphere can be defined as holodirected in complexes in which the bonds to ligand atoms are directed toward the surface of encompassing sphere, while hemidirected refers to those cases where the bonds to ligand atoms are directed only to a part of the coordination sphere, leaving a gap in the distribution of bonds to the ligand [179–183]. Lone pair activity may depend on the following factors: (i) low or high coordination number, (ii) hard or soft ligands, (iii) attractive versus repulsive interactions among ligands, (iv) fewer or more electron donation from ligands to metal [184].

## Chapter 2

### 2. Materials and instruments and methods

#### 2.1. Instruments and softwares and materials

##### 2.1.1. Instruments

- (i) Elemental analysis (CHNS) were performed on a Hekatech elemental analyzer for C, N, H and S analyses of samples.
- (ii) The ATR-IR spectra were recorded in the range 400–4000  $\text{cm}^{-1}$  on a Bruker Alpha spectrometer.
- (iii) X-ray diffraction measurements were performed using a *Siemens P4* diffractometer with monochromated Mo ( $K\alpha$ ) radiation for lanthanide, silver, copper and lead compounds and Ag ( $K\alpha$ ) radiation for lead compound of formula  $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$  at room temperature via Stoe IPDS diffractometer.
- (iv) TGA and DSC analysis were carried down by using instrument netzsch sta 449 F1.
- (v) Autoclave, general purpose acid digestion vessel 25 ml with PTFE cup and cover.

##### 2.1.2. Software

- i) 3D scheme of structures were drawn by *Mercury 3.7* and *Diamond 4.1.2*.
- ii) The resolutions of 3D scheme of structures were improved by *POV-Ray 3.7*.
- iii) Diagrams drawing have been done by means of *Origin Pro 8.5*.

##### 2.1.3. Materials

All the starting materials and solvents for synthesis were purchased from commercial supplier Sigma–Aldrich and Merck and also used as received without purification.

## 2.2. Synthesis methods of compounds

### 2.2.1 Silver coordination polymer

#### Synthesis of complex $[\text{Ag}_2(\text{HPO}_3\text{CH}_2\text{COOH})]_n$ (1)

Slow diffusion of aqueous solution of Ag (I) nitrate with ligand solution in H-Tube was carried out in light exclusion.  $\text{AgNO}_3$  (2mmol) was dissolved in 3 ml water and carefully placed in right wing of H-tube. Phosphonoacetic acid (1mmol) and sodium hydroxide (2mmol) were dissolved in 3 ml water and carefully placed in left tube. The tube was slowly filled by EtOH and sealed. After several weeks the colorless crystals were formed on inner surface of tube and suitable for X-ray structural analysis. Yield: *Ca.* 69% based on Ag. Elemental analysis: *Anal.* Calc. for  $\text{Ag}_2\text{C}_2\text{H}_3\text{O}_5\text{P}$  (353.75): C, 6.78 ; H, 0.848 ; O, 22.61 . Found: C, 6.70 ; H, 0.834 ; O, 22.61%. IR spectra:  $\nu(\text{cm}^{-1}) = 2369(\text{w}), 2221(\text{w}), 2159(\text{w}), 1522(\text{vs}), 1410(\text{s}), 1363(\text{m}), 1207(\text{s}), 1178(\text{m}), 1158(\text{s}), 1122(\text{m}), 1041(\text{m}), 953(\text{m}), 912(\text{s}), 867(\text{m}), 818(\text{m}), 634(\text{s}), 568(\text{s}), 518(\text{m}), 499(\text{s}), 469(\text{s})$ .

### 2.2.2 Lanthanide coordination polymers

#### 2.2.2a. Neodymium coordination polymer $\{[\text{Nd}_2(\text{FDA})_3(\text{DMF})(\text{H}_2\text{O})_2] \cdot \text{DMF} \cdot (\text{H}_2\text{O})_2\}_n$ (2)

2,5-Furandicarboxylic acid (1.5 mmol) and neodymium nitrate (1mmol) were poured into capped tube. Then DMF (10 ml) was added into tube and the reagents were stirred powerfully. Afterwards, the tube was sealed and put into oil bath and heated around 120 °C. The pale pink-colored crystal was formed within five days. They were collected and washed by acetone and distilled water. Yield: *Ca.* 43% based on Nd. *Anal.* Calc. for  $\text{C}_{24}\text{H}_{30}\text{N}_2\text{Nd}_2\text{O}_{22}$  (986.48) : C, 29.2; H, 3.04; N, 2.89. Found: C, 30.01; H, 3.06; N, 2.78 %. IR ( $\text{cm}^{-1}$ ): 3560 (w), 3290 (m), 3115(w), 2271 (w), 2205 (w), 2075(w), 2044(w), 1983(w), 1651 (m), 1639 (m), 1623(m), 1562(vs), 1548(vs), 1438(w), 1366(vs), 1223(m), 1198(m), 1165(m), 1104(m), 1061(m), 1023(m), 832(m), 821(vs), 782(vs), 674(m), 664(vs), 615(s), 491(s).

#### 2.2.2b. Samarium coordination polymer $\{[\text{Sm}_2(\text{FDA})_3(\text{DMF})(\text{H}_2\text{O})_2] \cdot \text{DMF} \cdot (\text{H}_2\text{O})_2\}_n$ (3)

2,5-Furandicarboxylic acid (1.5 mmol) and samarium nitrate (1mmol) were poured into capped tube. Then DMF (10 ml) was added into tube and the reagents were stirred powerfully. Afterwards, the tube was sealed and put into oil bath and heated around 120 °C. The pale pink-colored crystal was formed within five days. They were collected and washed by acetone and distilled water. Yield: *Ca.* 50.05 % based on Sm. Elemental analysis: *Anal.* Calc. for

$C_{24}H_{30}N_2O_{22}Sm_2$  (998.72): C, 28.84; H, 3.004; N, 2.80. Found: C, 29.04; H, 3.00; N, 2.84 %. IR ( $cm^{-1}$ ): 3365 (m), 2274 (w), 2214 (w), 2076(w), 2021(w), 1651(m), 1638 (m), 1623(m), 1561(vs), 1549(vs), 1375(vs), 1223(m), 1198(m), 1165(m), 1104(m), 1061(m), 1012(m), 833(m), 822(vs), 783(vs), 675(m) , 664(vs) , 615(s) , 491(s).

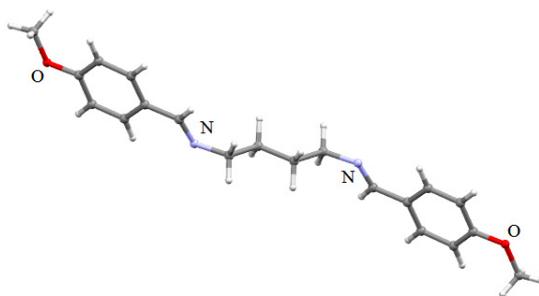

### **2.2.2c. Cerium coordination polymer $[Ce(pdc)(DMF)_2(NO_3)]_n$ (4)**

Pyrazole-3,5-dicarboxylic acid (1.5 mmol) and cerium nitrate (1mmol) were dissolved in DMF (10 ml) and the mixture was stirred powerfully. Afterwards, the mixture was transferred into teflon-lined autoclave vessel (25 ml) and sealed and heated around 150 °C for 4 days. Subsequently, the mixture was moderately cooled down in rate of 5 °C per hour for 48 hours. The transparent crystals were formed and collected and washed by acetone and water. Yield: *Ca.* 72% based on Ce. Elemental analysis: *Anal.* Calc. for  $C_{11}H_{16}CeN_5O_9$  (642.23) : C, 20.55; H, 2.49 ; N, 10.90 %. Found: C, 20.64 ; H, 2.44 ; N, 10.85 %. IR ( $cm^{-1}$ ): 3375 (m), 2300 (w), 2215 (w), 2040(w), 1674(vs), 1623(m), 1556 (s), 1489(vs), 1444(s), 1297(m), 1202(m), 853(w), 833(vs), 783(vs), 770 (m), 738 (m), 715(m).

### **2.2.3. Copper (I) and Schiff-base coordination polymer**

#### **a) Preparation of ligand 1. [ N,N'- bis (4-methyl-benzylidene)butane-1,4-diamine] (L<sub>1</sub>)**

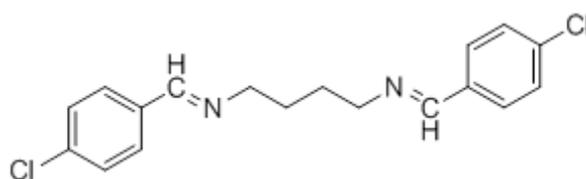

The solution of 4-Methoxy benzaldehyde (10 mmol) in 40 mL methanol was stirred and heated gently (ca. 60 °C) for 10 min. The solution of 1,4-Diaminobutane (5 mmol ) in 10 mL methanol was added dropwise with constant stirring. The mixture was heated for 2 hours and then allowed to cool over the night. The resulting crude solid was collected and filtered and washed several times with methanol. Yield: *Ca.* 97%. Elemental analysis: *Anal.* Calc. for  $C_{20}H_{24}N_2O_2$  (324) : C, 74.07 ; H, 7.40 ; N, 8.63. Found: C, 74.17; H, 7.35; N, 8.60 %. IR ( $cm^{-1}$ ): 3074 (w), 2832 (m), 2541 (m), 2909(m), 1644(s), 1605(s), 1578(s), 1508(m), 1441(m), 1379 (m), 1299 (s), 1177(m), 1165(m), 1045 (s), 1001(w), 830(vs), 769(w), 743(w), 609(m).

**Figure 2.1:** Schematic view of Schiff-base ligand [ N,N'- bis (4-methyl-benzylidene)butane-1,4-diamine] (L<sub>1</sub>)

**b) Preparation of ligand 2. [ N,N'- bis (4-chloro-benzylidene)butane-1,4-diamine] (L<sub>2</sub>)**

The solution of 4-Chlorobenzaldehyde (10 mmol ) in 40 mL methanol was under stirring and heating moderately for 15 min. 1,4-Diaminobutane (5 mmol ) in 10 mL methanol was added dropwise with constant stirring. The mixture was heated around 50–60 °C for 2 hours and then allowed to cool overnight at room temperature. The resulting crystalline solids were collected and filtered and washed several times with methanol. The FT-IR analysis was carried out and the peak at 1646.51 cm<sup>-1</sup> was assigned to C=N group. *Anal.* Calc. for C<sub>18</sub>H<sub>18</sub>N<sub>2</sub>Cl<sub>2</sub> (332.9): C, 64.88; H, 5.41; N, 8.41. Found: C, 64.80; H, 5.40; N, 8.38 %. IR (cm<sup>-1</sup>): 3067 (m), 2964 (m), 2939 (m), 2909(m), 2857(m), 2836(m), 1646(vs), 1592(s), 1570(m), 1483(m), 1448(w), 1403(m), 1372(m), 1335(m), 1212(w), 1185(vs), 1039(m), 1008(m), 849(vs), 775(w), 708(w), 544(s), 503(s).

**Figure 2.2:** Schematic view of Schiff-base ligand [ N,N'- bis (4-chloro-benzylidene)butane-1,4-diamine] (L<sub>2</sub>)

**2.2.3a. Preparation of [Cu((μ<sub>N,N'</sub>-4-MeO-ba)<sub>2</sub>bn)Br]<sub>n</sub> (5)**

CuBr (3 mmol ) was dissolved in 10 mL acetonitrile and L<sub>1</sub> ( 3mmol ) was dissolved in 5 mL Chloroform. Method is combination of layering in test tube and slow evaporation. First at all, the acetonitrile solution was layered onto ligand solution in test tube and allowed them to diffuse slowly. After diffusion, the solution was put at room temperature to slow evaporation without any turbulence. After 2 days, the yellow crystals were formed. The FT-IR analysis was carried out and the peak at 1644 cm<sup>-1</sup> was assigned to C=N which shifted to lower frequency around 1625 cm<sup>-1</sup> in complex form. *Anal.* Calc. for C<sub>20</sub>H<sub>24</sub>CuBrN<sub>2</sub>O<sub>2</sub> (467.45) : C,

51.34; H, 5.13; N, 6.00 %. Found: C, 51.30; H, 5.15; N, 5.97 %. IR ( $\text{cm}^{-1}$ ): 3362(w), 3015(w), 2971(w), 2947(w), 2852(w), 1620 (s), 1598(s), 1461(m), 1443(m), 1420(w), 1351(m), 1303(s), 1255(m), 1171(vs), 1116(w), 1028(vs), 1014(m), 965(w), 861(vs), 831(w), 730(w), 524(s).

### 2.2.3b. Preparation of $[\text{Cu}((\mu_{\text{N},\text{N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$ (6)

CuI (3 mmol) was dissolved in 10 mL acetonitrile and L<sub>1</sub> (3mmol) was dissolved in 5 mL Chloroform. The method is similar to preparation complex (5). *Anal.* Calc. for  $\text{C}_{20}\text{H}_{24}\text{CuIN}_2\text{O}_2$  (514.45): C, 46.65; H, 4.66; N, 5.44%. Found: C, 46.61; H, 4.62; N, 5.39 %. IR ( $\text{cm}^{-1}$ ): 3067 (w), 2963(w), 1620 (m), 1601 (s), 1572 (m), 1510(s), 1458(w), 1393(m), 1309(vs), 1257(vs), 1024(vs), 1003(m), 962(w), 861(vs), 837(s), 809(w), 739(w).

### 2.2.3c. Preparation of $[\text{Cu}((\mu_{\text{N},\text{N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$ (7)

CuI (3 mmol) was dissolved in 10 mL acetonitrile and L<sub>2</sub> (3mmol) was dissolved in 5 mL Chloroform. The method is similar to preparation complex (5). *Anal.* Calc. for  $\text{C}_{18}\text{H}_{18}\text{CuIN}_2\text{Cl}_2$  (523.34): C, 47.43; H, 4.60; N, 7.37. Found: C, 46.59; H, 4.69; N, 7.19%. IR ( $\text{cm}^{-1}$ ): 3055(w), 2039(w), 2907(w), 1624(s), 1585(m), 1478(s), 1454(m), 1408(w), 1354(w), 1296(w), 1169(m), 1089(s), 1008(w), 970(m), 857(vs), 835(vs), 749(w), 506(vs).

## 2.2.4. Lead coordination polymers

### 2.2.4a. Preparation lead compound $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$ (8)

$\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$  (1mmol), and  $\text{NaN}_3$  (2 mmol) were loaded into one arm of branched tube. Both arms were slowly filled by acetonitrile and the tube was completely sealed. The arm filled by reagents was immersed in oil bath at 68 °C while other arm was kept at room temperature. The colorless tiny crystals were formed on inside surface of cooler arm within one week in 25% base on lead. The crystals were collected and washed by acetone. Yield: *Ca.* 25% based on Pb. Elemental analysis: *Anal.* Calc. for  $\text{C}_4\text{H}_6\text{N}_{12}\text{O}_4\text{Pb}_3$  (907.78) : C, 5.29 ; H, 0.66 ; N, 18.51 %. Found: C, 5.23; H, 0.65; N, 18.49 %. IR (in  $\text{cm}^{-1}$ ):  $\nu$  2019 (vs), 2001 (m), 1485 (m), 1395 (vs), 1334(s), 1147(w), 1016 (m), 935 (w), 843 (w), 683(w), 660 (s), 642 (s), 617 (s).

#### 2.2.4b. Preparation of lead compound $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$ (9)

$\text{Pb}(\text{CH}_3\text{COO})_2 \cdot 3\text{H}_2\text{O}$  ( 1.5 mmol ) and  $\text{NaN}_3$  (1.5 mmol) were added to one arm of branched tube. The method is thermal gradient and similar to preparing method of complex (8). The colorless cubic crystals were formed on inside surface of cooler arm within 2 weeks in 48 % base on lead. The crystal was filtered and washed by acetone and methanol. Yield: *Ca.* 48% based on Pb. Elemental analysis: *Anal.* Calc. for  $\text{C}_{12}\text{H}_{18}\text{O}_{17}\text{Pb}_2\text{Na}_2$  (814.62): C, 17.68; H, 2.21; N, 0 %. Found: C, 17.68; H, 2.02; N, 0 %. IR (in  $\text{cm}^{-1}$ ):  $\nu$  1528 (vs), 1391 (vs), 1336 (m), 1047 (w), 1019 (m), 922 (w), 655 (m), 641 (vs), 616 (m), 482 (s), 467 (w).

#### 2.2.4c. Preparation of lead compound $[\text{Pb}(\text{DHBDA})]_n$ (10)

$\text{Pb}(\text{NO}_3)_2$  (1mmol ) was dissolved in 7 ml deionized water. Ligand L= 2,5-Dihydroxy-1,4-benzenediacetic acid (1.25mmol) was dissolved in 7 mL ethanol. The metal ion solution was poured into a test-tube, then the ligand solution was carefully layered on it. The test-tube was perfectly sealed. After standing at room temperature for almost two weeks, the fine crystals were formed. The crystals were collected and washed by deionized water and ethanol. The yield was around 41 % based on lead. Elemental analysis: *Anal.* Calc. for  $\text{C}_{10}\text{H}_8\text{O}_6\text{Pb}$  (431.35): C, 27.82; H, 1.85%. Found: C, 27.76; H, 1.94 %. IR ( in  $\text{cm}^{-1}$ ):  $\nu$  3340(w), 3197 (w), 3035(w) 3016 (w), 3010 (w), 2345 (w), 2188 (w), 2069 (w), 2010 (w), 1524 (s), 1498 (s), 1426 (vs), 1397 (vs), 1340 (s), 1281 (s), 1247 (s), 1221 (s), 1168 (m), 1147 (m), 946 (s), 908 (m), 886 (s), 852 (m), 775 (s), 662 (m), 572 (m), 487 (m).

## Chapter 3

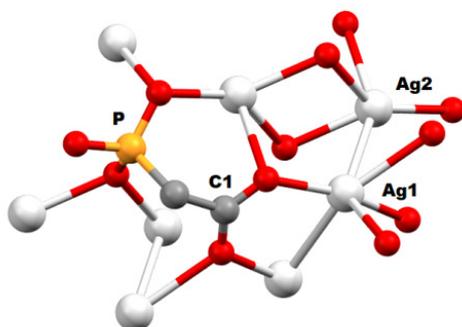

### 3. Results and discussion

#### 3.1. Silver coordination polymer $[\text{Ag}_2(\text{HO}_3\text{PCH}_2\text{COO})]_n$ (**1**)

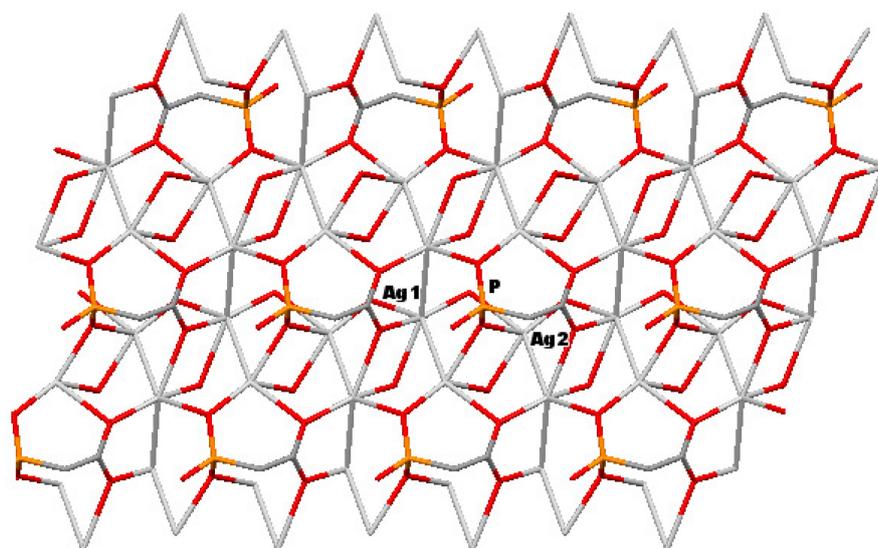

##### 3.1.1. Crystal structure determination

X-ray single-crystal diffraction analysis reveals that silver complex emerges as two-dimensional coordination polymer and there are two crystallographically non-equivalent silver atoms (Ag1 and Ag2) and one phosphonoacetic acid ligand in an asymmetric unit. This compound crystallizes in the triclinic system with  $P\bar{1}$  space group. The coordination sphere around the (Ag1) atom can be described as distorted tetrahedron, with four oxygen atoms (O1, O2, O3) from four individual ligands. The other silver atom (Ag2) possesses coordination number of four, formed by four coordinated oxygen atoms (O2, O3 and O5) from four different ligands, adopting distorted tetrahedron coordination sphere, (Figure 3.1 and 3.2). Crystallographic data are presented in (Table 1). In this compound, the Ag–O bonds are in range between 2.212(4) Å and 2.683(5) Å for Ag1–O and 2.364(4) Å to 2.856(5) for Ag2–O respectively which lie in normal ranges [185–193]. In compound (**1**), the argentophilic interactions between Ag1–Ag1, Ag1–Ag2 atoms are observed and the argentophilic distances are 3.0892(9) Å and 2.8733(9) Å respectively. [185–193] As matter of interest, The Ag1–Ag2 distance is slightly shorter than the Ag1–Ag1 interactions. But it is significantly less than twice the van der Waals radius for silver (3.44 Å) and therefore suggests a  $d^{10}$ – $d^{10}$  closed shell argentophilic interaction. In comparison, the expected range for argentophilic interactions is between 2.96 Å and 3.66 Å [194–201]. In this network, the ligand behaves as bridging ligand as it coordinates to silver atoms via oxygen atoms of both carboxylate and phosphonate moieties. The carboxylate groups are coordinated to silver atoms through coordination mode  $(\mu_4-\eta^2:\eta^2)$  [202–204] while the phosphonate moieties adopt coordination fashion  $\{1M, 1M, 1H-1M\}$  or  $(\mu_3-\eta^1:\eta^1:\eta^1)$  to construct the framework [205–206]. It is also worth to notice that P atom has a near tetrahedral C–PO<sub>3</sub> coordination environment, with angles  $\angle\text{O3-P-O4}$ ,  $\angle\text{O3-P-O5}$  and  $\angle\text{O4-P-O5}$  are 111.0°(3), 114.8°(3), 107.2°(3) and P–O bond lengths in the range 1.509(5)–1.562 (4) Å and a P–C bond length of 1.806(7) Å, respectively. Due to high bridging mode of oxygen atoms in the ligand, a two dimensional network is constructed, as illustrated with (Figure 3.2). The overall structure is best described as 2D neighboring layers

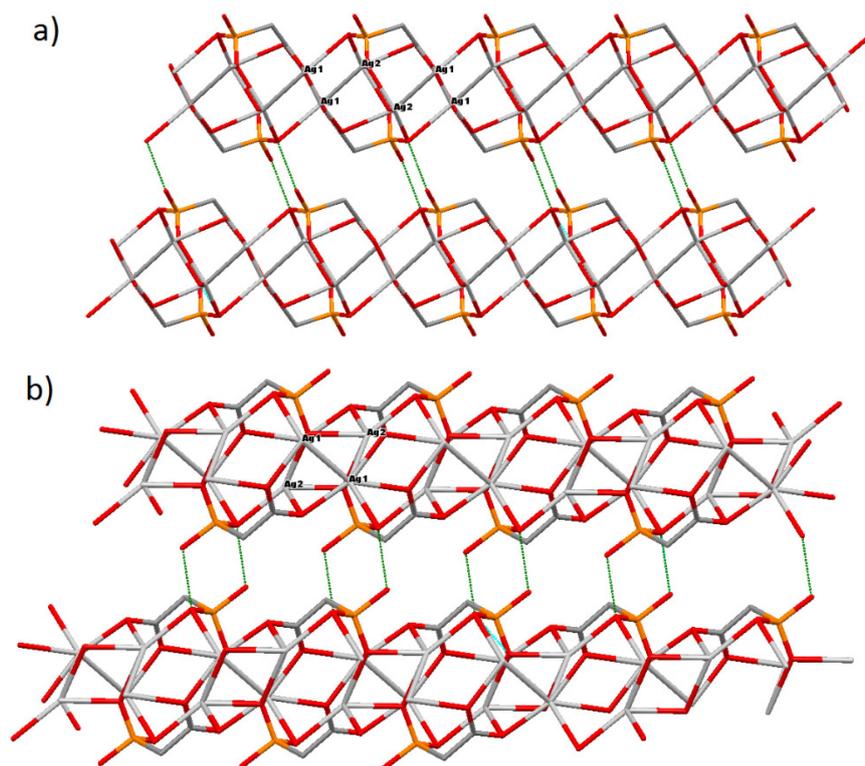

of silver complexes which are linked through O–H...O hydrogen-bonding interactions with short distances (O4...O3: 2.632 Å), to form a 3D supramolecular framework (Figure 3.3).

**Figure 3.1:** Molecular structure of silver compound

**Figure 3.2:** Schematic view of layered structure of compound (1)

**Figure 3.3:** Two different view of packing arrangement in silver compound along crystallographic a) *a*-axis; b) *b*-axis; Available interchain hydrogen-bonding interactions are presented as green dotted lines between layers

To conclude, a new silver coordination polymer with phosphonoacetic has been synthesized via slow diffusion method in mixture of water and ethanol as solvents. Actually some coordination polymers of transition metals have been reported, in which phosphonoacetic acid has been utilized in combination with co-ligands [207–210]. A new silver coordination polymer exhibits very unique structure without any coordinated or guest solvent molecules, hence it has very robust and interesting polymeric structure.

**Table 3.1:** Crystal data and refinement details for the X-ray structure determinations of the silver compound (1)

Silver compound (1)	
Empirical formula	C <sub>2</sub> H <sub>3</sub> Ag <sub>2</sub> O <sub>5</sub> P

### 3.1.2. IR Spectra of compound (1)

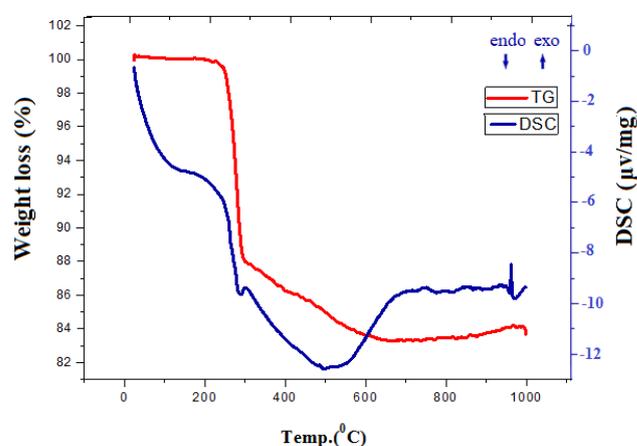

A parallel study of the IR spectra of silver compounds gives some interesting information regarding the binding sites of phosphonoacetic acid ligand. The absence of strong IR bands around  $1730\text{ cm}^{-1}$  in the spectra of silver compound implies that the carboxylic group is fully deprotonated [211–212]. The  $\Delta$  values, defined by Deacon and Phillips for asymmetric and symmetric stretching vibrations of carboxylate, relieves some qualitative information which correlate the data of the infrared spectra with the coordination modes of metal carboxylates. The  $\Delta$  value (ca.  $112\text{ cm}^{-1}$ ) is compatible with the presence of bridging carboxylate. For non-bridging carboxylate coordination, this  $\Delta$  separation is usually greater than (ca.  $350\text{ cm}^{-1}$ ) [213–214]. Deacon and Phillips have vastly investigated the FT-IR spectra of many metal carboxylate complexes with known crystal structure and they have finally come to a conclusion for the correlations between carboxylate stretching frequencies and their coordination sphere [213]. In the IR spectra of compound (1), two strong bands exist at  $1522\text{ cm}^{-1}$  and  $1410\text{ cm}^{-1}$  which are attributed to asymmetric and symmetric stretching vibrations of a bridging acetate functionality of the phosphonoacetate ligand, respectively. The difference of  $112\text{ cm}^{-1}$  between the asymmetric and symmetric stretching vibrations is ascribed to the syn–anti tetradentate bridging mode ( $\mu_4\text{-}\eta^2\text{:}\eta^2$ ) of the acetate group. In principle, the order of  $\Delta$  ( $\Delta = \nu_{as}(\text{COO}^-) - \nu_s(\text{COO}^-)$ ) for divalent metal carboxylates is followed by  $\Delta$  (bridging) <  $\Delta$  (monodentate) [213–220]. The lower values of  $\Delta$  (for example  $\Delta = 112$ ) compared to higher values strongly imply the presence of syn–anti bidentate bridging or chelating in comparison to the monodentate terminal coordination.

On the other hand, there is no peak found between  $3641\text{ cm}^{-1}$  and  $3349\text{ cm}^{-1}$ , which normally are assigned to  $\nu_{\text{O-H}}$  of water molecules that are involved in hydrogen bonds. Hence the absence of such peaks indicates the absence of water molecules. Furthermore, the sharp peaks in the  $953\text{--}1178\text{ cm}^{-1}$  region can be ascribed to the P–O and P=O stretching vibrations of phosphonate moieties.

### 3.1.3. Thermal analysis of compound (1)

The framework stability and thermal decomposition behavior of silver compound were studied by thermal gravimetric analysis (TGA) and differential scanning calorimetric (DSC) techniques under the air atmosphere in the temperature range between 25 and  $800\text{ }^{\circ}\text{C}$ . The TG/DSC curves are depicted in (Figure 3.4) and the decomposition of the organic material occurs only in two steps. The TGA curve exhibits that this compound has very high stability and it is stable upon to ca.  $260\text{ }^{\circ}\text{C}$ . The main mass loss of  $12.17\%$  onsets at  $260\text{ }^{\circ}\text{C}$  and is completed at  $300\text{ }^{\circ}\text{C}$ , with an exothermic DSC peak at  $289.1\text{ }^{\circ}\text{C}$ . This mass loss stage can be ascribed to partial decomposition of ligand. The silver compound undergoes a second mass loss of  $4.16\%$  between  $750$  and  $800\text{ }^{\circ}\text{C}$ . The total mass loss of  $16.33\%$  is in agreement with the theoretical values of  $15.56\%$ . For this compound, thermal decomposition product with percentage  $83.67\%$  can be assigned to  $\text{Ag}_4\text{P}_2\text{O}_7$  compound which corresponds well to calculated value  $84.7\%$ .

The new silver compound shows very high stability against the temperature rising. This material underwent the total mass loss ( $16.33\%$ ) by heating up around  $800\text{ }^{\circ}$  which indicates the higher thermal stability of new compound.

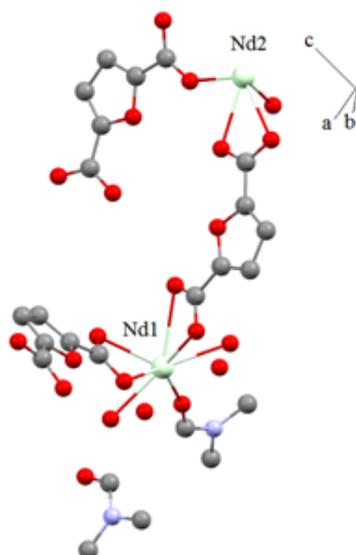

**Figure 3.4:** Thermal analysis curves of compound  $[\text{Ag}_2(\text{HO}_3\text{PCH}_2\text{COO})]_n$  along with Differential Scanning Calorimetric (DSC), recorded at various representative temperatures

## 3.2. Lanthanide coordination polymers

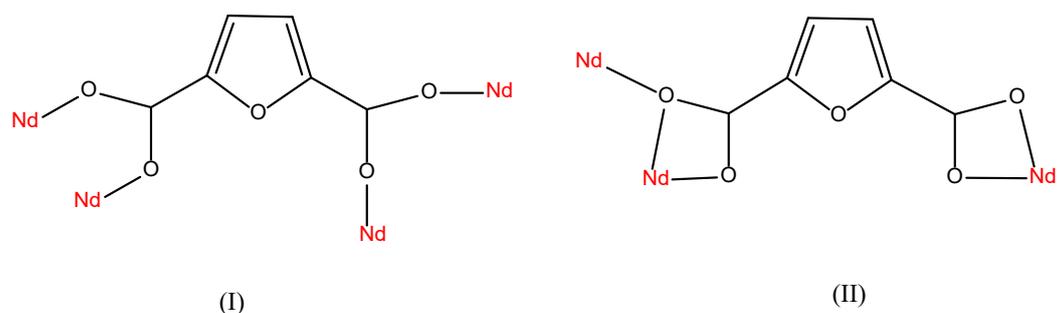

### 3.2.1. Crystal structure determination of Neodymium (2) and Samarium coordination polymers (3)

Neodymium and samarium coordination polymer were synthesized by reaction between 2,5-furan-dicarboxylic acid ( $H_2FDA = 2,5\text{-furandicarboxylic acid}$ ) and samarium and neodymium nitrate in DMF as solvent. The X-ray structural analysis reveals that neodymium compound  $\{[Nd_2(FDA)_3(DMF)(H_2O)_2] \cdot DMF \cdot (H_2O)_2\}_n$  and samarium compound  $\{[Sm_2(FDA)_3(DMF)(H_2O)_2] \cdot DMF \cdot (H_2O)_2\}_n$  are iso-structural and feature as three-dimensional coordination polymer and crystallize in the space group  $P2_1/n$ . Crystallographic data and structural refinements for both compounds are listed in (Table 3.3). Since both structures of neodymium and samarium coordination compounds are identical, neodymium coordination polymer is described in detail. In compound (2), each asymmetric unit contains of two crystallographically independent Nd(III) (Nd1, Nd2) ions, three  $FDA^{2-}$  ligands, three coordinated and two non-coordinated water molecules and one coordinated and one non-coordinated DMF molecules which is shown in (Figure 3.5). Nd1 ion is nine-coordinated and surrounded by six carboxylate oxygen atoms from four individual  $FDA^{2-}$  ligands and two oxygen atoms from two coordinated water molecules (O1W and O3W) and one oxygen atom from DMF molecule (O17) which adopts monocapped square antiprismatic coordination sphere with O–Nd1–O bond angles ranging from  $47.8$  to  $154.9^\circ$  in which the oxygen atoms of (O1W, O3W, O7 and O14) and (O1, O2, O6, O7) define upper and lower tetragonal caps while the (O17) atom occupied an axial position. Nd2 ion is also nine-coordinated and the coordination environment around each Nd2 ion are eight carboxylate oxygen atoms of five individual  $FDA^{2-}$  ligands and one oxygen atom from coordinated water molecule (O2W). Therefore, each Nd2 ion exhibits the coordination environment of slightly distorted monocapped square antiprism with O–Nd2–O bond angles ranging from  $49.8$  to  $158.3^\circ$  in which an axial position is occupied by oxygen atoms (O12), although the upper and lower tetragonal caps are assigned by oxygen atoms (O4, O9W, O9) and (O3, O8, O11, O13) respectively. Selected bond lengths and angles of compound (2) are given in (Table 3.4).

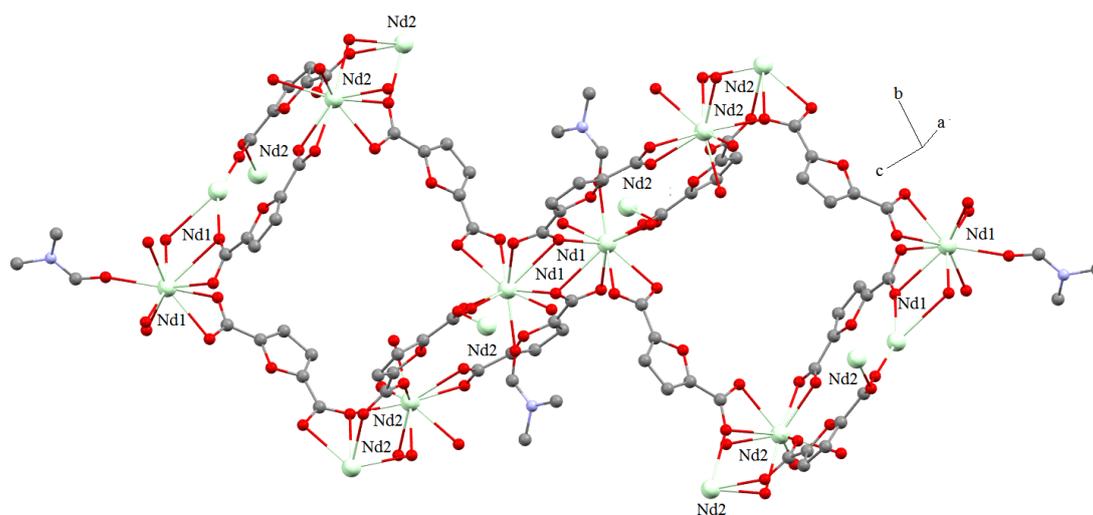

**Figure 3.5 :** Asymmetric unit of neodymium coordination polymer.

The two neighboring Nd1 ions are connected through the bridging behavior of oxygen atoms (O7) to generate the dinuclear unit. Furthermore there is the same for both Nd2 ions as dinuclear unit. By far, the oxygen atoms (O4) are bridging between adjacent Nd2 centres to compose a dinuclear unit (Figure 3.7). Moreover, the adjacent dinuclear units of Nd1 and Nd2 are further linked through bridging behavior of carboxylic oxygen atoms of two FDA<sup>2-</sup> ligands by using coordination mode ( $\kappa^2$ - $\mu_2$ )-( $\kappa^2$ )- $\mu_3$  (O14, O12, O7, O8 and O9), resulting two-dimensional layer illustrated in (Figure 3.6). Then the neighboring sheets are pillared through bridging by whole FDA<sup>2-</sup> ligands in  $\mu_4$ -bridge mode to form three-dimensional frameworks, (Figure 3.8 and 3.9). Obviously, FDA<sup>2-</sup> ligands also act as pillar of adjacent layers and coordinate to Nd(III) ions in two types coordination modes [221–223], (I) bis-bidentate chelating-bridging ( $\kappa^1$ -  $\kappa^1$ )-( $\kappa^1$ -  $\kappa^1$ )- $\mu_4$  and (II) ligand acts as pentadentate donor ( $\kappa^2$ -  $\mu_2$ )-( $\kappa^2$ )- $\mu_3$  which is illustrated with (Figure 3.6).

**Figure 3.6:** Different coordination modes of ligand (2,5-Furandicarboxylic acid) in compounds (2) and (3)

The Nd1–O and Nd2–O bond lengths vary from of 2.293(4) to 2.820(3) Å and 2.391(3) to 2.685(4) Å respectively, comparable to the usual Nd–O<sub>carboxylate</sub> bond lengths reported in previous works [224–228]. It is worth to note that Nd1–O7 bond distance 2.820(3) Å is considerably longer than that of Nd1–O2 2.531(4) Å, which is common for a tridentate carboxylate coordination [227]. Moreover, the angles formed at the metal atom by the chelate rings are quite small [O1–Nd1–O2, 50.85(1)°; O7–Nd1–O6, 47.8(1)°], leading to a distorted polyhedron around the neodymium ions.

### 3.2.2. IR spectra of compounds (2) and (3)

FT-IR spectra of neodymium and samarium compounds were recorded in the range 400–4000  $\text{cm}^{-1}$ . As expected, The IR spectra of both lanthanide compounds are quite similar and in good agreement with the X-ray diffraction structural analysis results. Meanwhile, in a typical spectrum of neodymium complex, the peak around 3100–3500  $\text{cm}^{-1}$  is attributed to the characteristic peak of O—H stretching vibration of water molecules which involves both coordinated and guest water molecules ( $\nu_{\text{O-H}}$ ). The sharp peak appears in region 1651–1548  $\text{cm}^{-1}$  and 1438–1366  $\text{cm}^{-1}$  are contributed to asymmetric and symmetric stretching vibrations of carboxylic groups [213, 224–228] which indicates that the carboxylate groups expose in different coordination modes. Furthermore, the absence of strong peak in the range 1685–1740  $\text{cm}^{-1}$  indicates that the ligands are fully deprotonated in polymeric network [227]. The FT-IR of C=O peak of coordinated DMF molecules is shown at 1638  $\text{cm}^{-1}$ , the stretching vibration of C—N bonds is at 1104  $\text{cm}^{-1}$ .

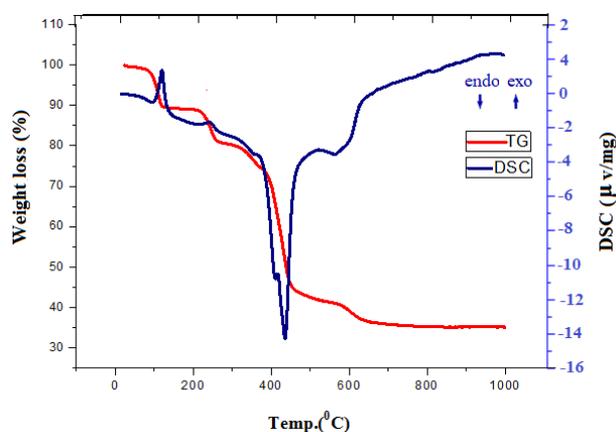

### 3.2.3. Thermal analysis of compounds (2) and (3)

The Thermogravimetric (TG) and the Differential Scanning Calorimetric (DSC) curves of neodymium and samarium coordination polymers were investigated to estimate stability and pathway of thermal decomposition in temperature range from 25 to 1000  $^{\circ}\text{C}$  under flowing of

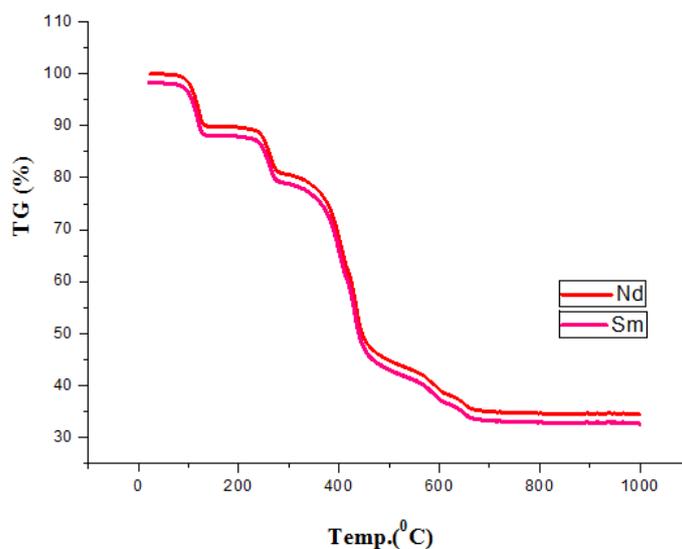

air atmosphere with a heating rate of  $10\text{ }^{\circ}\text{C cm}^{-1}$ , which is shown in (Figure 3.10 and 3.11). The TG and DSC curves of both compounds reveal approximately similar thermal stability and behaviors. In neodymium compound, the mass loss in the temperature range between 25 and  $800\text{ }^{\circ}\text{C}$ , occurring in one dehydration stage and four overlapped decomposition steps leading to final residue  $\text{Nd}_2\text{O}_3$ . The TG curve exposed a gradual mass loss of 7.03% from room temperature to  $130\text{ }^{\circ}\text{C}$ , accompanied by an exothermic DSC peak at  $114.4\text{ }^{\circ}\text{C}$ , can be attributed to the removal of two guest water molecules and two coordinated water molecules. Second step is an offset of decomposition of molecular skeleton, hence the decomposing of the water free coordination polymer of formula  $\text{Nd}_2(\text{L})_3 \cdot 2\text{DMF}$  takes place in temperature range between  $130\text{--}650\text{ }^{\circ}\text{C}$ , including four overlapping decomposition stages with two endothermic and one exothermic peaks. Final product is assigned to  $\text{Nd}_2\text{O}_3$  which is found 34.88%, agreed with calculated value 34.09%.

### 3.2.4. Crystal structure determination of cerium coordination polymer [Ce(pdc)(DMF)<sub>2</sub>(NO<sub>3</sub>)<sub>n</sub>] (4)

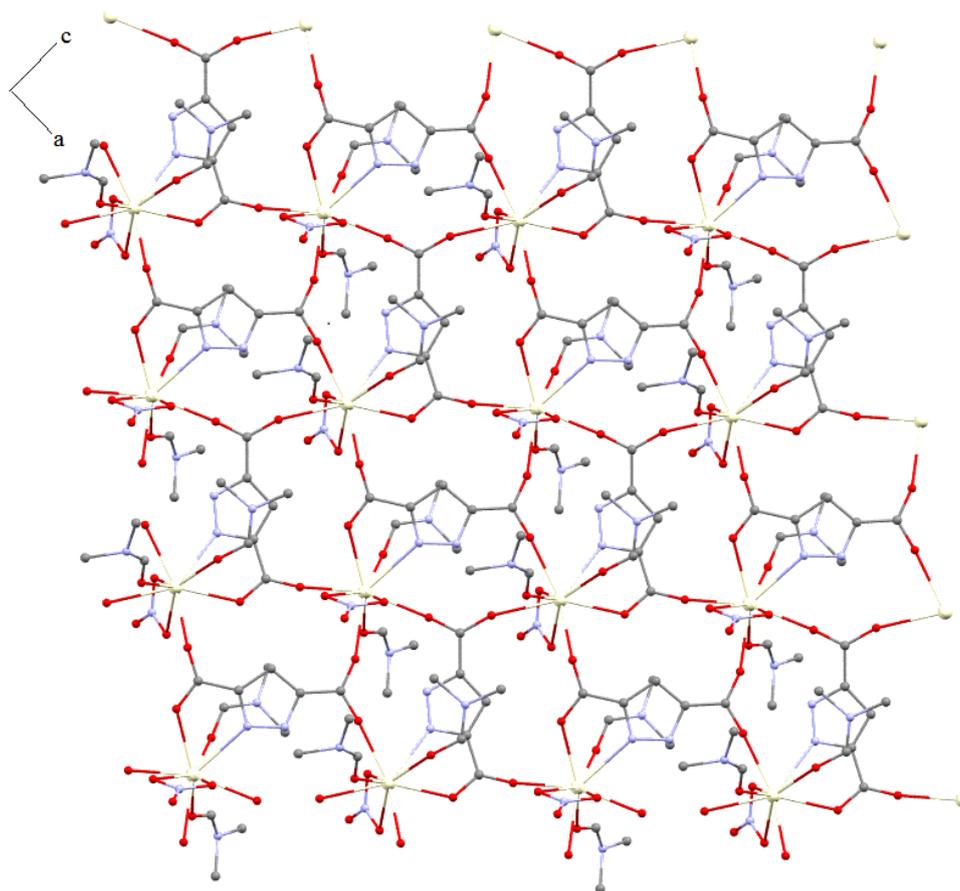

Cerium coordination polymer has been synthesized by reaction between 3,5-pyrazole-dicarboxylic acid ( $H_2pdc = 3,5$ -pyrazoledicarboxylic acid) and cerium nitrate in DMF as solvent. The X-ray crystallographic analysis reveals that cerium coordination polymer displays 2D polymeric structure, and it crystallizes in the orthorhombic system with  $Pna2_1$  space group  $\{a = 10.308(2), b = 19.023(2), c = 8.990(1) \text{ \AA}; \alpha = \gamma = \beta = 90^\circ\}$ . In a structure of compound (4), an asymmetric unit comprises one crystallographically independent cerium ion, one completely deprotonated  $pdc^{2-}$  ligand, two coordinated DMF molecules and one coordinated nitrate anion. Ce(III) ion is nine-coordinated, exposing slightly distorted monocapped square antiprismatic coordination sphere with O–Ce–O angles vary from  $71.4$  to  $142.6^\circ$  in which an oxygen atom of DMF molecule (O9) occupies an axial position along  $b$ -axis while three carboxyl oxygen atoms (O1, O3, O4) as well as DMF oxygen atom (O8) lie in the upper tetragonal caps and also one carboxyl oxygen atom (O2), two oxygen atoms from nitrate anions (O5, O6) and one nitrogen atom of  $pdc^{2-}$  ligand (N1) are attributed lower tetragonal caps respectively. The Ce–N bond length is  $2.671(6) \text{ \AA}$  while the Ce–O bond lengths range from  $2.464(6) \text{ \AA}$  to  $2.612(6) \text{ \AA}$ . These distances are comparable to the usual Ce–O<sub>carboxylate</sub> bond lengths reported in previous works [231–234]. As it is observed in (Figure 3.14), in compound (4), each  $pdc^{2-}$  ligand acts as heteroatomic chelating ligand and adopts a  $\mu_5$ - $\eta^2N,O, \eta^1O', \eta^1O'', \eta^1O'''$  coordination mode to link four Ce(III) ions [235]. Furthermore, the nitrate anion acts as chelating ligand and linked to Ce(III) ions through both oxygen atoms

(O5 and O6), occupying an axial position along *b*-axis. Moreover, both DMF molecules act as monodentate ligand and also are coordinated to Ce(III) ion through their oxygen atoms (O9, O8), lying on *b*-axis position, however they show *trans* configuration to nitrate anions around metal ion. Also, it is worth mentioning that each nitrate anion is located on *trans* position to DMF moieties of adjacent complex in polymeric network (Figure 3.13).

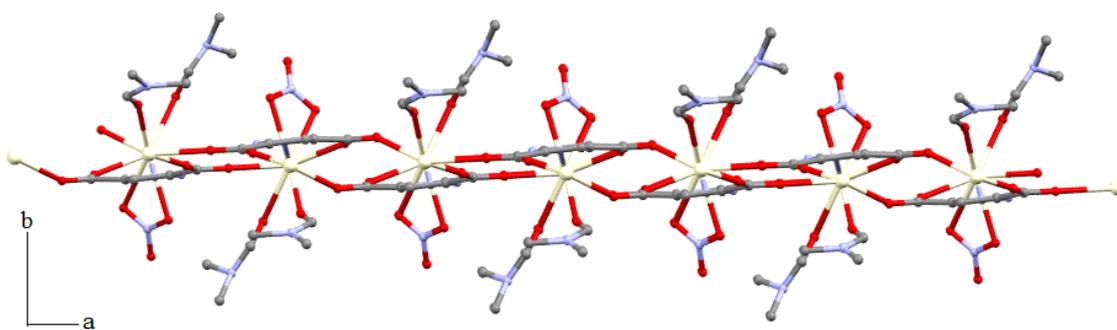

**Figure 3.13:** The coordination environment around cerium ions

As it is observed in (Figure 3.14), each  $\text{pdc}^{2-}$  ligand is coordinated to four Ce(III) atoms through four carboxylate oxygen atoms (O1, O2, O3 and O4) and one nitrogen atom Ce–N and also two neighboring Ce(III) ions are further linked to each other by chelating carboxylate oxygen atoms in fashions Ce–(O1)–(C1)–(O2)–Ce and Ce–(O3)–(C5)–(O4)–Ce, constructing rather square tetranuclear unit in which each Ce(III) atom is placed on corner. Interestingly, in each unit, the  $\text{pdc}^{2-}$  ligand is coordinated to metal atoms in different direction in comparison with adjacent units. For example, the  $\text{pdc}^{2-}$  ligand is coordinated to metal ions along *a*-axis direction while this ligand is bridged to metal atoms in *c*-axis direction in neighboring units. Finally, adjacent units are extended in two dimensions by edge sharing, generating a layer framework, as depicted in (Figure 3.14 and 3.15).

### 3.2.5. IR analysis of compound (4)

The IR spectra of cerium compound emerges the absence of free carboxylate groups by characteristic of no peak and absorption around  $1700\text{ cm}^{-1}$  [211–212]. The strong absorptions peaks in region  $1674\text{--}1556\text{ cm}^{-1}$  and  $1489\text{--}1444\text{ cm}^{-1}$  are assigned to anti-symmetric and symmetrical stretching vibrations of the coordinated carboxylate groups, respectively. The

difference between the anti-symmetric and symmetric carboxylate groups stretchings,  $\Delta$  ( $\Delta = \nu_{as} - \nu_s$ ), clarifies that the carboxylate groups in Ce (III) compound are coordinated as bridging multidentate ligand [213]. These observations are in accordance with the X-ray diffraction structural analysis. Moreover, the weak  $\nu(\text{NO}_3^-)$  out-of-plane bending vibration is observed at 853–770  $\text{cm}^{-1}$  [236–237].

### 3.2.6. Thermal analysis of compound (4)

In order to investigate the thermal stability of cerium coordination polymer, thermal gravimetric analyses and Differential Scanning Calorimetric (DSC) were carried out by heating range from 25 to 1000 °C under air atmosphere with a heating rate of 10 °C/min, as shown in (Figure 3.16). The TGA curve presents three stages of decompositions, accompanied with three distinctive exothermic peaks and also two endothermic effects. The large mass loss of 31.95% takes place with temperature range of 250–290 °C with moderate exothermic peak at 251 °C can be ascribed to collapse or oxidation of the coordination framework and the formation of decomposition intermediate species before the formation of final residue [238–239]. The temperature was increased from 290 to 425 °C, while the weight loss continued with two consecutive stages, combined with one moderate and one sharp endothermic peak. Further temperature rising between 370–425 leads total mass loss of 67.34% can be assigned to complete decomposition and removal of organic part. The last decomposition step occurs between 425 and 1000 °C which indicate the formation of  $\text{Ce}_2\text{O}_3$  residue with total mass loss of 67.34% which is comparable with the expected value of 68.01%.

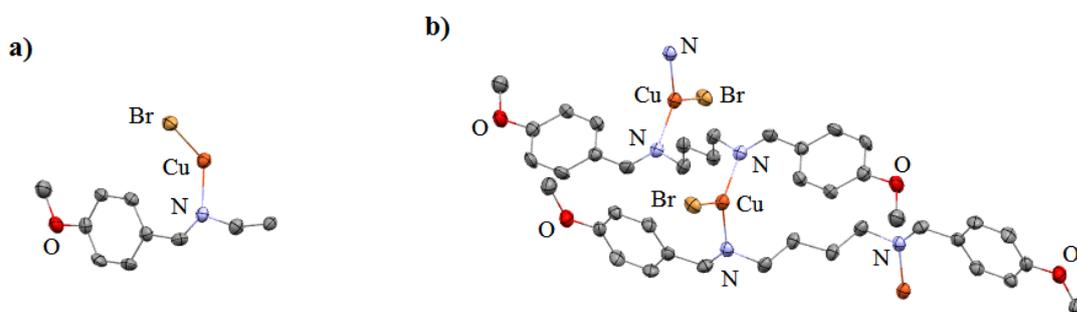

**Figure 3.16:** TGA-DTA curves of cerium compound (4)

### 3.3. Copper coordination polymers

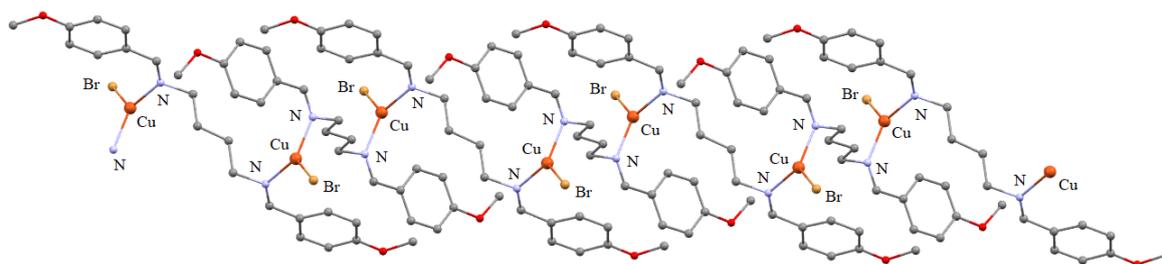

#### 3.3.1. Structure determination of $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ (**5**)

Self-assembly reaction of  $L_1$ , [N,N'-bis(4-methyl-benzylidene)butane-1,4-diamine] with CuBr gave a one-dimensional coordination polymer with formula  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ , as depicted in (Figure 3.18). Compound (**5**) exhibits a polymeric chain and crystallizes in the monoclinic space group  $C2/c$  and the asymmetric unit consists of a copper(I) ion, one bromide anion and one half of  $L_1$  (N,N'-MeO-ba)<sub>2</sub>bn ligand. Each copper (I) ion is coordinated by one bromide anion (Br) and two imino nitrogen atoms of two neighboring ligand molecules (Figure 3.17), thus the coordination environment around the metal ion can be described as slightly distorted trigonal planar with the N–Cu–N and N–Cu–Br angles which are  $126.9^\circ$  and  $116.6^\circ$  respectively.

**Figure 3.17:** a) asymmetric unit of compound (**5**); b) The view of molecule of copper compound (**5**) and planar  $\text{CuN}_2\text{Br}$  motif

In this compound, the ligand  $L_1$  acts as bis-monodentate bridging ligand through its imine nitrogen atoms, leading to polymeric chain of copper (I) complex (Figure 3.17 and 3.18). The both Cu–N bond lengths are equal ( $1.976 \text{ \AA}$  and  $1.976 \text{ \AA}$ ), hence it indicates the strong coordination of the ligands to the metal ion. Nevertheless, both bond lengths are within the normal range and correspondent to other copper (I) complexes that have been previously reported [240–250]. Crystallographic data are given in (Table 3.7).

**Figure 3.18:** One-dimensional copper compound (5) along *b*-axis

In compound (5), the large distances between two copper(I) ions (7.768 and 9.521 Å) prevents that bromide anion can connect them, however the shorter distances are found in some previous works in which halide anion can link two copper ions [242].

**Table 3.7:** Crystal data and refinement details for the X-ray structure determinations of the compounds (5), (6) and L<sub>1</sub> ligand.

### 3.3.2. Structure determination of $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$ (**6**)

The reaction between  $\text{L}_1[\text{N,N}'\text{-bis(4-methyl-benzylidene)butane-1,4-diamine}]$  and  $\text{CuI}$  yielded a one-dimensional copper coordination polymer of formula  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  shown in (Figure 3.20 and 3.21). The X-ray structural study shows that this compound crystallizes in monoclinic system with space group  $\text{C2/c}$ , and an asymmetric unit contains one copper (I) ion, one iodide anion, and one half of  $\text{L}_1$  ( $\text{N,N}'\text{-4-MeO-ba})_2\text{bn}$  ligand. The coordination sphere around each copper(I) ion consists of a coordinated iodine anion and two coordinated nitrogen atoms of imine groups from two symmetrically related schiff-base ligands (Figure 3.20). Hence, the copper (I) adopts the slightly distorted trigonal planar coordination sphere.

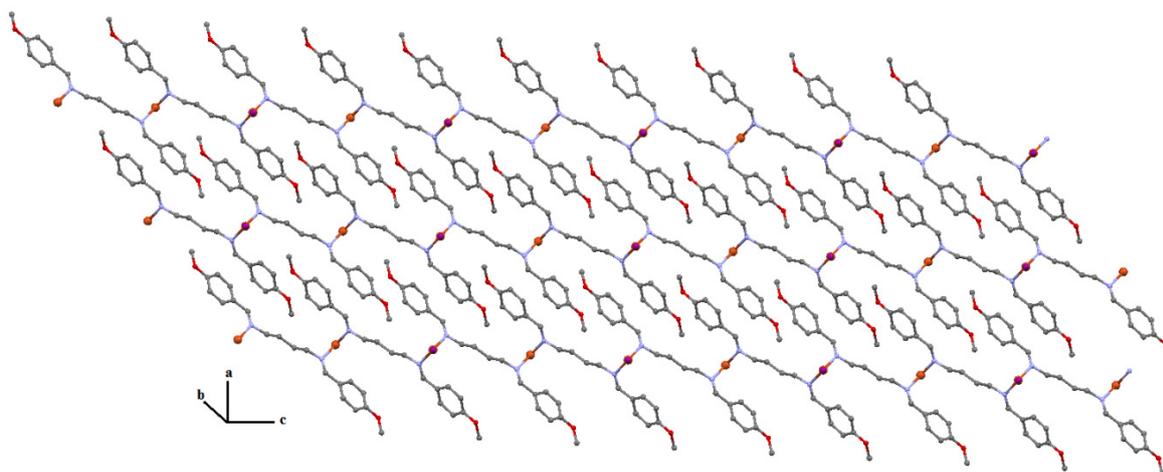

**Figure 3.20** : a) asymmetric unit of compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  (**6**); b) The view of molecule of copper compound and planar  $\text{CuN}_2\text{I}$  moiety

Similar to compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ , the ligand  $\text{L}_1$  also appears as bis-monodentate bridging ligand by using two nitrogen atoms of azomethine groups, constructing one-dimensional copper coordination polymer. In compound (**6**), the both  $\text{Cu-N}$  bond lengths are also identical (2.010 Å and 2.010 Å), although they are a little longer in comparison with  $\text{Cu-N}$  bonds in compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ . However, they are in normal range and are comparable to these bonds in the other reported copper (I) coordination compounds [240–256]. In compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$ , copper (I) ion also adopts slightly distorted trigonal planar coordination environment and  $\angle\text{N-Cu-N}$  and  $\angle\text{N-Cu-I}$  angles are  $129.5^\circ$  and  $101.0^\circ$  respectively (Figure 3.20 and 3.21). Crystallographic data and selected bond lengths and angles are given in (Table 3.7, 3.8 and 3.9).

**Figure 3.21:** Polymeric structure of copper complex  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  (**6**) along  $c$ -axis

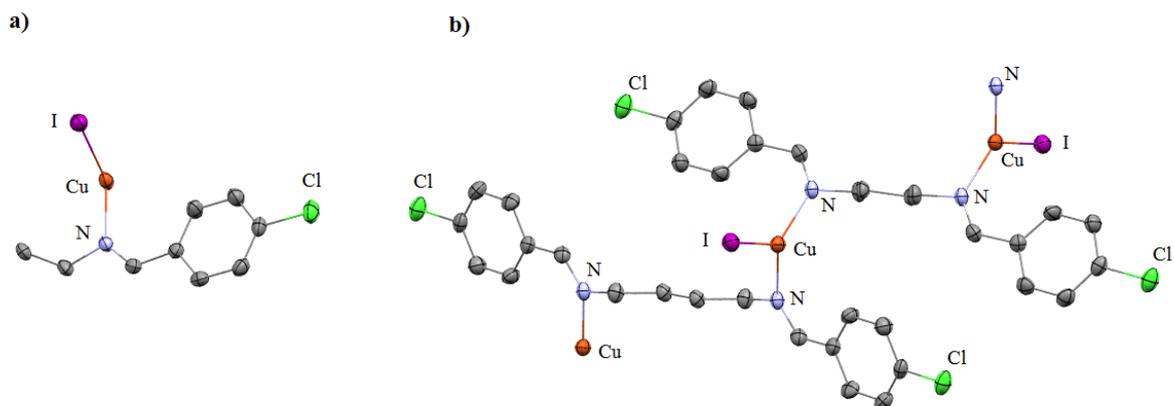

**Figure 3.22:** The coordination polymer chains of compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$ , extended along  $c$ -axis

In compound (**6**), the distance between two copper(I) ions (7.817 Å) is large to prevent that iodine atom can be bridge between them, however the shorter distance is found in some previous works in which the iodine anion acts as bridging ligand and links two copper ions [242].

### 3.3.3. Structure determination of $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$ (**7**)

The reaction between  $\text{L}_2[\text{N,N}'\text{-bis(4-chloro-benzylidene)butane-1,4-diamine}]$  and  $\text{CuI}$  in mixture of acetonitrile and dichloromethane provided a crystalline material with formula  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$  shown in (Figure 3.23 and 3.24). The X-ray structural analysis confirmed the formation of a one-dimensional polymeric structure of this compound through copper(I)–nitrogen coordination bonds. This compound crystallizes in the monoclinic system

with space group  $C2/c$  and a copper(I) ion, one iodide ion and one half of  $L_2$  ligand are observed overall in the asymmetric unit (Figure 3.23).

**Figure 3.23** : a) asymmetric unit of compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$  (**7**); b) The view of molecule of copper compound (**7**) and planar  $\text{CuN}_2\text{I}$  moiety

Compound (**7**) displays same coordination environment through two nitrogen atoms of two neighboring ligand molecules and iodine atom to Cu(I) ions, corresponding with compounds  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  and  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ . Also  $L_2$  ligand behaves similar to  $L_1$  ligand as bis-monodentate bridging ligand through its azomethine nitrogen atoms to form chain structure of copper complex. The Cu–N bond length is 1.978 Å and N–Cu–N and N–Cu–I angles are 125.7° and 117.1° respectively. Crystallographic data and selected bond lengths and angles are presented in (Table 3.10 and 3.11). Moreover, this is worth to note that the  $\text{Cu}\cdots\text{Cu}$  distances are (7.950 and 7.950 Å) which is considerably much more than an iodine anion can connect them [242]

**Table 3.10:** Crystal data and refinement details for the X-ray structure determinations of the compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$  (**7**)

### 3.3.4. IR spectra analysis of copper compounds (**5**), (**6**) and (**7**)

The IR spectra of the three copper coordination compounds have been investigated. In the FT-IR spectra of copper coordination polymers, the significant spectrum is relevant to stretching vibration of azomethine group and it shifted to lower frequencies in copper(I) compounds because of coordination to metal ions in comparison with free ligands. The stretching vibration spectrum of imine group  $\nu_{\text{C=N}}$  appears at  $1644\text{ cm}^{-1}$  and  $1646\text{ cm}^{-1}$  for free ligands,  $\text{L}_1 = \{(\text{N,N}'\text{-MeO-ba})_2\text{bn}\}$  and  $\text{L}_2 = \{(\text{N,N}'\text{-4-Cl-ba})_2\text{bn}\}$  respectively.  $\nu_{\text{C=N}}$  of  $\text{L}_1$  was observed at  $1620\text{ cm}^{-1}$  in compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$  (**5**) and at  $1625\text{ cm}^{-1}$  in compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  (**6**) respectively. This shift is attributed to the coordinated nitrogen atom of imine group to copper(I) ions in both compounds  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  and  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ . In compound  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-Cl-ba})_2\text{bn})\text{I}]_n$  (**7**) This band was observed at  $1624\text{ cm}^{-1}$  that has been shifted to a lower frequency relative to the free ligand  $\text{L}_2$  ( $1646\text{ cm}^{-1}$ ), due to the coordination of the imine nitrogen atom to the metal ion.

### 3.3.5. Thermal analysis of compounds $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$ (5) and $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$ (6)

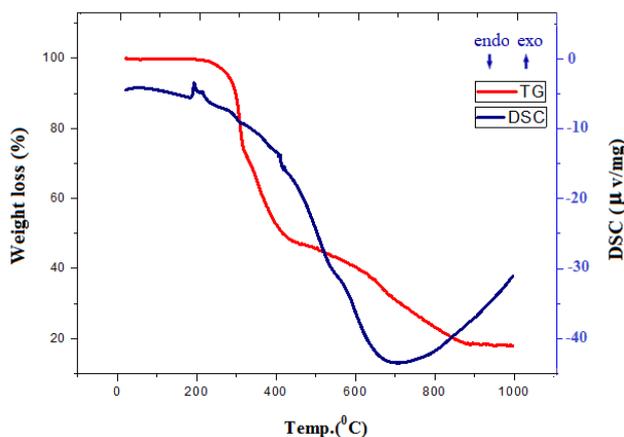

To determine the thermal stability of compounds (5) and (6), their thermal stability were carried out under a nitrogen atmosphere in the temperature range from 25 to 1000 °C. The goal is to investigate the thermal behavior of these coordination polymers since they were synthesized by similar ligand and under same reaction conditions. From TG curve of compound (5) (Figure 3.26), it can be observed that compound (5) remains stable upon to 220 °C. In the range between 225 and 290 °C, the structure starts to collapse, with a weight loss of 19.63% which is assigned to the first step decomposition of the organic ligand. Due to further increasing of the temperature, the combustion of the remaining organic ligand raised. The second weight loss of 33.49 % occurs in range of 290–450 °C. In this stage, the mass loss is attributed to further decomposition of organic structure. Finally, the last step of decomposition occurs in range 450–800 °C, leading to mass loss of 17.06 (calculated, 18,61%) and generation CuBr as the final residue with mass percentage of 29.89% which indicates that whole molecule framework collapsed and is good agreeable with calculated value 30.68%.

**Figure 3.26:** Thermogravimetric analysis (TGA) curves of compound (5), accompanied with Differential Scanning Calorimetric (DSC)

The TG curve of compound (6) indicates that it is stable up to 225 °C at which temperature it started to decompose (Figure 3.27). Removal of the ligand takes place with three decomposition stages in the range between 260 and 800 °C. The first weight loss of 28.72 % from 225 °C to 300 °C and second weight loss turns out in the range of 300–475 °C which is contributed to partial decomposition of organic part. Due to increasing temperature, the last decomposition stage occurred with mass loss of 28.98% which is assigned to total removal of remained

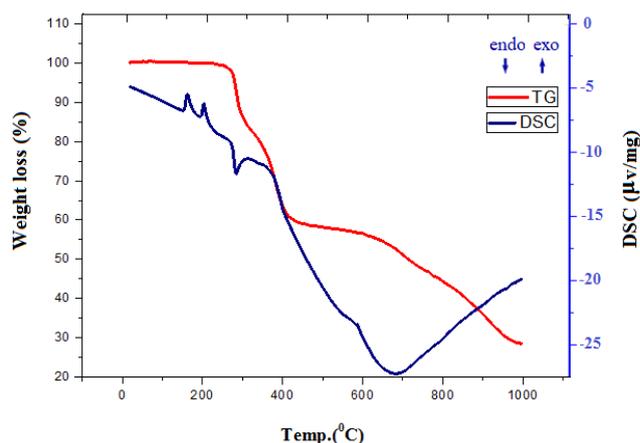

organic part which was observed in temperature range 450–800 °C, corresponding with calculated value 27.64%. The final product may be  $C_2Cu$  with mass percentage of 17.98%, which is in good agreement with the calculated value of 18.02 %.

**Figure 3.27:** Thermogravimetric analysis (TGA) and Differential Scanning Calorimetric (DSC) curves of compound (6)

### 3.3.6. Thermal analysis of compound $[Cu((\mu_{N,N'}-4-Cl-ba)_2bn)I]_n$ (7)

To investigate thermal stability of compounds (7) thermogravimetric analysis (TGA) was performed in the temperature range of 25–1000 °C under nitrogen gas. The TGA curve for this compound is illustrated with (Figure 3.28). This compound was stable up to 225 °C and then started to decompose upon rising temperature. The initial weight loss of 13.56 % occurs at 225–325 °C. The second continuous weight loss of 22.55% happened in the temperature range between 325 and 475 °C, which can be assigned to decomposition partially of ligand. The major weight loss of 28.09 % occurred at last stage of decomposition. This is assigned to remove completely the remained organic part which is comparable to calculated 30.05 %). The final residue can be  $CuCl_2$  with mass percentage of 27.15 % (calculated 25.67%).

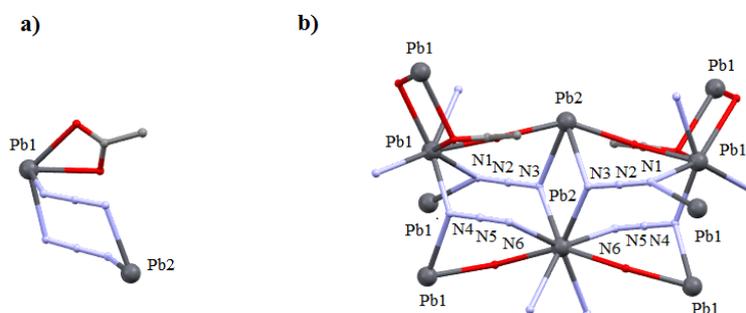

**Figure 3.28:** Thermogravimetric analysis (TGA) and Differential Scanning Calorimetric (DSC) curves of compound (7)

### 3.4. Lead coordination polymer

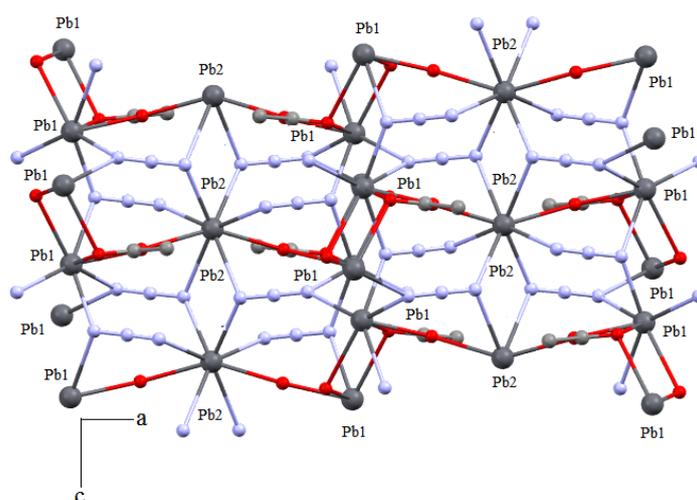

#### 3.4.1. Crystal structure determination of compound $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$ (8)

Crystalline material of compound  $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$  was produced by reaction of  $\text{Pb}(\text{CH}_3\text{COO})_2$  and sodium azide salt in ligand / metal ratio 2:1 in acetonitrile as solvent. Compound (8) is a 3D coordination polymer and crystallizes in orthorhombic space group *Pccn*. The asymmetric unit consists two crystallographically independent lead ions (Pb1 and Pb2), two azide ions and one acetate anion. Pb1 ion displays near pentagonal bipyramid coordination sphere with four nitrogen atoms from four different azide ions and three oxygen atoms from two acetate groups. The Pb2 ions show a square antiprismatic coordination environment arising from six nitrogen atoms from six individual azide ions and two oxygen atoms from two different acetate groups. In this compound, azide ions display coordination modes  $\mu_4-1,1,3,3$  and  $\mu_3-1,1,3$ . The acetate group is also coordinated to metal ions in coordination mode  $\mu_3-\eta^2:\eta^2$  [257]. As it is shown in (Figure 3.29b and 3.30), two Pb1 ions are linked by bridging of two oxygen atoms (O1) from two different acetate groups, forming four-membered dinuclear ring in which acetate groups are placed in *trans* configuration. Furthermore, Pb2 ions are interconnected between oxygen atoms (O2) from two neighboring acetate groups along *a*-axis (Figure 3.29b and 3.30). On the other hand, adjacent Pb2 ions are connected through chelating behavior of nitrogen atoms (N3) from two azide ligands along *c*-axis. The Pb2 and Pb1 ions are further linked to each other by the bridging behavior of azide ions to generate a 3D coordination network, (Figure 3.30 and 3.31). As it is mentioned above, the azide ion adopts two different coordination modes in this structure. For example, the azide

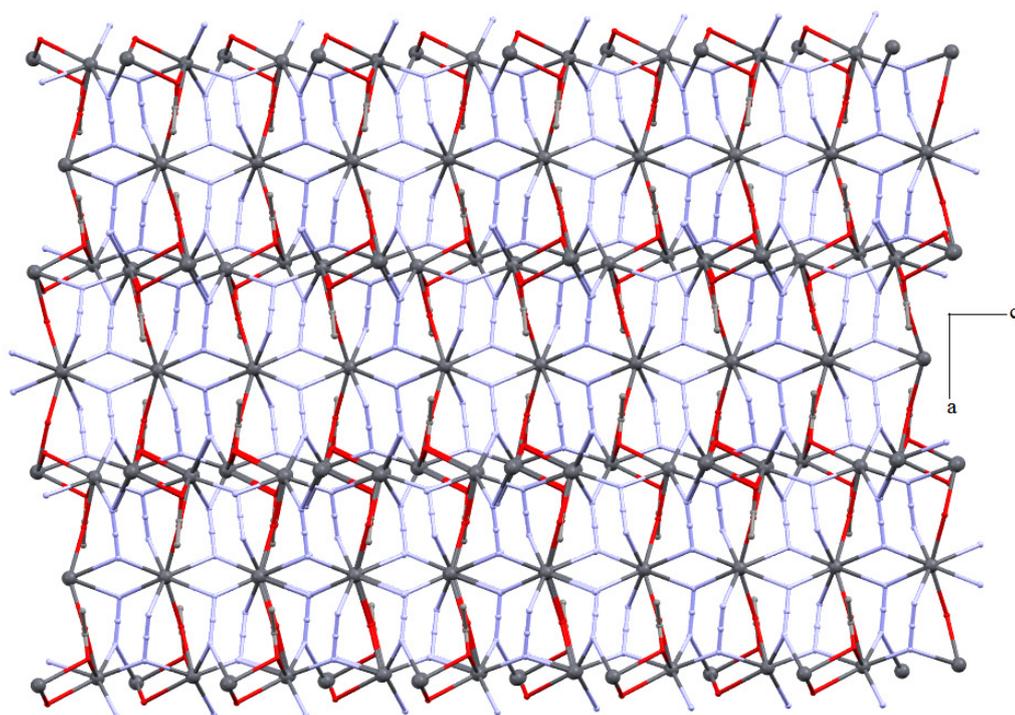

ion exposing coordination mode  $\mu_4-1,1,3,3$  connects two Pb2 ions via the nitrogen atom (N3) along *c*-axis while the nitrogen atom (N1) links two neighboring Pb1 ions along *b*-axis. The other azide ion with coordination mode  $\mu_3-1,1,3$  links two adjacent Pb1 ions via nitrogen atoms (N4), although the nitrogen atom (N6) coordinates to Pb2 ions. As matter of fact, the azide ions with high binding modes play a role for the formation of a 3D network since they link several metal ions in this structure. Crystallographic data and selected bond lengths and bond angles are presented in (Table 12, 13 and 14). In compound (**8**), the Pb–O bond lengths range from 2.545(4) to 2.687(4) Å for Pb1 and 2.687(4) Å for Pb2. Additionally, Pb1–N and Pb2–N bond lengths vary from 2.543(4) to 2.716(4) Å and 2.657(5) to 2.704(5) Å respectively, corresponding to the usual Pb–O and Pb–N bond lengths in the previous works [258–266].

### 3.4.2. Crystal structure determination of compound $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$ (9)

A new lead coordination polymer was synthesized by reaction of  $\text{Pb}(\text{CH}_3\text{COO})_2$  and sodium azide salt in ligand and metal ratio 1:1 in acetonitrile. This compound is a 3D coordination polymer and crystallizes in the orthorhombic system with space group  $\text{P2}_1\text{2}_1\text{2}_1$ . An asymmetric unit of this compound contains two crystallographically independent lead ions (Pb1 and Pb2), two crystallographically independent sodium ions (Na1 and Na2) and six acetate anions. As it is shown in (Figure 3.33 and 3.34), the both sodium ions (Na1 and Na2) are hexa-coordinated; however the coordination environment around each sodium ion is different. Na1 ions adopt distorted trigonal prismatic coordination environment while Na2 owns the configuration close to octahedral. Contrary to sodium ions, Pb ions (Pb1 and Pb2) show higher coordination numbers. The coordination sphere around the Pb2 atom by coordination of seven oxygen atoms of six anionic acetate ligands is defined as a distorted capped trigonal prism while Pb1 is eight-coordinated with O–Pb–O angles in range of 46.9 to 165.8° and exhibits hemidirected coordination environment in which the bonds to ligand atoms are directed throughout only part of the coordination sphere and there is an attributable void (or gap) in the distribution of bonds to the ligands (Figure 3.32) [263–265]. In this structure, the acetate anion acts as

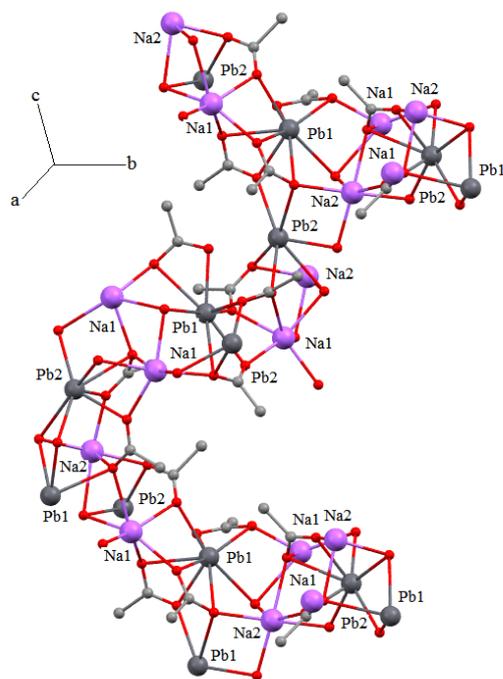

chelating, bridging ligand and is coordinated to metal ions through coordination modes  $\mu_4\text{-}\eta^2\text{:}\eta^3$ . As it can be seen in (Figure 3.32 and 3.33), the acetate groups bridge between the metal ions such as Pb1–O–Na1, Pb2–O–Na2, Na1–O–Na2 and Pb2–O–Na1 and because of high bridging mode and chelating behavior of acetate, the 3D coordination framework is constructed. In this compound, the Pb1–O and Pb2–O bond lengths range from of 2.43(2) to 2.738(13) Å and 2.422(13) to 2.674(14) Å respectively, comparable to the usual Pb–O bond lengths reported in previous works [258–265].

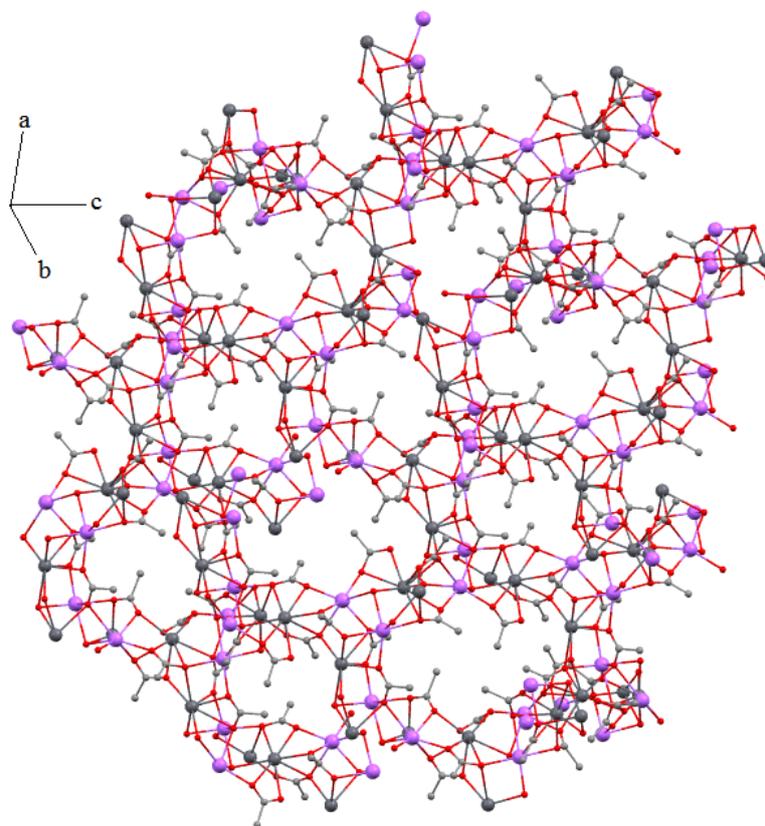

**Figure 3.32:** (A) Holodirected and (B) Hemidirected Coordination sphere [263–265]

**Figure 3.33:** a) asymmetric unit; b) molecular structure of compound  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  (9)

**Figure 3.34:** The structure of compound  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  (9)

**Figure 3.35:** View of three-dimensional coordination polymer of compound  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  (9) from *b*-axis

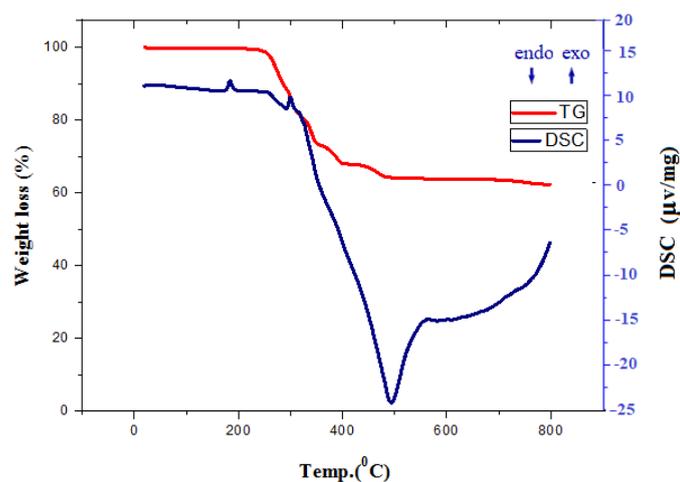

### 3.4.3. IR analysis of compounds (8) and (9)

In compound  $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$ , the FT-IR spectrum shows two peaks at  $1485\text{ cm}^{-1}$  and  $1395\text{ cm}^{-1}$ , can be assigned to symmetric and asymmetric stretching of the carboxylate groups in this complex respectively. A correlation of the carboxylate coordination modes to metal ions was studied by examining the difference  $\Delta\nu(\text{COO}) = \nu_{\text{as}}(\text{COO}) - \nu_{\text{s}}(\text{COO})$  of compound (8). The difference is 90, which implies that the carboxylic group of acetate ligands coordinated to Pb(II) ions in bridging mode and it is comparable with the X-ray single crystal structural analysis. The appearance of very strong absorption peak at  $2019\text{ cm}^{-1}$  in this compound is due to the asymmetric stretching frequencies,  $\nu_{\text{as}}(\text{N}_3)$  of the bridged azide ligands in coordination modes  $\mu_4-1,1,3,3$  and  $\mu_3-1,1,3$ . The strong intensity peak at  $1334\text{ cm}^{-1}$  and weak peak at  $1147\text{ cm}^{-1}$  can be attributed to symmetrical stretching vibrations,  $\nu_{\text{s}}(\text{N}_3)$  [266–268]. It is worth to notice, the highest frequency peak of  $\nu_{\text{as}}(\text{N}_3)$  is assigned to *end-on* binding (*i.e.*,  $\mu-1,1$ ) and the lowest frequency peak is due to the *end-to-end* binding of the azide ligand (*i.e.*,  $\mu-1,3$ ) which have been reported in previous coordination compounds [269–274].

In lead compound  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$ , two very strong peaks are at  $1528\text{ cm}^{-1}$  and  $1391\text{ cm}^{-1}$  are due to symmetric and asymmetric stretching of the carboxylate of acetate groups in the network. The difference  $\Delta\nu(\text{COO}) = \nu_{\text{as}}(\text{COO}) - \nu_{\text{s}}(\text{COO})$  of this compound is 137 which indicates the acetate groups are coordinated to lead ions by bridging mode [213].

### 3.4.4. Thermal analysis of compound (9)

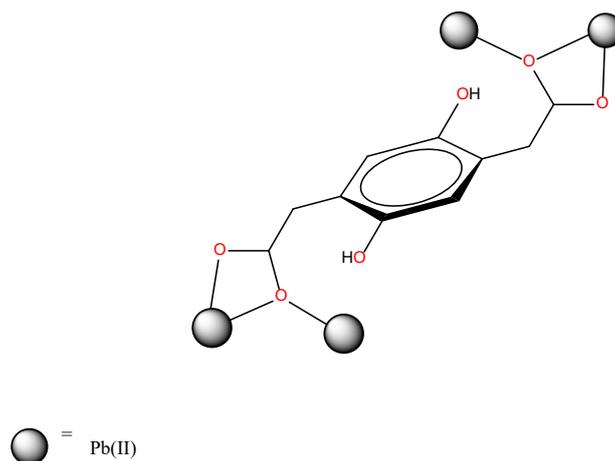

In order to examine the thermal stability of lead compound (9), thermal gravimetric (TG) and differential thermal analyses (DTA) were carried out in the temperature range between 25 and  $800\text{ }^\circ\text{C}$  in the static atmosphere of air (Figure 3.36). The TG curve of this compound indicates that this compound is stable up to  $230\text{ }^\circ\text{C}$  at which temperature the structure begins to collapse. The TG curve indicates the release of ligand molecules from 230 up to  $520\text{ }^\circ\text{C}$  with several short decomposition steps and two exothermic effects at  $176.7$  and  $300.8\text{ }^\circ\text{C}$  and one distinct endothermic effect at  $494$ , (Figure 3.36). The solid residue formed at around  $500\text{ }^\circ\text{C}$  is suggested to be  $\text{Na}_2\text{O}$  and  $\text{PbO}$ .

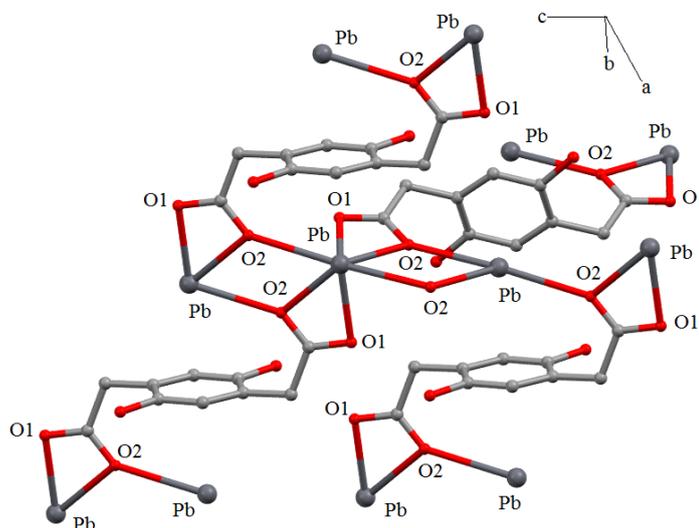

**Figure 3.36:** TG and DSC curves of lead compound  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  (**9**)

### 3.4.5. Structure determination of compound $[\text{Pb}(\text{DHBDA})]_n$ (**10**)

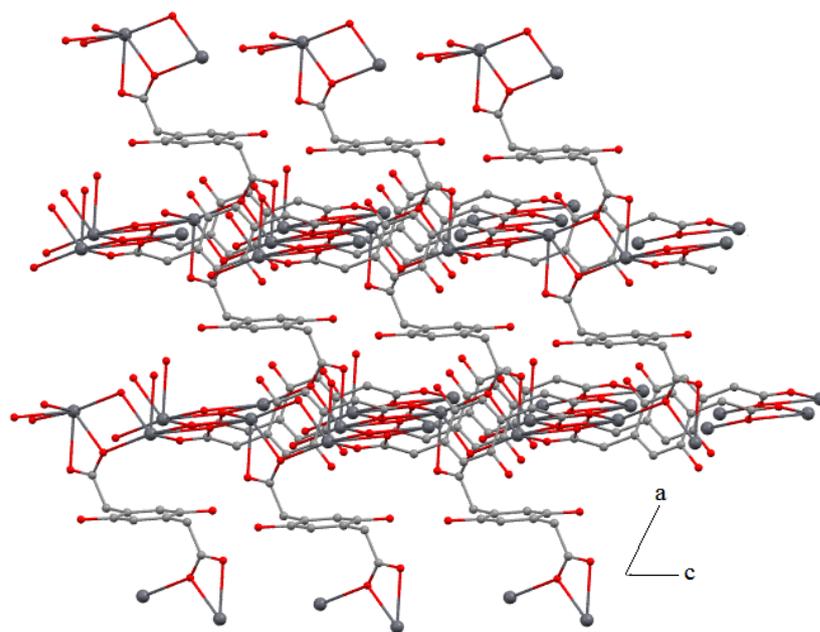

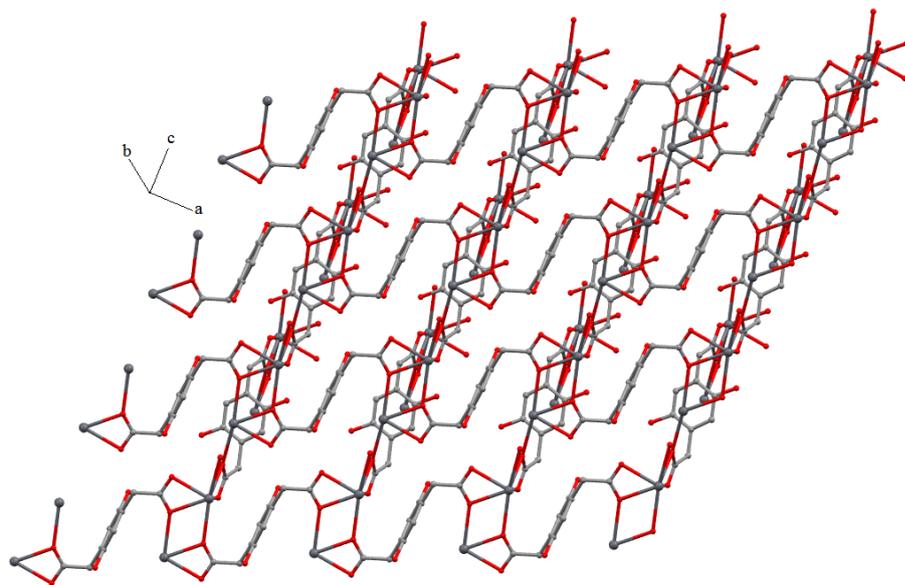

The reaction between  $\text{Pb}(\text{NO}_3)_2$  and ( $\text{H}_2\text{-DHBDA} = 2,5\text{-Dihydroxy-1,4-benzenediacetic acid}$ ), yielded a new lead coordination polymer of formula  $[\text{Pb}(\text{DHBDA})]_n$ . This compound represents a 3D coordination polymer in solid state and crystallizes in the monoclinic space group  $C2/c$ . The asymmetric unit of compound (**10**) comprises one lead (II) ion and one half of ligand 2,5-Dihydroxy-1,4-benzenediacetic acid. Each lead (II) ion owns coordination number six and shows hemidirected coordination sphere in which the  $\text{O-Pb-O}$  angles vary from  $167.1$  to  $51.5^\circ$  and  $\text{Pb-O}$  bond lengths are in range between  $2.469$  and  $2.738 \text{ \AA}$  [263–265]. The ligand 2,5-Dihydroxy-1,4-benzenediacetic acid behaves as chelating, bridging ligand and is coordinated to lead (II) ions through its carboxylate oxygen atoms ( $\text{O1}$  and  $\text{O2}$ ) in coordination mode  $(\mu_3\text{-}\eta^1:\eta^2)$ . Both carboxylate groups of the ligand are linked to metal ions in the same coordination fashion and they are oriented in polymeric network as *trans* configuration, while the oxygen atoms of hydroxyl groups remain uncoordinated (Figure 3.37). As it is observed in (Figure 3.38 and 3.39), the  $\text{Pb}$  ions are bridged to each other by chelating behavior of ligand to make a three-dimensional coordination network.

**Figure 3.37:** 2,5-Dihydroxy-1,4-benzenediacetate coordination modes in compound  $[\text{Pb}(\text{DHBDA})]_n$  (10)

#### 3.4.6. IR Spectra analysis of compound (10)

The symmetric and asymmetric vibrations of the carboxylate group are observed as strong peaks at  $1524\text{ cm}^{-1}$ ,  $1498\text{ cm}^{-1}$ ,  $1426\text{ cm}^{-1}$  and  $1397\text{ cm}^{-1}$  respectively. The various  $\Delta(\nu_{\text{as}}-\nu_{\text{s}})$  values indicate that the carboxylate anions coordinate to the Pb(II) ions in bridging mode [213]. Furthermore, the absence of a strong bond at  $1700\text{ cm}^{-1}$  corresponds to fully deprotonated carboxylate groups of the ligand. The relatively weak peak around  $3010\text{--}3035\text{ cm}^{-1}$  are due to C–H vibration involving the aromatic ring hydrogen atoms.

## Summary

The present work deals with the preparation and characterization of ten new coordination polymers prepared from different metal ions and ligands by different synthetic methods. In addition to the structural characterization of these compounds by means of X-ray single-crystal diffraction data, the focus is on the consideration of thermal and spectroscopic properties.

The new silver coordination polymer exhibits very unique, robust and interesting polymeric structure with high thermal stability. Two new lanthanide coordination polymers (neodymium and samarium) have been synthesized with  $H_2FDA = 2,5$ -furandicarboxylic acid in DMF as solvent via capped tube method. The compounds are iso-structural and exhibit three-dimensional coordination polymers. The goal of using DMF as the pure solvent instead of a mixture of water and other solvents was to synthesize new coordination polymer which might show a very intensive luminescence effect. The investigation has turned out that these compounds emerge no significant luminescence effect. As it has been reported in previous works in which the  $H_2FDA = 2,5$ -furandicarboxylic acid was used for construction of lanthanide coordination polymers in water as solvent, however the compounds have exposed very interesting luminescence properties [229–230]. A new cerium coordination polymer has been produced with ligand ( $H_2pdc = 3,5$ -pyrazoledicarboxylic acid) under solvothermal condition in DMF as solvent. Indeed, ligand ( $H_2pdc = 3,5$ -pyrazoledicarboxylic acid) is very versatile to construct coordination network by various coordination modes. Three copper (I) coordination polymers have been successfully synthesized via solvent diffusion technique in test tube. The compounds all display 1D polymeric structure with rather similar coordination environment around metal ions. Moreover, they are very stable against temperature rising. The compounds  $[Pb_3(CH_3COO)_2(N_3)_4]_n$  and  $[Na_2Pb_2(CH_3COO)_6]_n$  were synthesized under same synthesis conditions and starting materials but with different metal salt and ligand ratios. Interestingly, the both products show three-dimensional frameworks, however, they expose different coordination structures. Actually, the investigation shows that the changing metal salt and ligand ratio can result in the formation different structures of coordination networks, although they have been produced under the same reaction conditions. Compound  $[Pb(DHBDA)]_n$  has been made with ligand 2,5-Dihydroxy-1,4-benzenediacetic acid. This ligand molecule has been reported in very few works for constructing coordination compounds.

## Zusammenfassung

Die hier vorliegende Arbeit behandelt die Darstellung und Charakterisierung von zehn neuen Koordinationspolymeren, die aus unterschiedlichen Metallionen und Liganden durch unterschiedliche Synthesemethoden hergestellt wurden. Neben der strukturellen Charakterisierung dieser Verbindungen anhand von Röntgen Einkristall Beugungsdaten steht die Betrachtung der thermischen und spektroskopischen Eigenschaften im Fokus. Das neue Silber-Koordinationspolymer weist einen einzigartigen, robusten und interessanten Aufbau mit hoher thermischer Stabilität auf. Zwei neue Lanthanoid-Koordinationspolymere  $\{[\text{Ln}_2(\text{FDA})_3(\text{DMF})(\text{H}_2\text{O})_2] \cdot \text{DMF} \cdot (\text{H}_2\text{O})_2\}_n$  ( $\text{Ln} = \text{Sm}, \text{Nd}$ ) wurden mit  $\text{H}_2\text{FDA} = 2,5$ -Furandicarbonsäure in DMF als Lösungsmittel mit verschlossenem Glasreaktor im Maßstab Technik synthetisiert. Die Verbindungen sind Iso-strukturell und zeigen drei-dimensionale Koordinationspolymere. Das Ziel der Verwendung von DMF als reines Lösungsmittel anstelle einer Mischung aus dem Wasser und anderen Lösungsmitteln war die Synthese eines neuen Koordinationspolymers, das einen sehr intensiven Lumineszenzeffekt zeigen könnte. Die Untersuchung hat ergeben, dass diese Verbindungen keinen signifikanten Lumineszenzeffekt aufweisen. Wie in früheren Arbeiten berichtet wurde, in denen die  $\text{H}_2\text{FDA} = 2,5$ -Furandicarbonsäure für den Aufbau von Lanthanoid-Koordinationspolymeren in Wasser als Lösungsmittel verwendet wurde, haben die Verbindungen sehr interessante Lumineszenzeigenschaften gezeigt [229–230]. Ein neues Ce-Koordinationspolymer wurde mit einem Liganden ( $\text{H}_2\text{pdc} = 3,5$ -Pyrazoledicarbonsäure) unter Solvothermen Bedingungen in DMF als Lösungsmittel hergestellt. In der Tat ist Ligand ( $\text{H}_2\text{pdc} = 3,5$ -Pyrazoledicarbonsäure) sehr vielseitig, um ein Koordinationsnetzwerke durch verschiedene Koordinationsmodi aufzubauen. Drei Kupfer (I) -Koordinationspolymere wurden erfolgreich mit der Lösungsmitteldiffusionstechnik im Reagenzglas synthetisiert. Die Verbindungen zeigen alle eine 1D-Polymerstruktur mit einem annähernden Koordinationsumfeld um die Metallionen herum. Darüber hinaus sind sie sehr stabil gegen den Temperaturanstieg. Die Verbindungen  $[\text{Pb}_3(\text{CH}_3\text{COO})_2(\text{N}_3)_4]_n$  und  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  wurden unter den gleichen Synthesebedingungen und mit den gleichen Ausgangsstoffen synthetisiert, jedoch mit unterschiedlichen Metallsalz und Liganden Verhältnissen. Interessanterweise zeigen beide Produkte drei-dimensionale Gerüste, die jedoch unterschiedliche Koordinationsstrukturen aufweisen. Tatsächlich zeigt die Untersuchung, dass das sich ändernde Metallsalz- und Ligand-Verhältnis zur Bildung unterschiedlicher Strukturen von Koordinationsnetzwerken führen kann, obwohl sie unter den gleichen Reaktionsbedingungen hergestellt wurden. Die

Verbindung  $(\text{Pb}(\text{DHBDA}))_n$  wurde mit Ligand 2,5-Dihydroxy-1,4-benzoldiessigsäure hergestellt. Nur in sehr wenigen Arbeiten zur Herstellung von Koordinationspolymeren wurde dieser Ligand verwendet.

# Appendix

## A.1. The TG and DSC curves of new coordination polymers

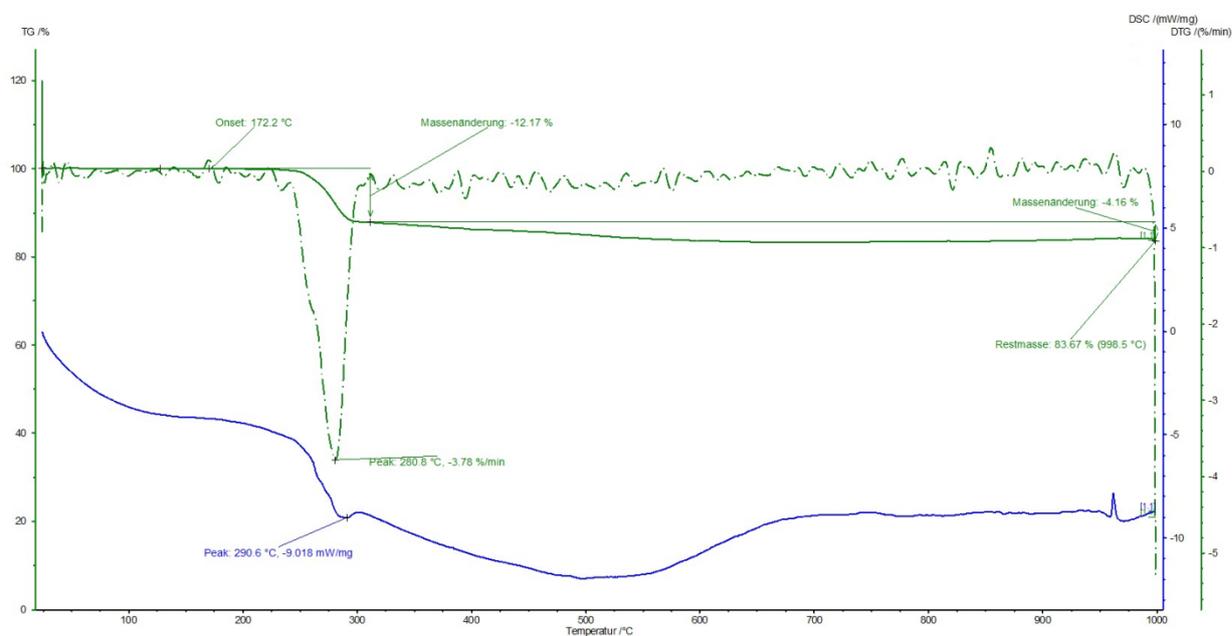

Figure A.1.1. TG/DSC curves of silver coordination polymer,  $[\text{Ag}_2(\text{HO}_3\text{PCH}_2\text{COO})]_n$  (1)

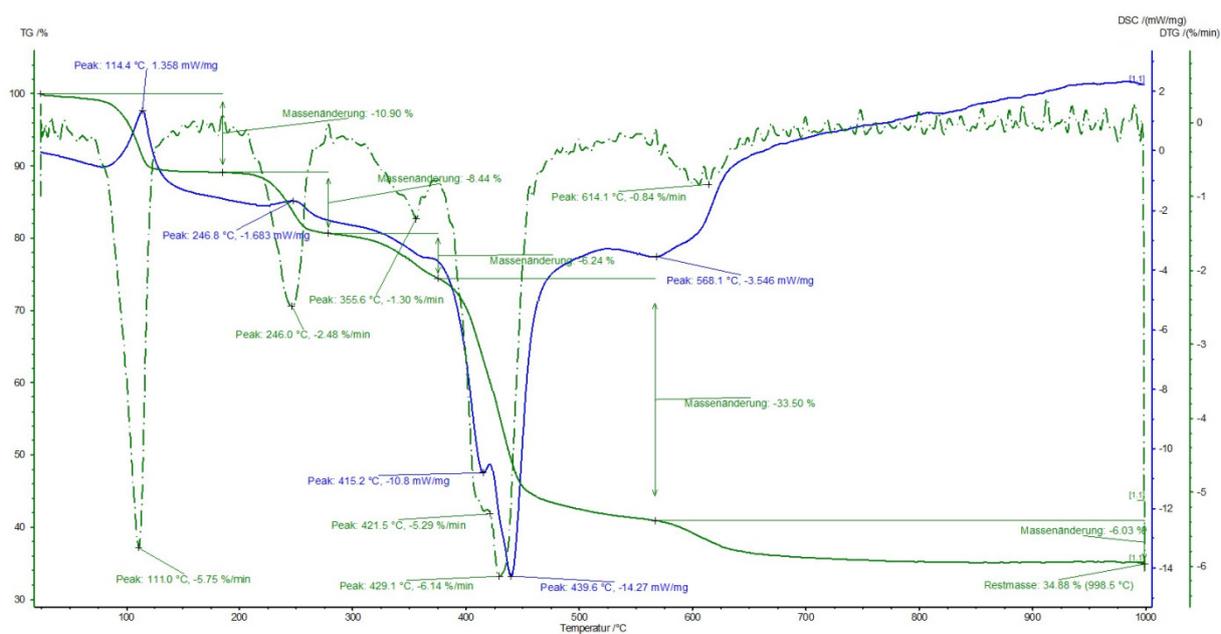

Figure A.1.2. TG/DSC curves of coordination polymer,  $\{[\text{Nd}_2(\text{FDA})_3(\text{DMF})(\text{H}_2\text{O})_2] \cdot \text{DMF} \cdot (\text{H}_2\text{O})_2\}_n$  (2)

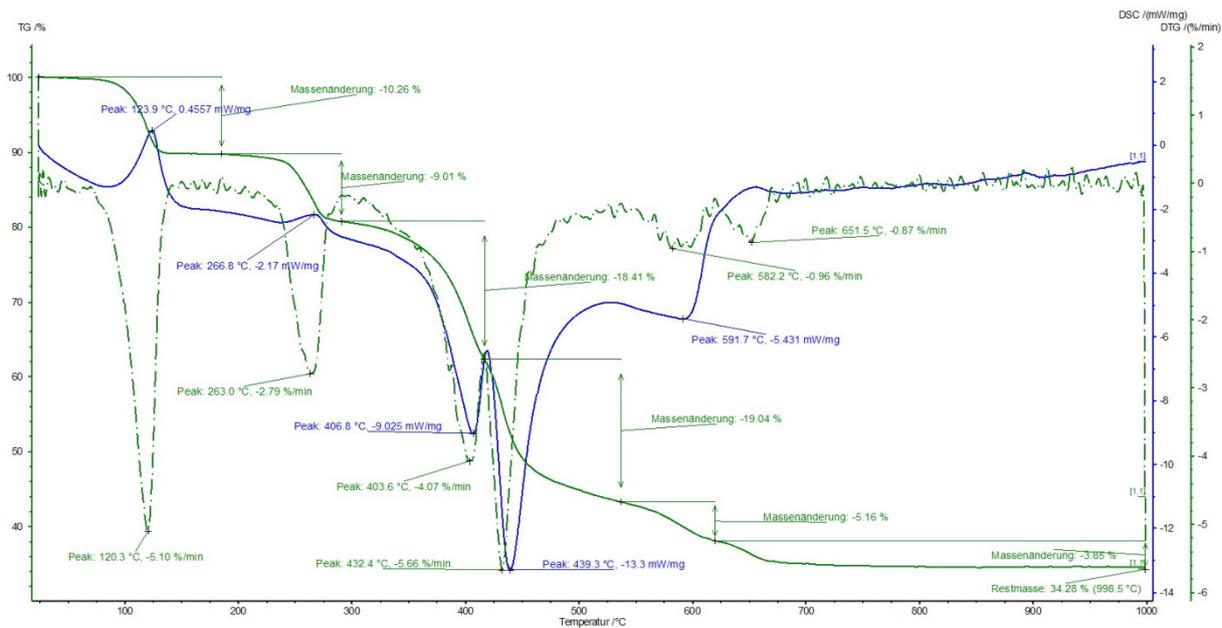

Figure A.1.3. TG/DSC curves of coordination polymer,  $\{[Sm_2(FDA)_3(DMF)(H_2O)_2] \cdot DMF \cdot (H_2O)_2\}_n$  (3)

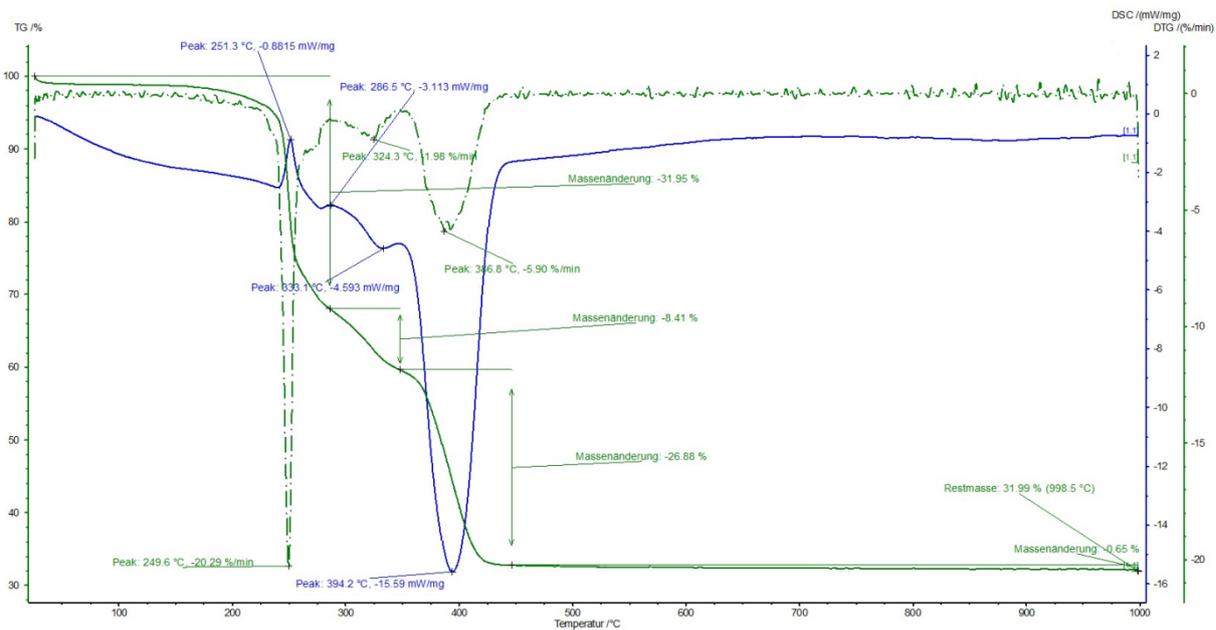

Figure A.1.4. TG/DSC curves of cerium coordination polymer,  $[Ce(pdc)(DMF)_2(NO_3)]_n$  (4)

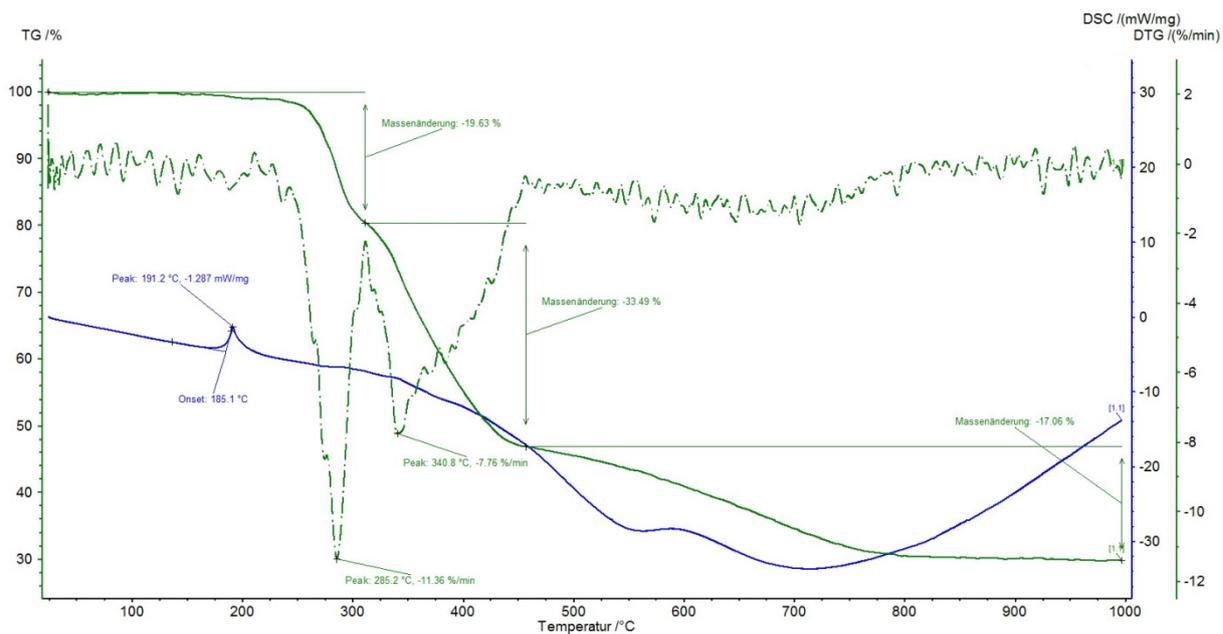

Figure A.1.5. TG/DSC curves of copper coordination polymer,  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{Br}]_n$  (5)

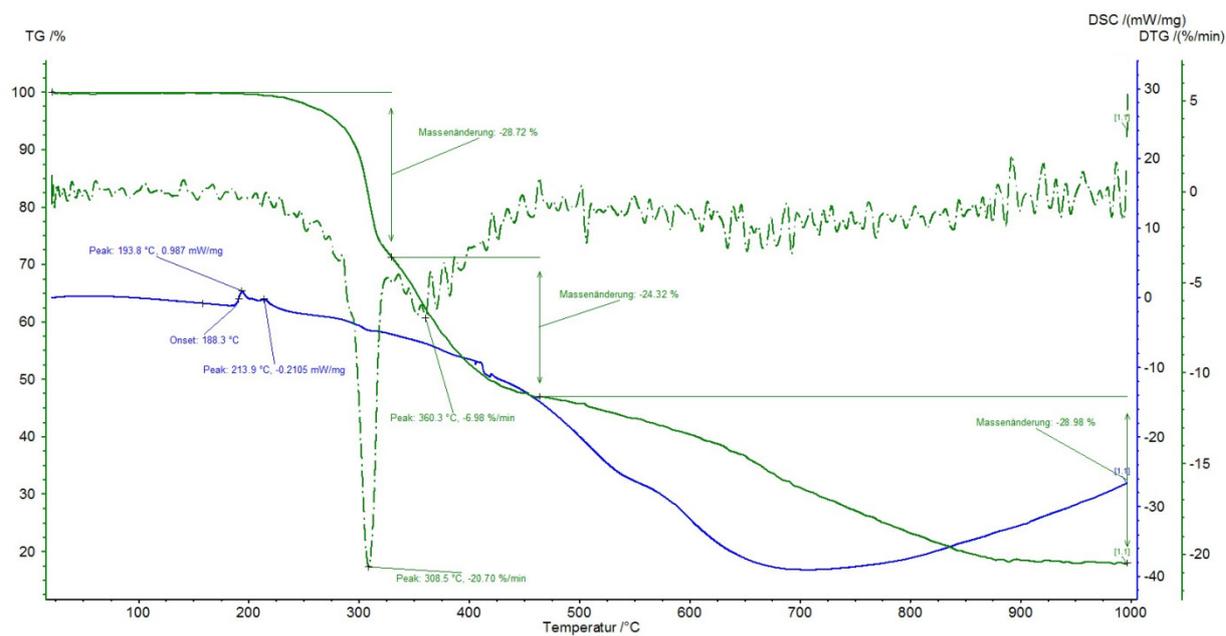

Figure A.1.6. TG/DSC curves of copper coordination polymer,  $[\text{Cu}((\mu_{\text{N,N}'}\text{-4-MeO-ba})_2\text{bn})\text{I}]_n$  (6)

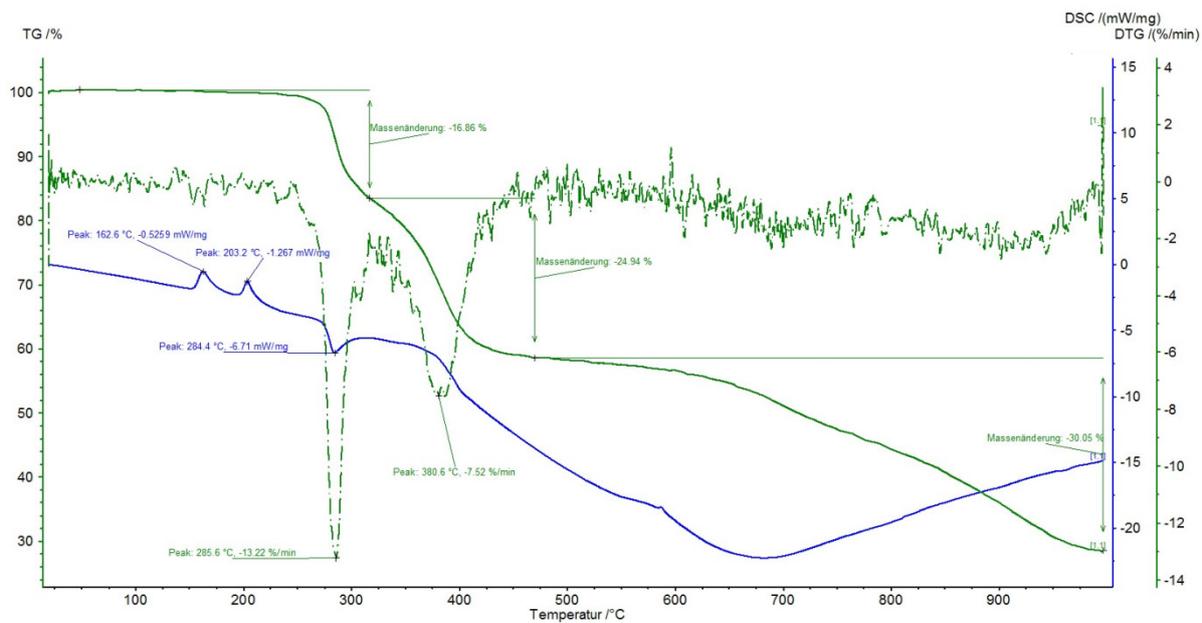

Figure A.1.7. TG/DSC curves of copper coordination polymer,  $[\text{Cu}((\mu_{\text{N,N}'-4\text{-Cl-ba})_2\text{bn})]_n$  (7)

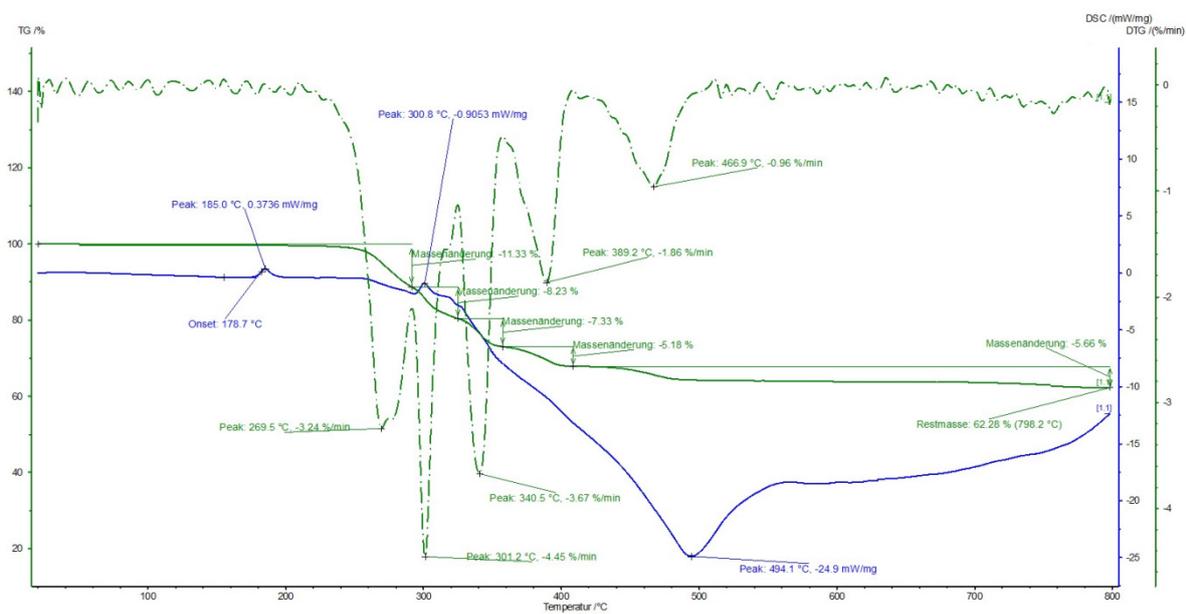

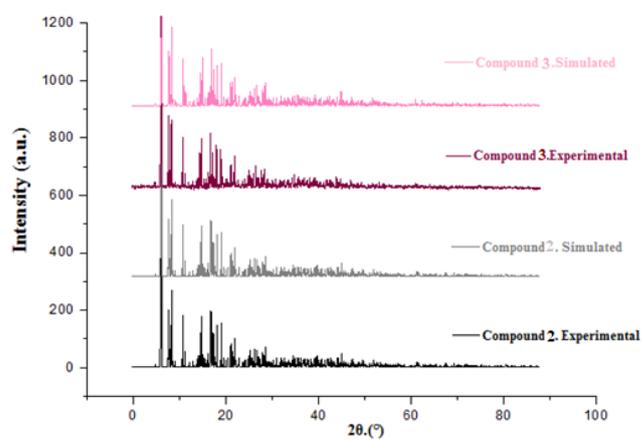

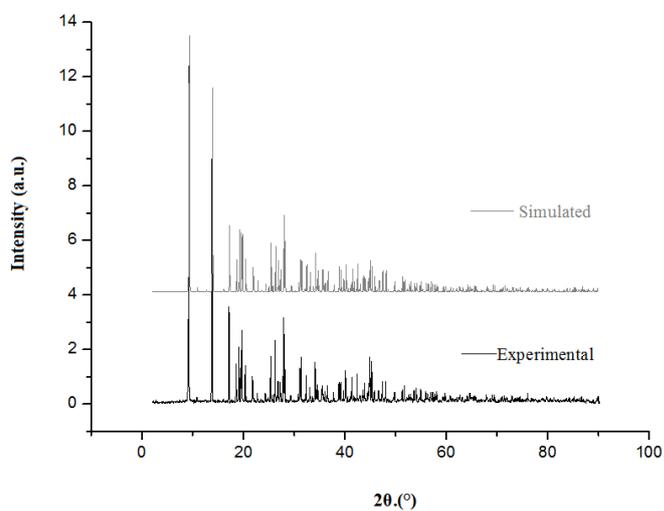

Figure A.1.8. TG/DSC curves of lead coordination polymer,  $[\text{Na}_2\text{Pb}_2(\text{CH}_3\text{COO})_6]_n$  (9)

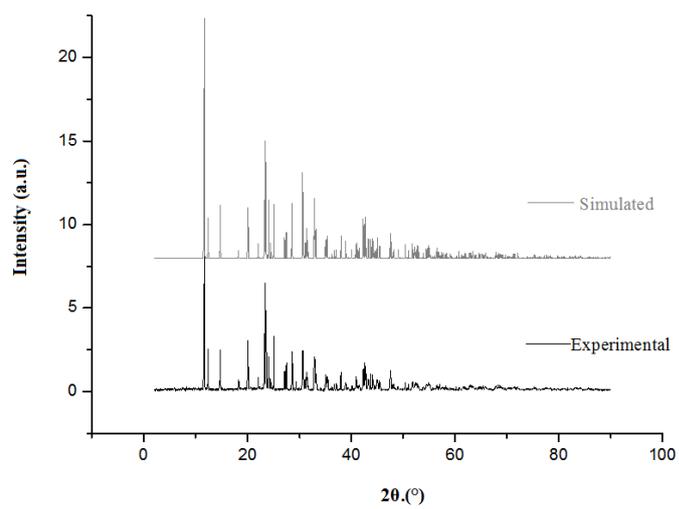

## A.2. (XRD) Simulated and experimental patterns

**Figure A.2.1.** Experimental and Simulated powder X-ray diffraction patterns for compound **(2)** (neodymium coordination polymer) and **(3)** (samarium coordination polymer)

**Figure A.2.2.** XRD patterns: (gray) simulated pattern based on single crystal data of cerium compound **(4)** and (black) experimental pattern

**Figure A.2.3.** (XRD) Simulated and experimental patterns of compound [Pb(DHBDA)]<sub>n</sub> (10)

## Symbols and Abbreviations

CP	Coordination polymer
MOF	Metal organic framework
SBU	Second building unit
NLO	Non linear optic
SMM	Single-molecule magnets
SCM	Single-chain magnets
POM	Polyoxometalate
EE	End-to-end
EO	End-on
MO	Molecular orbital
1D	One-Dimension
2D	Two-Dimension
3D	Three-Dimension
∠	Angles

## Materials

bmdt	<i>N,N</i> -bis(4-methoxybenzyl)diethylenetriamine
py	pyridine
dca	dicyanamide
tem	tricyanomethanide
TBC	1,3,5-tricyanobenzene
TEB	1,3,5-tris(4-ethynylbenzotrile)benzene
TEBB	1,3,5-tris(3-ethynylbenzotrile)benzene
BPCN	4,4'-biphenyldicarbonitrile
tcnb	1,2,4,5-tetracyanobenzene
pyz	pyrazine
HBz	Benzoic acid
Pym	Pyrimidine
pydz	Pyridazine
4,4'-bipy	4,4'-bipyridine
2,2'-bipy	2,2'-bipyridine
H <sub>2</sub> pzdc	2,3-pyrazinedicarboxylic

tpt	2,4,6-tris(4-pyridyl)-1,3,5-triazine
tpb	1,3,5-tri(4-pyridyle)-benzene
tri	triazine
NH <sub>2</sub> trz	4-amino-4 <i>H</i> -1,2,4-triazole
H <sub>4</sub> BTA	biphenyl-3,3',4,4'-tetracarboxylic acid
bib	1,2-bis(imidazole-1-yl methyl)benzene
titbm	1,3,5-tris(imidazole-1-ylmethyl)-2,4,6-trimethylbenzene
bimp	bis(4-imidazolphenoxy)methane
H <sub>2</sub> bdc	1,4-benzenedicarboxylic acid
btc	benzene-1,3,5-tricarboxylic acid
2-pyc	pyrazine-2-carboxylate
ppca	4-(pyridine-4-yl)pyridine-2-carboxylic acid
Phen	1,10-Phenanthroline
Bpe	(1,2-di(4-pyridyle)ethylene)
Bpa	(1,2-di(4-pyridyle)ethane)
Bpp	(1,3-di(4-pyridyle)propane)
HAT	1,4,5,8,9,12-hexaazatriphenylene
tpyt	5,10,15,20-Tetra(4-pyridyl)-prophine
H <sub>2</sub> btm	Bis(tetrazolyl)methane
H <sub>4</sub> adip	5,5'-(anthracene-9,10-diyl)diisophthalate
bpydb	4,4'-(4,4'-bipyridine-2,6-diyl)dibenzoate
addi	5,5'-(acridine-2,7-diyl)diisophthalate
azpy	4,4'-azopyridine
NNO	Nicotinate N-Oxide
H <sub>2</sub> FDA	2,5-furandicarboxylic acid
H <sub>2</sub> pdc	3,5-pyrazoledicarboxylic acid
(N,N'-MeO-ba) <sub>2</sub> bn	N,N'- bis (4-methyl-benzylidene)butane-1,4-diamine
(N,N'-4-Cl-ba) <sub>2</sub> bn	N,N'- bis (4-chloro-benzylidene)butane-1,4-diamine
H <sub>2</sub> -DHBDA	2,5-Dihydroxy-1,4-benzenediacetic acid

## **Solvents**

DMF	Dimethylformamid
DMSO	Dimethylsulfoxide
EtOH	Ethanol
MeOH	Methanol
DME	Dimethoxyethane
S <sub>1</sub>	Solvent 1
S <sub>2</sub>	Solvent 2

## **Thermal analysis**

TGA	Thermal gravimetric analysis
DSC	Differential scanning calorimetric
Exo	Exothermic
Endo	Endothermic
Temp	Temperature

## **IR Spectroscopy**

$\Delta$	$\Delta$ values, Deacon and Phillips
$\nu_{as}(COO^-)$	Asymmetric stretching vibration of carboxyl group
$\nu_s(COO^-)$	Symmetric stretching vibration of carboxyl group
S	Strong
VS	Very strong
M	Medium
W	Weak

## Lebenslauf (CV)

### Mona Feizbakhsh Bazargani

---

#### Persönliche Daten:

**Name:** Mona Feizbakhsh Bazargani

**Geburtsdatum /-Ort :** 21.09.1982 Tehran / Iran

**Nationalität :** Iranisch

#### Studium:

- **2012-2018 / Anfertigung einer Dissertation in Anorganischer Chemie / Friedrich-Schiller- Jena Universität / in Jena / Deutschland**  
Betreuer: Professor Dr. Christian Robl
- **Thema der Doktorarbeit:** “Synthesis and characterization of ten new 1D, 2D and 3D-coordination polymers with oxygen and nitrogen containing ligands by using different metal cations”.
- **2007 – 2010 / Master der Naturwissenschaft ( MSc ) in Anorganischer Chemie / Karaj Islamic Azad Universität / in Karaj / Tehran / Iran**  
Betreuer: Associate Professor Dr. Afshin Rajabi Khorrami  
Co- Betreuer: Professor Dr. Hamidreza Khavasi und Associate Professor Dr. Ali Mahmoudi
- **Thema der Masterarbeit:** “Synthesis and characterization of metal ion imprinted polymers for thallium and cadmium ions extraction from natural and industrial waters by SPE method”.
- **2000 – 2005 / Bachelor der Naturwissenschaft ( BSc ) in Angewandter Chemie / Karaj Islamic Azad Universität/ in Karaj / Tehran / Iran**
- **Thema der Bachelorarbeit:** “Investigation of modifications’ parameters of syrup in evaporation part”.  
Betreuer: Assistant professor Dr. H. Baheri

Co- Betreuer: M. Sepaveh “Unternehmer der Zuckerfabrik ”.

- 1996 – 2000 / Moallem Schule , Rasht, Gilan, Iran

Diploma in Experimenteller Wissenschaft

### **Publikationen:**

- **Pyridine-Functionalized TiO<sub>2</sub> Nanoparticles as a Sorbent for Preconcentration and Determination of Ultra-Trace Palladium Ions:**

Mohammad Karimi<sup>1</sup>, Mona Feizbakhsh Bazargani<sup>2</sup>, Forouzan Aboufazeli<sup>1</sup>, Hamidreza Lotfizadeh<sup>1</sup>, Omid Sadeghi<sup>1</sup> and Ezzatollah Najafi<sup>1</sup>.

In Current World Environment Vol. 7(2), 227-232 (2012).

- **2-[(1H-Imidazol-2-yl)disulfanyl]-1Himidazol:** Mona Feizbakhsh Bazargani, Laleh Talavat, SoheilaNaderi and Hamid Reza Khavasi,  
in Acta Crystallographica Section E Structure ,2012

- **Immobilization of Metalloporphyrin on Functionalized Magnetic Nanoparticles as a Catalyst in Oxidation of Cyclohexene: Novel Modified Fe<sub>3</sub>O<sub>4</sub> Nanoparticles with Triethoxysilane Agent :**

Omid Sadeghi, Mostafa M. Amini, Mona Feiz Bakhsh Bazargani, Azadeh Mehrani, Amineh Aghabali, Maryam Adineh, Vahid Amani, Kheirollah Mehrani,

In J Inorg Organomet Polym, (2012) 22:530–535, DOI 10.1007/s10904-011-9563-x

### **Stipendien:**

- April 2013-Juli 2017 Doktorandenstipendium des Deutschen akademischen Austauschdienst (DAAD)
- Juli - Januar 2019 Promotionsabschlussstipendien der Graduierten-Akademie der Friedrich-Schiller-Universität Jena

Jena 04.07.2018

Mona Feizbakhsh Bazargani

## **Declaration of authorship / Selbstständigkeitserklärung**

I certify that the work presented here is, to the best of my knowledge, original and the result of my own investigation, except as acknowledged, and has not been submitted, either in part or whole, for a degree at this or any other university.

Ich erkläre, dass ich die vorliegende Arbeit selbstständig und nur unter Verwendung der angegebenen Hilfsmittel, persönlichen Mitteilungen und Quellen angefertigt habe und dass ich nicht die gleiche, eine in wesentlichen Teilen ähnliche oder eine andere Abhandlung bei einer anderen Hochschule als Dissertation eingereicht habe.

Jena, 04.07.2018

Mona Feizbakhsh Bazargani
