Figure 1 is an overview of the overall framework and workflow of our method using PubMed.

As shown, both topic mining and the initial relation extraction can be carried out in parallel. The relation extraction method computes and produces a bag of relations for an article. In parallel, the topic detection method produces an ordered list of topical words or concepts from the same article, which are ranked by the likelihood of being the topic. The two results are then fused to produce the final result of the key topic relations. Two preprocessing tasks are carried out to produce a list of keywords as topic word candidates.

Preprocessing for Keyword Detection Using MeSH and Gene Symbols

We used Medical Subject Headings (MeSH) and Gene Symbols as terms for a standard vocabulary. These two thesauri together include entity names of diseases, chemicals and genes in PubMed articles. We adopted a classic simple method to recognize MeSH and Gene Symbols from articles.

Many MeSH concepts can be recognized from the articles directly with an exception. There is a loose tree structure in MeSH, so some of the parent concepts are also a part of the child concept, for example, “Abdomen” and “Acute Abdomen”. The latter is a child concept of the former, and the entire parent concept is part of the child concept. Both of the concepts can be recognized correctly, however, if the term “Abdomen” were to be considered a false-positive recognition in the sense of being over-general within the more specific child concept of “Acute Abdomen”. We have developed a method to eliminate this kind of error.

We extracted all MeSH concepts and ignored the original tree structure. We compared every pair of concepts in the extracted list, and built a new structured order of MeSH concepts. We labeled words like “Abdomen” as central words and “Acute Abdomen” as an extended word, with other words labelled as isolated words. We thus divided MeSH concepts into 3 groups, with each word in a central word group being connected to its extended words within an extended word group. Therefore, we used members of the central words group and the isolated words group as a thesaurus for recognizing entities in PubMed articles. Once a center word was recognized, we extended the thesaurus to its extended words and if there is a match for one of its extended words, we replaced the center word with its extended word. This way, we increased the level of specificity of what is being recognized to match the level of reference in the article, so as to eliminate...
the kind of over-generalization error that would otherwise result.

Gene symbols, on the other hand, are highly specific and unambiguous, and thus entirely different than the anatomical and pathophysiological level concepts in the natural language with English words. With our approach, the mismatch rate is surprisingly low, and we can recognize gene symbols directly from topic blocks in tests, including abstracts.

**Handling Abbreviations and Pronouns**

Many articles use abbreviations and pronouns instead of MeSH words. These abbreviations and pronouns cannot be recognized as MeSH words, so we replace them with the words they stand for. Abbreviations are explained in the first time they are used, we only need to locate the definition of abbreviations and replace them throughout the whole paper with the original MeSH words. As for the pronouns, they do not have a fixed meaning, so we replace them with the nearest noun or noun clause they qualify. Since not every pronoun stands for a MeSH word, we do not need to replace all pronouns. Therefore, we find all MeSH words and use them to replace pronouns related to them as long as the semantic distance between them is short enough.

**Structure-Based Probabilistic Model for Topic Concept Recognition**

Traditional topic mining or keyword detection methods mostly use word frequency as the main feature. While recognizing the importance of word frequency, we also observe that spatial distribution of words in an article is another very valuable feature in text analysis, for topic word detection in particular. The two features are complementary to one another, so we develop a statistical model for topic words and use it in a simple Naïve Bayesian classifier for topic word detection, which appears to be adequate.

The main assumption of this approach is the recognition of the structural partitions in a paper or article, either in the text, such as the Objective-Methods-Results-Conclusion division which is standard for most abstracts found in PubMed, and which we use for developing our statistical model. In doing so, 1000 abstracts were randomly chosen from the PubMed repository. Topic keywords for each abstract were determined from visual examination, with the help of topic mining tools. The frequency of candidate topic keywords appearances in each of the above-mentioned partitions is computed and reported in Table 1.

<table>
<thead>
<tr>
<th>Topic Words</th>
<th>Average Count</th>
<th>Average Appearance rate (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>1.92</td>
<td>100</td>
</tr>
<tr>
<td>Objective/Background</td>
<td>1.92</td>
<td>78.57</td>
</tr>
<tr>
<td>Method</td>
<td>1.15</td>
<td>64.29</td>
</tr>
<tr>
<td>Result</td>
<td>2.08</td>
<td>85.71</td>
</tr>
<tr>
<td>Conclusion</td>
<td>2.23</td>
<td>100</td>
</tr>
</tbody>
</table>

As shown above, the “conclusion” section has the highest frequency of the candidate topic words. The 100% figure shows just how carefully authors made sure to include topic-related candidate keywords in the conclusion section in this particular random sample of abstracts. We believe these

**Table 1-Distribution of Topic Words as Candidate Keywords**

<table>
<thead>

<td>2.23</td>
<td>100</td>
</tr>
</tbody>
</table>

frequency numbers can be taken as a reasonable initial approximation of the structural distributions of topic words to determine the “truly topic-representative” Keywords.

**Topic Detection and Relation Prediction Using Naïve Bayesian Classifier**

Above, we described how a traditional frequency based method can help discover keywords of an article. The method depends only on the frequency of candidate keywords in the article, and, as shown in Table 1, the location of such candidate keywords in a particular section of structured text can help to identify the topic words which the authors may have intended as keywords Therefore, we introduced this location of potential topic-keywords within each partition of the text as features and built a Naïve Bayes classifier to discover the most frequently occurring and this likely intended topic-related keywords.

Each keyword identified during the preprocessing phase is extracted, and represented by a feature vector of six specific numerical features, with each feature being a count of occurrence of this keyword in a specific partition.

\[ t, ob, m, r, c, e > \]

where \( t \) is the title, \( ob \) is the objective/background part, \( m \) is the method part, \( r \) is the result part, \( c \) is the conclusion part and \( e \) is the number of distinct entities appearing in the same and adjacent sentences for this keyword.

All the potential keywords for an article can thus be represented by a 6 x N matrix with a row for each keyword, forming the feature space for the article, where \( N \) is the total number of keywords.

\[
\begin{pmatrix}
  \ t^1 & ob^1 & m^1 & r^1 & c^1 & e^1 \\
  \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
  t^N & ob^N & m^N & r^N & c^N & e^N
\end{pmatrix}
\]

We decided to use Naïve Bayes Classifier for “true” keyword detection for its simplicity and ease in training. Maximum likelihood is used to estimate the parameters of the probabilistic model assuming a normal distribution of samples in the feature space. The prior probabilities of positive and negative sets for a “true” keyword are defined below.

\[
P(pos) = \frac{pSize}{pSize + nSize} \quad P(neg) = \frac{nSize}{pSize + nSize}
\]

With features assumed to be drawn from a normal distribution, the probability of each feature is

\[
p = \frac{1}{\sqrt{2\pi} \sigma} \exp(-\frac{(x-\mu)^2}{2\sigma^2}), \text{ where } \sigma \text{ is the variance and } \mu \text{ is the mean value, so we can then define the posterior probabilities for a “true” keyword conventionally as:}
\]

Posterior probability of positive entity,

\[
p_{posterior}(pos) = P(pos)p(title|pos) \times p(abstract1|pos) \times p(abstract2|pos) \times p(abstract3|pos) \times p(abstract4|pos) \times p(differentEntity|pos)
\]

Posterior probability of negative entity,

\[
p_{posterior}(neg) = P(neg)p(title|neg) \times p(abstract1|neg) \times p(abstract2|neg) \times p(abstract3|neg) \times p(abstract4|neg) \times p(differentEntity|neg)
\]

When we try to determine the “true” topic keywords of an article, we calculate the feature matrix of this article, and run each row through our Naïve Bayes classifier. As defined previously, each row represents all features of an entity or
potential keyword, with the classifier returning the positive and negative posterior probabilities for each row. We compare the results and look at the posterior likelihood or odds ratio, and if it is greater than 1 we consider the entity to be a "true" topic-relation keyword in the article, and not otherwise. This simplest of Bayesian approaches can be made more sophisticated by using two thresholds for accepting or discarding a potential keyword for an article, with those potential topic words falling in the uncertainty region left for further processing. However, for the present test of our methods, the simple binary accept-reject strategy proved adequate.

**Pattern-based Relation Extraction**

As mentioned above, we adopted a prespecified pattern-based relation extraction approach as the first phase of our overall hybrid method. We used a sentence parser to divide each sentence into sentence components. Components within a sentence are connected by grammar, and our patterns are built on this. For example, "... pulsatile hemodynamics may be related to amyloidosis and tau-related neurodegeneration...", is a sentence found in the conclusion of the abstract of PubMed article with PMID 24225352. The words "hemodynamics" and "amyloidosis" are recognized as MeSH entities. We define a pattern $P(E_r, E_p, C_r, C_p)$, where $E$ is the extracted entity, and $C$ is the corresponding sentence component of this entity. In a specific pattern, $E$ represents a single attribute of a MeSH concept or gene symbol. In the example above, this pattern should match the relation, $P(\text{MeSH}, \text{MeSH}, \text{SUBJ}, \text{OBJ})$. For each given pair of components, we have 4 possible combinations of entities. Combined with component pairs, we define 16 base patterns. Other modified patterns then are taken to be variants of these base patterns.

Our pattern-based relation extraction method matches entities within a limited syntactic distance, therefore the entities matched by the method are highly likely to have a relation between them.

**Fusion of Topic Mining and Initial Relation Extraction**

In general, there are two possible choices of order for running both methods serially. If we run relation the extraction method first, we get a bag of relations. Then, running topic mining second within these relations we would get key relations. However, the words in relations are limited to several trigger words and entities extracted by patterns. This means we run the topic mining method on a small set of words and there is great possibility that the words appearing in relations repeatedly have nothing to do with the topic, because we have no guarantee that the relations are related to topic of the article. If we run topic mining method first, we get an ordered list of words. These words are ordered by the possibility of being the topic of the article. Then we can run the relation extraction method on these words. The results of this are likely to be minimal, as topical entities of an article do not need to function as trigger words. And, if the topical entities of an article cannot trigger relation extraction patterns, we do not get a result. Therefore, running both methods in serial is not ideal.

**Experiments and Results**

We evaluated our method by testing it against with an implementation of an existing topic extraction algorithm combined with an existing topic mining method called SCRET. Two thousand randomly selected (by PMID) article abstracts are used for the experiment. The sample articles all satisfy the structural assumption mentioned above. Both methods are implemented in Python3 with modules of BioPython [12] and NLTK [13].

**SCRET**

SCRET produces an empty list of results on 2000 sample articles. Since it is a combination of two algorithms designed for different purposes, this outcome is not a surprise. The method both algorithms adopted dealt with words and phrases differently, and naturally there is little chance that the results of both algorithms can be merged easily. It appears a combination of two algorithms with different purposes is not an effective way to solve such newer, combined problems. However, the idea of combining the two methods is not necessarily irrelevant, we just should not combine the algorithms directly. This is why we developed KREM.

**KREM**

The 2000 sample articles with conclusions within abstracts all contain over 3 entities within the title and abstract. There are 312 articles that do not have key relations. The rest have key relations and 967 of them have only one key relation, 533 of them have 2 key relations, 137 of them have 3 key relations, 22 of them have 4 key relations, 4 of them have 5 key relations and 5 of them have over 6 key relations. Over 89% of the articles have 1 or 2 key relations. This is consistent with our definition for key relation, if an article is really about an entity-relation, there should be key relations within topic blocks and the number of key relations is limited because the topic of an article is limited. KREM uses topic distribution probabilities in order to avoid the problem in serial implementation in SCRET.

**Comparison to RE and SCRET**

Traditional pattern-based relation extraction method is not developed for our purposes, but it still can extract relations from PubMed articles. SCRET is a direct combination of relation extraction and topic mining and it mostly satisfies our needs. We compare these two methods to KREM. We selected 50 pieces of articles from PubMed by searching a specific term and manually reviewing each article to make sure these are key relations in each articles. We apply these three methods on this set of articles, the results are shown in Table 2 below.

<table>
<thead>
<tr>
<th>Table 2 – Comparison of relation extraction algorithms</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Object</strong></td>
</tr>
<tr>
<td>Count of articles with relations</td>
</tr>
<tr>
<td>Max count of relations from one article</td>
</tr>
<tr>
<td>Average count of relations</td>
</tr>
<tr>
<td>Count of articles with key relations</td>
</tr>
</tbody>
</table>
From Table 2, we can conclude that a direct combination of relation extraction and topic mining cannot provide usable results.

Discussion

We found that lists of results from relation extraction and topic mining differ entirely, and it is difficult to merge them directly, i.e. there are often very few or no similar or identical MeSH words in both lists, so an exact, simple automatic syntactical comparison of the two lists usually produces zero results. Pattern-based relation extraction method finds all relations that fit pre-set patterns, but many of them are not topic-related. Traditional relation extraction methods do not usually recognize key relations well, whereas key relations can be typically found among the results of traditional relation extraction. Based on those relations, we cannot conclude what the main topic of a paper might truly be. KREM returns a limited number of relations, with most of these relations being a true topic or part of the true topic.

Conclusion

We have developed a new practical method for topic word detection and relation extraction to address some of the limitations with existing approaches. It is based on the observation that when a passage of text, such as an abstract of a biomedical article in PubMed, is divided into standard sections, using the statistics of potential topic-related keywords in each separate section can be used as the basis for later Bayesian fusion and then a more reliable second step of topic detection. Preliminary results of testing on a sample of 2000 randomly selected article abstracts show that both methods justify our hypothesis about the structural correlation of topic words, and demonstrate the potential of the new KREM method. Extracted key relations can be viewed as one type of structured summary for an article. Since the semantics of such types of summaries are well understood, they can readily be used for constructing or expanding a knowledge network or ontology. The proposed method has made some important simplifying assumptions about the abstracts of an article being organized in a known structure. This assumption may not apply in longer texts and in some forms of publications, thus limiting the usage of this approach. We are now working on a natural language understanding tool to automatically analyze articles that do not comply with our main assumption of being able to preprocess and partition the article, labeling each partition for further analysis.

Knowledge Management in Health Technology SMEs

Juhamatti Huusko, Sirpa Kuusisto-Niemi, Kaija Saranto

Department of Health and Social Management, University of Eastern Finland, Kuopio, Finland

Abstract
The purpose of this study was to examine knowledge management’s (KM) role in small and medium-sized (SMEs) health technology enterprises, which employ fewer than 250 employees. In this study, KM is understood as the ability to achieve competitive advantage by utilizing management knowledge and making it profitable. The health technology enterprises use modern technology to resolve health-related issues. The research data was acquired from Finnish health technology SMEs. The questionnaire was sent to 140 enterprises, generating 25 responses, or a 17.9% response rate. According to the results, health technology enterprises have not adopted KM concepts, nor do they have the necessary resources to do so. SMEs’ KM use is informal: information is transferred informally through human interaction, rather than through information systems. In the SMEs, KM is not perceived as important, although it is seen as associated with the enterprise’s financial performance through the potential in making the knowledge profitable.

Keywords:
Knowledge Management; Biomedical Technology; Medical Informatics

Introduction
Technological and scientific developments have changed our understanding of business. According to Freedman, Taylorism refers to scientific management focused on the work processes, such as how a certain work phase is efficiently executed. Today, the business environment is changing rapidly, and organizations that apply Taylorism principals are not able to reform quickly enough [1]. The health sector is similarly changing, facing challenges like aging, rising costs, growing demands, demographic changes, and free markets [2]. The health technology industry can offer solutions to these challenges, and could considerably affect health promotion and economic growth. According to the European Union, health technology as an industry consists of diagnostic and treatment methods, medical devices, pharmaceuticals, rehabilitation, prevention methods and supporting systems [3]. The health technology industry can provide new business opportunities and have major economic impacts. For example, in Finland, health technology is an economically significant industry. In 2014, Finnish health technology enterprises exported products and services worth 1.8 billion euros [4].

In general the KM research is in a pre-science phase and is progressing towards academic maturity and normal science [5]. It is argued that KM is affected by economics, sociology, philosophy, and psychology. Three management practices that have significantly influenced KM are information management, quality management, and human factors movement [6]. Although organizations are not aware of the information’s value, KM is a way to satisfy customer needs or even exceed customer expectations [7].

Knowledge management focuses on achieving organizational goals and making knowledge productive, which it does by motivating people and stimulating intrapreneurship, whereby employees act like entrepreneurs. Although SMEs use certain KM instruments to evaluate, acquire, develop, and share knowledge, as well as to determine the knowledge gap, the SMEs do not necessarily call managing information “KM” [8]. Traditionally, KM’s research focus has been on larger enterprises [9]. However, both large enterprises and SMEs need KM principles in order to survive in a modern, competitive society. Although the SMEs could achieve greater innovation and productivity by capturing, storing, sharing, and disseminating knowledge, their managers do not see KM investment as sufficiently profitable. The SMEs’ KM is usually informal, which means that the knowledge is processed through human interactions rather than information and communications technology (ICT) systems. The managers and owners think that KM is not a business-critical function, and that it is therefore unnecessary for business success. This conflicts with the academic literature, as studies show that both small and large enterprises should invest in KM for the sake of competitiveness maximization, as well as increasing survival probability [10].

Obviously, due to limited resources, SMEs need to be more creative in how they manage knowledge. In fact, SMEs should put effort into managing knowledge because they can use their expertise to gain competitive advantages. The SMEs tend to manage knowledge instantly and without modern ICT. Although they use ICT in various operations, technology’s KM use is limited [11]. Knowledge is a primary resource in organizations, and if managed properly, positively affects economic efficiency, innovation, and customer service [12].

Wong and Aspinwall [13] have characterized SMEs’ KM as follows:

1. SMEs lack KM understanding, especially regarding its key concepts;
2. SMEs have only slowly adapted formal and systematic KM practices because they do not see it as a high priority.

This study’s aim is to examine KM’s role in SME’s health technology sector. The researchers wanted to investigate how these enterprises understand KM, how constantly increasing data is managed, and whether these enterprises use information systems to process this data. To our knowledge, very few studies cover these interests. Although KM in SMEs has gained some attention in academic research, few researchers have been interested in health technology SMEs specifically. To that end, our research question was as follows:
1. What is knowledge management like in the health technology industry?

Health technology industry research is important from both a theoretical and pragmatic perspective. This paper’s goal is to increase SMEs’ awareness of KM.

Methods

For this descriptive study, a literature search was conducted using databases such as Elsevier and EBSCOhost. The aim was to find scientific papers with themes that engaged with SMEs’ KM, specifically within the health technology industry. The following inclusion criteria were applied for study selection:

1. Published in peer-review journals;
2. Focus on SMEs’ KM;
3. Published between 1990 and 2016.

The literature search indicated that no measurement tool was created for use in SMEs’ KM, specifically within the health technology context. Based on the literature review, a questionnaire was formed using an online survey tool called Webropol. The questions were tightly structured multiple-choice questions and Likert-scale questions. The questionnaire consisted of six demographic questions and nine wider questions concerning themes like informatics and KM. For example, the respondents were asked for their opinions about KM’s role in their organization, as well as how information loss is handled in case of retirement. The questionnaire was pretested by nine testers. Some changes were made based on the testing. The survey data was acquired from the Finnish health technology industry SMEs in early 2016. The survey focused on senior SME managers’ and board members’ views. The online survey was sent primarily to these groups, but snowball sampling was also executed to allow for questionnaire forwarding to other enterprise members. This study’s suitable enterprises were reached via their homepages and were included in the survey if they met the inclusion criteria:

1. The enterprises were SMEs (staff headcount < 250, turnover ≤ 50 M eur);
2. Their headquarters were located in Finland;
3. They use modern technology to produce services and products that promote health.

The questionnaire was sent to 140 managers, primarily Chief Executive Officers (CEOs) and Chief Technology Officers (CTOs). The respondents received a covering letter where they were informed that their identity or enterprise could not be identified and all the collected data will be destroyed after completing the study. In total, 25 participants responded, generating a 17.9% response rate. The collected data was analyzed using IBM SPSS Statistics 21 software. Due to a relatively low response rate, the analysis used was descriptive statistics. The aim was to provide sample size summaries, such as means and medians, as well as to present demographic information, including age, sex, and education level. The summaries are described using percentages and figures.

Results

In this study, the SMEs were divided into three categories: micro (fewer than 10 employees), small (10–49 employees), and medium (50–250 employees) enterprises. In this study, enterprise size varied between 1–180 employees (Figure 1). A total of 40% of the respondents worked in micro enterprises, while 48% worked in small enterprises, and 12% worked in medium enterprises.

The respondents were asked about ICT outsourcing reasons. Approximately 60% of the respondents stated that outsourcing is a way to save costs, 80% stated that outsourcing can help better allocate available resources, and 84% thought that they do not have the necessary knowledge to maintain their ICT infrastructure. Beyond this, 88% of the respondents stated that the ICT information systems provide knowledge associated with competitive advantages and, in general that the ICT provides managers with useful and up-to-date information. The use of modern ICT increases knowledge and information system usability, providing information that informs decision-making. Almost every respondent (96%) highlighted that ICT is significant in knowledge sharing.

In this study, it was essential to examine knowledge’s significance in management. To that end, 84% of the respondents noted that their enterprises are dependent on certain employees and entrepreneurs. Therefore, certain employees were seen...
as irreplaceable. Meanwhile, 92% of the respondents had an academic degree, which supports the idea that health technology enterprises are knowledge-intensive companies that enhance human capital. In addition, 92% of these respondents stated that the networks, knowledge, and customer relationships were important enterprise resources.

The enterprises were aware of knowledge loss due to employee attrition. In the survey response, 80% of the respondents pointed out that the best way to prevent knowledge loss is to share jobs among multiple employees. Furthermore, apprenticeship was seen as a practical way for reducing knowledge attrition, as apprenticeship is a system whereby experienced and inexperienced employees work side-by-side. Beyond this, a good way to retain the enterprise’s knowledge is to cultivate team spirit, which encourages asking for help and the organization culture being open and transparent. A total of 96% of the respondents stated that their enterprise used at least one way to prevent knowledge loss, while one of the respondents stated that this has not been taken into account at all (Figure 3).

![Figure 3 – Ways to prevent knowledge loss due to employee attrition (n = 25)](image)

The respondents were asked for their opinion about KM’s role in the enterprise’s financial performance. Approximately 96% of the respondents stated that KM is associated with the financial performance, while 84% saw KM as a way to provide management models. Applying KM was seen as a way of providing practical implementation expertise. Furthermore, KM was associated with cost-efficiency, in addition to being linked to value creation and having the potential to be used for identifying strengths, weaknesses, opportunities, and possible threats. Beyond this, respondents stated that KM could be used to make knowledge profitable.

The respondents were asked to describe KM’s role in SMEs at a general level (Table 1). The aim was to examine the health technology enterprises managers’ views on KM, as well as to compare the findings with those of previous studies. It was found that action is the main way to create, share, transfer, and utilize knowledge in SMEs, with KM being adapted slowly in most of the enterprises participating in the study. The importance of KM received mixed feelings.

### Discussion

This study’s aim was to examine the role of KM in health technology SMEs. The results show that health technology enterprises can be seen as knowledge-intensive enterprises that emphasize human capital. The enterprises’ individuals fulfill an essential role, as the enterprises are dependent on certain employees and entrepreneurs. The employees and managers’ expertise is relevant for the enterprises, and their jobs require both creativity and problem-solving skills.

In light of this study, health technology SMEs’ KM is similar to the previous literature’s findings. Health technology enterprises’ use of KM does not differ from other SMEs fields. The SMEs have not adopted KM concepts [8–10], and according to these results, the major obstacle to KM’s wider use is resource scarcity, which also applies to health technology enterprises.

Thus, SMEs’ KM cannot be compared with larger enterprises. Based on the results, it is assumed that SMEs’ KM is understood in different ways.

It is important to note that health technology enterprises often offer products and services designed for managing knowledge, and their business models are based on creating, sharing, using, and managing that knowledge. Despite the previous findings, the enterprises themselves have not adopted KM concepts. Based on these results, in some enterprises, product development and marketing absorbs the vast majority of the available resources, which results in scarce resources available for KM.

Beyond this, SMEs’ KM tends to be informal, with knowledge being processed in human interactions rather than formally in ICT systems. Although the managers and owners think that KM is essential for their enterprise’s success, the resource scarcity forces them to focus on other functions. In this study, health technology SMEs have slowly adapted formal KM practices and do not take full advantage of information technology. Health technology enterprises should invest in KM because it allows the enterprises to gain a competitive advantage [9, 10] and because it is related to financial success and thereby considered an important business function. Applying KM principles can make knowledge productive [7, 11]. It is also essential to recognize that KM can aid in satisfying, or in some cases, even exceed customer expectations [6].

Although the response rate was relatively low, all the respondents completed the questionnaire with no missing data. Therefore, researchers concluded that the questionnaire was well
designed and it functioned properly. The low response rate may originate from the lack of respondents’ resources, such as time. It is our assumption that the managers of SMEs are very busy and they do not necessarily have time for extra activities. On the other hand, it is essential to ask, are themes concerning knowledge management somewhat sensitive? Despite the response rate, this study provides new findings related to the role of KM in SMEs. This study provides insight as to how knowledge is managed in the industry that applies modern technology in a health care setting. It would be necessary, in a further investigation, to carry out surveys and interviews, e.g., mixed methods studies applying quantitative and qualitative data. This method would deepen the understanding of KM in SMEs. In addition, further research should collect data internationally to generate more observations. At the time that our data was collected, Finland had 300 health technology enterprises. In the near future, this number could rise significantly, as the global need grows for high-quality yet affordable health care. Beyond this, technology keeps evolving, and we cannot know for sure what is possible in the future.

In this study, it is worth noting that only 12% of the managers were women. Further studies could examine why women rarely act as managers. Is it because of women’s own lack of interests, or perhaps because of general attitudes towards women as managers? It is important to realize that, for example, in Finland, the majority of health care employees are women. It could be necessary to survey more women health technology industry managers and collect their views as well. It is also important to study what kind of efforts are required to manage rapidly increasing rate of new information and how this affects the decision-making in the health technology enterprises. Further studies could also examine how to manage this information overload and how to transfer it into services and products. Examining KM in the health technology sector could enhance our knowledge and help KM progress towards academic maturity [4].

Conclusion

In this study, we examined KM’s role in health technology SMEs. We were able to define KM’s role in these enterprises. We conclude that these enterprises want to focus on their core business and that due to lack of resources KM is not fully utilized. We believe that it is essential in informatics to examine privately owned health technology enterprises because it is plausible that these enterprises will increasingly process and maintain our health information. As their role in health care grows and as technology evolves, it is essential to require these enterprises to pay more attention to KM processes in order to create, share, use, and properly manage knowledge.

Acknowledgements

We would like to thank all of the health technology enterprises that participated in this study.

Effects of Implementing a Tree Model of Diagnosis into a Bayesian Diagnostic Inference System

Satoshi Iwai, Yoshimasa Kawazoe, Takeshi Imai, Kazuhiko Ohe

*Department of Biomedical Informatics, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan

Abstract
To estimate a diagnostic probability similarly to experts using answers to interviews, we developed a system that fundamentally behaves as a Bayesian model. For predefined interviews, we defined the sensitivity and specificity related to one or more diagnoses. Additionally, we used a predefined parent–child relation between diagnoses to decrease the number of parameters to set. After calculating the disease probability, we trained the model using the difference of post-test probability between computer calculations and three experts’ opinions. We evaluated the effects of setting up tree structures. When using a tree structure, the model trained faster and produced better fitting results than the model without tree structure. Training with multiple raters’ training data confused the model. The scores worsened in later epochs. Herein, we present the new method’s benefits and characteristics.

Keywords:
Machine Learning; Decision Support Systems, Clinical; Expert Systems

Introduction
Impressive progress has been forthcoming in knowledge representation, machine learning, and data mining for knowledge discovery, and in temporal representation and reasoning [1]. For clinical decision support, some trials have used accumulated data from electronic medical records [2]. However, machine learning methods cannot accommodate rare diseases because appropriate datasets are difficult to obtain. Furthermore, when using EMR data, the possibility exists of learning an incorrect pattern. Machine learning and data mining methods depend heavily on the dataset to be learned. For some aspects of medical knowledge, the introduction of expert knowledge is necessary.

For expert systems that were studied actively in the 1980s, experts crafted knowledge bases [3]. The system was able to accommodate the knowledge implemented on it. However, maintaining knowledge bases for those systems was difficult because medical knowledge has also changed. Therefore, it became necessary to update the knowledge base according to these changes [4]. The most important difference between an expert system and a human doctor is that the expert system is unable to obtain feedback from patients. We devised a system that assumed feedback from manual input by a doctor.

An earlier expert system, INTERNIST-1, used “evoking strength” and “frequency” values that were pre-defined by physicians from reviews of the literature [3]. However, those values included subjective elements that were not based on specific numerical theory. Therefore, the values led to multiple interpretations [5]. Instead of these values, we used sensitivity and specificity, which have been defined theoretically.

To reach a clinical judgment, physicians usually hypothesize some diagnoses and estimate their respective probabilities. They obtain additional data by conducting interviews. Subsequently, the physicians estimate the diagnoses’ respective probabilities. After estimating the probabilities, they choose whether to conduct more tests or to treat the patient without subjecting the patient to risks of further diagnostic tests [6]. This study assesses an approach to simulate specialists’ clinical reasoning. We fundamentally used a simple Bayesian model to calculate these probabilities. Additionally, we incorporated the pre-defined tree structure of diseases. This model requires sensitivity and specificity of the interviews to the specific disease, but those values are difficult to determine. We trained these values using the probability of a diagnosis estimated by the experts using answers to patient interviews. We evaluated the effects of implementing a tree model when the model calculated the probability of clinical diagnosis and estimated the sensitivity and specificity.

Methods
Based on a serial Bayesian approach to calculate the respective probabilities of the diagnoses, we developed a computer program to derive differential diagnoses from responses to two-choice interviews. Necessary sensitivity and specificity for the calculations were set in advance for each interview, but these were updated in training from expert opinions. They converge to more appropriate values. To simplify the system and to examine a study of training methodology specifically, we chose dizziness and vertigo as chief complaints. Cases of dizziness and vertigo are often encountered in emergency departments. Reportedly, the history and initial clinical examination of the patients have high sensitivity and specificity for differentiating central and peripheral vertigo [7].

Defining Diagnoses Model
In the emergency department, the granularity of the differential diagnosis differs from that of general outpatients. The differentiation process might be terminated with an upper disease concept. We considered this broader concept of the disease as one differential diagnosis and organized this concept into a tree form (Fig. 1). We used the assumption that the disease concept characteristics are also applicable to child diseases. Statistical characteristics of the relation between interviews and diseases are also inherited to some degree. The model, which was defined from one emergency physician’s perspective, was reviewed by another otolaryngologist.
In this experiment, 27 DtoQ relations were prepared.

We chose 17 interview queries that are usually posed to dizziness or vertigo patients. Each interview sentence relates to one or more diseases or disease concepts defined above. We designate this relation as a “Diagnosis to Question” (DtoQ) relation. Each DtoQ relation has three attributes: sensitivity, specificity, and an assumed answer. The assumed answer is the answer to a question that is assumed if the disease is present. We regarded the interviews as tests, using them to calculate post-test probability. Table 1 is a 2×2 contingency table showing the frequency of patients who answer the interview. Theoretically, sensitivity is a value that is calculated using formula (1): it is the proportion of those who have a disease, who also respond with the assumed answer to the question. Specificity is a value calculated using formula (2): it is the proportion of those who do not respond with the assumed answer (those who answer no if the assumed answer is yes). We cannot know these actual values. Therefore, we pre-determined them from a physician’s perspective. Examples of values are presented in Table 2.

\[
\text{Sensitivity} = \frac{a}{a+c} \quad (1) \\
\text{Specificity} = \frac{d}{b+d} \quad (2)
\]

Table 1 – 2×2 Contingency Table of Responses

<td>d</td>
</tr>
</tbody>
</table>

\[
\text{Certainty Value} = \frac{\text{post test Odds}}{1+\text{post test Odds}} \quad (7)
\]

Calculating Certainty

General

We defined the post-test probability as a certainty value. This value was calculated using a serial Bayesian approach, which uses an assumption that each related interview correlates independently to a diagnosis probability. Post-test odds for a diagnosis are calculated by multiplying the pre-test odds. All positive likelihood for interviews for which answers are positive (patient’s answer is the assumed answer) and all negative likelihood for negative ones (opposite answer of the assumed answer) (3). Odds are calculated using formula (4). The positive likelihood ratio and negative likelihood ratio are calculated using formulas (5) and (6). Finally, the certainty value is calculated using formula (7). We cannot estimate the disease probability precisely. Therefore, we assumed pretest probabilities of 0.1 for all diseases.

\[
\text{post test Odds} = \prod \text{LR}^+(\text{if test = Pos}) \\
\times \prod \text{LR}^-(\text{if test = Neg}) \\
\times \text{Pre_test Odds} \\
\text{Odds} = \frac{\text{probability}}{1-\text{probability}} \quad (4)
\]

\[
\text{LR}^+ = \frac{\text{Sensitivity}}{1-\text{Specificity}} \quad (5) \\
\text{LR}^- = \frac{1-\text{Sensitivity}}{\text{Specificity}} \quad (6)
\]

Using Tree-form Diagnoses

We defined the disease structure in tree form. As described above, the statistical characteristics of a child disease is assumed to be similar to that of the parent disease. If the odds of one diagnosis are updated using the formula presented above, then the odds of the child diagnosis will also be updated. For example, stroke is a child diagnosis of central vertigo, and central vertigo is a child diagnosis of vestibular syndrome. Therefore, if the answer is “No” to the question “Do you see darkness or flashing in front of you?”, then the examination probability of “stroke,” “central vertigo,” and “Vestibular syndrome” is increased. When a specific question such as “Do you have headache or neck pain?” is answered, only the probability of “stroke” might be updated. In this way, one can rank diagnoses with maximum efficiency during an interview.
Preparation to Train from Experts

Forward Calculation

After setting up all these calculation methods, we created 100 simulated patients, and assumed one specific diagnosis for each patient. To simplify a problem, we used six diagnoses that are commonly encountered in emergency departments: presyncope, stroke, brain tumor, vestibular neuritis, Meniere’s disease, and benign paroxysmal vertigo. For each patient, we simulated patient responses to interviews using a predetermined sensitivity. Examples of simulated responses to interviews are presented in Table 3. Examples of calculated certainty for the simulated patient are presented in Table 3 and Table 4.

Table 3 – Simulated Answers of a Patient Affected by Benign Paroxysmal Positional Vertigo (BPPV)

<table>
<thead>
<tr>
<th>Interviews and Answers (Excerpt)</th>
<th>Differential Diagnoses (top 5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do you see darkness or flashing in front of you?: NO</td>
<td>Certainty value</td>
</tr>
<tr>
<td>Will the dizziness go well if you keep still?: YES</td>
<td>Wernicke encephalopathy</td>
</tr>
<tr>
<td>Did the dizziness occur suddenly?: YES</td>
<td>Vestibular neuritis</td>
</tr>
<tr>
<td>Are there any initial neurologic symptoms?: NO</td>
<td>Brain tumor</td>
</tr>
<tr>
<td>Do you drink alcohol every day?: YES</td>
<td>Central vertigo</td>
</tr>
<tr>
<td>Is your blood pressure high (180 or higher, or 40 higher than usual)?: NO</td>
<td></td>
</tr>
</tbody>
</table>

Obtaining an Expert Opinion

After defining simulated patients, we produced training data by diagnosing these patients. The computer calculates the post-test probability as a numerical value of 0–1. We can estimate the difference of the probability if we have an accurate value of the post-test probability estimated by physicians. However, physicians do not use numerical probability values in this manner. Therefore, we created a translation table to fill this gap (Table 5).

Table 5 – Certainty Value – Word Translation Table

<table>
<thead>
<tr>
<th>Word</th>
<th>Certainty Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Very likely</td>
<td>1</td>
</tr>
<tr>
<td>Doubtful</td>
<td>0.8</td>
</tr>
<tr>
<td>Possible</td>
<td>0.6</td>
</tr>
<tr>
<td>Negative</td>
<td>0.2</td>
</tr>
<tr>
<td>Never</td>
<td>0</td>
</tr>
</tbody>
</table>

Using this table, instead of determining the certainty value with numbers, physicians choose words that reflect their degree of confidence from a predetermined word list. If the physician is unable to determine a specific diagnosis, up to two diagnoses to which each certainty word is assigned can be entered. Three physicians evaluated patients and produced diagnoses with certainty using this method. Raters 1 and 2 are emergency physicians. Rater 3 is an otolaryngologist. An input example is presented in Table 6.

Table 6 – Examples of Expert Opinions

<table>
<thead>
<tr>
<th>Diagnosis</th>
<th>Certainty</th>
</tr>
</thead>
<tbody>
<tr>
<td>Benign paroxysmal positional vertigo</td>
<td>Very likely</td>
</tr>
<tr>
<td>Meniere's Disease</td>
<td>Possible</td>
</tr>
</tbody>
</table>

Training from Expert Opinions

For diagnoses for which the certainty value was determined by experts, we calculated the difference of certainty values between a human model and a computer model. In the example presented above, experts claim that the patient is likely to have benign paroxysmal vertigo (BPPV), but believe it might be Meniere’s disease. The certainty words are translated into a certainty value using Table 5. We assumed that the difference between a human certainty value and computer certainty value derives from the difference between their assumptions of sensitivity and specificity. The larger the gaps, the greater the correction to the sensitivity and specificity ofDtoQ list needs to be. To adapt the computer model to the expert diagnostic model, we used the following steps.

Listing up DtoQ relations to update values

It is impossible for physicians to ascertain certainty values for all differential diagnoses. Therefore, we limited the number of diagnoses a physician can input to two, as described above. The number of diagnoses obtained was so varied that we decided to use only the top diagnoses of their input.

Updating values

We used the extent of the difference between the calculated diagnosis and the human diagnosis as the degree of value update. Let \( \delta \) be the degree of difference. In the example presented above, the certainty value gap for BPPV between a human and computer is \( \delta = 1 - 0.797 = 0.203 \), which indicates a slight difference between human knowledge and computer knowledge. In one interview Q1, assuming that this patient answered “assumed answer,” then it is necessary to update the 2×2 contingency table of answers (Table 1). We now have gained the knowledge that at least one more patient has a disease and responded with the assumed answer, so we made it a rule to add weight to “a” of Table 1 and then subtracted weight from “b”. Letting \( k \) be a constant, the contingency table after calculation can be shown as Table 7.

Table 7 – 2×2 Contingency Table After Updating

<table>
<thead>
<tr>
<th>Interviews</th>
<th>Disease</th>
<th>Present</th>
<th>Absent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assumed</td>
<td>( a+k\delta )</td>
<td>( b-k\delta )</td>
<td></td>
</tr>
<tr>
<td>Not assumed</td>
<td>c</td>
<td>d</td>
<td></td>
</tr>
</tbody>
</table>

The DtoQ model we prepared has only sensitivity and specificity values. We must prepare the ratio of patients with disease. To calculate a–d, the ratio of the patients who have the disease must be ascertained using formula (8).

\[
\text{Prevalence} = \frac{a+c}{(a+b+c+d)}
\]

(8)

For this study, we set no specific value of disease prevalence for each disease. We assumed 0.3 for all diseases. It is meaningless to ascertain the absolute value of patients because \( k \) can be changed. With this assumption, we were able to calculate \( a \) and \( b \) respectively using sensitivity and specificity.
After calculating all these values, sensitivity and specificity can be updated using the following formulas (9 and 10).

\[
\text{Sensitivity} = \frac{a}{(a+b+c)}
\]

\[
\text{Specificity} = \frac{d}{(b+c+d)}
\]

### Evaluating Models

Differences in the certainty values described above were calculated for physicians’ top diagnosis of one patient, and were averaged for all test patients. We designate each as a difference score. The lower this score is, the better the model fits the expert opinions. First, 100 patients were assigned randomly to 80 training sets and 20 test sets, and were averaged for five-fold cross validation. We calculated the scores with each training cycle, which we call epochs. One epoch is equivalent to 80-patient training. Experiment 1: To evaluate the effects of structurizing diagnosis in a tree model, we compared the learning curve by all raters. Experiment 2: To ascertain how this method will function with multiple raters, we evaluated the learning curve by training with multiple raters. In one epoch, the model was trained with 2–3 training data together for each patient. For score calculation, we averaged the difference scores by raters whose data were used to train the model after each epoch. We calculated the inter-rater reliability.

### Results

In all experiments, the average difference of certainty values decreased with the number of training cycles. Learning curves of experiment 1 are presented in Fig. 2. By using the tree form in calculation, the score decreased faster. The score became lower with the tree structure for all raters’ training data. However, the score fluctuated in later epochs for rater 3.

![Learning Curves of Raters 1, 2 and 3](image)

In experiment 2, a learning curve with all combinations of raters fluctuated in later epochs (Fig. 3). With a tree structure, a learning curve with raters 1 and 2 showed no tendency to fluctuate until epoch 1000 (Fig. 4).

### Discussion

Experiment 1 demonstrated that the tree structure of the diagnosis model improves learning speed based on expert opinions. The results fitted better than the model without a tree structure. Experiment 2 showed that if we use training data from raters with different specialties, the training curve fluctuates and increases.

### Effects of Tree Structure with a Single Rater

The learning curve shows that the model fits the expert opinion better and faster when one incorporates the tree structure into calculations (Fig. 2A). However, the learning curve shapes varied among raters (Figs. 2B, 2C). The latent disease models of experts that mutually differ might affect the learning curve shape. For rater 3, the curve began to fluctuate from about 350 epochs when we do not incorporate a tree structure, and 500 epochs when we incorporate it. The tree structure of diseases allows updating of many DtoQ relations. Consequently, fitting to the model was done more quickly. Around the epochs of fluctuation, the model appears to be confused by inconsistent training data. The tree structure...
might have positive effects on accommodating experts’ knowledge.

**Effects with Multiple Raters**

Experiment 2 showed that training by data from multiple physicians also produces the fluctuation problem (Figs. 3, 4). It did not converge to a specific value for any combination of raters in the model without tree structure (Fig. 3). It also fluctuated with combinations of raters 1 and 3, and raters 2 and 3, and all three raters in the tree model (Fig. 4). However, the score did not fluctuate with a combination of raters 1 and 2 with a tree model within 1000 epochs (Fig. 4). Results show that introduction of the disease tree model seems to stabilize the fluctuation tendency also in training with multiple raters. The model might accept a more inconsistent training set when incorporating a tree structure. Table 8 shows that two physicians having the same specialty ( RATERS 1 and 2, both emergency physicians) have higher inter-rater reliability than physicians between different specialties (RATERS 1–3, 2–3). The experts’ models might be similar if their specialties were the same. The problem of fluctuation seemed to be a result of fitting to inconsistent training data. To understand the characteristics of the fluctuation, we conducted an additional experiment to calculate difference scores from training data instead of test data. Results show that the increase of the score in later epochs also occurs when calculating the difference score with the training data (not presented in this paper). If the model is overfitted, then the difference score will decrease in the training set and will increase in the test set. We were unable to assert that the overfitted model increased the score in later epochs. It remains unclear why the score will increase, but lowering the learning rate with the epoch might relax this problem.

**Characteristics of This Method**

This method shows some superiority over methods examined in earlier studies. First, the number of parameters, sensitivity, and specificity to each question were less than those of simple Bayesian networks. Fewer training sets are necessary to train the model. Moreover, it becomes easier to manage sensitivity and specificity.

Secondly, the system can learn the DtoQ relation to a partially completed interview. Using this system, one can calculate the diagnosis using a partial answer to the interview. Therefore, we can estimate the error and then update the knowledge base.

Thirdly, the predefined sensitivity and specificity values do not need to be exact. By accumulating training data, one can learn the values of sensitivity and specificity of experts. Eventually, the system will be able to make the same judgments as experts.

Fourth, we can accommodate rare diseases with pre-definition of sensitivity and specificity. Even if the specificity and sensitivity cannot be calculated from the data, one can input clinical knowledge into this system.

**Limitations**

This study was affected by some limitations. First, the pretest probability was assumed to be equal for all diagnoses. Each disease’s probability might differ in different clinical settings and for patients of different age or gender. Therefore, the prevalence of disease in the situation must be input to calculate the post-test probability accurately.

Secondly, the certainty value – word translation table is arbitrary. Some physicians might infer that a diagnosis is “very likely” for a certain patient, whereas other physicians might regard it as “doubtful,” even if they regard the diagnosis to be valid to the same degree.

Thirdly, the number of features to update for a given training set might be insufficient. The physician might have made decisions using information that was not included in the model. The low number of raters is also noteworthy. In future works, we plan to clarify the relations between fluctuation phenomena, model overfitting, and inconsistent training data. Many points of system improvement remain. Nevertheless, this prototype is expected to play an important role in elucidating system problems.

**Conclusion**

For this study, we assessed effects of integrating a disease tree structure into a Bayesian model for calculating post-test probability. The tree structure improved the learning rate without increasing the number of model parameters. Results also show that inconsistent training data tend to affect the model adversely. Future works will investigate means of stratifying and estimating prevalence and prior probabilities.

This paper presented an approach to acquire specialists’ latent knowledge and to develop clinical reasoning model. This approach can be useful for developing consultation systems that will be helpful for situations in which access to specialists is restricted.

**Acknowledgements**

The authors declare that they have no conflict of interest associated with this study or this report describing it. We gratefully acknowledge the rating efforts of two raters.

Abstract

A variety of data models have been developed to provide a standardized data interface that supports organizing clinical research data into a standard structure for building the integrated data repositories. HL7 Fast Healthcare Interoperability Resources (FHIR) is emerging as a next generation standards framework for facilitating health care and electronic health records-based data exchange. The objective of the study was to design and assess a consensus-based approach for harmonizing the OHDSI CDM with HL7 FHIR. We leverage a FHIR W5 (Who, What, When, Where, and Why) Classification System for designing the harmonization approaches and assess their utility in achieving the consensus among curators using a standard inter-rater agreement measure. Moderate agreement was achieved for the model-level harmonization (kappa=0.50) whereas only fair agreement was achieved for the property-level harmonization (kappa=0.21). FHIR W5 is a useful tool in designing the harmonization approaches between data models and FHIR, and facilitating the consensus achievement.

Reference standards; Observational study; Vocabulary, controlled

Introduction

Integrated Data Repositories (IDRs) [1-2] are needed to combine molecular and phenotypic data, making data available for use with analytic tools. This is especially important for clinical research investigators with limited computing resources. In a 2010 survey conducted by the Clinical and Translational Science Award (CTSA) consortium [3], IDR was defined as a data warehouse integrating various sources of clinical data to support queries for a range of research-like functions. Survey results suggest that individual organizations are progressing in their approaches to the development, management, and use of IDRs as a means to support a broad array of research. A variety of data models have been developed to provide a standardized data interface that supports organizing clinical research data into a standard structure in such IDRs. These data models include the Observational Medical Outcomes Partnership (OMOP) Common Data Model (CDM) [4-5], the National Patient-Centered Research Networks (PCORnet) CDM [6], and the Informatics for Integrating Biology and the Bedside (i2b2) Star Schema [7].

OMOP was a public-private partnership established to inform the appropriate use of observational healthcare databases for studying the effects of medical products. The OMOP community is actively using the OMOP CDM [4-5] for their various research purposes. Observational Health Data Sciences and Informatics (OHDSI) has been established as a multi-stakeholder, interdisciplinary collaborative to create open-source solutions that bring out the value of observational health data through large-scale analytics. The OHDSI collaborative includes all of the original OMOP research investigators and develops its tools using the OMOP CDM, which will continue to be an open-source, community standard for observational healthcare data.

The PCORnet CDM [6] is based on the Mini-Sentinel CDM and has been informed by other distributed initiatives such as the HMO Research network, the Vaccine Safety Datalink, and the ONC Standards & Interoperability Framework Query Health Initiative. The CDM leverages standard terminologies and coding systems for healthcare to enable interoperability and ensure responsiveness to evolving data standards.

The i2b2 is an open-source clinical data analytics platform that provides a component-based architecture and a flexible analytical database design [7-9]. The i2b2 Star Schema was developed as a CDM that enables conformant transformation of patient data to a common data structure and representation of meaning. i2b2-based solutions have been widely used in clinical research communities such as the Shared Health Research Information Networks (SHRINE) [10], and the PCORnet [11]. Building on the i2b2 framework, the tranSMART platform [12-14] is an analytic platform that also incorporates the ability to load molecular datatypes, including those derived from next generation sequencing (NGS).

These data models serve well as a layer of standardization for clinical research data within their own research network; however, if the investigators want to reuse and integrate these research datasets and applications in broader clinical research communities across different research networks they still face huge challenges. This situation demands a global data model as a reference standard to facilitate data model harmonization and data integration.

HL7 Fast Healthcare Interoperability Resources (FHIR) is emerging as a next generation standards framework for facilitating health care and electronic health records-based data exchange [15]. However, it has been a challenging issue for the standards and research communities to build a consistent and measurable approach for enabling the consensus achieving in terms of data model harmonization efforts. The objective of the study is to design and assess a consensus-based approach for harmonizing the OHDSI CDM with HL7 FHIR. We leverage the FHIR W5 (Who, What,
When, Where, and Why) Classification System [16-17] for designing the harmonization approach and assess its utility in achieving the consensus among curators using a standard inter-rater agreement measure. The outcome of this study would provide guidance to harmonize different data models with FHIR in future.

Methods

Materials

OMOP CDM

The OMOP CDM is “designed to support the conduct of research to identify and evaluate associations between interventions (e.g., drug exposure) and outcomes (e.g., adverse effects) caused by these interventions” [5]. The design principles of the CDM include: 1) suitable for purpose; 2) data protection; 3) design of domains; 4) rational for domains; 5) standardized vocabularies; 6) reuse of existing vocabularies; 7) maintaining source codes; 8) technology neutrality; 9) scalability; and 10) backwards compatibility. The CDM defines table schemas in a person-centric manner. As of September 18, 2016, version V5.0.1 of the CDM was released, which contains 39 tables in 6 categories: standardized clinical data, standardized health system data, standardized health economics, standardized metadata, standardized vocabularies and standardized derived elements. In fact, terminology normalization enabled by standard vocabularies with focus on SNOMED CT, LOINC and RxNorm is a strong characteristic of the OMOP CDM. Figure 1 shows a diagram highlighting the high-level relationships among the tables and categories.

![Figure 1 - A diagram highlighting the high-level relationships among the tables and categories. (Source from the OMOP CDM document)](image)

HL7 FHIR Core Resources

Detailed Clinical Models (DCMs) have been regarded as the basis for retaining computable meaning when data are exchanged between heterogeneous computer systems [18-19]. Amongst the emerging national and international initiatives on the standardization of DCM modeling are the Clinical Informatics Modeling Initiative (CIMI) [20] and FHIR [14]. The primary goal of CIMI is to "improve the interoperability of healthcare systems through shared implementable clinical information models (A single curated collection)”, FHIR builds around the concept of “resources”. “Resources” here means small discrete concepts with clearly defined scope that can be maintained independently. Resources are the smallest units of a transaction, and each resource has a unique id that aligns with RESTful design philosophy. As of September 16, 2016, the version Draft Standard for Trials Use (DSTU) 2 has been released and the version of STU 3 was placed under ballot. Figure 2 shows a collection of FHIR core resources under the FHIR Clinical category in the released DSTU 2.

![Figure 2 – A screenshot showing a collection of FHIR core resources under the Clinical category in the released DSTU 2](image)

Measure the Consensus in the Model-Level Harmonization

The OMOP CDM consists of a collection of table schemas. Each table schema represents a particular OMOP domain, which is analogous to the resources as defined in FHIR. In the model level, we design the following two approaches to align the table schemas with the FHIR resources. The first approach is to categorize the OMOP table schemas using the FHIR W5 resource categories, and the second approach is to map the OMOP table schemas directly with the FHIR core resources.

For the first approach, we extracted all table names and their textual descriptions from the OMOP CDM documentation website [5]. We designed a mapping application using an Excel spreadsheet that allows curators to assign a FHIR W5 resource category to each OMOP table name. As a pilot study, we asked the project team members to use the mapping application to assign the FHIR W5 resource category independently. The purposes of the pilot study are two-fold: 1) to examine the inter-rater agreement for categorizing the
OMOP table schemas; and 2) to examine the domain coverage of the OMOP CDM by comparing with the FHIR core resources. Figure 3 shows the spreadsheet-based mapping application for the first approach.

For the second approach, we extracted the OMOP table names and their descriptions under the category of “standardized clinical data” [5] and the FHIR core resource names and their definitions from the DSTU2 version. We also designed the Excel spreadsheet-based mapping application. We used four SKOS mapping properties (exactMatch, closeMatch, broadMatch, and narrowMatch) as the mapping types. As a pilot study, we asked each project team member to use the mapping application to map the OMOP table schemas under the category of “standardized clinical data” to the FHIR core resources individually. The purpose of the pilot study is to examine the inter-rater agreement for creating the mappings.

Figure 3 –A screenshot of the spreadsheet-based mapping application for the FHIR W5 resource category.

Measure the Consensus in the Property-Level Harmonization

In the property level, we extracted the field names, data types and descriptions of a particular OMOP table from the OMOP CDM documentation website [5]. Similarly, we designed a mapping application using an Excel spreadsheet (Figure 4) that allows curators to assign a property category to a particular OMOP table field. As a pilot study, we asked project team members to assign a FHIR W5 property category to the field names from two OMOP tables: Observation and Drug_ Exposition. The purpose of this pilot study is to assess the utility of the FHIR W5 property category system in achieving consensus among curators and in serving as a proxy for aligning the table field names with the FHIR resource properties.

Figure 4 –A screenshot of the spreadsheet-based mapping application for the FHIR W5 property category.

Inter-Rater Agreement Analysis

As described previously, we asked project team members to complete the mappings independently. Fleiss’ kappa statistics was calculated to assess inter-rater agreement [21]. The measure calculates the degree of agreement in classification over that which would be expected by chance. The Kappa statistics value of 1 (k = 1) reflects complete agreement among raters and, a value of zero or less (k ≤ 0) shows no agreement.

Results

Model-Level Harmonization: Inter-Rater Agreement Analysis For the FHIR W5 Resource Classification System

Five project team members were asked to complete the mapping spreadsheets and four valid responses were received. The average time used for the FHIR W5 Resource Category approach was 26 minutes (range from 24-30 minutes) whereas the average time used for the direct mapping approach was 29.25 minutes (range 17-35 minutes).

The overall Fleiss’ kappa statistics for categorizing the OMOP CDM tables with the FHIR W5 Resource Classification System was calculated as 0.50 whereas the overall Fleiss’ kappa statistics for directly mapping the OMOP CDM tables with the FHIR core resources was calculated as 0.48. The results indicated that for both harmonization approaches, the team achieved moderate agreement.

Model-Level Harmonization: Domain Coverage Between OMOP CDM and FHIR

After we calculated the Fleiss’s kappa statistics, we had a team discussion to resolve the disagreement and achieved the consensus. Table 1 shows the distribution of the FHIR core resources and OMOP CDM tables by the FHIR W5 resource category.

</table>

The results indicated that the OMOP CDM covers the domains in all 6 categories as defined by FHIR W5. The distribution of the OMOP CDM tables in the category of clinical (33%), financial (13%) and administrative (18%) is comparable with FHIR. The percentage of the OMOP CDM
tables in the category of infrastructure (8%) and workflow (5%) is lower than that in FHIR whereas the percentage of the OMOP CDM tables in the category of conformance (23%) is higher than that in FHIR. Interestingly, the OMOP CDM tables in the category conformance are all classified in the sub-category "conformance terminology," highlighting the OMOP CDM design principles emphasizing the use of standardized vocabularies.

Property-Level Harmonization: Inter-Rater Agreement Analysis for the FHIR W5 Property Classification System

Similarly, five project team members were asked to complete the mapping spreadsheets and four valid responses were received. The average time used for the OMOP Observation table was 15.75 minutes (range 8-30 minutes) and the average time used for the OMOP Drug Exposure was 16.75 minutes (range from 7-30 minutes).

The overall Fleiss’ kappa statistics for categorizing the fields in the OMOP CDM tables “Observation” and “Drug Exposure” with the FHIR W5 Property Classification System were both calculated as 0.21. The results indicated that for the property categorization approach, the team only achieved fair agreement. One of the main reasons is because that the FHIR W5 Property Classification System is new to most of the team members and only a limited documentation is available. We anticipate that more training orientation to curators would help improve the inter-rater agreement.

Property-Level Harmonization: Alignment between the FHIR Resource Elements and the OMOP Table Fields

We aligned the fields of the two OMOP tables Observation and Drug Exposure with the elements from the FHIR resource Observation and DrugAdministration (based on the FHIR W5 Report [16]) based on the FHIR W5 Property Classification System. The alignment results as shown in Table 2 indicated that a number of property categories including class, context, identifier, when, done, where, who, actor, who, focus are aligned reasonably well. A list of fields in both OMOP tables were categorized in the property category “what”, indicating this “what” category may need to be refined to have more specific subcategories.

Table 2 – The alignment results between the FHIR resource elements and the OMOP table fields.

Discussion

The use of data integration standards plays a critical role in the increasing adoption of the OHDSI CDM-based data repositories for clinical observational studies [22]. While the OHDSI Vocabulary CDM [23] and its vocabulary services [24] have provided a solid foundation for enabling semantic interoperability across different clinical and research systems, the heterogenous data model use in these systems remains a major barrier for data integration and sharing. The emerging HL7 FHIR aims to serve as a global reference standard for exchanging healthcare and EHR data, and mappings to FHIR from different data models would greatly facilitate the secondary use of EHR data for clinical and translation research including the observational studies. Therefore, a number of independent efforts in harmonizing between FHIR and OHDSI CDM are currently underway. For example, Choi and Duke’s team has developed a preliminary prototype known as the OHDSI on FHIR platform with OHDSI CDM mappings to FHIR resources [25]. Actually, the FHIR Infrastructure Work Group is developing a Data Access Framework (DAF) FHIR Implementation Guide which includes the guidance on creating profiles and data element mappings between FHIR and OMOP CDM (mainly in the model level) [26]. However, consensus building is a critical yet challenging factor in harmonizing and standardizing the mappings between different data models. Our consensus-based approach using the FHIR W5 category system is a preliminary effort in helping achieve the community-based agreement in a consistent and measurable manner.

Conclusions

In this study, we designed and assessed a consensus-based approach for harmonizing the OMOP CDM with HL7 FHIR. We leveraged a FHIR W5 (Who, What, When, Where, and Why) Classification System for designing the harmonization approaches and assessed their utility in achieving the consensus among curators using a standard inter-rater agreement measure. We demonstrated that the FHIR W5 classification system is a useful and promising tool for designing the harmonization approach between a data model and FHIR, and for facilitating the consensus achievement among curators. Future work includes: 1) building and refining the FHIR W5 Ontology using a community-based approach; 2) mapping the FHIR W5 ontology with other real-world data models (e.g., PCORnet CDM, i2b2); and 3) enhancing the mapping applications for effectively facilitating the alignment between various data models and FHIR.

Text Data Mining of Aged Care Accreditation Reports to Identify Risk Factors in Medication Management in Australian Residential Aged Care Homes

Tao Jianga, Siyu Qiana, David Haileya, Jun Ma, Bing Yua

Abstract

This study aimed to identify risk factors in medication management in Australian residential aged care (RAC) homes. Only 18 out of 3,607 RAC homes failed aged care accreditation standard in medication management between 7th March 2011 and 25th March 2015. Text data mining methods were used to analyse the reasons for failure. This led to the identification of 21 risk indicators for an RAC home to fail in medication management. These indicators were further grouped into ten themes. They are overall medication management, medication assessment, ordering, dispensing, storage, stock and disposal, administration, incident report, monitoring, staff and resident satisfaction. The top three risk factors are: “ineffective monitoring process” (18 homes), “noncompliance with professional standards and guidelines” (15 homes), and “resident dissatisfaction with overall medication management” (10 homes).

Keywords:
Risk Factors; Medication Errors; Nursing Homes

Introduction

With population aging, the demand for aged care services around the world is increasing. Associated with the aging process is an increased level of frailty and chronic diseases, which pose major challenges to RAC services [1]. Residential aged care homes in Australia provide accommodation, nursing care and personal care services for the frail older people [2]. Previous research suggests that people living in RAC homes have a higher exposure to various risk factors than their counterparts in the community [1]. Long-term and complex chronic conditions associated with the aging process are the main challenges for nursing staff to provide appropriate care to these people [2]. The high demands for appropriate care and regulatory compliance have led to high cost and burden for aged care services [3]. Formal aged care services in Australia are predominantly financed by taxpayers with some contributions from service users [4]. In order to protect residents’ safety and enhance the quality of the services, the Australian government has imposed stringent accreditation and safety standards through its aged care accreditation program administered by Australian government Aged Care Quality Agency (ACQA).

The aged care accreditation program in Australia focuses on continuous quality improvement strategies [5]. It includes an accreditation process and monitoring of ongoing performance against standards [5]. It is an effective approach to risk management and quality improvement of government-subsidized RAC homes [4]. In Australia, RAC homes are required to meet the accreditation standards at all times to ensure a high standard of care and services [6]. If a home fails in the accreditation, a timetable for improvement with a deadline will be developed by the ACQA [7]. Meanwhile, the agency monitors the home’s progress in making improvements. If the home does not meet all the requirements before the deadline, the agency may conduct a review audit which may result in the home’s accreditation certification being revoked and the home will lose legibility for receiving government subsidy.

The aged care accreditation system is established to manage potential risks in RAC homes. The accreditation process starts with self-assessment, followed by a desk audit, a site audit, the decision whether or not to accredit the home and the publication of the accreditation report [4].

Self-assessment, desk audit and site audit can help the RAC homes to identify the risk areas and risk factors [7]. The accreditation teams’ findings, the decision of the accreditation agency about whether an RAC home has met the 44 expected outcomes is the official verdict about the home’s risk management system. Therefore, a risk management approach is essential for RAC homes to pass the accreditation [7].

The whole process of risk management includes identifying risks, assessing the risks, developing risk management plans, implementing risk management actions and re-evaluating risks which have occurred in the process of delivering aged care services [7]. A vulnerable area where risks for resident safety might occur in RAC homes is medication management.

Residential aged care homes must support and safely manage each resident’s medication need [8]. It is reported that residents take an average of seven to nine medications [9-12]. As medication management is a complex process involving prescription, ordering, delivery, administration, monitoring, evaluation and documentation [13], errors such as wrong drug that are detrimental to medication safety may occur in any stage [14]. The error rate is between 28% and 40% [15, 16]. The occurrence of these errors may be increased by nurses’ high physical and mental load [17] and large amount of medication to be administered under time pressures [18]. Therefore, this research aimed to identify the risk factors related to medication management in RAC homes.

Methods

We followed a three-step process to extract the data from the aged care accreditation reports in Australia: (1) report collection, (2) section/paragraph extraction, and (3) keywords/terminology identification (see Figure 1).
Step 1. Report Collection

Data were sourced from the website of the Australian ACQA [19]. 3,607 copies of aged care accreditation reports published between 7th March 2011 and 25th March 2015 were downloaded, all in PDF format and each was about 24 pages in length.

The reports were converted from PDF to txt files. Errors generated during the conversion, such as misspellings, broken lines and unnecessary symbols were fixed. The first author manually compared the converted text files with the original PDF documents, finding that the incorrect character encoding was concentrated on list characters like ‘•’ in PDF format. These characters were converted to ‘?’ or ‘????’ in the txt format. Otherwise, the errors did not influence reading the content.

Step 2. Section/Paragraph Extraction

Text data in the collected reports were classified and labelled with the representative key words. For example, the text in comments and recommendations about medication management was labelled with the keyword “medication management”. Text about whether the home met or did not meet the accreditation outcome of medication management was labelled with “met” or “not met”. Following this labelling rule, information labelled included state name, assessment date, the name of an RAC home, its location, and comments on each of the 44 expected outcomes.

Information about report name, name of an RAC home, location, and comments and recommendations on the outcomes was extracted and loaded into a designed PostgreSQL database for storage and further analysis. In total, 3,607 records were stored. Each record contained the text data extracted from the section about medication management in the original accreditation reports.

Step 3. Keywords/Terminology Identification

Records showing that a home failed in medication management were selected for qualitative analysis. We used a manual process to classify and summarize all the risk factors from the section of the accreditation report for medication management. This process was conducted until no further risk factors were identified.

Then each sentence in the section of medication management was carefully read to understand the reason for failure, which was mapped to and labelled as a risk factor for medication management. This label was stored in the PostgreSQL database. Constant comparison was made with the labels among the records to classify or amalgamate them. This led to the generation of a classification table (see Table 1). The number of times that a risk factor was mentioned in the reports was also counted.

Results

Only 18 out of 3,607 RAC homes (0.5%) did not meet medication management outcome. 21 risk factors, for the RAC homes to fail in medication management, were identified. These factors were grouped into 10 categories: overall medication management, medication assessment, ordering, dispensing, stocking, administration, monitoring, incident reporting, staff satisfaction and resident satisfaction (see Table 1).

There were three risk factors in the overall medication management. 15 (83%) of the failed RAC homes did not comply with professional standards and guidelines. 2 (11%) RAC homes did not have consistent policies and procedures to guide staff, or did not adequately review these policies and procedures. In one RAC home, the medical officers and pharmacist did not regularly evaluate and review residents’ medication needs and preferences.

Four RAC homes did not assess residents who self-administered medications or received PRN medication. In one RAC home, the risk factor for the ordering process was not actioned upon residents’ medication orders in accordance with the medical officer’s directives. Another RAC home did not have a pre-packed medication system from a pharmacist in medication dispensing.
There were two risk factors in medication stocking. Two RAC homes did not have adequate stock or medications ran out. Five RAC homes did not store and dispose medications safely and securely.

There were four risk factors in the medication administration process: (1) medication charts did not contain complete and sufficient information in three RAC homes; (2) in eight RAC homes, medications were not administered, consistently safely and correctly, e.g. at appropriate intervals, not following prescribed orders, or inconsistent administration process; (3) in one RAC home, controlled medications prescribed for individual residents were used for other residents; and (4) in two RAC homes, medications being administered were not ordered by a medical officer.

The two risk factors for monitoring included (1) monitoring processes were not in place or were not effective; which happened in all failed RAC homes; and (2) four RAC homes did not monitor staff practice.

There were two risk factors for incident reporting: (1) medication incidents were not identified, analysed and acted upon (2 RAC homes); (2) medication incidents were not consistently followed up with the relevant parties (2 RAC homes).

<tr>
<td></td>
</tr>
</tbody>
</table>

There were three factors for staff satisfaction. These included (1) not conducting competency assessment (3 RAC homes); (2) insufficient staffing (1 RAC home); and (3) not providing education to staff in relation to medications (1 RAC home).

There were two risk factors for resident dissatisfaction. Residents were either not satisfied with medication management (10 RAC homes) or not satisfied with the way medications were given (2 RAC homes).

The top risk factor was “ineffective monitoring process”, which occurred in all 18 failed RAC homes. The second frequently stated risk factor was “noncompliance with professional standards and guidelines”, occurring in 15 failed homes (83%). Resident’s dissatisfaction about the overall medication management was the number three risk factor, indicated in 10 failed RAC homes (56%). Risk factors about staff practice were also quite often mentioned in the reports. These included inconsistency in staff practice to administer medication (8 homes, 44%) and unmonitored staff practice (4 homes, 22%).

Discussion

This study identified 21 risk factors for the RAC homes to fail in medication management in accreditation. It contributes in the knowledge area of aged care risk management.

A medication management process includes prescription, ordering, dispensing, administration, recording and review, storage and disposal [20]. For resident safety, the whole medication management process requires monitoring. We found that “ineffective monitoring process” is the biggest risk factor for the RAC homes to fail in medication management. Our finding is in line with that of another study which found that 70% of adverse drug events in RAC homes were caused by inadequate monitoring of the medication management process [21].

The second major risk factor in medication management is “noncompliance” with professional standards and guidelines. Another notable finding is that staff practice at each stage of medication management is important for medication safety. For example, checking the package of medication will ensure the expired medication would not be administered to a resident. Therefore, developing an effective monitoring system is of critical importance for safe medication management in the RAC homes.

The limitation of this study was the nature of any secondary study, with all the findings drawn from analysis of the accreditation reports. As only 18 out of 3,607 ACAR reports reported failure in medication management for a RAC home, evidence collected from this information source might be limited. In addition, these publicly available reports only summarised high level information. There was inadequate details about what exactly led to failure in medication management. Therefore, we cannot infer how risks happened and what can be done to prevent and control these risks.

The strength of the study is, for the first time, providing a nationwide overview of the reasons for the Australian RAC homes to fail the accreditation outcome in medication management. It gives some insight into aspects of safety-related issues in RAC homes, which may be helpful for future studies.
Conclusion

Using text data mining method, this study identified 21 risk factors for the RAC homes in Australia to fail in medication management accreditation standards. These risk factors fell into 10 categories: overall medication management, medication assessment, ordering, dispensing, stock, administration, monitoring, incident report, staff satisfaction and resident satisfaction. It provides accurate information about which aspects of medication management that the RAC homes in Australia failed in the four year period from 2011 to 2015. This information is useful for RAC home managers and the aged care quality improvement agency to use to improve medication management in this care setting. Future research can be focused on how to best implement a monitoring mechanism to improve medication safety and resident satisfaction with the medication management process.

An Ontology-Based Approach to Estimate the Frequency of Rare Diseases in Narrative-Text Radiology Reports

Charles E. Kahn, Jr.

Department of Radiology and Institute for Biomedical Informatics,
University of Pennsylvania, Philadelphia, Pennsylvania, USA

Abstract

This study sought to use ontology-based knowledge to identify patients with rare diseases and to estimate the frequency of those diseases in a large database of radiology reports. Natural language processing methods were applied to 12,377,743 narrative-text radiology reports of 7,803,811 patients at an academic health system. Using knowledge from the Orphanet Rare Disease Ontology and Radiology Gamuts Ontology, 1,154 of 6,794 rare diseases (17.0%) were observed in a total of 237,840 patients (3.05%). Ninety of 2,129 diseases (4%) with known prevalence less than 1 per 1,000,000 were observed in the database, whereas 100 of 173 diseases (58%) with prevalence greater than 1 per 10,000 were observed; the difference was statistically significant (p<.00001). Automated ontology-based search of radiology reports can estimate the frequency of rare diseases, and those diseases with higher known prevalence were significantly more likely to appear in radiology reports.

Keywords:
Information Storage and Retrieval; Knowledge Bases; Rare Diseases

Introduction

A rare disease, sometimes called an "orphan disease," is defined in the United States as a condition that affects fewer than 200,000 Americans (prevalence < 0.06%) and in Europe as one that affects fewer than 1 in 2,000 individuals (prevalence < 0.05%) [1; 8]. Approximately 6,800 rare diseases have been identified [17]. Although each disorder is itself rare – some with prevalence of less than 1 per million – in total, they affect about 5% of the population, which is about one-half the prevalence of diabetes mellitus. People who suffer from rare disease pose substantial clinical and economic burdens [9]. To address these challenges, several national rare-disease registries have been established [23; 24]. The multilingual Orphanet database (http://www.orpha.net) provides knowledge about rare diseases for patients, family members, clinicians, and researchers [2; 19]. The database has been derived from the biomedical literature and validated by international experts. Orphanet's database includes the diseases' names, estimated prevalence, mode of inheritance, age of onset, and age of death. The Orphanet Rare Disease Ontology (ORDO) allows computational analysis by providing a standardized vocabulary for rare diseases that expresses relationships between diseases, genes, and other relevant features. ORDO integrates a classification scheme, gene-disease relationships, epidemiological data, and connections with other terminologies. The Radiology Gamuts Ontology (RGO; http://www.gamuts.net), an ontology that links diseases and conditions to their imaging findings, has been integrated with ORDO [4; 12].

The purpose of this study was twofold: (1) to evaluate the large-scale use of natural language processing (NLP) techniques and ontology-based knowledge to identify rare diseases in a large database of radiology reports and (2) to compare the estimated frequencies of the diseases with their known prevalence in the population.

Methods

Radiology Reports Database

This research project was approved by the organization's Institutional Review Board, and was compliant with the U.S. Health Insurance Portability and Accountability Act of 1996 (HIPAA). A database of reports of 12,377,743 diagnostic and interventional radiology procedures on 7,803,811 distinct patients served as text corpus for the investigation. The reports were generated from September 1988 through October 2015 by more than 350 radiologists in training and attending radiologists at three urban teaching hospitals of a single, U.S. university-based health system. The database included the full text of the radiology reports plus identifying information such as each patient's medical record number, age, and sex.

Ontologies

ORDO (version 1.0.20, modified 14 December 2012) contained 6,794 disease entries. For each disease, a query string was generated. Forty-three Orphanet disease names that contained non-English text characters were converted in automated fashion using UTF-8–to–ASCII mappings. For example, "Behçet disease" was converted to "Behcet disease" and "Waldenström macroglobulinemia" was converted to "Waldenstrom macroglobulinemia." To augment the search, synonyms were obtained using a web-service interface to the Radiology Gamuts Ontology (RGO), a knowledge resource of diseases and their imaging manifestations that has been mapped to ORDO [12]. Because disease names in ORDO and RGO are normalized, possessive forms of disease names were generated as needed. For example, the search for ORDO entity "Waldenström macroglobulinemia" (Orpha ID 33226) included synonyms "Waldenstrom macroglobulinemia", "Waldenström's macroglobulinemia", "lymphoplasmacytic lymphoma", "Waldenstrom disease", and "Waldenstrom's disease" (https://api.gamuts.net/names/742). The query string specified a search for the appearance of one or all of those terms.
The report database was queried using software located on a server within the health system's secure internal network. The query software automatically presented web-service requests to the application programming interface (API) of a radiology report text search engine (Montage version 3.0.1, Montage Healthcare Solutions, Inc., Philadelphia, PA). The search engine incorporated a proprietary negative-expression (negex) filter to maximize the likelihood of retrieving true-positive cases. The web service used Representational State Transfer (REST) syntax, and returned data encoded in the JavaScript Object Notation (JSON) syntax.

Case Retrieval

Reports were aggregated by patient, and the total number of patients for each disease was recorded. The number of total disease occurrences was computed as the sum of the number of patients with each disease. This sum is the upper bound on the total number of patients, as an individual patient may have had more than one disease. The probability of having at least one disease – that is, the overall prevalence of having a rare disease – was estimated as the complement of the probability of having none of the diseases. Thus, given the frequency of each disease, \( p_i \), one can estimate the probability of having any disease as \( p = 1 - \prod_i (1 - p_i) \).

A "disease occurrence" was defined as the presence of a positive mention of a disease in one or more radiology reports of a specific patient. Thus, the number of occurrences for a specific disease represented the number of patients with that disease. "Disease frequency" was defined as the number of patients with each disease. This sum is the upper bound on the number of patients for each disease.

We estimated the case-retrieval system's precision and recall using a sampling technique described previously [10; 13; 16]. The 6,794 diseases and 12,377,743 reports yielded more than 84 billion pairwise combinations, which precluded exhaustive review. We used both "microaveraging" (which considers all disease-report pairs as a single group) and "macroaveraging" (which computes the metrics by disease) of the precision and recall estimates; macroaveraging is preferred because it weights queries equally.

To establish a reference standard, the author reviewed pairs of diseases and reports to indicate whether a positive mention of the disease was present or absent in the report. Negated expressions (e.g., "No evidence of ...") and conjunctural expressions ("Rule out ...") were assigned as "absent." To eliminate potential bias, the disease-report pairs were presented in random order, and the reviewer was not aware of whether the disease was meant to be present or absent in the report.

Precision is analogous to positive predictive value; it indicates how many retrieved reports are truly positive. We estimated precision in a sample of 10 positive reports for each of the 20 most common diseases. Reports were reviewed manually to determine if a positive mention of the disease was present (true positive [TP]) or absent (false positive [FP]). Precision was estimated as \( TP / (TP + FP) \) for each disease.

Recall is analogous to sensitivity; it measures the fraction of relevant reports that labeled as positive. For the 20 most common diseases, the number of true positive (TP) reports was estimated as the number found with the disease multiplied by the overall precision value. Then, for each disease, we sampled 10 reports in which positive mention of the disease was absent. Those reports should be negative; the "Sample TN" is the number of true negative (TN) reports among the 10 sampled for each disease. Based on the Sample TN value, we extrapolated to the entire set of negative reports. Recall was computed as \( TP / (TP + TN) \). The example provided in [13] helps explain the calculation. For values of precision, \( P \), and recall, \( R \), we computed the F1 score, the harmonic mean of precision and recall, as \( 2 \cdot P \cdot R / (P + R) \).

Results

Females constituted 4,694,083 patients (60.2%) and were the subject of 7,234,080 reports (58.4%). Patients under 20 years of age comprised 489,974 reports (3.9%) (Figure 1). Of the 6,794 Orphanet rare diseases, 1,154 (17.0%) were observed in at least one patient in the report database. There were a total of 237,840 disease occurrences in the report database, which corresponded to 3.05% of all patients. The aggregate prevalence of rare disease was estimated at 3.00%, or approximately 234,324 patients.

The 20 rare diseases that appeared most frequently in the radiology reports accounted for 103,402 (43.4%) of the 237,840 disease occurrences (Table 1). Among the least frequently appearing diseases, 234 appeared in only 1 patient, and 368 diseases appeared in 2 to 10 patients. A sample of 20 diseases that did not appear in the collection of reports is shown in Table 2.

Figure 1— Age distribution histogram.

Table 1— The 20 most frequent rare diseases in the radiology report database.
Rare diseases present important medical and social challenges [22]. The current study demonstrates the ability to apply ontology-based knowledge to estimate the frequency of almost 6,800 rare diseases in a large corpus of narrative-text radiology reports. The frequency of diseases in the report database showed overall correspondence with known prevalence data, in that diseases with unknown or smaller prevalence values (e.g., < 1 per million) were less likely to appear in the report database. Similarly, rare diseases in Orphanet that had been mapped to diseases in RGO were significantly more likely to appear in the set of reports, probably because the diseases were more common and because they were more likely to involve radiological findings. Frequencies for individual disorders did not necessarily correspond closely to known prevalence values, but the observed values could be useful to rank diseases for diagnosis based on imaging findings. As such, one might consider them to represent "radiological prevalence" values, in that they indicate the frequency with which the conditions appear in radiology reports.

The estimated disease frequencies may have been subject to several biases. First, the study used radiology reports from a single academic medical institution, which may have reflected the nature of a university-based specialty clinical practice and/or the conditions for which the institution had particular expertise. Second, the report database had a limited number of children; many rare diseases have onset and mortality in childhood, and such patients were underrepresented in the patient population. An affiliated children's hospital, whose reports were not included, likely attracted pediatric rare-disease patients preferentially. Third, many rare diseases do not entail imaging findings, and may not have been mentioned in the reports. Fourth, radiology reports do not necessarily contain comprehensive information about the patient: the referring provider may not have mentioned the disease in the clinical information, and the radiologist may not have reported it.

Adjustment of several of the search queries was needed in order to accommodate idiosyncratic aspects of the Montage
search engine and terms in the ontologies. For example, initial queries for "small cell lung cancer" identified reports containing the phrase "non-small cell lung cancer"; similarly, searches for "Hodgkin's lymphoma" resulted in reports containing "non-Hodgkin's lymphoma." After the initial queries were adjusted to explicitly exclude the "non-" prefix, the revised queries resulted in high precision and recall. The Gamuts ontology included the term "TOF" as a synonym for "tetralogy of Fallot"; that abbreviation, however, yielded false-positive disease occurrences where it was detected in a number of reports where "3D TOF" had been used to indicate "three-dimensional time-of-flight." Given its overwhelming use in MRI reports, "TOF" was excluded as a search term.

Systems for natural language processing (NLP) have shown high performance in identifying and classifying radiology reports, and offer a promising approach to extract measurable information from conventional narrative ("free-text") reports [5; 18]. An NLP system successfully determined the presence of more than 20 clinical indications and imaging findings from a database of 889,921 chest radiographic reports [11]. Negative-expression ("negex") filtering techniques have identified positive and negative instances of imaging findings with accuracy in excess of 97% [6; 7]. PRESTO, the predecessor to the commercial system used in the current study, showed 91% precision and 97% recall in detecting adrenal findings in 32,974 abdominal CT reports [25].

To understand the challenges inherent in automated approaches to report classification, it is instructive to consider two diseases with known prevalence greater than 1 in 1,000. The first, ventricular septal defect (VSD; Orpha number 1480), was seen in 844 patients; this observed frequency of 108 patients per million was an order of magnitude less than the prevalence specified in Orphanet. The second disease, "Non-classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency" (Orpha number 95698), was not observed in any report. One can speculate that the disease's longer name made it less likely to be identified in radiology reports. The term "congenital adrenal hyperplasia" was found in 145 patients, and "21-hydroxylase deficiency" was found in only two patients.

Ongoing work centers on the use of ontology-based knowledge and imaging phenotypes, that is, findings identified in imaging studies. ORDO has been linked to the Human Phenotype Ontology (HPO), a resource that categorizes the manifestations of diseases, predominantly congenital or genetic disorders [15; 21]. One research opportunity is to identify constellations of phenotypic findings that may point to patients with otherwise undiagnosed rare diseases. Integration of HPO and the Gamuts ontology is in development to better identify phenotypic manifestations of disease. The integration of these ontologies enables the investigation to identify new patterns of association and/or causality among imaging findings and diseases. Ongoing work includes the analysis of the frequency of a more comprehensive set of diseases and imaging findings to explore their prior and conditional probabilities. This growing effort in "deep phenotyping" integrates disease information and detailed phenotype information, such as imaging biomarkers, to support precision medicine [20].

Conclusion

Text-search and NLP techniques can be applied to estimate the frequency of rare diseases in a large database of radiology reports. Ontologies such as ORDO and RGO help organize medical knowledge so that automated systems can make inferences from that knowledge [3]. The increasing availability of large datasets in radiology and the tools to analyze them can lead to better data-driven understanding of radiology practice [14].

Abstract

Open access provides an alternative opportunity of publishing research articles besides the traditional subscription-based publication model. Facilitating higher visibility, accessibility, and dissemination, among others, open access addresses modern needs of our information and communication society. Though these factors are vital, there also do exist initial problems to become prevalent. Especially, costs like article publication charges seem to have an impact on the author’s decision not to publish open access. In order to gain a deeper insight on incentives for open access publishing (as well as on barriers for not publishing open access), we developed a specific survey within the scope of our Trans-O-MIM project. Conducted at HEC2016, we primarily involved participants of the Annual General Assembly of the International Medical Informatics Association (IMIA). As main incentives and motivation for open access publishing had been identified: article indexing, impact factor, accessibility/availability, dissemination, and visibility.

Keywords:

Open Access Publishing, Motivation, Surveys and Questionnaires

Introduction

In recent years, a change in the publication landscape can be observed. Besides the traditional publication model, an alternative model is about to establish itself [1-3]. Open access publishing aims to fulfill needs of modern information and communication society. The Internet allows publishing journal articles or even whole journals online and the open access model takes on this development by offering all content freely available to readers. Also, many research funding organizations and governments have changed their policies and demand to publish funded research outcomes open access [4, 5]. To finance this new publication model, authors are often charged so-called article publication charges (APC). Nearly all journals offer their authors an open access option [6]. But the mere fact that there is a new possibility of publishing research articles does not necessarily mean that authors make use of it. Currently, only about 13% of all research papers are published open access [7]. Besides all positive attributes of open access publishing - for example higher visibility and citation rates - there are also many concerns. Significant barriers to open access publishing are an often-higher effort for the authors and the above-mentioned publication charges [8, 9].

When authors make a decision how to publish their work - traditional or open access - they are usually influenced by certain factors. Within the framework of the project “Trans-O-MIM” (full title “Strategies, models and evaluation metrics for the goal-oriented, stepwise, sustainable and fair transformation of established subscription-based scientific journals into open-access-based journals with Methods of Information in Medicine as example”) [10, 11], funded by the German Research Foundation (DFG), we intended to identify incentives tempting authors into publishing open access. These results are conceived to help transform the journal Methods of Information in Medicine successfully into an open access journal.

The goal is to explore factors that influence authors positively in matters of open access publishing. To compose a good, and later on accepted, open access business model, it is crucial to understand the needs and wishes of researchers and authors, respectively. By means of a survey among medical informatics scientists we explored decisive incentives.

Most importantly in the decision-making process for a journal is Impact Factor, a fast turnaround time and most of all the publication charges. This leads to the question of to which limit these charges are considered as appropriate and tolerable. In this context, it is moreover presumed that most of the authors do not have that much experience in open access publishing. For the utilization of the survey results this hypothesis shall be investigated additionally.

At the beginning of this investigation several general research questions were collected. These were broadly diversified in terms of incentives for open access publishing. General thoughts in this context were (e.g.):

- how experienced authors are in open access publishing
- if incentives are actually required and if so who needs to be incentivized
- whether there are other factors that may influence authors in their decision for publication

This constituted the initial point for more detailed questions derived from a broader context and the methodology of surveys and survey design.

In the subsequent sections, we describe the questionnaire intended to get answers to these questions, its conduct and results. Furthermore, we will discuss these findings pertaining to an adequate open access business model and close with a conclusion.
Methods

We designed a questionnaire in order to ask experts from the fields of medical informatics, biometry, and epidemiology about their knowledge regarding existing open access journals and about their incentives to publish research articles open access. The paper-based version of our questionnaire was created in cooperation with and typeset by Schattauer Publishers (Figure 1); each optimized in terms of presentiveness and usability.

Our questionnaire contains a short introduction about the "Trans-O-MIM" DFG-project and a guidance how to fill in the questionnaire. The questionnaire itself consists of eight questions, namely:

1. Which factors influence your decision to choose a journal? (importance on a scale from 1 = not important to 10 = very important; 0 = not applicable)
   a. Articles are indexed e.g. in PubMed Central
   b. Impact Factor of a journal
   c. Publication charges
   d. Prestige of a journal
   e. Visibility and dissemination
   f. Topic fits optimally to the journal
   g. Ability to attach supplementary materials/data
   h. Members of the editorial board
   i. A fast turnaround time
   j. Anything else, please specify

2. Have you ever published a journal manuscript in open access?

3. Do you know any open access journals in field of Medical Informatics, Biometry and / or Epidemiology?

4. If you answered the previous question with "yes", have you already published in one of them?

5. What is your motivation to publish in an open access journal?

6. Which amount of article processing charges (APC) is appropriate and which is tolerable in your opinion?
   a. Up to 1,000 €
   b. 1,001 € to 1,500 €
   c. 1,501 € to 2,000 €
   d. 2,001 € to 2,500 €
   e. More than 2,501 €

7. What are the three main reasons for you NOT to publish your work in an open access journal?

8. Do you have any other comments, e.g. on the incentives to publish in an open access journal?

Before our questionnaire was printed, a review with three experts in the fields of publishing and medical informatics was done. The experts mentioned were the current and the senior Editor-in-Chief of the journal "Methods of Information in Medicine" and a member of the DFG-committee for research libraries and information systems. All questions were discussed and improved based on the input of these experts. Afterwards, an online version of our survey was developed using a specific tool called "eSurvey Creator" [https://www.esurveycreator.com] (as shown in Figure 2).
IMIA’s Annual General Assembly about our survey and invited all of them to participate. In addition, we also offered all conference participants to take part in our survey.

In order to merge survey results, we digitalised the completed paper-based questionnaires before evaluation. Responses presented in results section are given in original. Only free text answers were summarized and numerated for ease of exposition.

Results

35 [70%] out of 50 participants of IMIA’s 2016 General Assembly took part in our survey. Furthermore, 27 additional participants of HEC2016 filled-in the survey. Results shown in this section are based upon questionnaires gathered from IMIA’s 2016 General Assembly.

Question 1

Starting with the first question dealing with influence factors on journal decisions, the following results were achieved.

Table 1 – “Which factors influence your decision to choose a journal” (question 1) – results in absolute values (*)

(*) Additional influence factors specified by participants were: “Appear on the government list of journals that release budget for the university”, “brings out future updates on the topics published”, “good and transparent review process (with feedback)”, “good experience, excellent review process, well written constructive reviews”, “government policy”, “open review process”, “Quality of reviews” and “submission system”.

Questions 2

Going on, 26 [74.3%] from our 35 participants have already published a journal manuscript in open access, whereas 8 [22.9%] did not while 1 [2.9%] stated “n.a.”.

Questions 3

26 participants answered the question if they know any open access journals in the field of medical informatics, biometry and / or epidemiology. 17 [65.4%] out of these 26 participants knew at least one open access journal whereas 4 [15.4%] did not, while 5 [19.2%] stated “n.a.”. Journals mentioned more than once were “Journal of Medical Internet Research (JMIR)”, “BioMed Central (BMC)” and “Public Library of Science (PLOS)”.

Questions 4

Those 17 participants who answered ‘yes’ to the previous question were asked if they have already published in one of the journals mentioned. 8 [50%] did whereas 7 [43.8%] did not, while 1 [6.3%] stated “n.a.”. Journals mentioned more than once here were BMC and JMIR. One participant did not answer this question.

Question 5

Regarding the motivation to publish in an open access journal - answered by 33 participants - the following answers were given more than once:

1. accessibility / availability – 15 times [45.46%]
2. dissemination – 9 times [27.27%]
3. visibility – 8 times [24.24%]
4. citations / fast process / (funding) policy – 4 times each [12.12% each]
5. fast review – 2 times [6.06%]

Question 6

Talking about article publication charges (APCs) all 35 participants answered the question with the following results.

Table 2 – “Which amount of article processing charges (APC) is appropriate and which is tolerable in your opinion” (question 6) – results in absolute values

<table>
<thead>
<tr>
<th></th>
<th>appropriate</th>
<th>tolerable</th>
<th>n.a.</th>
</tr>
</thead>

<td>11 [31%]</td>
</tr>
<tr>
<td>1.001€ to 1,500€</td>
<td>6 [17%]</td>
<td>9 [26%]</td>
<td>20 [57%]</td>
</tr>
<tr>
<td>1.501€ to 2,000€</td>
<td>2 [6%]</td>
<td>10 [29%]</td>
<td>23 [66%]</td>
</tr>
<tr>
<td>2.001€ to 2,500€</td>
<td>1 [3%]</td>
<td>1 [3%]</td>
<td>33 [94%]</td>
</tr>
<tr>
<td>more than 2,500€</td>
<td>1 [3%]</td>
<td>1 [3%]</td>
<td>33 [94%]</td>
</tr>
</tbody>
</table>

When no answer was given on paper-based version here, we classified the answer as “n.a.”.

Question 7

When being asked about the main reasons for them not to publish their work in an open access journal - answered by 31 participants - the following answers were given more than twice:

1. costs – 21 times [68%]
2. reputation – 6 times [19%]
3. no funding / review (process) – 4 times each [13% each]
4. impact factor / quality – 3 times each [10% each]

Question 8

With respect to the last question, two out of six comments gave additional information addressing open access and were not already covered by another question of the survey:

- “There should be a means to waive for discount. The page charges for the author depending on the quality of content, value addition to the confirmity and economic status of the authors(s).”
- “Having so many invitations to become a reviewer / editorial board from open access journals. I doubt the quality or reviewers. I hope MIM make full use of current selected reviewers.”

Discussion

Even though 60 percent of our participants already published in open access journals, many of them seem less ambitious in addressing the open access paradigm in depth. When talking about open access, costs will always be one of the first remarks on the table.

Regarding explanatory factors for journal decision in general, article indexing has been declared as most important; and more important than the impact factor and/or prestige of a journal as second priority. Visibility and dissemination as...
third priority had also been declared as being more important than publication charges.

Among the main five motivations for publishing open access, accessibility and availability, dissemination, visibility, citations and a fast processing time had been mentioned. On the downside, participants had been concerned about costs (above all), reputation, no funding, the review process, impact factor and quality.

In terms of costs, article publication charges (APCs) up to 1,000€ had been thought of as being appropriate whereas article publication charges (APCs) up to 2,000€ had been thought of as being tolerable in general tendency.

Limitations

A limitation to this survey is the small number of participants. For the evaluation of our questions we only had 35 answered questionnaires. However, these participants were experts in their field (medical informatics, biometry and epidemiology) so their opinions may have a particularly high explanatory power. Moreover, this survey was kept rather general and preset leading solely to first insights.

Future perspectives

Based on the presented survey and its results we intend to conduct another significantly larger study. Therein researchers in the field of medical informatics will be asked about incentives for open access publishing in detail. The study may also be accompanied by semi-structured interviews of experts to gain new ideas in terms of incentivizing open access publishing for authors.

Conclusion

In conclusion, there have not been any novel findings at all based on the survey. There is indication that open access does not seem to be a big talking point among scientific researchers according to our findings. If so, what is the basis for this circumstance? Although all influence factors seem to be (and have already been) well-known, it turned out to be more difficult than expected to successfully transform well-established subscription-based scientific journals into open access journals. Although number of participants was small we wanted to share our findings as they provide indicatory first impressions. Based on these insights, a follow-up study as mentioned above is going to take place in 2017/2018.

Abstract
Over the past 8 years the openEHR Clinical Model program has been developing a Web 2.0 approach and tooling to support the development, review and governance of atomic clinical information models, known as archetypes. This paper describes the background and review process, and provides a practical example where cross standards organisation collaboration resulted in jointly agreed clinical content which was subsequently represented in different implementation formalisms that were effectively semantically aligned. The discussion and conclusions highlight some of the socio-technical benefits and challenges facing organisations who seek to govern automic clinical information models in a global and collaborative online community.

Keywords:
Informatics; Crowdsourcing; Common Data Elements

Introduction
Historically, most collaboration in the health technology domain has been through formal balloting of message or document specification standards within standards development organisations (SDOs) such as ISO TC215 or HL7 International. This approval process has had some significant success over many years in supporting interoperability of health data, however this approach is not transparent, responsive or agile enough for development, maintenance and governance of larger numbers of more atomic clinical information models.

The Clinical Models Program [1] at the openEHR Foundation [2] has developed an alternative, crowdsourced approach to the development, publication and governance of the openEHR clinical information models, known as archetypes. This methodology emphasises openness, transparency and accountability to the community.

The Clinical Knowledge Manager tool was developed directly as a result of the experience of openEHR Clinical Program leadership in working with distributed groups using technical tools such as widely used software versioning and revision control systems. It quickly became apparent that there was not only a need for versioning governance but also life cycle and naming governance plus a critical process to ensure appropriate review of the archetypes to ensure that each was fit for use in implementations.

This openEHR methodology is now in use by a number of national and jurisdictional eHealth programs around the world who are using archetypes published in this manner to underpin their local health IT infrastructure.

Background
The Clinical Model program at the openEHR Foundation is responsible for management of a set of clinical information models, known as archetypes, on behalf of the international openEHR community. The scope of responsibility includes:

- development of a set of coherent and consistent archetypes,
- community review and approval of the archetypes as fit for use, using a collaborative peer-review process;
- publication and life cycle management of each archetype; and
- ongoing maintenance and governance of each archetype.

Each archetype is a computable specification for a single clinical concept – intended to be a maximal data set for a universal use case. In practice, the aspirational intent of a maximal data set is usually adjusted to a practical, but inclusive, data set that can be re-used across multiple clinical scenarios.

The program utilizes an online tool to support the activities of the program – the openEHR Clinical Knowledge Manager (CKM) [3]. This tool has three main purposes – it is a public library of archetypes; an open collaboration portal; and underpins the community’s requirements for complex clinical knowledge governance.

The CKM tool allows open access to all clinical information models. Registration is required to actively participate within the CKM community – membership is free and open to any interested individual or group. A broad range of professions is represented including, but not limited to:

- Clinicians;
- Informaticians;
- Software engineers;
- Terminologists;
- Academics/students;
- Administrators; and
- Consumers.

As of December 18, 2016, the openEHR CKM has:

- 500 active archetypes in varying life cycle stages, comprising an estimated 6000 data points;
• 1628 registered users from 88 countries: and
• 24 languages represented.

Communities in Norway, Australia, United Kingdom, Slovenia, Canada and Brazil are actively collaborating and sharing archetypes to minimise ‘reinventing the wheel’.

**openEHR peer-review process**

A small number of Clinical Knowledge Administrators are appointed to collectively take responsibility for the operations of the CKM instance. They appoint editors who are charged to develop and enhance the clinical content of each archetype from its initial draft through to a published state. The CKM tool supports this iteration by enabling the editors to run a series of review rounds to gather and collate reviewer feedback and manage the associated version and audit controls.

An archetype peer-review round is manually initiated by an Editor. They invite a subset of registered CKM reviewers - selected to ensure an appropriate cross section of professions, health domains and geographical location are represented. In addition, anyone who has a special interest in participating and requests an invitation to that review will also be included. Reviewing is optional and reviewers can opt out of any review invitation.

Review rounds are typically sent out for a period of two weeks. This review period can be adjusted by editors on a per review basis.

Reviewers can comment on any or all components of the archetype, guided through the various components by a ‘wizard’ process. They can also respond to a some specific questions asked by the editor and targetting opinions on identified editorial issues. The only mandatory response is a final recommendation about readiness for publication:

• **Accept** – ready for publication;
• **Minor Revision** – trivial changes only (usually spelling/grammar), otherwise ready for publication without further community review;
• **Major Revision** – significant changes are needed, requiring further community review;
• **Reject** – not fit for publication or fundamentally flawed: and
• **Abstain** – no recommendation.

At the end of the review period the editors meet, usually via teleconference, to collectively respond to the feedback, update the archetype with agreed changes and decide on the next steps. If all recommendations are ‘Accept’ or ‘Minor Revision’ then consensus has been achieved and after the minor changes are applied, the archetype is ready to be published. If ‘Major Revision’ or ‘Rejected’ are recorded, then further review rounds are usually required until consensus is achieved.

All review comments plus the responses of the editors to each reviewer comment are captured as a record of provenance and viewable by all registered users, ensuring transparency of the desicion process and accountability of the editors to the user community.

**Approach**

The following narrative outlines openEHR approach using a recent example of a complex cross-SDO collaboration between the openEHR and HL7 communities for representation of Adverse Reaction Risk information models, also known as Allergy/Intolerance within the HL7 community. This narrative has been constructed retrospectively from audit trails and review round records captured within 3 CKM instances based the international openEHR community, Norway and Australia.

The very first iteration of the draft candidate for the Adverse Reaction archetype was authored in April 2006 by a single Australian clinical informatician, Dr Sam Heard. It was one of the first archetypes uploaded to the openEHR CKM [3] on 23 July 2008 [4]. In July 2009 this archetype commenced its’ first collaborative peer-review in the openEHR CKM.

In November 2010, Australia’s National eHealth Transition Authority (NEHTA, now known as the Australian Digital Health Agency [5]) forked the archetype and brought it into the Australian CKM [6,7] environment and ran a series of five archetype reviews during the period to June 2011. The resulting archetype content formed the basis for adverse reaction data points in CDA documents which are used to transmit health information from Australian primary care clinical systems into the PCEHR (now known as ‘My Health Record’).

The Australian archetype formed the basis for a further iteration by Dr Heather Leslie which included feedback from international reviewers plus a variety of other resources including academic papers [9,10] and documents published and available at the time by NHS England [11,12], Microsoft’s Clinical User Interface group [13,14], and the Royal Australian College of General Practitioners [15]. It was uploaded as a fork to the international CKM in January 2012 [16] and an international peer-review round was commenced.

In May and June 2014, further harmonisation by Dr Ian McNicoll merged feedback from the international review with content from HL7’s FHIR resource and RMIM publications available at the time. In June 2014, due to the major structural changes it was uploaded as a new archetype [17] – the ‘Adverse Reaction (FHIR/openEHR)’ archetype with the intent of conducting a series of joint FHIR and openEHR reviews and generating both a FHIR resource AND an openEHR archetype with matching, clinically verified content at the end of the process.

In July 2014 the first joint openEHR/FHIR review was initiated. Four editors were appointed to facilitate the reviewer feedback – two from openEHR and two from HL7 and the resulting archetype was uploaded into the international CKM in October 2014 and a second review round initiated.

Concurrently, the Norwegian Nasjonal IKT team forked the archetype into the Norwegian CKM [18] in November 2014. Resolution of the second openEHR/FHIR review round did not occur until June 2015, nearly 7 months later, due to delays caused by waiting for FHIR ballot results. This feedback was incorporated this feedback into the next archetype revision [19].

In June 2015 the third joint openEHR/FHIR review round commenced in the international CKM. Simultaneously, the archetype was updated in the Norwegian CKM, aligned the international archetype and translated to Norwegian [20]. Subsequently, in early August 2015, the first review round commenced in the Norwegian CKM. Feedback from this review was added to the international feedback so that parallel archetype development could evolve in English and Norwegian, each archetype revision now incorporating feedback from the international openEHR, Norwegian and HL7 communities.
The resulting archetype was uploaded to the international CKM in October 2015 [21] and the fourth openEHR/FHIR review round commenced. Soon after the second Norwegian review round commenced using the latest aligned and translated version of the archetype [22].

At the completion of the November 2015 review round and analysis of reviewer feedback, the editors agreed that a consensus about the archetype clinical content had been reached amongst the participating reviewers. In the openEHR archetype, all FHIR-specific components were removed and published as the ‘Adverse reaction risk’ archetype. The original archetype was rejected – this archetype persists in the international CKM as part of the provenance/audit trail for the published archetype but marked as not for current use.

During the review process, the FHIR team maintained an equivalent FHIR resource, adopting the changes agreed through the review process. This was the evolving artefact that was reviewed by the FHIR community. At the time of archetype publication, the content of the archetypes and the FHIR resource were aligned.

The Norwegian team updated their version of the archetype to align the content and the translation. They initiated a final review in Norwegian, commencing in late November 2015. At its conclusion the Norwegian archetype was also published within their local CKM and is now governed autonomously by the Nasjonal IKT team as per their national mandate. The agreed intent of the international and Norwegian teams is to continue to collaborate when change requests arise or new requirements are identified. These two openEHR archetypes remain semantically aligned as of December 18, 2016.

Results

It has been possible to collate review related data from each of the three CKM instances that have been used as part of the evolution of the Adverse Reaction Risk archetype through to publication.

A view of the review process is shown in Figure 1.

Discussion

This Adverse Reaction Risk archetype started its’ journey as the brainchild of a single clinical informatician. After a journey of many twists and turns the final published archetype is the result of voluntary contributions from over 126 individuals, see Table 1, each contributing according to their professional background and expertise during 13 review rounds carried out in 3 CKM instances.

Table 1— Contributors statistics for each archetype

There has been no further formal joint collaboration between the openEHR and FHIR communities since the November 2015 publication. At that point in time, the great majority of clinical content in both the resulting openEHR archetype and FHIR resource were aligned as a consequence of the joint review process.

Subsequently it appears that the FHIR resource has continued to evolve in isolation, effectively splitting from the jointly-agreed artefact, apparently due to further requirements being identified in HL7 implementations [23]. This divergence is unfortunate, but unsurprising. It highlights that in order to achieve cross-SDO standardisation of information models there will need to be a willingness to commit to an ongoing maintenance process as well.

Inclusion of the HL7 community was extremely evaluable in order to gather broader expert input and has no doubt improved the quality of the archetype. The final archetype was agreed in terms of the clinical content and then a pure openEHR archetype and a corresponding FHIR resource were developed, based on that common clinical content. This was a significant achievement, likely inevitable without a strong commitment from each party to maintain alignment.

From the openEHR point of view, the timing and frequency of the HL7/FHIR balloting process caused significant delays to the joint collaborative phase, resulting in an expected three to six months timeline for a complex information model blowing out to eighteen months. The frequent and short review cycles used by the CKM editors reflects a more agile and iterative approach targeting a single information model at a time.

The traditional SDO process is usually a closed activity in which value is placed on participation only by credentialled individuals, determined either by financial membership or nomination as an expert. By contrast, in the global Web 2.0 crowdsourced environment in which the openEHR communities of interest operate, the opposite conditions largely apply. The openEHR methodology places enormous weight on broad participation, accountability of those in roles of authority to every member of the community, and transparency at every level of governance:

1. **Participation is open and free** – participation is open to anyone who is willing to participate to the extent of their ability. It is not limited to individuals or organisations who have current paid memberships, who are nominated as ‘experts’, or who have been designated as ‘credentialled’ experts. This may be challenging to many but it supports input from the broadest professions, health domain expertise and geographical sources.

2. **Everyone can participate according to their expertise**. The user interface and review processes in the CKM tool has been developed specifically to ensure that non-technical experts, such as grassroots clinicians, can participate equally alongside the technology savvy. It removes the need for clinicians to acquire additional technical skills in order to participate. All feedback is encouraged, ranging from the smallest grammatical correction through to solutions for the most complex informatics or implementation conundrums.
3. **Transparency.** All of the activities and decision-making within CKM is transparent to registered users, including but not limited to:

- Archetype reviews, especially:
  - acknowledgement of all participants and their roles;
  - clear association between reviewer comments and resulting editorial decisions;
  - number of contributions; number of review rounds; and
  - composition of the reviewer community to ensure that an appropriate expert group has been involved.
- Threaded, unmoderated discussion threads;
- Change requests by registered users and editorial responses; and
- Archetype audit trail.

If a registered user is not happy with decisions there are a number of ways of raising this with editors or via public discussion boards.

4. **Rapid and agile archetype publication.** In the work that the openEHR Clinical Modelling Program have done to date, the typical archetype review process involves 4 review rounds to achieve broad agreement on the structure and data points. Sometimes further review rounds are required, usually focussed on refinement of archetype descriptions and metadata. With an average review round duration of two weeks, this means that an archetype requiring six review rounds could potentially be published in twelve weeks. Archetypes based on established and agreed clinical content such as evidence-based scales and scores can often be published in one or two review rounds – corresponding to between two and four weeks. Assuming modest editorial resources are available, when multiple archetypes are being reviewed simultaneously it is possible to publish archetypes in efficient and effective timeframes.

By contrast, the traditional SDO ballot process would not be sustainable in the openEHR environment where the intent is to develop, review and publish all clinical archetypes required for all clinical data recording. There is a practical need for archetype review rounds to be:

- Managed as a sequence of short, frequent review rounds that result in progressively refined iterations of the archetype;
- Initiated independently of other archetypes and for a variety of reasons, including initial publication, management of change requests and maintenance processes; and
- Run when required - sometimes in parallel with other archetype reviews and at other times on an ad hoc basis to resolve a specific issue.

5. **Shared archetypes amongst communities.** There are now a number of groups using the CKM tool as the basis of national or jurisdictional standardisation of data sets. The traditional SDO process does not usually reveal the primary authors or contributors to their published standards, although they will possibly be known to SDO members. However the openEHR approach prioritizes transparency at every level of governance and for editors to be accountable to the CKM community:

- Free and open membership;
- Detailed audit trails to ensure accurate provenance and recording of editorial changes;
- Visibility of reviewer contributions and editorial responses;
- Statistics about the review process, including:
Acknowledgement of all participants; number of contributions; number of review rounds; and background of all reviewers to ensure an appropriate reviewer community.

After publication of the adverse reaction archetype, collaboration between the openEHR CKM and Norwegian CKM teams has been active and ongoing. It has been successful largely because both groups are committed to working together and sharing the editorial work required to facilitate the reviewer feedback. openEHR and Norwegian editors meet regularly to collaborate on solutions to modelling challenges, coordinate archetype reviews and update archetypes with feedback from both organisations. Reviews continue to be run in parallel in English and Norwegian on a range of archetypes - core content and specialised; simple and complex; crossing a broad range of clinical scenarios and professions. Archetype publication is based on the collective opinions of the communities that support both organisations. Both groups are willing for this to be extended to include other SDOs or national eHealth programs on request.

Conclusion
Clinical information modelling governance has been a new and largely untested challenge until recently – most of our collective experience in governance of health data standards has been at the complete message or document data set level. The Clinical Knowledge Manager tool was developed directly in response to identification of the need for efficient and responsive iterative refinement of the archetypes in response to identified requirements, especially during implementations – finding the sweet spot in the tensions between governance and evolution to ensure that the information models were safe and fit for use.

Clinical knowledge governance is a complex, evolving and poorly understood domain. The key to success of the openEHR approach, as described, is the result of humans choosing to collaborate to make a difference in the healthcare domain, using technology as the means to solve a shared problem. It is a socio-technical solution – a combination of the openEHR technical specification for an electronic health record architecture, a pioneering online knowledge governance tool, clinician engagement and a web 2.0 approach to harnessing the collective efforts of a community of volunteers.

Further analysis needs to be carried out to explore the impact of this approach as the number of published archetypes increases so that trends, patterns and conclusions can be identified.

Disclosure
The Clinical Knowledge Manager tool was developed by Dr Heather Leslie and Ocean Health Systems.

A Semi-Automatic Framework to Identify Abnormal States in EHR Narratives

Xiaojun Ma, Takeshi Imai, Emiko Shinohara, Ryota Sakura, Kouji Kozaki, Kazuhiko Ohe

Abstract
Disease ontology, defined as a causal chain of abnormal states, is believed to be a valuable knowledge base in medical information systems. Automatic mapping between electronic health records (EHR) and disease ontology is indispensable for applying disease ontology in real clinical settings. Based on an analysis of ontologies of 148 chronic diseases, approximately 41% of abnormal states require information extraction from clinical narratives. This paper presents a semi-automatic framework to identify abnormal states in clinical narratives. This framework aims to effectively build mapping modules between EHR and disease ontology. We show that the proposed method is effective in data mapping for 18%-33% of the abnormal states in the ontologies of chronic diseases. Moreover, we analyze the abnormal states for which our method is invalid in extracting information from clinical narratives.

Keywords:
Ontology; Machine learning; Natural language processing

Introduction
In order to understand diseases, one must adequately capture abnormal states in diseases. With support from Japan’s Ministry of Health, Labour and Welfare, we have been involved in developing a disease ontology [1,2], wherein a disease is captured as a causal chain of abnormal states. So far, medical experts have described the causal chains of approximately 6,000 diseases across 13 medical departments. The disease ontology provides domain-specific knowledge, answering questions such as “what abnormal states cause a disease?” and “how might a disease progress, and what symptoms may appear?”. We believe that disease ontology is a valuable knowledge base in medical information systems such as deep phenotyping in support of precision medicine. For the practical use of disease ontology in clinical applications, automated mapping between electronic health records (EHR) and disease ontology is indispensable. An investigation has been conducted to specify clinical data sources where information can be extracted to identify abnormal states. The investigation is based on an analysis of 4,718 (643 distinct) abnormal states of 148 chronic diseases. We categorize data sources in EHR as clinical notes, exam reports, laboratory data, treatment orderings, and demographics, which each require different mapping techniques. From the investigation results, approximately 41% of the abnormal states are supposed to be identified in unstructured clinical notes or exam reports. Therefore, our study first explores techniques of mapping clinical narratives to abnormal states, which involves machine learning and natural language processing (NLP).

In previous studies, Informatics for Integrating Biology and the Bedside (i2b2) has organized NLP challenges including identifying patient smoking [3] and obesity [4] status from English-language discharge summaries. A common method exploited by the participants can be summarized in two steps: (1) retrieve relevant sentences or passages via keyword or rule-based search, (2) build sentence-level or passage-level classifiers to determine status, which we refer to here as polarity classification. In this paper, we present a general framework, extended from the conventional method, for extracting information from clinical narratives to identify abnormal states in disease ontology. The difference between our study and the i2b2’s challenges lays in the following aspects: (1) all available clinical notes in EHR are used in our study including discharge summaries, progress notes, nursery notes, which incorporate a wide variety of narratives; (2) the clinical narratives in our study are written in Japanese, which requires Japanese language processing such as morphological analysis. The improvements we have made to the method include the following: (1) adopting a semi-automatic keyword expansion for candidate sentence retrieval, using both knowledge-driven and data-driven approaches; (2) applying Synthetic Minority Over-sampling Technique (SMOTE) [5] to solve class imbalance problem in polarity classification; and (3) introducing a mechanism of using existing labeled data to automatically label unlabeled data, which reduces the labeling costs of machine learning for polarity classification.

Our study focuses on chronic diseases across the life span including diabetes, hypertension, dyslipidemia, chronic kidney disease, and ischemic heart disease. The objective of our study is to propose a general framework to efficiently build mapping modules between clinical narratives and abnormal states in ontologies of chronic diseases. In this paper, we discuss the technical requirements to identify abnormal states in clinical narratives, and we validate the applicability of the proposed framework using EHR data from the University of Tokyo Hospital. Experiments demonstrate that the proposed method is effective in EHR data mapping for 18%-33% of the abnormal states in the ontologies of chronic diseases.

The rest of the paper is organized as follows. The following section introduces the results of the investigation into abnormal states. The Methods section describes the proposed framework. The Experiment Section describes experiments designed to evaluate the performance. In the Discussion section, we discuss the proposed method and those abnormal states whose mapping modules cannot be realized by our framework. The final section presents our conclusions.
Investigation of Abnormal States

Based on an analysis of 4,718 (643 distinct) abnormal states of 148 chronic diseases by medical experts, we found that 384 abnormal states (59%) are potentially able to be mapped to combinations of clinical information, such as clinical notes, exam reports, laboratory data, treatment orders, and demographics (see Table 1). Figure 1 gives an example of disease ontology for angina pectoris with descriptions of categories of data sources. Laboratory data, treatment orders, and demographics are structured data, which are easy to access. Clinical notes and exam reports are in unstructured narrative form, where approximately 41% of the abnormal states are supposed to be identified.

We further analyze the abnormal states that require information extraction from narratives. We classify them into overlapping categories of “easy” and “difficult”. The “easy” abnormal states are described by word-level expressions in EHR and have concrete clinical meanings, which can be identified by terms like synonyms, hypernyms or hyponyms. The “difficult” abnormal states are those described at sentence level, or expressed in abstract terms, or that require numerical extraction from text. The distributions of “easy”, “easy/difficult”, and “difficult” abnormal states are shown in Table 2. We believe that the general framework proposed in this paper is applicable in mapping EHR narratives to “easy” ones, which accounts for 18%-33% of all the abnormal states in the ontologies of chronic diseases.

Methods

The workflow of the proposed framework for building mapping modules between clinical narratives and abnormal states is shown in Figure 2.

Preprocessing

Input texts are normalized, which involves full and half width conversion, upper/lower case mapping, and orthographical variants correction. The normalized texts are split into paragraphs based on line break and then paragraphs are decomposed into sentences based on Japanese punctuation characters.

Candidate Sentence Retrieval

Sentences related to an abnormal state are retrieved by keyword search with duplicates removed. We first make a list of keywords manually for an abnormal state and then implement keyword expansion to generate a set of keywords for sentence retrieval. If a keyword has known irrelevant multiple concepts, search rules are made to exclude irrelevant sentences from search results. For keyword expansion, two kinds of approaches are taken. One is dictionary-based, which implements synonym keyword expansion based on concept unique identifiers (CUI) of the Unified Medical Language System (UMLS: Japanese MeSH, Japanese MedDRA) [6]. The other is to train word2vec [7] to obtain similar words in learned vector space. We train two word2vec models using two corpora. One model is trained on a corpus consisting of Japanese medical tutorials including one Japanese medical textbook, Merck Manual professional [8] and home editions [9], and Wikipedia pages related to medicine.

The other model is trained on real EHR narratives using a dataset described as DS2 in the Experiments section. Japanese morphological analysis (JMA) is conducted to generate word
tokens beforehand, among which nouns are used to train word2vec models. The JMA is based on a customized medical dictionary.

**Polarity Classification**

For each retrieved sentence, affirmation or negation (polarity) of an abnormal state is determined. It is a classification problem, where three methods are applied to build classifiers.

**Keyword Look-up (KL)**

With respect to some keywords, their presence can directly indicate polarity. For example, the existence of “bi=” (“bi” is an abbreviation of “brinkman index”) implies that the patient is a smoker.

**Rule-based Algorithm (RA)**

Regular expressions are created to determine the polarity of sentences retrieved by some keywords, especially English keywords such as “smoker”, “smoking”, and “obesity”. In the case of abnormal states of disease names such as “diabetes”, and “dyslipidemia”, it is rare to see their negations and the negative expressions are quite similar across diseases. Therefore, limited negative expressions can be collected for polarity classification and shared by multiple disease names.

**Machine Learning (ML)**

Sentences related to symptoms and those related to lifestyle issues retrieved by Japanese keywords show great variety in the contexts in which they appear. In these cases, machine learning is applied.

We use linear support vector machine (SVM) as a base algorithm and bag-of-words (BoW) as features. To construct a BoW feature for each sentence, the JMA is conducted to tokenize each sentence into words. The window size of words used to construct features is adjusted for the best performance.

For an abnormal state, affirmative sentences are often much more common than negative ones. For those data with severe class imbalance problem, SMOTE is applied.

We constructed a KL or RA by viewing approximately 20 keyword expansion (see column “Eva on KE”). It is expensive in terms of both time and financial cost. In our proposed method, recall depends on the effectiveness of keyword expansion. Therefore, at this stage, we present increased ratios of retrieved clinical notes by keyword expansion instead.

### Experiments

#### Data Description

The data for this study is based on EHR data from the University of Tokyo Hospital, involving a great variety of types of clinical notes, including discharge summaries, progress notes, nursery notes. Exam reports are usually transcribed in clinical notes, so the data we used includes texts of both clinical notes and exam reports.

**Dataset 1 (DS1)**

We collected all clinical notes generated in 2015 at the University of Tokyo Hospital, which is denoted as DS1. DS1 is composed of approximately 170,000 clinical notes, which we used to evaluate our method.

**Dataset 2 (DS2)**

In order to train word2vec model for keyword expansion, we collected a dataset denoted as DS2. DS2 consists of approximately 60,000 clinical notes generated from 2010 to 2015 at the University of Tokyo Hospital, which contain at least one of the following disease names: chronic kidney disease, is-chemic heart disease, and arteriosclerosis.

### Experimental Settings and Evaluation Methods

Two things we concern are: first, “how precise is identification of an abnormal state”, and second, “how many patients with a given abnormal state are recalled”.

Evaluation of polarity classification answers the first question. We constructed a KL or RA by viewing approximately 20 candidate sentences. For each KL or RA classifier, if the total number of candidate sentences in DS1 is much higher than that used for classifier construction, we sampled approximately 100 sentences to create test data for evaluation. To construct a training set for a ML, we randomly sampled 250 sentences, if available, from candidate sentences retrieved from DS1. For those abnormalities for which there were not enough candidate sentences, all of the available sentences were used. The training sets were manually labeled and five-fold cross validation was conducted to evaluate the performance of ML classifiers.

A direct answer to the second question is achieved by computing patients’ recall for every abnormal state. This requires annotation by medical experts, which is extremely expensive in terms of both time and financial cost. In our proposed method, recall depends on the effectiveness of keyword expansion. Therefore, at this stage, we present increased ratios of retrieved clinical notes by keyword expansion instead.

### Experimental Results

We applied our proposed framework to 10 abnormal states, which are summarized in Table 3.

#### Effectiveness of Keyword Expansion

The keyword expansion grew the keyword lists for candidate sentence retrieval. Table 3 shows the increased percentages of retrieved notes from DS1 compared to those retrieved before keyword expansion (see column “Eva on KE”).

#### Performance of Polarization Classification

Table 3 gives the methods of polarity classification for each abnormal state and their performance measured in macro-averaged precision (Avg. P), recall (Avg. R), and F1 score (Avg. F1), as well as classification accuracy (CA).

We found that for most abnormal states with dataset size above 100-250, F1 increases more slowly and standard deviation of
F1 converges. The observation is basically consistent with a previous study [10] of the i2b2 Smoking Challenge, which states that accuracy increases slowly when the training set size is over 200 using hold-out validation. Therefore, in this study, we used 250 labeled sentences for each ML (except for the abnormal state of pulmonary congestion which has only 142 candidate sentences available in DS1). The performance shown in Table 3 for ML is based on fully manually annotated data without introducing RLC.

* Negation of a disease name is extremely rare, so only CA is given.

Figure 4 – Effect of dataset size on F1 scores

Availability of RLC

In the experiments on polarity classification using the fully manually annotated data, ML models for chest pain, fever, overhydration, pulmonary congestion and tachycardia showed the best performance with the same word count window in feature construction, which uses eight tokens after the keywords. All these abnormal states are symptoms. We assume that their candidate sentences may have similar contexts. A new experiment was designed to verify RLC based on these five abnormal states of symptoms.

In order to measure similarity between feature spaces of retrieved sentences containing the five symptoms, we computed the cosine similarity between word count vectors of the 250 annotated sentences for every two symptoms, which is shown in Table 4. Table 5 describes the performance (F1 scores) of the ML models trained on data of one symptom to predict polarity for the other four symptoms. The Pearson correlation coefficient between Table 4 and Table 5 is 0.422, indicating moderate positive correlation.

We applied RLC to the five abnormal states of symptoms, using labeled data of one symptom (source domain) to reduce the labeling costs of the other four (target domain). The rates of reduced labeling costs, that is, the proportions of automatically labeled data in the target domains, are shown in Table 6, ranging from 1.6% to 69.7%, averagely 32.4%. Table 7 gives the macro-averaged F1 scores of five-fold cross validation of polarity classification using the RLC outputs, which is similar to the performance using the fully manually annotated data as shown in Table 3.

Discussion

Applicability of the Proposed Framework

Our proposed framework is useful in mapping clinical narratives to abnormal states that are described by word-level expressions and have concrete clinical meanings. Keyword expansion and polarity classification are two key processes in our method.

Table 3 shows that the keyword expansion increases the number of retrieved clinical notes by 51% on average, which demonstrates the effectiveness of keyword expansion in improving recall. We also found that word2vec is able to find candidate keywords that the dictionary-based method cannot obtain, such as orthographical variants, obsolete terms but still in use, and informal expressions used locally in each hospital. However, keyword candidates outputted by word2vec show low precision, which requires manual selection. In future work, refining word representation learned from corpora by using semantic lexicons [11] may be a promising approach to outputting keyword candidates more efficiently.

As for the polarity classification, the proposed framework solves two problems in building ML classifiers: class imbalance and labeling costs. We applied SMOTE to solve the former problem, improving the macro-averaged F1 scores of cross validation by 5% to 10%. The F1 scores with SMOTE applied
are shown in Table 3. For the latter problem, we introduced RLC. Figure 4 shows that the size of the training data set necessary to build a high-performance ML classifier is above 100-200. Labeling training data for every abnormal state is time-consuming. RLC reuses existing labeled data to automatically label those unlabeled data that are similar to the existing labeled ones, thus reducing labeling costs. From Table 4 and Table 5, when the training and the test data come from different domains, moderate positive correlation exists between the cosine similarity of their feature spaces and the performance of the models. It is reasonable to consider using data in source domain to annotate data in target domain if they have similar feature spaces. Based on the experiments on the five abnormal states of symptoms, Table 6 and Table 7 demonstrate that RLC can reduce the labeling costs by 32.4% on average, achieving similar performance as using the fully manually annotated data. The rate of reduced labeling costs possibly depends on the dataset size of the source domain, and the similarity between feature spaces of the source and target domain. RLC is a simple and effective way of reducing labeling costs in our proposed framework.

Limitations of the Proposed Framework

Our proposed framework is useful in mapping clinical narratives. The proposed framework is invalid in identifying some abnormal states whose information is supposed to be contained in clinical narratives. We summarize these kinds of abnormal states as follows.

Some abnormal states are expressed at sentence level in EHR like “feel pain in chest”, and “the spleen is enlarged”. These kinds of expressions are missed in candidate sentence retrieval which is based on keyword search in our proposed method. Abnormal states like “stress” and “systematic inflammation” have abstract clinical meanings, which causes difficulty in collecting keywords for retrieving candidate sentences.

Some abnormal states such as “exertion” usually appear with other states such as “chest pain upon exertion”, and “difficult respiration upon exertion”. Thus, retrieved sentences do not focus on “exertion” but respond to multiple abnormal states. Therefore, mapping module should be established between EHR and a cluster of abnormal states in disease ontology. Extraction of numerical information such as body weight, body mass index (BMI), and blood pressure is necessary for identifying some abnormal states like “obesity” and “hypertension”. Numerical extraction from narratives requires more sophisticated NLP techniques.

Future Directions

Our future work will include the following: (1) building modules of mapping other data sources such as laboratory data and treatment orders to disease ontology; (2) developing sophisticated NLP techniques to identify the abnormal states in narratives that cannot be achieved by the proposed method; (3) exploiting structures in disease ontology to infer those abnormal states that have no trace of evidence in EHR.

Conclusions

In this paper, we have proposed a general framework to identify abnormal states in EHR narratives, which is applicable in data mapping for 18%-33% of the abnormal states in the ontologies of chronic diseases. The proposed method exhibits improvement over the conventional method by applying keyword expansion based on UMLS and word2vec, and by introducing SMOTE and RLC in ML for polarity classification.
Application of Ontology Technology in Health Statistic Data Analysis

Guo Minjiang, Hu Hongpu, Lei Xingyun

Institute of Medical Information/Center for Health Policy and Management, Chinese Academy of Medical Sciences, Beijing, China

Abstract

Research Purpose: establish health management ontology for analysis of health statistic data. Proposed Methods: this paper established health management ontology based on the analysis of the concepts in China Health Statistics Yearbook, and used protégé to define the syntactic and semantic structure of health statistical data. Results: six classes of top-level ontology concepts and their subclasses had been extracted and the object properties and data properties were defined to establish the construction of these classes. By ontology instantiation, we can integrate multi-source heterogeneous data and enable administrators to have an overall understanding and analysis of the health statistic data. Conclusion: ontology technology provides a comprehensive and unified information integration structure of the health management domain and lays a foundation for the efficient analysis of multi-source and heterogeneous health system management data and enhancement of the management efficiency.

Keywords:
Disease Management; Semantics; Models, Statistical

Introduction

As the Chinese health system reform is deepened constantly, to analyze the statistical data of health care system efficiently becomes more and more important for decision-makers to formulate policies, assess the progress and predict trends. However, the increasing number of terms used in the health statistic data leads to challenges for information staff. It is difficult for them to achieve an adequate understanding of the concepts denoted by the terms and to grasp the concepts’ interrelations, which hinders data analysis [1].

Ontology is the part of the information system that explicitly commits it to a certain conceptualization of the world [2, 3]. In the health sciences, ontological techniques are applied towards a variety of goals among knowledge modeling, organization, integration, and exploitation for studies about genomics, anatomy and so on [4]. It can present the scenario from the perspective of the service user, from that of the overall organization, or from that of a sample to be analyzed. Many ontology work has been done in this field. The Unified Medical Language System (UMLS) which was developed by the National Library of Medicine (NLM), is an information retrieval ontology. UMLS is a set of files and software that bring together many health and biomedical vocabularies and standards to enable interoperability between computer systems[5]. The Open Biomedical Ontology (OBO) is a biomedical data ontology, which is a collection of ontologies, such as gene ontology, cell type, plant ontology and sequence ontology. OBO makes the data generated in biomedical research to form a single, consistent, cumulative expansion and easy to operate on the algorithm as a whole [6]. GALEN is a clinical information ontology, which produces a computer-based multilingual coding system for medicine. The ontology is divided into 2,738 modules, which are organized according to the tertiary tree structure, and the relationship is grouped together [7]. The existing ontology research work provides an effective tool for integrating large amounts of medical data. Although health management data is different from the medical data, these types of research studies still provide insights for organizing health management data.

In consideration of the above problems, based on a systematic analysis of core concepts in health statistic data, we have constructed a system that focuses on the use of data from China Health Statistics Yearbook combined with health management ontology. This article describes the conceptual model of the ontology and defines the syntactic and semantic structure of health statistical data, as well as the terminologies generally accepted by health administrators. Through the construction and application of the health management ontology, it aims to integrate and share various health management data resources in the operation of the health system.

Methods

Materials

Health information resources are featured with interdisciplinary, large, and low-standardized vocabulary. Currently, the ontology for management is usually constructed according to different features of the respective disciplinary domain and the specific project, and there is not a systematic and engineered ontology construction method. A lot of management ontology construction methods are summarized from a single project or case [8]. On one hand, the size and scope of the ontological concept cannot fully meet requirements of health administrators for operating management of the health system. On the other hand, the ontology constructed can hardly complete an overall analysis of the whole operating process of the health system. Health statistical yearbooks serve as an important basis for providing a comprehensive understanding of the health system status, determining tasks and objectives of the health work, and implementing decisions of the health management and reform. Its indexes best embody the core concept, object and relevance of health system management and are suitable for constructing a comprehensive and systematic ontology of the domain of health management.
In order to understand the themes and structures in health management, we established a data model based on the star model, and used a text similarity calculation method to identify the dimensions and correlations of indicators. Data structure and relationship of health statistics yearbooks were expressed in the model. Therefore, taking the index and dimension names in the yearbooks as the text source, this research extracted the core objects and relationships in the health statistic data to integrate and analyze the operating information resources of the health management.

**Methods**

There are many methods of ontology construction, such as the skeletal methodology [9], TOVE methodology [10], METHONTOLOGY methodology [11], 7-step methodology [12], etc. By referring to these methods, this article makes some proper adaptations according to the features of the application requirements of this domain. Its general strategy is to use the top-down (first, design the top-level concepts, then provide detailed, step-by-step information) and bottom-up (first, collect domain concepts from domain documents as many as possible, then generalize them step by step) method. The specific construction flow is indicated in Figure 1, mainly including the demand analysis, resource reusing, building the ontology framework, adding instances, formalizing the ontology and ontology evaluation.

![Figure 1– Health Management Ontology Construction Flow](image)

**Concept Extraction**

We took the China Health Statistical Yearbooks in 2004-2010 as an example, which are divided into different topics as required by health management. In reference to the UMLS and OBO ontology system, we followed two principles to extract the concepts of the top-level ontology. One is the peer principle, which means that concepts of the top-level ontology have the consistent scope of expression. The other is the relevance principle, which means that different concepts are related to each other objectively. On these bases, we defined the topics with a wide scope of coverage in the “yearbooks” as the top-level ontology concepts; and we combined the topics with narrow scopes of coverage into a new topic as the top-level ontology concept; topics reflecting the health management efficiency indexes, such as the level of people’s health and causes of residents’ disease, injury and death, were not defined as the top-level ontology concepts. Upon the aforesaid analysis, we extracted six classes of top-level ontology concepts in the health management domain, which are the health institutions, health personnel, health facilities, health funds, health services, and health insurance.

**Tools**

At present, optional mature tools for the ontology development both home and abroad include Protégé, OntoEdit, WebODE, etc. In consideration of the usability and openness, this research uses Protégé 5.0 for development and chooses OWL as the language to describe the administrative ontology of the health system.

**Results**

By analyzing the concepts, objects and relationships involved in the health statistical yearbooks, this article defines the concepts, terminologies and their properties presented in the health system.

**Data cleansing**

First, we built a star data model for the statistical data. Every table in the yearbook is split per its properties and by indicator, time, geographic region and dimension, to form a star schema centered on “Yearbook data table” by dimensional tables.

Second, it was necessary to determine the correlation among indicators to extract the concept and relationship. Since the indicator name and dimension name are text information, we applied a text similarity calculation method to automatically identify the “dimensions” and the “upper level indicators”. A positive maximal matching principle of the semantic analysis method was applied to calculate the similarity. Then the created “indicator table” and “dimension table” were utilized to determine the dimension of an indicator via a custom macro program to find out its corresponding upper level indicators.

After that, a star schema structure was finally created, in which, the concept and the relationship is clearly defined (table 1).

**Terminology Definition**

To define the conceptual vocabulary properly is a key process in ontology construction. Only a good conceptual hierarchical structure can describe the knowledge structure of the health system clearly and accurately. Based on the top-level ontology concepts defined above, we classify their underlying relationships and terminologies hierarchically. We used some class of Ontology of Medically Related Social Entities from OBO, but in order to incorporate it with the Chinese health management system, some class names have been modified.

### TABLE 1-DIMENSION TABLE EXAMPLE

</tbody>
</table>
After formulating the hierarchical tree of terminological data sets, we collected all concepts, semantics, attributives and instances for aggregation, review, and cleaning.

Healthcare provider organizations refer to the organizations providing the society with services of medical health care, disease control and health inspection or are engaged in medical scientific research and on-the-job medical training, for example, hospitals, basic health institutions, and special public health institutions. Healthcare providers refer to people working in healthcare provider organizations for medical treatment, prevention and healthcare, medical scientific research, and in-service education, for example, doctors, nurses, pharmacists, medical technicians, administrators and logistics workers. Health facilities refer to the facilities used in health institutions to provide the society with various health services, for example, houses, beds, and medical equipment. Health funds refer to incomes and expenses in the operating process of the health system, for example, medical incomes and pharmaceutical incomes. Health services refer to medical health services provided by various health institutions for the society, for example, medical services, public health services, and women and children healthcare. Medical security systems refer to systems providing security for the medical health services for all populations, for example, the new rural cooperative medical care system, the basic medical insurance system for employees in urban areas, and the basic medical insurance system for urban residents.

After formulating the ontological terminology sets of the health system domain, we needed to establish the conceptual classification tree, systemize and define the connotation of each concept in the general concept table, analyze the relationships between different concepts, make induction and deduction, and build the relational model of all concepts by class/subclass or class/instance. Each sub-tree contains an independent modularized knowledge model. By use of OWL, we describe the major class resources of health management domain ontology as indicated in Figure 2. The classes are connected by “is_a” to show the inheritance of them.

**Object Properties**

In order to reflect the structures and rules existing in different concepts of the health system, we also needed to describe the class relationships after concept extraction. There are mainly six relationships:

- “inheres in” is used to describe the relationship between “health care provider” and the “health care provider organization”.
- “is bearer of” is used to describe the relationship that a “health care provider organization” bears a “health care provider”.
- “Earn” is used to describe the relationship that a “health care provider organization” or a “person” earns the “health fund”.
- “Expense” is used to describe the relationship that a “health care provider organization” or a “person” or “health service” expends the “health fund”.
- “Provide” is used to describe the relationship that a “health care provider organization” provides a “health service”.
- “Insure” is used to describe the relationship that a “health security system” insures a “health care provider organization” or “health service”.

The inverse properties are also defined.

**Data Properties**

The data property mainly reflects relationships between classes and data. The value types of a property mainly include boolean, byte, date, float, int, string, and time. For example, properties used to define a health institution include the ownership, sponsorship, location, area, medical insurance scheme, scale, etc. The concept of hospital has properties such as the grade and class in addition to properties of a health institution.

The object properties and data properties of the health management ontology created in this article are indicated in Figure 3 and Figure 4.

**Relationship Definition**

The ontology defines the property to define the class relationship, which is implemented by setting the domain and range of the properties. There are mainly two properties. One is the object property, used to relate an individual to another; the other is the data property, used to relate an individual to the data type.
Ontology Instantiation

After defining the class and property structure of the health system, we can instantiate the ontology, which can be implemented by a manual entry, machine import and artificial semantic annotation. In this article, we input three instances via the manual entry window of protégé: a general hospital “Peking Union Medical College Hospital”, a doctor “Zhang San”, and equipment “MRI”. The relationships of the three instances are indicated automatically in ontograf as shown in Figure 5. We can see the line combined “Peking Union Medical College Hospital” and “MRI” show the relationship: Zhang San – work in - Peking Union Medical College Hospital.

Application

By ontology instantiation, we can integrate multi-source heterogeneous data and enable administrators to have an overall understanding and analysis of the health statistic data. Figure 6 shows the operation interface of data analysis upon the construction of the integrated data of the health management domain ontology and establishment of the “health data analysis platform”, which can also be established by relational database but requires a lot of data processing work. By clicking any index on the figure, we can be linked to its related instance and recompose the figure for the convenience of classification and aggregation of the health system data.
Discussion

Using the index and dimension names in the health statistical yearbooks as the text sources, this article constructs the domain ontology of the health system, defines the concepts of top-level ontology, core terminologies object properties and data properties, applies the ontology to the “health data analysis platform” to facilitate the aggregation and classification analysis of the platform data, and lays a foundation for the final implementation of the domain’s special knowledge bases based on the ontology. However, as the data of the health system have a wide scope and limited degree of openness, currently, the instance data still need to be expanded. Subsequent work includes further improvement of the ontology by ontology learning, ontology evolution by dynamic updating and automatic expansion of special knowledge bases.

With the continuous openness of health data, there will be huge amount of health data for management and policy research, including new organization types, provider types, insurance types and so on, which will drive the ontology to evolve. Use of the health management ontology can also be employed in other health management information systems by rapidly integrating different sources and heterogeneous data and helping supervisors to quickly grasp the development trend, and make decisions.

Conclusion

As the age of precision medicine is approaching, data become more and more important for the development and prediction of the health industry. It becomes more necessary to have a deep understanding of historical data by intelligent analysis so as to know the industry status and predict development trends accurately. To construct an appropriate ontology structure is the basis for efficient and comprehensive intelligent analysis. Taking China Health Statistical Yearbook as an example, by extracting various concepts and relationships, this article forms a comprehensive and unified information integration structure of health management domain and lays a foundation for efficient analysis of multi-source and heterogeneous health system management data and enhancement of management efficiency. In the future, combining with the industrial requirements of health system management and the analysis methods of big data, we will dig deeper into the data and fully exert the supporting role of informatization in the development of the health cause.

Abstract

Interoperability among medication classification systems is known to be limited. We investigated the mapping of the Established Pharmacologic Classes (EPCs) to SNOMED CT. We compared lexical and instance-based methods to an expert-reviewed reference standard to evaluate contributions of these methods. Of the 543 EPCs, 284 had an equivalent SNOMED CT class, 205 were more specific, and 54 could not be mapped. Precision, recall, and F1 score were 0.416, 0.620, and 0.498 for lexical mapping and 0.616, 0.504, and 0.534 for instance-based mapping. Each automatic method has strengths, weaknesses, and unique contributions in mapping between medication classification systems. In our experience, it was beneficial to consider the mapping provided by both automated methods for identifying potential matches, gaps, inconsistencies, and opportunities for quality improvement between classifications. However, manual review by subject matter experts is still needed to select the most relevant mappings.

Keywords: Topical; Pharmaceutical Databases

Introduction

Medication terminologies and ontologies commonly categorize medications by similar properties such as therapeutic intent (i.e., muscle relaxants or analgesics), chemical structure (i.e., sulfonylureas or tetracyclines), mechanism of action (i.e., proton pump inhibitors or beta-adrenergic blockers), or sometimes combinations of the above (i.e., tricyclic antidepressants or amphetamine anorectics). Sets of drugs that share the same property used as a classification criterion (e.g., therapeutic intent) are generally referred to as medication classes (or simply classes in the context of this work). Interoperability among medication classification systems is known to be limited [4], yet it is important for clinical decision support (CDS), allergy checking, translational research, and organizing medication lists [3]. Our objective is to investigate the mapping of the U.S. Food and Drug Administration (FDA) established pharmacologic class (EPC) concepts to the SNOMED CT Substance hierarchy. More specifically, we provide an evaluation of ontology matching techniques and we describe lessons learned mapping medication classifications.

Established pharmacologic classes (EPCs)

In January 2006, the FDA established requirements for prescribing information for pharmaceutical products [2]. The labeling revisions provided additional information and established the structured product label (SPL) format for prescription medication labeling in order to make it easier for health are professionals to access, read, and use prescription medication information. Part of the labeling revisions requires that the statement “(Drug) is an (EPC) indicated for (indication(s))” appear under the Indications and Usage section [1]. The EPC membership is determined by the FDA to classify the medications into medication classes to which the active ingredient belongs; for example, albuterol is a beta2-adrenergic agonist. However, unlike many other medication classes, the EPCs are not organized into a hierarchy, despite the presence of logical groupings in the EPCs. The absence of an EPC hierarchy makes the use of EPCs difficult for accessing and using prescription medication information, and may limit the use of SPLs in clinical decision support [12]. In contrast, SNOMED CT does have a robust medication class hierarchy and could be used to help organize the EPCs.

Medication class representation in SNOMED CT

SNOMED CT is maintained and distributed by SNOMED International (London, UK). SNOMED CT includes clinical terms used in healthcare, among which are two medication hierarchies, namely the Pharmaceutical/biologic Product and Substance hierarchies. However, for this study, we focused on the Substance hierarchy. Medications in SNOMED CT can belong to multiple medication classes, as can the medication classes themselves. For example, Figure 1 shows the medication classifications in the Substance hierarchy for albuterol are listed as a Respiratory sympathomimetic agent, Selective beta-2 adrenoceptor stimulant, and Ethanolamine.
Ontology matching

Medication classes are present in most medication ontologies. Comparing and matching ontologies is not a new concept, and can be performed through various techniques [6]. Due to the time and labor-intensive nature of manual matching between ontologies, automatic techniques, such as lexical and instance-based matching have been developed [8; 9; 11]. Lexical matching compares medication classes based on their names (such as Proton Pump Inhibitor [EPC] matching with Proton pump inhibitor [Substance]) and is probably the most common technique for assisting manual matching. However, some authors have suggested that lexical matching may not be appropriate for comparing medication classes [7; 11]. On the other hand, instance-based matching compares the overlap of medication class members (instances) from one medication class to those of another, which may better represent the intended meaning of the medication class than using the class name. Winnenburg et al. used lexical and instance-based matching techniques as tools for medication class ontology matching [11], and Mortensen et al. used instance-based matching to compare medication classes between ontologies as a method of quality assurance to identify medication classes in need of review and/or updating [8]. However, these prior studies did not evaluate these ontology matching techniques against an expert-reviewed reference standard or provide guidance on which threshold for medication class match significance for instance-based matching.

The specific contribution of this study is to evaluate automated mapping techniques against a reference standard with application to the mapping of EPCs to SNOMED CT medication classes. Moreover, we conducted a sensitivity study to determine optimal thresholds for the instance-based techniques suggested by Winnenburg et al.

Methods

Data sources

We used the DailyMed index file (February 2014) to develop the list of EPCs with their corresponding medication unique identifiers (UNILs), and SNOMED CT (March 2014 release) for the Substance hierarchy. We used RxNorm (March 2014 release) to map medications between the EPCs and SNOMED CT using the RxNorm concept unique identifier (RxCUI) for the medication active ingredient (IN). RxNorm represents medications as ingredients (INs), precise ingredients (PINs), and multiple ingredients (MINs). We excluded MINs from the analysis because they may be represented as individual ingredients in the hierarchies and are inconsistently represented in medication classification systems.[10] For example, Combivent® (MIN RxCUI:2141999) does not exist in any medication classes, but the ingredients ipratropium (an anticholinergic agent) and albuterol (a beta2-adrenergic agonist) do belong to medication classes. The PINs typically represent salt forms and esters of INs, so we normalized the medications to IN RxCUIs before analysis. For example, albuterol maps to an IN (RxCUI:435) whereas albuterol sulfate maps to a PIN (RxCUI:142153), yet both would be considered the same active ingredient, albuterol, so we normalized them to the IN (RxCUI:435).

Identifying medications and medication classes

As shown in Figure 1, we first obtained a list of EPCs with their respective medications from DailyMed. In SNOMED CT, medications are mixed in with the medication classes at varying levels in the hierarchy, which can make separating the medications from the medication classes challenging. Therefore, for each medication (such as albuterol), we used RxNorm to identify the IN RxCUI (435 for albuterol), and then used RxNorm to map albuterol to the corresponding SNOMED CT concept identifier (372897005 for Substance). We then walked up the SNOMED CT hierarchies to identify medication classes with albuterol listed as a medication.

For example, albuterol has asserted membership to the medication classes Respiratory sympathomimetic agent, Selective beta-2 adrenoceptor stimulant and Ethanolamine in the Substance hierarchy. We would then infer albuterol membership in ancestor medication classes through transitive closure. For example, since Selective beta-2 adrenoceptor stimulant is a subclass of Beta-adrenoceptor agonist, we would, therefore, infer that albuterol was also a member of Beta-adrenoceptor agonist, which would continue up the hierarchy to a Symptomimetic and Autonomic agent. Figure 1 shows the asserted relationships with solid arrows and inferred relationships using dashed arrows. To simplify the analysis, we excluded very broad, top-level classes, such as Drug allergen (Substance), Chemical (Substance), and Drug or medicament (Substance), which would not provide meaningful alignment.

Mapping medication classes from EPC to SNOMED CT

Lexical matching techniques

Lexical matching compares medication classes based on their name. Some lexical matching techniques, such as those used in this project, include exact, normalized, and approximate text matching applied to main terms and synonyms. For example, beta2-adrenergic agonist [EPC] would match (partially) with Selective beta-2 adrenoceptor stimulant though synonymy and normalization despite differences in hyphenation (ie, beta2 vs beta-2) or use of adrenergic agonist vs adrenoceptor stimulant. For lexical matching, we utilized the matching and searching algorithms in Termworks (Apelon Inc., 2013, Hartford, CT). Termworks would normalize the medication class names by stemming (ie. matching based on the root of the word, such as “stimul” from “stimulant, stimulators, stimulating, stimulator”) and then provide the top lexical match based on an internal scoring system, giving priority to exact, normalized, then approximate matches, in decreasing order. Termworks used synonyms from the target terminology, SNOMED CT.

Instance-based matching techniques

Instance-based matching techniques compare classes based on the class members they share, in our case medications. Here, we adopted the framework by Winnenburg et al [11]. In summary, EPC concepts were compared to each class in SNOMED CT in a pairwise manner if the classes shared at least one active ingredient. We calculated medication class similarity using the equivalence score (ES) between two classes as the modified Jaccard coefficient to account for small sample size in medication classes [11]. The ES gives a score from 0 to almost 1, with 0 meaning no overlap and higher scores representing greater similarity (overlap) of medication classes. For example, beta2-adrenergic agonist [EPC] has 7 ingredients, of which, all 7 overlap with the 7 ingredients in Selective beta-2 adrenoceptor stimulant (Substance), giving an ES of 0.941. The Winnenburg framework also supports the identification of inclusion relations between classes through an inclusion score. However, in the present investigation, we ignored the inclusion score and focused on equivalence relations between
classes. Analysis was completed using STATA 13 (StataCorp. 2013. College Station, TX).

**Developing a reference standard**

The reference standard was developed to contain mappings from the EPCs to SNOMED CT Substance hierarchy. To summarize, two pharmacist informaticists (SN and JP) served as subject-matter experts (SMEs). First, SMEs elicited the meaning of the EPC name and mapped it to an equivalent class in SNOMED CT; then, if there was no equivalent class, the EPC was mapped to a related class using child_of relationships. If both attempts failed, we concluded that no mapping could be established. During the mapping exercise, the SMEs independently reviewed and rated the top lexical EPC to SNOMED CT pairs from Termworks, and all instance-based EPC to SNOMED CT pairs with an ES ≥ 0.2. An ES ≥ 0.2 was qualitatively chosen to provide a limited number of pairs for manual review that had a reasonable overlap. Priority was given to equivalent relationships, if no equivalent relationship was found, then the child of relationships were used. If the pair was not equivalent, SMEs sought the most proximal SNOMED CT concept providing a more general, yet true representation of the EPC concept using child_of relationships. The SME ratings agreed 90.1% of the time with an average weighted kappa of 0.736, and discrepancies were resolved by discussion and consensus. Next, the ratings based on the automated methods were combined and the SMEs used clinical knowledge to review, investigate, and correct the mapping results, discrepancies, and unmatched EPCs. The reference standard underwent various quality assurance and verification reviews, including a full review of all mappings. The final mapping set was reviewed, and discrepancies reached consensus by an expanded group of physicians and FDA pharmacists.

**Evaluating matching techniques against the reference standard**

We used descriptive statistics to assess the contributions of each automated matching technique, along with their precision, recall, and F1 score (harmonic mean of precision and recall) compared to the reference standard. We also evaluated if the final equivalent pairs were predicted using lexical, instance-based matching, or both. To compare the lexical and instance-based matching, we limited the analysis to the top lexical match and top instance-based match using only equivalent pairs with the highest ES for each EPC. We then conducted sensitivity analysis across a range of ES thresholds for instance-based matching to determine which threshold provided the best F1 score for finding equivalent pairs.

Of note, in order to maximize the number of suggested matches (recall), we did not use the inclusion score to filter out those matches with a high ES that could also correspond to child_of relationships.

Since instance-based matching is dependent on shared instances, we removed EPCs that did not have medications that could be mapped to SNOMED CT using RxNorm (such as radioactive therapeutic agents like iodine ion I-131 and various allergenic extracts). We identified 2,963 Substance classes that shared at least one medication with the EPCs.

**Manually established reference standard**

About half (284) of the 543 EPCs had an equivalent class in SNOMED CT, while most of the remaining (205) had a child_of relationship. Fifty-four EPCs could not be mapped to SNOMED CT, such as sodium-glucose cotransporter 2 inhibitor [EPC] (new therapeutic target not in SNOMED CT at the time of analysis), calcific dissolution agent [EPC] (mix of various medications with a common therapeutic intent, but not classified by therapeutic intent in SNOMED CT), and potassium channel opener [EPC] (somewhat vague mechanism of action for a specific medication).

**Comparison to the reference standard**

Using only the top match for each EPC, lexical matching identified 526 potential matches, whereas instance-based matching identified 282 potential matches.

**Optimal threshold for the equivalence score (ES)**

Sensitivity analysis across a range of ES thresholds showed that an ES ≥ 0.3 was the optimal threshold, maximizing precision and recall. Table 1 shows the performance of instance-based matching for identifying equivalent pairs with an ES ≥ 0.3.

<table>
<thead>

<td>0.554</td>
</tr>
</tbody>
</table>

**Contributions of each technique for equivalent mappings**

As shown in Table 1, both lexical and instance-based matching had low-performance overall (F1 score was 0.498 and 0.554, respectively). Lexical matching had better recall, but lower precision than instance-based matching, which is not surprising, because the lexical matching produced more potential matches than the instance-based matching did.

Out of all 284 equivalent EPC to SNOMED CT pairs, there were 98 identified correctly only by lexical matching, 65 only by instance-based matching (ES ≥ 0.3), 78 identified by both, and 43 identified by manual review only.

**Examples and failure analysis**

**Lexical matching techniques**

There were cases where instance-based matching was able to identify a correct match, but lexical matching was not, and in some cases, lexical matching recommended a contradictory class as equivalent in attempts to maximize recall with approximate matches. For example, lexical matching suggested Androgen Receptor Inhibitor [EPC] be mapped to Androgen receptor (substance); yet, instance-based matching correctly identified Synthetic antiandrogen (substance).

Lexical mappings typically failed to identify matches due to the use of synonyms and ambiguous meaning of class name or differences in classification type, such as between structural and functional groupings or mixing structural and functional classifications. The lexical matching tended to suggest mappings to terms other than medication classes, (i.e.,

---

S.D. Nelson et al. / Interoperability of Medication Classification Systems: Lessons Learned Mapping EPCs to SNOMED CT
receptors, antigens, lab test ingredients), such as Acetylcholine Release Inhibitor [EPC] and Acetylcholine (substance). In contrast, instance-based matched did not suggest pairs other than medication classes. Another limitation of lexical matching was that many of the suggested pairs had similar names but different meanings, which caused look-alike/sound-alike type errors for SMEs reviewing hundreds of pairs, such as Mood Stabilizer [EPC] and Mast cell stabilizer (substance).

Additionally, lexical matches were typically correct or incorrect, with very few "close" matches, whereas instance-based matching presented many close matches that pointed the mapper to the correct part of the SNOMED CT tree.

**Instance-based matching techniques**

Instance-based matching is intrinsically dependent on the classes sharing instances. Potential errors in the instance-based matching were mainly due to small numbers in class size. For example, RANK Ligand Inhibitor [EPC] with the medication denosumab was mapped by the SMEs as a child of Bone resorption inhibitor (substance); however, Bone resorption inhibitor does not include denosumab, instead, denosumab is a child of Monoclonal antibody agent (substance).

Instance-based matching also had problems with the multiple levels of granularity of SNOMED CT. For example, multiple medication classes were considered equivalent due to a high ES, such as xanthine oxidase inhibitor [EPC] matching with Anti-gout agent (substance) with an ES of 0.516, and Xanthine oxidase inhibitor (Substance) with an ES of 0.775. Both substance classes were potential matches, but Anti-gout agent (substance) is the parent of Xanthine oxidase inhibitor (Substance). This also occurred with benzodiazepine [EPC] matching with 6 medication classes from SNOMED CT. To help sort this out in our automated analysis, we only used the highest ES scoring pair for each EPC.

Additionally, there were some classes that had high ES ratings but were considered to be child of relationships due to how the medication class was named, such as the use of qualifiers like "analog" or "recombinant". For example, Folate Analog [EPC] was considered a child of Folic acid (substance). Finally, since instance-based matching is dependent on the medication classes having common medications, it was unable to find matches for EPCs without active ingredients listed in them, such as Adrenergic Decongestant [EPC], or classes where the instances could not be mapped to the SNOMED CT.

**Discussion**

**Lessons learned**

Overall, comparing and mapping medication classification systems is a very challenging task. Each classification system has its own way of grouping medications, each using different grouping criteria. Thus it is not possible to simply insert one classification system into another since each classification system has its own “world view”, use case, and area of interest, which has resulted in the proliferation of many terminology standards. However, the automatic matching methods helped facilitate the mapping process, for both equivalence and partial mappings. The lexical and instance-based matching methods were each able to correctly identify about half of the 284 manually created equivalent medication pairs (176 and 143, respectively). However, used in combination, the two approaches were able to find 221 of the 284 pairs, and identify most of the child of relationships, indicating that these approaches have their own individual strengths and weaknesses. Each method contributed specific results, though they may occasionally contradict, we found that providing both results (using OR logic) provided the best compromise and mapping facilitation. Our results suggest that a combination of lexical and instance-based matching could provide improved automated matching suggestions.

Previous studies have not been able to determine an ES threshold for instance-based matching. From our sensitivity analysis, we concluded that an ES threshold of 0.3 or greater provided a good balance between precision, recall and the number of pairs for SMEs to review. Despite the lexical bias in the development of the reference standard, instance-based matching performed slightly better than lexical matching in identifying equivalent pairs and was also useful later in identifying some child of relationships. The instance-based scores presented in this paper improve upon those proposed by the framework and provide a reference of expected scores; however, scores may vary depending on use case and need to be validated in different data sets. Additionally, due to the incomplete nature of the EPCs, these values likely represent the lower bound of performance for instance-based mapping.

**Application of results**

First, we found these automated mapping methods to be useful in supporting the development of a mapping between medication classification systems. We want to point out that the goal of these automated matching methods is not to identify 100% correctly the first time, but to help narrow down the thousands of potential matches to a more manageable list so that someone knowledgeable of both terminologies can review, validate, or correct the mappings. Therefore, we found that manual mapping and SME review are still needed, but that the use of lexical and/or instance-based matching facilitated the process and could point the mapper to the right section in the other ontology (particularly true for the instance-based method). These matching methods also reduced the amount of curation needed for the mapping and can be generalized to virtually any pair of medication classification systems (beyond EPCs and SNOMED CT).

Second, we also found these methods useful for quality assurance and validation. For example, both EPC concepts and SNOMED CT classes switched between grouping active ingredients by chemical structure and by therapeutic intent, which was variable within and between the two classification systems; however, we found that the instance-based method was able to inform the meaning of the class names, such as if the class was grouped using structural or functional properties. The variation of naming and grouping medications was especially apparent with the EPCs, such as the use of antibacterial versus antimicrobial classifications. For example, the EPC concept Macrolide [EPC] only has erythromycin listed in it, Macrolide antibacterial [EPC] has only fidaxomicin listed in it, and Macrolide antimicrobial [EPC] has azithromycin, clarithromycin, and erythromycin listed as instances, yet all these instances are antibacterial agents with a macrolide structure, while other non-antibacterial agents with a macrolide structure (i.e. tacrolimus or sirolimus) are not included in the Macrolide [EPC] class. One would expect that the concept Macrolide [EPC] would contain all medications with a macrolide structure, not just erythromycin. These inconsistencies arise because there was previously a lack in standardization in how EPCs were assigned [4]. We also found apparent gaps in SNOMED CT related to agonist/antagonist classifications, such as Dopamine-2 Receptor Antagonist [EPC] and Gamma-Aminobutyric Acid A Receptor Agonist [EPC]. Inconsistencies and unused medication classes were reported to the FDA and SNOMED International to help improve the medications classifications. Since then, SNOMED International has been
SNOMED CT using extensions. SNOMED CT could have medication classes added to mappings did not account for inferred relationships caused by decision support remains to be studied, especially as the useful for navigation purposes, and their utility in clinical between EPCs and SNOMED CT were found to be mainly considered class instances in the final mappings. The mappings such was biased in favor of lexical matching, as we did not consider class instances in the final mappings. The mappings between EPCs and SNOMED CT were found to be mainly useful for navigation purposes, and their utility in clinical decision support remains to be studied, especially as the mappings did not account for inferred relationships caused by mappings. EPC concepts that could not be mapped to SNOMED CT could have medication classes added to SNOMED CT using extensions. Secondly, instance-based matching is dependent on classes sharing instances. There were many empty and incomplete EPC classes, such as Narcotic Antitussive [EPC] not having any instances, dextromethorphan not listed as an antitussive, and erythromycin as the only instance in Macrolide [EPC]. Additionally, this study was limited to active ingredients mapped in RxNorm with RxCUIs and SNOMED CT identifiers. Some active ingredients were excluded because they are outside of the scope for RxNorm, such as allergens, pollens, foods, and herbals. These results likely represent the lower bound of the instance-based mapping performance.

Conclusion

Comparing and mapping between medication classes is a challenging task due to the different ways of classifying medications. Using lexical and instance-based matching, with manual review, we were able to map most of the EPCs to medication classes in SNOMED CT. Each method had its own unique strengths, weaknesses, and contributions. The use of instance-based matching in addition to lexical matching can help map or compare medication classes. The evaluation and comparison of ontologies is a complex process, and while these automated matching techniques can help, manual review by subject-matter experts is still needed for mapping between medication classification systems.

Interoperability of Disease Concepts in Clinical and Research Ontologies: Contrasting Coverage and Structure in the Disease Ontology and SNOMED CT

Satyajeet Raje, Olivier Bodenreider

U.S. National Library of Medicine, National Institutes of Health, Bethesda, MD, USA

Abstract

**Objectives.** To contrast the coverage of diseases between the Disease Ontology (DO) and SNOMED CT, and to compare the hierarchical structure of the two ontologies. **Methods.** We establish a reference list of mappings. We characterize unmapped concepts in DO semantically and structurally. Finally, we compare the hierarchical structure between the two ontologies. **Results.** Overall, 4478 (65%) of the 6931 DO concepts are mapped to SNOMED CT. The cancer and neoplasm subtrees of DO account for many of the unmapped concepts. The most frequent differentiae in unmapped concepts include morphology (for cancers and neoplasms), specific subtypes (for rare genetic disorders), and anatomical subtypes. Unmapped concepts usually form subtrees, and less often correspond to isolated leaves or intermediary concepts. **Conclusion.** This detailed analysis of the gaps in coverage and structural differences between DO and SNOMED CT contributes to the interoperability between these two ontologies and will guide further validation of the mapping.

Biological Ontologies; Systematized Nomenclature of Medicine; Unified Medical Language System

Introduction

Different ontologies are used to represent disease concepts in biomedical research and in clinical settings. The Disease Ontology (DO) is widely used in the research community, especially in genomic and cancer research. SNOMED CT is primarily used in healthcare and clinical settings. Interoperability between these two important ontologies is critical for translational applications in biomedicine. For example, research findings about a disease (coded with DO) and clinical findings from EHR data about the same disease (coded with SNOMED CT) can be analyzed together only if the DO and SNOMED CT codes for the disease are mapped together.

In this paper, we investigate the coverage of disease concepts between DO and SNOMED CT. More specifically, we identify and characterize the concepts present in DO but not covered by SNOMED CT. We also analyze the differences in hierarchical structure between the two ontologies.

Background

**Resources**

**Disease Ontology**

The Disease Ontology (DO) [1] is part of the Open Biomedical Ontologies (OBO) [2] collection and is used in several research projects. The ontology is implemented using description logics (DL) and available in the Web Ontology Language (OWL) format. We worked with the August 2016 release of the Disease Ontology. This version has 6931 active disease concepts. Some concepts in DO have explicit cross-references (represented by “obo:hasDbXref” relations) to concepts from SNOMED CT and other bio-ontologies. In this paper, we refer to these cross-references as “mappings”.

**SNOMED CT**

The Systematized Nomenclature of Medicine - Clinical Terms (SNOMED CT) is the largest clinical terminology. We used the March 2016 release of SNOMED CT (US Edition), as this is the version cross-referenced by the August 2016 version of DO. SNOMED CT contains over 300,000 clinical concepts, with about 100,000 disease concepts. As for DO, SNOMED CT is developed using description logics. However, since SNOMED CT is distributed in a proprietary format, we converted it to OWL using the script provided as part of the release. We processed the OWL versions of DO and SNOMED CT using the Java OWL API.

**UMLS**

The Unified Medical Language System (UMLS) Metathesaurus [3], developed by the U.S. National Library of Medicine, provides mappings across concepts from various standard biomedical terminologies and ontologies, including SNOMED CT. However, the UMLS does not currently integrate the Disease Ontology. The UMLS provides a RESTful API to identify lexical matches among all the concepts from its sources. Each UMLS concept is linked to one of 15 Semantic Groups, including Disorders. Using UMLS allows us to leverage the rich synonymy across all its source vocabularies for mapping and the semantic characterization of its concepts for consistency checking. We used the 2016AA release of UMLS in this research as it contains the March 2016 release of SNOMED CT.

Related work

Kibbe et. al. [4] report on the overall coverage of the DO and its cross-references to other terminologies in their update on the Disease Ontology. In this study, we perform a deeper analysis of the cross-references to SNOMED CT specifically.

Previous work has investigated the coverage of concepts within specific subdomains of medicine [5]. It has been demonstrated that the UMLS semantics can be exploited successfully for mapping across vocabularies [6]. In previous work from our group, Dhombres et. al. [7] evaluated the coverage of phenotypes across the Human Phenotype Ontology (HPO) [8] and SNOMED CT. Fung et. al. [9] assessed coverage of rare diseases in ICD and SNOMED CT. In this paper, we use similar techniques for assessment of disease concepts between DO and SNOMED CT.

To the best of our knowledge, this is the first attempt to contrast the coverage and structure between DO and SNOMED CT.
Methods

Our approach to investigating the coverage and organization of disease concepts in DO and SNOMED CT can be summarized as follows. We first establish a reference list of mappings of DO concepts to SNOMED CT. We characterize the unmapped DO concepts semantically and structurally. Finally, we compare the hierarchical structure between the two ontologies.

Establishing a reference list of mappings

As shown in Figure 1, to establish a reference list of mappings, we start by updating the mappings provided by DO, from which we filter out semantically inconsistent mappings. We identify additional mappings lexically using the UMLS.

Updating and filtering mappings provided by DO

From the mappings (“cross-references”) to SNOMED CT provided by DO, we remove those mappings to retired SNOMED CT concepts and resolve the mappings to “moved” (remapped) concepts in SNOMED CT. Because DO concepts are expected to represent diseases, we consider semantically inconsistent and filter out those mappings to concepts outside the “Clinical finding” hierarchy of SNOMED CT, which contains all diseases, disorders and findings.

Finding additional lexical mappings

We leverage the UMLS in an attempt to identify lexical mappings for those DO concepts without any mappings to the “Clinical finding” hierarchy of SNOMED CT. More specifically, we first extract the labels for each DO concept, including preferred terms and synonyms. We take advantage of the rich set of synonyms provided by the UMLS to map these terms to UMLS concepts, using exact or normalized string matches. Finally, as we did for the mappings provided by DO, we select semantically consistent lexical mappings by restricting the mappings to the “Clinical finding” hierarchy of SNOMED CT.

All semantically consistent mappings (from DO cross-references or obtained lexically) form the reference list of mappings used in the rest of this investigation. All other DO concepts are considered unmapped.

Characterizing unmapped DO concepts

We characterize the unmapped DO concepts semantically and structurally, and analyze the differentiae (e) between unmapped concepts and their parent(s).

Semantically. To identify whether coverage is better for some types of diseases than others, we compute the distribution of mapped and unmapped DO concepts with respect to the top-level subtrees of DO.

Structurally. To investigate whether unmapped DO concepts are isolated unmapped leaf concepts, subtrees of unmapped concepts, or unmapped intermediary concepts, we cluster them into groups of hierarchically related concepts (“connected components” in graph theory parlance).

Differentiae. Moreover, for isolated unmapped leaf concepts and subtrees of unmapped concepts, one author (OB) performed a manual review to identify the differentiae (e) between each unmapped DO concept and its immediate parent concept(s). For example, the unmapped DO concept “ovarian germ cell teratoma” differs from its parent concept “ovarian germ cell cancer” by the addition of a morphology distinction (teratoma is a morphologic type of cancer).

Comparing hierarchical organization between DO and SNOMED CT

DO and SNOMED CT both represent disease concepts and share important classificatory principles (e.g., by localization, by etiology, by morphologic type). Therefore, we expect their hierarchical organization to be similar. In other words, we expect that most hierarchical relations present in one ontology will also be present in the other. And we do not expect that two hierarchically related concepts in one ontology will have no hierarchical relation or will be considered the same concept in the other ontology.

In practice, we take each pair of hierarchically related concepts (direct parent-child pair) present in one ontology and examine the relations between the two concepts in the other ontology. As illustrated in Figure 2, we consider 4 patterns of hierarchical relations across ontologies.

1. The two concepts are in the same direct parent-child relation in both ontologies.
2. The hierarchical relation is direct in one ontology but indirect in the other. The two ontologies are consistent,
but the ontology with the indirect relation is finer grained than the other.

3. The hierarchical relation present in one ontology is missing from the other. The two ontologies are inconsistent.

4. The two hierarchically related concepts in one ontology map to the same concept in the other ontology. The two ontologies are inconsistent.

To make this comparison possible, we restrict it to pairs of concepts in which both concepts have a reference mapping to the other ontology. Since there may exist multiple mappings for an individual parent or child concept, we compare all possible parent-child pairs. We apply this method in both directions (i.e., both from DO to SNOMED CT concepts and from SNOMED CT to DO).

Results

Establishing a reference list of mappings

Updating and filtering mappings provided by DO

There were 12,470 mappings to SNOMED CT provided by DO as cross-references. We removed 224 mappings to retired SNOMED CT concepts and resolved 6552 mappings to moved concepts. A total 4195 DO concepts have one or more mappings to SNOMED CT (involving 8352 mappings).

Of the 8352 mappings, we filtered out 1184 semantically inconsistent mappings. After this filtering step, 336 DO concepts were left with no mapping. In most cases, a disease concept from DO was mapped to a concept in the “Morphologic abnormality” hierarchy of SNOMED CT. For example, “mixed cell type cancer” [DOID:154] mapped to “Mixed tumor, malignant (morphologic abnormality)” [SCTID:8145008].

Of the 3859 DO concepts with at least one semantically consistent mapping, 3334 had only semantically consistent mappings, while 525 had at least one inconsistent mapping.

Finally, of the 3334 DO concepts with only semantically consistent mappings, 1950 concepts had a single mapping (e.g., “Cycloplegia” [DOID:10033] mapped to “Cycloplegia (disorder)” [SCTID:68158006] only), while 1384 had multiple semantically consistent mappings. Of these 1384 concepts, 110 had a mapping to concepts in both the “Disease” and the “Clinical Findings” hierarchies, usually to a disease its associated finding. For example, “Mevalonic aciduria” [DOID:6050452] is mapped to “Mevalonic aciduria (disorder)” [SCTID:124327008] and “Hyperimmunoglobulin D with periodic fever (finding)” [SCTID:234538002].

Overall, as shown in Figure 3, of the 6931 disease concepts in DO, 3859 (56%) were mapped to SNOMED CT through at least one semantically consistent mapping provided by DO, 336 (5%) had only semantically inconsistent mappings, and 2736 (39%) were unmapped.

Finding Additional Lexical Mappings

Leveraging lexical mapping through the UMLS, we identified a mapping to SNOMED CT for 619 (20%) of the 3072 DO concepts with no semantically consistent mapping.

Figure 3- Breakdown of explicit mappings of the DO concepts

Figure 4- Distribution of mapped versus unmapped concepts within top level subtrees of the Disease Ontology. Numbers indicate the actual number of concepts in each subtree.
Overall, our reference list of mappings includes 7949 semantically consistent mappings covering 4478 (65%) of the 6931 DO concepts, mapped to 6440 unique SNOMED CT concepts.

Characterizing unmapped concepts

*Semantically.* Of the 6931 DO concepts, 2453 (35%) remained unmapped to SNOMED CT. Figure 4 shows the distribution of mapped and unmapped concepts by the top-level subtrees of DO. Concepts belonging to multiple subtrees are counted multiple times. The top subtrees for unmapped concepts include cancers, neoplasms, diseases of the thoracic sys tem, immune system diseases, and nervous system diseases. In contrast, very few of infectious diseases remain unmapped.

*Structurally.* The 2453 unmapped concepts can be grouped into 261 clusters of hierarchically related concepts (connected components). From a structural perspective, unmapped concepts fall under three possible categories: isolated unmapped leaf concepts, subtrees of unmapped concepts, and unmapped intermediary concepts.

We found 401 cases of isolated unmapped leaf concepts, namely 214 with a single parent and 187 with multiple parents. For example, “multiple mucosal neuroma” [DOID:5155] is the only unmapped child of “neuroma” [DOID:2001], which means that all of its siblings (e.g., “Neurilemmoma” [DOID:3192]), are mapped to SNOMED CT. Of note, 69 of these leaf concepts are the only child of their parent.

We found 1806 unmapped concepts in subtrees of unmapped concepts. These are clusters where none of the concepts is mapped, while they share a common mapped ancestor. For example, the subtree rooted at “chromosomal deletion syndrome” [DOID:0060388] contains 35 concepts, including “distal 10q deletion syndrome” [DOID:0060390] and “chromosome 15q11.2 deletion syndrome” [DOID:0060393].

Finally, we found 246 cases of unmapped intermediary concepts (located between a mapped ancestor and a mapped descendant). 58 are intermediary “grouper” concepts in DO with all of its parents and children mapped to some SNOMED CT concept. 50 of these concepts sit between a single mapped parent and child. An example is “multifocal dystonia” [DOID:0050837]. This concept is unmapped to SNOMED CT, while its parent, “dystonia” [DOID:543], and child, “hemidystonia” [DOID:0050846], are mapped to SNOMED CT.

</tbody>
</table>

*Differentiae.* We examined all 2207 unmapped concepts that are isolated leaf or in subtrees, which represent the majority (90%) of the 2453 unmapped concepts, and analyzed how they differed from their parent concept(s). The most frequent differentiae, listed in Table 1 along with examples, include morphology (for cancers and neoplasms), specific subtypes (for rare genetic disorders), and anatomical subtypes. Of note, about a third of the unmapped concepts have more than one differentia. Typically these concepts have more than one parent. For example, “urethra adenocarcinoma” is a child of both “adenocarcinoma” (anatomical differentia) and “urethra cancer” (morphology differentia).

Comparing hierarchical organization between DO and SNOMED CT

We found 4233 direct parent-child pairs among the mapped DO concepts and 5772 among the mapped SNOMED CT concepts. After classifying each pair of hierarchically related concepts into the four patterns of hierarchical relations across ontologies presented earlier, we established the distribution of patterns shown in Table 2.

As mentioned earlier, in a given pair of hierarchically related concepts, each concept can be mapped to more than one concepts. Therefore, a pair of hierarchically related concepts can exhibit more than one pattern. To simplify the analysis, we distinguish between patterns indicative of semantic consistency (a and b) and patterns indicative of semantic inconsistency (c and d). Only about 30% of the hierarchical relations in DO and SNOMED CT are semantically consistent between the two ontologies (a/b only). The other hierarchical relations are either completely (c/d only) or partially inconsistent (a/b and c/d). This analysis reveals critical differences in hierarchical organization and concept orientation (i.e., whether two concepts correspond to the same entity) in the two ontologies.

Table 2- Characterization of the mapped parent-child concepts in comparison to the relation between their corresponding mapped concepts. The types are illustrated in Figure 2 above.

<table>
<thead>
<tr>
<th>Mapping direction</th>
<th>Type (a) or (b) only</th>
<th>Type (c) or (d) only</th>
<th>(a or b) &amp; (c or d)</th>
<th>Total pairs</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO to SNCT</td>
<td>1198 [28%]</td>
<td>1075 [25%]</td>
<td>1978 [48%]</td>
<td>4233</td>
</tr>
<tr>
<td>SNCT to DO</td>
<td>1842 [32%]</td>
<td>2792 [48%]</td>
<td>1138 [20%]</td>
<td>5772</td>
</tr>
</tbody>
</table>

Here are examples of relations for patterns. (The arrow, \(\rightarrow\), represents the “child of” relation).

- For the DO relation “peliosis hepatis” [DOID:914] \(\rightarrow\) “hepatic vascular disease” [DOID:272], there is a direct corresponding relation in SNOMED CT, “Peliosis hepa- tis (disorder)” [SCTID:58008004] \(\rightarrow\) “Vascular disorder of liver (disorder)” [SCTID:235878005]. The two ontologies are perfectly aligned in this case.

- For the DO relation “diphtheritic cystitis” [DOID:13306] \(\rightarrow\) “cystitis” [DOID:1679], there is an indirect corre- sponding relation in SNOMED CT, “Diphtheritic cystitis (disorder)” [SCTID:48278001] \(\rightarrow\) “Bacterial cystitis (disorder)” \(\rightarrow\) “Infective cystitis (disorder)” \(\rightarrow\) “Cystitis (disorder)” [SCTID:38822007]. The two ontologies are semantically consistent, but SNOMED CT is finer-grained in this case as its two intermediary concepts are missing from DO.
• For the DO relation “portal hypertension” [DOID:10762] → “hepatic vascular disease” [DOID:272], there is no corresponding hierarchical relation in SNOMED CT between these two concepts. Instead, “Portal hypertension (disorder)” [SCTID:34742003] and “Vascular disorder of liver (disorder)” [SCTID:235878005] are in different parts of the “disorder of abdomen” hierarchy. In this case, the two ontologies are inconsistent.

Discussion

Pre- vs. post-coordination

Most biomedical terminologies, including DO, only consider pre-coordinated concepts. In other words, there is no built-in mechanism in DO to combine existing concepts to derive new concepts. As a result, only existing, pre-coordinated concepts are available to applications (e.g., for annotation purposes). In contrast, SNOMED CT supports post-coordination through a compositional grammar [10], which reflects semantic constraints expressed in the SNOMED CT concept model [11]. For this reason, SNOMED CT tends to adopt a parsimonious approach to pre-coordination, i.e., avoid pre-coordinating what can be expressed through post-coordination.

As shown in Table 1, the combination of differentiae morphology and anatomic site is the single most frequent combination. While pre-coordinated concepts are generally easier to use, the proliferation of pre-coordinated concepts may add unnecessary to the terminology.

Resolving multiple mappings

The mappings (cross-references) to SNOMED CT provided by DO frequently involve multiple SNOMED CT concepts (many mappings). Even after filtering out semantically inconsistent mappings (e.g., mapping of a disorder to a morphology concept), many multiple mappings remain.

In fact, in our reference mapping, 1384 (42%) of the 3334 DO concepts with mapping to SNOMED CT have multiple (semantically consistent) mappings to SNOMED CT. Of these, there are 110 concepts with a mapping to both a “Disease” concept and a “Clinical Findings” concept. In such cases, the “Disease” concept could be given precedence. The remaining 1274 DO concepts have multiple mappings within the same hierarchy. In this case, the structural analysis we performed can help guide the mapping. Mappings involved in semantically consistent patterns of hierarchical relations (namely type a and b) could be given precedence.

Conclusion

Overall, 4478 (65%) of the 6931 DO concepts are mapped to SNOMED CT. The cancer and neoplasm subtypes of DO account for many of the unmapped concepts. The most frequent differentiae include morphology (for cancers and neoplasms), specific subtypes (for rare genetic disorders), and anatomical subtypes. Unmapped concepts usually form subtypes, and less often correspond to isolated leaf concepts or isolated intermediary concepts. This detailed analysis of the gaps in coverage and structural differences between DO and SNOMED CT contributes to the interoperability between these two ontologies and will guide further validation.

Abstract

Psychiatry aims at detecting symptoms, providing diagnoses and treating mental disorders. We developed ONTOPSYCHIA, an ontology for psychiatry in three modules: social and environmental factors of mental disorders, mental disorders, and treatments. The use of ONTOPSYCHIA, associated with dedicated tools, will facilitate semantic research in Patient Discharge Summaries (PDS). To develop the first module of the ontology we propose a PDS text analysis in order to explicit psychiatry concepts. We decided to set aside classifications during the construction of the module, to focus only on the information contained in PDS (bottom-up approach) and to return to domain classifications solely for the enrichment phase (top-down approach). Then, we focused our work on the development of the LOVMI methodology (Les Ontologies Validées par Méthode Interactive - Ontologies Validated by Interactive Method), which aims to provide a methodological framework to validate the structure and the semantic of an ontology.

Keywords:
Ontology; Psychiatry; Social Factors

Introduction

The descriptions of cases with mental disorders are various, heterogeneous and encompass many aspects of personal history, family history and many facets of dysfunctions and subjective symptoms. The large amount of information available in psychiatry stresses the need to improve our ability to detect, quantify the behavior and model the symptoms or dysfunctions associated with psychiatric disorders. Tackling the challenge of modeling information is one field of knowledge engineering. Ontologies are created for many purposes, including semantic researches, data retrieval and formal reasoning. The validation of the modeling is an important step in the process of ontology development. This step ensures the adequacy of the ontology and reduces maintenance costs.

We propose ONTOPSYCHIA, an ontology for psychiatry, divided into three modules: social and environmental factors of mental disorders, mental disorders and treatments. The use of ONTOPSYCHIA, associated with dedicated tools, will allow to perform semantic research in Patient Discharge Summaries (PDS), to represent co-morbidity, to index PDS for the constitution of cohorts, and to identify resistant patient profiles. We assume that this approach can help reach a consensus on descriptive categories of mental disorders as well as a model to correlate social context, event and mental health. As part of this work, we developed a method for structural and semantic validation of ontologies. This method, LOVMI, relies on existing tools and an interactive approach with the experts of the modeled domain. In this paper, we present the development process of the module on social and environmental factors of mental disorders, and its validation with LOVMI methodology.

We conducted a first review of the literature in the domain of classifications and ontologies in psychiatry. We found that reference classifications in psychiatry (such as the ICD, the DSM or the RDoC project) are barely used in knowledge modeling. Furthermore, ontologies that model these classifications, such as the Mental Disease Ontology to describe and categorize mental disorders \cite{1,2}, are usually not available. As regards these, and ontologies dealing with social issues such as SNOMED, much remains un tapped in the field of mental illness. Therefore, we note a gap in the formal representation of psychiatric disorders and social factors impacting these diseases. The second part of our literature review confronted us with problems linked to ontology validation. Overall, the developed methods do not deal with all aspects of validation. Most of them only address the structural validation or the semantic validation. Finally, few offer easy-to-implement and semi-automatic solutions.

Methods

The distinctive features of our project have to do with the choice to model the environmental and social factors that can affect the patient’s life and the choice of a modular approach. We chose a modular approach to deal with the amount of knowledge available in psychiatry. Each concept of ONTOPSYCHIA is denoted both by a preferred label in English and in French, and by alternative labels (synonymous terms, acronyms). The labels come from the list of extracted terms and from nomenclatures (DSM, ICD and SNOMED). To develop our ontology we followed the generic methodology illustrated by Charlet et al. \cite{2} that combines a top-down and a bottom-up approach. This method allows access to terms that represent concepts in use. During the construction of the ontology, we focused only on information contained in PDS (top-down approach). Indeed, classifications modelling social or environmental factors as the SNOMED 3.5FR make some associations of terms that did not satisfy our expectations (e.g. “mendiant” (~ beggar) and “fainéant” (~ lazy person) are synonyms). We returned to domain classifications only to enrich our ontology (bottom-up approach).
Material

The corpus used in our work is composed of nearly 8,000 PDS, which represents a volume of around 5,804,000 words. These PDS are from the university hospital department of therapeutic and mental health of Sainte-Anne Hospital, the biggest psychiatric hospital in Paris. These PDS are semi standardized, in Word format and not anonymous. They cover a ten-year period. For several years, the diagnostic is provided at the end of the PDS with the CIM 10 code.

Terms extraction

We extracted specialized terms of our corpus with the term extractor YATEA, a tool used for identifying groups of words that can correspond to specialized terms in a text [3]. However, YATEA requires an input of corpus segmented in words and sentences tag with part of speech information using the annotator TREETAGGER. Unfortunately, the annotator TREETAGGER gave poor results for French: many words were not recognized and annotated as such. The rest of the treatments was impacted by this incorrect annotation. Therefore, we opted for the annotator MELT that offered a better annotation rate on our specialized corpus. Then, we developed a TREETAGGER converter for both format and tag in order to be able to use the corpus annotated by MELT with YATEA.

Domain conceptualization

To conceptualize the domain from the list of extracted terms previously, we followed recommendations of METHONTOLOGY [5]. Firstly, we built a glossary of validated terms into concepts with their definition(s) and all lexical equivalent(s) in natural language. Secondly, we built all subsumption relations, the taxonomy. Finally, we built relations between concepts. Throughout the development of the taxonomy, we considered the semantic commitment from Bachimont et al. [6]. This commitment involved the differential principle. This principle enables us to determine the significance of a concept according to its position in the tree (subsumption relation), by similarities and differences with neighbors (parents and siblings). It implies that no concept of an ontology can have two parents. The last step of the conceptualization is about ontology enrichment. This enrichment can be realized by alignment with other resources or by integration of new concepts from other resources.

LOVMI validation of the model: Ontology Validation with an Interactive Method

The method of validation is based on the criteria defined by Poveda-Villalón et al. [7]: human understanding, logical consistency, modeling issues, ontology language specification, real world representation and integration in semantic applications. They were established following a sound field study. Our method used a series of existing tools to validate the structure of the ontology. Interactive interviews with domain specialists were conducted to validate the semantic. LOVMI validation is performed in six steps: validation (1) of consistency, (2) of other structural aspects, (3) of labels, (4) of choices of label and (5) of semantic with experts and (6) of semantic in an application. These steps are neither linear nor cyclic. They may be carried out independently, in whole or in part. The user can skip a step to come back to it later.

Results

Material

In order to use our corpus, we had to anonymize the PDS. We used Medina [8] software (which has been developed following the HIPPPAA law). We anonymized seven ID including first and last name of patients, practitioners, and all persons quoted in the PDS, social number, address, date, names of hospital and phone number. This step has been made semi automatically. Medina helped us to annotate the named entities, but we had to check the validity of these annotations. Then we automatically removed all named entities annotated with Medina. All PDS have been checked by hand by authorized persons from the clinical department. This work required the equivalent of one person working full-time for a month.

Terms extraction

We extracted exactly 198,615 words. We removed all terms under a frequency of four in the corpus. Consequently, we dealt with an exhaustive list of 27,744 terms related to the psychiatry domain, to validate by hand. In this list, we removed numeral expressions, drug names, disorders and symptoms, leaving only concepts about social life or environmental events. One person, not specialized in the psychiatry domain, performed this task. This also explains the importance we gave to the validation of the modeling.

Domain conceptualization

Following METHONTOLOGY’s recommendations, we first validated a list of concepts from our 27,744 terms related to the field of social and environmental factors of mental disorders. At this stage, we validated about 1,100 terms into concepts with their definitions and lexical equivalent(s) in natural language. Secondly, we started to develop the taxonomy. We divided the modeled domain in four major classes that never changed despite adjustments within these four classes: (1) Attribute – adjectives describing more precisely the concepts; (2) Concept of social life – concepts to organize all concepts extracted from the corpus and dealing with social aspects (e.g. education, social situation or civil situation); (3) Human being – to represent all human entities; and (4) Groups – to formalize the primary considered group, such as company, institution, service or clinic. Thirdly, we built relations between concepts. This taxonomy of relations evolved a lot from the first version of our ontology. At the beginning of the development, we had 12 relations only, whereas now we can count 199 relations between concepts.

Table 1 provides the concept number in each of the four major classes. The class “Concept about social life” is the main topic of the conceptualized domain (the social and environmental factors), and, consequently, it is the one containing more concepts. In addition, we can notice that the concepts under “human being” are highly connected. That can be explained by connections between individuals: 111 object properties are only describing relations between family members. Among these family members relations around 33 are connected with concepts about social life and others are connected with other human beings who are not family members (such as friends or boyfriends). We do not present the class reserved to attributes, as it is only a list of adjectives.
In table 2, we notice that the subclass number is higher than the class number. This means that around 250 concepts possess two parents or more (only “Human Being” can have more than one parent, for example an “adoptive sister” is an “adoptive sibling” plus a “female individual” plus a “sister”). This does not conform to the differential principle. Basically, two types of explanations can be given to this remark: (1) the Family Health History Ontology (FHHO) which enriches the “Human Being” section contains more than 150 concepts with two parents; (2) some concepts of the ontology needed to be represented by two concepts. Our goal is to use this ontology in an annotation system. Consequently, it was easier, whenever possible, to model concepts with two parents rather than with a logical restriction.

Table 2 – Social and environmental factors module metrics

<table>
<thead>

</thead>
<tbody>
<tr>
<td>1478</td>
<td>199</td>
<td>11</td>
</tr>
</tbody>
</table>

Table 2 – Some statistics on the social and environmental factors module. The classes numbers include the two parents concepts.

Finally, we tried to align our model with the SNOMED-3.5 version française (French version). However, we quickly needed to move away from this modeling. Indeed, we identified some associations of terms that did not satisfy our expectations: for example mendiant (beggar) and fainéant (lazy person) are considered synonyms. Consequently, the module finally contains only 93 concepts aligned on the SNOMED-3.5VF. We decided to wait for an official French version of the SNOMED CT before trying a new alignment with our ontology. In order to enrich our model, we included the FHHO [9] that conceptualizes (1) members of family and relations between them, (2) and health states with diagnosis. Even though we were not interested in the second part of FHHO, we took all classes modeling family members. However, we re-organized them to match our modeling choices. In FHHO, all members are defined under a structuring concept (e.g. “Adopted Cousin” is an “Adopted Kin Relation”). In order to avoid the hierarchical system, we modified all structuring concepts into individual concepts (e.g. “Adopted Kin Relation” is in ONTOPSYCHIA the concept “Adaptive Individual”).

LOVMI validation of the model: Ontology Validation with an Interactive Method

In order to test our validation method, we used LOVMI to validate our module on social and environmental factors of mental disorders. We followed each step one by one.

Step 1 – Consistency validation

During the development of the ontology, we used HERMIT reasoner to regularly check the consistency of our model.

Step 2 - Validation of other structural aspects

Once the conceptualization ended, we used the on-line tool OOPS [7] to check human understanding, modeling problems and specification ontology language. We found several mistakes such as: two cases of the pitfall “creating unconnected ontology elements”; two cases of the pitfall “defining wrong inverse relationships”; 153 cases of the pitfall “missing domain or range in properties”; or the pitfall “using different naming conventions in the ontology” concerning the entire ontology.

Step 3 – Label validation

Then, we used SPARQL query language to check that all concepts had one unique preferred label in English and one unique preferred label in French. We counted three missing preferred label in French and 186 missing preferred label in English. This gap in English can be explained by a significant number of legal and educational concepts that cannot be translated in English. These concepts cover the French law or the French education system and not an international system that could be equivalent for everyone. Yet, to be consistent with our modeling choices, we decided to provide a lexical translation (so a preferred label in English) to a maximum of them. When it was absolutely not possible to find an appropriate lexical translation, we gave them the preferred label “No Equal Word”. On this day, we count 38 of these concepts.

During the validation of labels, we also found a total of about ten English preferred labels and two French preferred labels that were not single. Finally, we counted around 35 similar lexical preferred labels, which were not similar as language tag. For example, “discrimination” is the same lexical unit both in French and English, so it was appearing twice, once with the English tag and once with French tag.

Step 4 - Validation of the choice of labels

Once all these steps were completed, we only had to check whether our labeling choices were correct. We used the method from Aimé and Charlet [10]. Following this method, we found out that for 76 concepts (about 5% of the concepts) we had to change their preferred label according to the usage of this concept in the corpus. For example, some acronyms are more common than their developed form such as SAMU for “service d’aide médicale urgente” (“emergency service”), or some synonyms such as “emploi” (“job”) for “travail” (“work”).

Step 5 - Validation of semantic in interaction with experts

We implemented an interactive validation method in order to foster a common understanding of the ontology. This method is based on communication between domain players and ontologists who participated in the development of ONTOPSYCHIA. To involve the domain players, we reported on our project through meetings, presentation tools or presentation on the project impact assessment. Simultaneously, we made our ontology available for domain players via WEBPROTEGE. Each player could visualize the conceptual taxonomy of the ontology (including axioms and relationships). Then, we asked them to meet in small groups to...
enable active discussions on the modeling. In case of disagreement, the domain players were invited to raise their concerns and formulate solutions.

Validation sessions were held in groups of two (a clinical psychologist and a psychiatrist) and lasted about two hours. Each player had his own computer and therefore access to the ontology on WEBPROTEGE. Each group had to work to interact on the same concepts to initiate discussions and debates. The conversations were recorded to allow the ontologist to keep a record of all interviews. Players were invited to comment on free text on WEBPROTEGE, as a summary of the points raised during discussions on a concept or on a branch of concepts. This contributed to the interactions between the actors. Those not present during the validation session had access to discussions, could provide answers or participate. Once these recommendations were set, the ontologist did not provide further guidance to the actors. He interacted only with them to explicit modeling choices found ambiguous by the actors. For example, the concept “education” could refer to “public education” or “parenting education”, in such case it is important to verbally disambiguate the concept definition (even if this definition is already included in the ontology.)

To validate all modules on environmental and social factors that can affect the patient’s life, we organized four validation sessions. Each session was conducted by the ontologist who developed the model and by two practitioners (a clinical psychologist and a psychiatrist). It allowed us to validate the tree, but not the resulting conceptual relationships. We calculated that we can validate in average 164 concepts per hour. However, each concept or branch of concepts does not require the same validation time. In our modeling, we found that the concepts fall into two categories according to the denoted degree of subjectivity. The more subjective a concept is, the longer is the validation. The time specified here is based on recordings from the first group of the first validation phase.

The concepts not subject to interpretation concern the branches that model objective formal concepts, with little latitude for interpretation. For example, we can mention the concepts modeling “school education” as “educational establishment” or “schooling”. We counted 124 of these concepts for the first validation phase. They were validated very quickly, without asking questions. In total, we recorded 43 seconds of oral communication time and five written comments on all of these concepts.

The concepts subject to definition, contextual or personal interpretation concern the objective concepts, but subject to a personal, contextual or definitional interpretation. We have for example to define with domain players whether a “companion” is perceived differently from a “husband”, and therefore used differently in the domain language; or whether the term “intimate relationship” means in the context of the domain a “very close emotional relationship between two individuals” or a “sexual relation”. We counted 97 of these concepts validated in around 40 minutes, so we estimated an average validation time for definitional and contextual interpretation. Finally, the meaning of certain concepts can be perceived very differently from one individual to another. These concepts have led to deep conversations to reach a consensus around the modeling. Specifically, the concepts related to personal events such as “a dismissal” can be perceived negatively or positively (e.g. as relief, in the case of a person suffering from burn-out). We counted 13 of these concepts subject to personal interpretation in the first validation phase. Each of these concepts generated about 15 minutes of discussion and seven reviews.

We can draw several conclusions from these validation sessions. In these four groups, no dominant appeared; everyone was speaking from his own experience and professional skills. The full view of the conceptual hierarchy helped players to understand the meaning of concepts and their level of relevance in the ontology. This enabled them to understand the modeling strategies. In some cases, it also helped the players to validate entire branches of concepts. This allowed a considerable time saving. Finally, viewing the axioms that define the classes enabled players to identify gaps (e.g. for the ontologist, the concepts “home” and “accommodation” are residential places, as for the leaders it was essential to add the definition of the type of housing as “collective” or “individual”).

Step 6 - Validation in semantic application

The last step of the validation process consists of using the ontology in a dedicated application. In order to identify patient profiles, we need to annotate our corpus with concepts modeled in ONTOPSYCHIA. To that end, we designed a prototype of an annotation system to automatically find concepts in our corpus. We developed our system with UNITEX/GRAMLAB, “an open source, cross-platform, multilingual, lexicon and grammar based corpora processing suite. UNITEX is a corpora-processing system based on automata-oriented technology. With this tool, you can handle electronic resources such as electronic dictionaries and grammars and apply them. You can work at the levels of morphology, lexicon and syntax”.

We tested our system with a sample of 20 PDS with a total of around 15,270 words. Firstly, we envisaged the corpus annotation by hand, followed by a comparison of the system’s results. However, we encountered difficulties in identifying social concepts when reading PDS, and only one person was available for this work. Consequently, we decided to change our method and we first annotated the PDS with the system. Then, the only corrector considered whether the annotations were correct and identified the missing annotations.

In table 3, the number of 724 total annotated concepts includes 706 annotated preferred labels, and, consequently, 18 annotated alternative labels. This result confirms again that our choice of preferred labels was relevant. Indeed, only a few alternative labels have been annotated. We also count 401 annotated concepts of the social branch, 238 annotated concepts of the human being branch and 67 annotated concepts of the group branch. Then, we observe a good rate concerning precision and recall. Specifically, we have 18.1% of missing annotations and 16.2% of annotations performed that are incorrect. However, we observe that the incorrect annotations are not caused by a poor labeling choice, but rather by faulty analysis of the context of appearance of the concept. For example, the concept “trouble” never appears alone in PDS and yet the system allowed its annotation without context (e.g. trouble are always defined according to what is troubled: “attention trouble”). Therefore, this type of error indicates a mistake of the annotation system itself and not a mistake in the modeling of the domain. Amidst the missing annotations, we can infer from the testing on annotation that it allows the lexical and conceptual enrichment of our ontology. Consequently, it could be possible to consider the annotation system as a tool to enrich ontologies.
Although the experts were not easily available for validation, their involvement during the interviews was very useful and productive. Indeed, they were involved and interested in the project as well as in the task they were requested to perform. Conversely, when they were asked to proceed with the same validation assignment alone, without interaction with the ontologist nor with their colleagues, they did not show the same level of involvement.

**Discussion**

In our literature review about ontology validation, we found that all methods could be divided into methods to validate the structure and methods to validate the semantic. We aimed to define a method crossing these two challenges to have an end-to-end method. The most complex and time-consuming task of validation is the semantic validation by players of the domain, actors or experts. We found a solution using collaborative tools by organizing sessions of validation to involve them in the validation process. Eventually, the hardest challenge is less the interest of experts for the validation than the availability of experts. We also spotlighted the importance of a testing phase in an application to validate the ontology adequacy, as well as to enrich the model.

The major observation from this study is the absolute necessity of domain players/experts’ involvement. The domain players and experts are the owners of the academic and practical knowledge of their domain of expertise. For this reason, they cannot be replaced by automatic algorithms. Additionally, we recommend that, before planning ahead a modeling project, we make sure that the experts would be able to invest themselves in the project and allocate sufficient time to the related activities. The most challenging task we encountered was to involve the concerned experts, follow up on the time allocated to validate the ontology and increase their awareness regarding the time necessary to reach the quality they need in the targeted ontology. Therefore, establishing method based on interactions between the experts and the ontologist is essential and certainly save time and eases the process. After we set up the LOVMI methodology, we organized four validation sessions with six different players and took about three hours per player.

**Conclusions**

In this paper, we presented the development of a specific module related to social and environmental factors of mental disorders within ONTOPSYCHIA, the psychiatry ontology, and we mainly focused on the end-to-end validation methodology. First, we used a bottom up approach, extracting specialized terms from our corpus composed of Sainte Anne Hospital PDS. This first phase was concluded by the conceptualization of specialized terms into a domain ontology following the key aspects of METHONTOLOGY. During the second phase, we focused our work on the development of an end-to-end validation methodology. We established the LOVMI method, providing a methodological framework to validate the structure and the semantics of any domain ontology.

This work confirmed the overarching aim of ONTOPSYCHIA, that is to associate it with dedicated tools in order to: (1) perform semantic research in Patient Discharge Summaries (PDS), (2) represent the comorbidity, (3) index PDS for the constitution of cohorts and (4) identify resistant patients’ profiles. We also postulate that this approach can help reach a consensus on descriptive categories of mental disorders.

We will add two modules to complete ONTOPSYCHIA: a module about mental disorders and a module about treatments. To develop the module about mental disorders, we chose a top down approach to ensure the alignment between current classifications. We aligned the DSM IV and the CIM 10 on the DSM V classification. We still have to validate this module following the LOVMI methodology. Regarding the development of module about treatments, we used a semi-automatic method, by extracting medication from an official list of marketing authorization. When these last modules will be built, we plan to assemble the three modules under the upper level ontology Basic Formal Ontology (BFO).

Abstract

Cultivated by the Patient-Centered Outcomes Research Network (PCORnet), thirteen regional clinical data research networks (CDRNs) are taking shape across the U.S. The PCORnet common data model was carefully planned, and the data marts assembled by the more than 80 data-contributing institutions (nodes) are undergoing, in 2016-2017, a series of data characterization cycles. PCORnet will adjudicate each node’s—and thereby, in a significant way, each CDRN’s—readiness or unreadiness for multi-institution research. Certifying each node’s quality and fidelity is of course essential. But in understanding network readiness there is an additional, vital dimension—one that has received too little attention. It is the development of knowledge about the nature of a CDRN’s data, in its federated sense. With visualizations, how might one grasp the meta-data of a CDRN? We outline an approach that builds upon the HealthLNK Data Repository, a forerunner to the Chicago Area Patient-Centered Outcomes Research Network (CAPriCORN) CDRN.

Patient Outcome Assessment; Metadata; Electronic Health Records.

Introduction

Cultivated by the Patient-Centered Outcomes Research Network (PCORnet), thirteen regional clinical data research networks (CDRNs) are taking shape across the U.S [1-3].

PCORnet is part of the Patient Centered Outcomes Research Institute, which was authorized by the Patient Protection and Affordable Care Act of 2010. The PCORnet common data model was carefully planned, and the data marts assembled by the more than 80 data-contributing institutions (nodes) are undergoing, in 2016-2017, a series of data characterization cycles. PCORnet will adjudicate each node’s—and thereby, in a significant way, each CDRN’s—readiness or unreadiness for multi-institution research. Certifying each node’s quality and fidelity is of course essential. But in understanding network readiness there is an additional, vital dimension—one that has received too little attention. It is the development of knowledge about the nature of a CDRN’s data, in its federated sense. With visualizations, how might one grasp the meta-data of a CDRN? We outline an approach that builds upon the HealthLNK Data Repository [4-6], a forerunner to the Chicago Area Patient-Centered Outcomes Research Network (CAPriCORN) CDRN [7,8].

The HealthLNK Data Repository is a de-identified assembly of electronic health records (EHR) of adults 18-89 years old, from seven Chicago health care institutions: five large academic medical centers, one large county health care system, and a network of community health centers. HealthLNK also created a software application to merge and de-duplicate the patient identifiers across the institutions [4]. Data from the seven institutions are thereby woven together at the individual level via de-identified hashing. While the repository is maintained in a centralized system, housed in an enterprise data warehouse behind a secure firewall at Northwestern University, HealthLNK is a shared resource, to provide insight on the health of the Chicago community, and to identify opportunities to improve care. As a new repository it has proved efficient in providing data for studies of patterns of care among patients with these diverse conditions: diabetic ketoacidosis [6], diabetic retinopathy [9], gastrointestinal endoscopic procedures [10], systemic lupus erythematosus [12], and non-emergent conditions in the emergency department [12].

HealthLNK was designed by many of the same Chicago institutions that subsequently developed CAPriCORN, which is one of the thirteen PCORnet CDRNs. CAPriCORN includes the seven HealthLNK institutions plus four more. The hashing-and-matching software that HealthLNK developed for merging, de-duplicating, and de-identifying patient identifiers across the institutions has been adopted by CAPriCORN and some other CDRNs in PCORnet. For all of these reasons HealthLNK provides an opportunity to describe a CDRN at a federated level. How does one go about exploring a federated repository’s strengths and weaknesses, and building its meta-data? The purpose of this activity is not to test a hypothesis but rather to build pre-research knowledge. It may help investigators shape hypotheses and methods. It also may guide decisions about future sponsored opportunities to pursue.

Here we provide an overview of HealthLNK (as reflective of a nascent CDRN) from various angles:

- Contributions and interdigitations by datatype:
  - Demographics
  - Diagnoses
  - Procedures
  - Laboratory results
  - Vital signs
  - Medications
- Overlap between the institutions’ populations
- Emergency, inpatient, and outpatient encounters
- Subpopulations based on particular health conditions, or number of institutions visited
- Mortality
- Geographic scope

Methods

Retrospective data from 2006 to 2012 were available in the HealthLNK data repository. We used SQL queries to intersect the six principal data tables: demographics, diagnoses, procedures, laboratory results, vital signs, and medications.
For this Venn diagram we report the number of patients in the six-way and five-way intersections, and the single data type zones. We also determined in which institution(s) each patient had at least one diagnosis record. These diagnosis data are the substrate for a six-set Venn diagram, and some smaller diagrams focused on inpatient or emergency department encounters in a set of four institutions. In the analyses of diagnosis records we excluded one institution because it had data from only two years, and because a six-way Venn diagram is easier than a seven-way version to interpret visually. The template for our six-way Venn diagram is the one authored by Jeremy Carroll, PhD (then of Hewlett-Packard) [13].

Because CDRNs may have particular value in examining those patients who sought health care in more than one institution, we described additional dimensions of some scenarios for multi (or single) institution use, per patient. We examined institutional cross-over for patients with cancer, and for those who were the victim of a stabbing or gunshot wound. We also examined, among patients who had one or more diagnosis records in two institutions, how many diagnosis records the patient had from each institution. We also calculated the mortality rate by number of institutions visited.

The geographic analysis of Cook County (Chicago and nearby suburbs) and DuPage County (additional western suburbs), Illinois reflects the density of the HealthLNK population: number of unique patients in HealthLNK in each zip code divided by the total zip code population (U.S. Census). The map was drawn using ArcGIS software (Esri, Redlands, CA). We included all seven institutions in the geographic analysis.

The geographic analysis of Cook County (Chicago and nearby suburbs) and DuPage County (additional western suburbs), Illinois reflects the density of the HealthLNK population: number of unique patients in HealthLNK in each zip code divided by the total zip code population (U.S. Census). The map was drawn using ArcGIS software (Esri, Redlands, CA). We included all seven institutions in the geographic analysis. Encounter dates in HealthLNK are provided by the data-contributing institutions as MM/YYYY. HealthLNK’s rules forbid comparison of the institutions by name.

Results

There are 3,697,707 unique patients in the 2006-2012 instance of the HealthLNK database (seven institutions). The numbers of unique patients by data type are shown in Table 1.

Based on records in the Diagnosis Table (using the six institutions with more than two years of data), the distribution of number of distinct calendar months (with an encounter) per patient is shown in Figure 1. Across the 7-year retrospective period, about half of the patients had encounters in no more than two distinct calendar months. Patients by combination of data types are depicted in Figure 2. About one-sixth of the patients have all six data types, and slightly more than one-third have five of six data types. About one-fourth have only one data type (mostly demographics or vital signs); these single-type scenarios suggested that some data were omitted by one or two institutions in the extract/transfer/load procedures; their code will be revised in the next data refresh. Figure 3 shows the number of institutions visited per patient.

Characteristics of patients by number of institutions visited are shown in Table 2. In the Diagnosis Table, we studied International Classification of Diagnosis, 9th Revision (ICD-9) codes, by number of institutions per patient. Among the small population with an encounter at all six institutions, more than 50% had an ICD-9 code for depression, and more than 40% for lack of housing. The frequencies of ICD-9 codes for drug abuse, chronic alcoholism, and suicidal ideation were also above 40%.

Figure 1 – Number of unique calendar months in which each patient had encounters (based on the Diagnosis Table)

Figure 2 – Venn diagram (with truncated edges), six data types: the one, five, and six-way intersections are shown

Figure 3 – Number of institutions visited per patient (based on the Diagnosis Table). Circles scaled by number of patients
We also examined use of multiple institutions, within three subpopulations (again using the six institutions analyzed for Figure 3). A cohort with any malignancy diagnosis (which may include some patients who were evaluated and were found not to have cancer) was defined based on the presence of any ICD-9 diagnosis code in the range 140 to 209.99. A cohort with melanoma was defined based on at least one ICD-9 diagnosis code containing 172. A cohort with melanoma was defined based on at least one ICD-9 diagnosis code containing 172. A cohort with knife or gun-shot injury was defined by this set of ICD-9 E-codes: E965, E965.0, E965.1, E965.3, E965.4, E965.5, E965.8, E965.9, E966, E970, or E974. This analysis (Figure 4) considered visits of any type, for any diagnosis, among these three cohorts. Those with any malignancy diagnosis are counted on the primary y-axis; those with melanoma or knife or gunshot injury on the secondary y-axis. Use of more than one institution was least among those with melanoma. Use of more than one institution was more common among those with knife or gun-shot injury.

![Figure 4 – N of institutions visited, among three cohorts](image)

Apart from the issue noted above wherein one institution sent its type “E” encounters with a type “I” label, the Diagnosis Table and Procedure Table records sent to HealthLNK by the participating institutions were strong (Figures 5a and 5b).

When we examined the encounter types by “E,” “I,” and “O” (emergency department, inpatient, and outpatient, respectively), we noticed that one institution, which we know has a busy emergency department, had sent no type “E” but a very large number of type “I” records. Because of this apparent data transfer error, we excluded that institution from the “EIO” analyses. We also excluded the network of community health centers (all outpatient) and the institution with two years of data. Among the other four institutions, patient characteristics by number of institutions visited is shown in Table 3.

![Figure 5 – Distribution of Diagnosis (top) and Procedure (bottom) Table records, respectively, by institution](image)
By contrast, not all of the institutions sent a full set of laboratory results. It can be helpful when visualizing a new CDRN to compare the distribution of institutions across different laboratory results. Figure 6 provides examples.

![Figure 6 - Eight laboratory results by institution (BUN: Blood Urea Nitrogen; ESR: Erythrocyte Sedimentation Rate; A1c: Hemoglobin A1c; ANA: Anti-nuclear antibody)](image)

In this way we discerned more than the fact that one institution provided only diabetes-related results. The distinctive institutional distributions of gentamicin levels and of acetaminophen levels reflects, it turns out, differences in actual care patterns (one of the hospitals in HealthLNK truly predominates in the number of patients evaluated with suspicion of acetaminophen toxicity) as well as technical (informatics) idiosyncrasies on the part of the data-supplying institutions.

The geographic distribution of the population (including all 7 institutions) in HealthLNK is illustrated in Figure 7. When we examined the patients with visits to two institutions, we found that in many cases, there existed only one (or a few) diagnosis record(s) in one of the two institution that the patient visited (Figure 8).

![Figure 7 - Zip codes in darker blue have a larger population in HealthLNK (as a proportion of U.S. Census population)](image)

More than 40% of these patients had only one or two diagnosis records in the second institution. About 33% of these patients had more than five diagnosis records in the second institution.

### Discussion

In this survey of a forerunner to a PCORnet CDRN, we illustrated several dimensions in which it may be helpful to build understanding of the meta-data. In analyses after review of Table 1, we found that not all institutions sent laboratory data. One institution sent only diabetes-related laboratory results, in preparation for a specific research project. We then further learned about nuances by laboratory test. We also conducted indepth visualizations of the quality of various data elements in several domains (data not shown), such as variation between (and within) institutions in microbiology culture laboratory results.

Not unexpectedly, Figure 1 shows that most patients in a multi-institution, outpatient and inpatient EHR database have relatively few health care encounters over the years. Venn diagrams like that in Figure 2 are useful in planning potential studies of quality-of-care metrics. The zone with all (five) other data types, except for medication data, will be important to consider when calculating metrics in which the numerator is based on the use of a particular class of medication. Not unexpectedly, Figure 3 shows that the vast majority of patients visited no more than one institution over the years. Under 3% visited more than two institutions.

Table 2 shows that those who visited a higher number of institutions visited were more likely to men, African-American, and patients with publicly-financed or self-pay health care coverage. Mortality was strongly associated with number of institutions visited between 1 and 5. There were no deaths in the small group of patients who visited 6 institutions. The latter group had a very high rate of psychiatric diagnoses, sub-stance abuse, and homelessness. Table 3 shows that among patients with at least one hospitalization during the study period, those who were hospitalized in multiple institutions over time were more likely to be men and to be African-American. The direction of these associations was the same for the number of emergency department institutions visited over the years.

Figure 4 suggests that the degree of “crossover” between institutions will have to be examined project by project, as patterns may well vary among different study cohorts. The contrasts between Figures 5a/5b and 6 suggest that additional exploration of (federated) meta-data for laboratory tests is needed.

![Figure 8 - Diagnosis records per patient in the one of the two institutions, among patients who visited two institutions](image)

The geographic distribution in Figure 7 is consistent, in general, with the locations of the HealthLNK institutions. Within the city limits, HealthLNK’s population penetrance is lowest on the northwest and southwest sides of Chicago. Those neighborhoods are served, to a substantial degree, by hospitals that are not part of HealthLNK. In this context, it is worth considering what percentage HealthLNK is, of Chicago’s overall health care plant. Based on publically available data, we calculate that the HealthLNK hospitals account for approximately 40% of the acute care adult inpatient beds in the city, and approximately 30% of the labor and delivery beds. Figure 8 suggests additional health services research...
work we may pursue in examining patients’ use of more than one institution in a CDRN.

CDRNs and other multi-institution networks vary in geographic scope, types of constituent institutions, degree of centralization of data (and, hence, meta-data), etc. Those in a city (or any locale) might ask what proportion of total hospital beds in the area are within the network. The techniques we describe in examining overlaps of data types and populations may assist other networks in understanding care patterns and the network’s relationship with its milieu. One might ask questions like: For newborns in a CDRN, to what extent does the CDRN have data on well-child visits in the ensuing years? What are the implications for child health research projects?

Networks can also build meta-data knowledge about particular data elements. In Table 2 above, we use the six categories of health insurance stored in HealthLNK. But what is the consistency and fidelity with which the institutions mapped their granular health insurance values to the six categories? We have begun comparing these mapping details and will build our meta-data knowledge to the point where we plan to offer new guidance to all networks in categorizing insurance.

The principal limitation of this project is that it is pre-research visualization rather than hypothesis driven work. Nevertheless, we think that this type of work is necessary—and needs more attention paid to it—in order to support the more specific research projects that will follow.

Conclusion

The HealthLNK project has substantially informed the work now underway in the CAPriCORN CDRN. In turn, the work in both CAPriCORN and PCORnet will help standardize and will enhance future versions of the HealthLNK repository.

Abstract
The time has come to end unproductive competitions among different types of biomedical terminology artefacts. Tools and strategies to create the foundation of a seamless environment covering clinical jargon, clinical terminologies, and classifications are necessary. Whereas language processing relies on human interface terminologies, which represent clinical jargon, their link to reference terminologies such as SNOMED CT is essential to guarantee semantic interoperability. There is also a need for interoperability between reference and aggregation terminologies. Simple mappings between nodes are not enough, because the three kinds of terminology systems represent different things: reference terminologies focus on context-free descriptions of classes of entities of a domain; aggregation terminologies contain rules that enforce the principle of single hierarchies and disjoint classes; interface terminologies represent the language used in a domain. We propose a model that aims at providing a better flow of standardized information, addressing multiple use cases in health care including clinical research, epidemiology, care management, and reimbursement.

Keywords:
Terminology as Topic; Dictionaries as Topic; Knowledge Bases

Introduction
The evolution of electronic health records has been accompanied by the development of numerous and increasingly sophisticated lexical, terminological and ontological tools and resources, supporting structured data entry and processing of unstructured narratives [1]. A major challenge is to preserve meaning from descriptions of individual subjects of care to descriptions of populations, as well as from medical care to biomedical research. Attempts to do so have often neglected the fundamental reconciliation between different genres of biomedical terminologies used for these different purposes and use cases [2]. These genres include ontologies, reference terminologies, interface terminologies, and classifications (in this paper referred to by the more general term "aggregation terminologies" [3]). The reconciliation approach in [4] proposes to address this issue in two steps, links to and from:

- Interface terminologies and reference terminologies
- Reference terminologies and aggregation terminologies.

The two-step approach is required to prevent "confusion of concepts and the words used to express those concepts" [5], which is essential in order to achieve better interoperability at a time where clinicians, documentation specialists, epidemiologists, health care administrators, payers and health service researchers increasingly require that clinical data captured at one place be processed and analysed in different application contexts.

Methods
In the following we analyse the different terminology genres (interface, reference, and aggregation terminologies) and provide arguments that justify this distinction.

Interface vocabularies
Mainstream work on terminology and ontology during the last twenty years has been guided by a normative perspective, primarily driven by the English speaking community. Apart from increasingly incorporating principles of Applied Ontology [6] into terminologies and thesauri (with the Gene Ontology [7] and SNOMED CT [8] being the most prominent examples), the labelling of the nodes in these system has mainly followed a top-down strategy, with naming conventions emphasizing maximally self-explanatory and unambiguous labels such as "Malignant tumour of thyroid gland (disorder)". However, these labels, as clearly understandable as they are, do often not represent the language used by clinicians (e.g., "Thyroid Ca").

This gap is typically filled by (human) interface terminologies [9], i.e. collections of language expressions that actually occur in medical documentation. Such interface terms are typically the building blocks of clinical narratives but also are used as text values for structured data entry. However, there are several issues with interface terms, which often make them unsuitable for labelling reference terminology content:

- Interface terms tend to be as short as possible, and therefore ambiguous out of context. Abbreviations and acronyms play a major role, e.g. "CA" may mean "calcium", "cancer", and "cholic acid".
- Interface terms have different meanings in different user groups, characterised by medical professions and medical specialties, regional dialects and geographic
names (e.g. "GWB": "general well-being", but in New York hospitals also: "George Washington Bridge").

- The meaning of interface terms may change across time, e.g., the acronym "AIDS" has been used, for a long time, for "Acquired Immunodeficiency Syndrome", although other expansions such as "Acquired Iatrogenic Death Syndrome" can be found in the literature.

As a consequence of the dynamics of clinical and scientific language, good interface terminologies require continuous maintenance. Interface terms need to be harvested from "living" language sources. They need to be set in a context, which makes their different meanings transparent, e.g. "Ureter Ca", "Ca level", instead of just "Ca". Only under these conditions, they can be reliably anchored within reference terminologies.

**Reference terminologies**

In contrast to interface terminologies, reference terminologies should provide stable and well-defined representational units (aka "concepts", "classes", "descriptors" or – confusingly – "terms"). The stability of these units relies not only on unambiguous textual labels, but also on textual definitions or scope notes, links to external standards, as well as on formal-ontological definitions usually based on Description Logics [10], typically using or referring to the OWL [11] language, like in SNOMED CT. E.g., the SNOMED CT concept Pancreatitis is defined as being logically equivalent to a disorder like in SNOMED CT. E.g., the SNOMED CT concept Pancreatitis is defined as being logically equivalent to a disorder with inflammatory morphology that is located at some pancreas structure.

Connection of reference terminologies with other terminology system must address epistemically-"infested" content [13], i.e. reference to a concept within a discourse context that expresses negation, doubt, intention or risk. Interface terminologies may include terms like "suspected leukaemia" (in some languages like German even fused in a single term, "Leukämieverdacht"). The same is found in aggregation terminologies like ICD-10 "Glaucoma suspect" (H40.0) or "Observation for suspected tuberculosis" (Z03.0). This requires that the reference terminology provides a mechanism to deal with epistemic contexts. SNOMED CT's attempt to this is the context model (the "Situation with explicit context" hierarchy branch), which, however, exhibits several weaknesses under ontological scrutiny [14]. An ontologically founded model to represent both clinical entities and information entities and to connect them with each other was proposed in SemanticHealthNet [15]. This approach used OWL expressions to describe the compositional structure of information models, all of which under the BioTopLite class "information object". The relation between information objects and clinical entities or classes thereof is done via the object property "represents".

**Aggregation terminologies**

Aggregation terminologies contain rules that enforce the principle of single hierarchies and disjoint classes. This makes them mostly suited for statistical analyses. The most important aggregation terminology is the International Classification of Diseases.

Our experience of linking reference terminologies with aggregation terminologies is based on the ICD – SNOMED CT harmonization process, including a preliminary SNOMED CT – ICD 10 mapping based on expert knowledge of both coding and medicine [16], and on extensive work on the 11th revision of ICD [17]. ICD-11 was designed on top of a multi-component architecture [18]. We here focus on the component to be released first, probably in 2018, viz. the Mortality and Morbidity Statistics [19].

Fig.1 shows the three building blocks of a terminology ecosystem constituted by clinical language resources (left), reference terminologies with or without ontological foundation (centre) and the building blocks of advanced or aggregation terminologies.

**Results**

In this section we present the results of our scrutiny of current terminology systems, propose a general typology and provide some recommendations for their further evolution.

**Lack of interface terms in reference terminologies**

The need of interface terms becomes obvious when matching terminologies with clinical narratives such as clinical notes or discharge summaries. In an experimental study on the coverage of English and Swedish SNOMED CT releases used as annotation vocabulary for a corpus created out of hybrid clinical document samples in several languages [21], a nearly equivalent rate of concept coverage (87%) contrasted with a neatly different, and generally lower coverage of terms; with 47% for Swedish compared to 68% for English. This difference is due to the fact the Swedish SNOMED CT has only one term per concept, whereas the English SNOMED CT version has more than two, on average. These results demonstrate the need for language-specific interface terminologies, and they put in question whether a simple enrichment of a clinical reference terminology with interface terms, as practiced by IHTSDO for English and Spanish is really sufficient.

**Local interface terminology efforts are needed**

We support ongoing national terminology building efforts as decentralised bottom-up activities, starting with a systematic collection of commonly used words and phrases in daily communication between patients and health professionals. For instance, an effort to build an interface terminology for German linked to SNOMED CT codes semi-automatically has already resulted in more than 1.8 million interface terms, not including short forms like acronyms and abbreviations for which methods of disambiguation and resolution are currently tested [22]. If such efforts are costly, they are more helpful for guaranteeing the use of reference terminologies and the seam-
less flow of meaningful clinical information than huge top-down reference terminology translation efforts.

It can also be useful to relate interface terminologies with thesauri like MeSH. Theseauri lack formal-ontological foundation [12], but provide precise textual definitions. Here, Pancreatitis is described by the scope note "Inflammation of the pancreas". Although such a description does not use a formal language it may support a mapping to an ontology-based reference terminology such as SNOMED CT.

General typology of terminology genres and interfaces

Based on our experience we propose the following distinction between terminology systems to integrate the three terminology blocks and the two interfaces between the blocks:

(First order) axiom-based systems – generally using description logics (DLs), which provide axioms for sub-class / super-class relations and existential restrictions (e.g. "every instance of A is located in some instance of B"). From these axioms, class hierarchies may be inferred algorithmically by DL reasoners [23]. Typically, this leads to poly-hierarchies. The semantics are that all statements are necessarily true in all possible interpretations. Such systems are open-world [10], and negation means necessarily false, i.e. false in all possible interpretations. No exceptions are allowed. All statements are first order, i.e. about all individuals in a class; statements about the classes themselves are not allowed.

Closed world systems – e.g. logic programming and database systems – have in common that their semantics is based only on what is held explicitly in the system – hence closed world. If hierarchies are present, they must be stated explicitly and cannot be inferred. False means "not provable in the closed world of the system". Therefore, new information about that world can falsify previous conclusions; exceptions may therefore be allowed. Consequently, universal subclass-superclass relations that must hold in any world cannot be inferred, because closed world statements can be proved in the closed world, they just cannot be proved universally for any world. This is typical of rule-based systems. They prescribe what to do in particular situations e.g., in languages for decision support systems. They are the foundation for mono-hierarchical aggregation terminologies and for queries on representations: Mono-hierarchical aggregation terminologies (aka statistical classifications), characterized by single hierarchies and disjoint classes, supported by a large corpus of exclusion and inclusion rules, as well as by coding guidelines, which vary between use cases (e.g. coding for reimbursement vs. coding for mortality statistics) and local contexts. Examples are ICD-9 and ICD-10, the upcoming ICD-11 linearization(s), other WHO classifications, and national catalogues (like, e.g. the German OPS procedure classification) [24].

Queries on representations – which may be used to extract information about any of the above kinds of representation artefacts – as opposed to the knowledge represented. The query languages SPARQL [25] with its specialised extension for DLs and the SNOMED CT Expression Constraint Language [26] are particularly important in medical applications for linking axiomatic systems to aggregation terminologies, because they support formalizations of the characteristic residual classes not classified under and not elsewhere classified. Examples for exclusions are the ICD-10 classes under I10-I15, characterised as "Hypertensive diseases, excluding complicating pregnancy, childbirth and the puerperium".

Knowledge Organization Systems (or "terminologies" in general) provide hierarchies based on loosely defined "broader-than" / "narrower-than" relations between terms or groupings thereof, which are first of all seen as streamlining the navigation among human language terms for which also synonymy and other semantic relations can be asserted. The most popular knowledge organization system in the field of biomedicine is the MeSH thesaurus [12] with its multiple tree structure and entry terms. In MeSH, negation has no formal meaning, nor is it built upon any explicit ontological foundation.

![Figure 2: Architecture from Fig. 1, applied to SNOMED CT and ICD-11, with one or more linearizations (e.g. the ICD-11 Mortality and Morbidity Linearization) as example of an aggregation terminology as a possible end product. The ICD-11 common ontology is a subset of SNOMED CT. Linearizations are built using language-specific labels from interface terminologies (value sets), which can also be extended by clinical language synonyms, e.g. by additional thesauri like [20]. The colours have the following meaning: Green: Axiom based systems; Pink: Closed world systems including dictionaries; Orange: knowledge organization systems; Blue: queries on representations and annotations; Red: Mono-hierarchical aggregation terminologies.](image-url)

Fig. 2 summarizes the links between three blocks of a specific terminology ecosystem, with different kinds of resources and technologies, regarding the content of SNOMED CT, a subset of it that qualifies as common ontology for ICD-11, and additional resources that secure the architectural principles of aggregation terminology linearizations.

In closed-world systems like ICD-x and other aggregation terminologies it can be asserted that something is true in the world of the representation. For instance, it is sufficient in the above example, to assert a hypertensive disease code as long as there is no evidence that the patient is pregnant or in the perinatal phase. That is, they are usually true, or true under certain conditions, but not necessarily true by definition. The latter would occur when using axiom-based systems were used for axiomatising the content of aggregation terminologies: Using logical negation for representing hypertensive disease as above would entail that any patient classified as hypertensive was not pregnant or in the perinatal phase. This kind of entailment is not intended by aggregation terminologies.

Therefore, if axiom-based systems such as SNOMED CT are to be linked to aggregation terminologies such as ICD-x, queries on representations are needed. It is the underlying axiom-based system in description logic that allows SNOMED CT to fulfil the twelve Cimino criteria for controlled vocabularies [27, 28]. By its Expression Constraint Language, SNOMED CT provides a means of formulating queries on that representation to bridge between its reference terminology and aggregation terminologies.

In the case of the link between SNOMED CT and ICD-11 Mortality and Morbidity Statistics version [19] as one of different possible end products, the ICD-11 Common Ontology...
For a component-based architecture as sketched in Fig.2: and classifications rules, we suggest the following vocabulary. Necessary truths, closed world knowledge, navigation associations, inference terminologies supporting aggregation terminologies, but also value sets that provide canonical names raise another issue, viz. imprecision. Interpreting these terms (like “Diabetes mellitus”) at face value, is not consistent with their exact meaning, such as Diabetes mellitus in patients that are not pregnant or in the perinatal phase. Shortcut concept “alignments” that firstly rely on lexical criteria and which (falsely) infer equivalence of meaning from string equivalence of identifiers, are therefore inherently imprecise.

Conclusions

A major difficulty in reconciling interface terminologies, reference terminologies (e.g., SNOMED CT) and aggregation terminologies (e.g., ICD-11) was understanding the roles of the different terminology types and how they are related to the distinctions between (i) kinds of terminological/ontological knowledge, (ii) meaning of language expressions, (iii) the things they denote, (iv) necessary truths about classes of things, and (v) use case specific interface terms, explanations and rules. Our suggested typology of representational artefacts could help prevent difficulties in specifying terminology architectures like the one underlying ICD-11. In order to ease understanding of the distinctions between statements of necessary truths, closed world knowledge, navigation associations, and classifications rules, we suggest the following vocabulary for a component-based architecture as sketched in Fig.2:

- The open world component comprising first-order necessary truths, thus constituting the ontological basis of reference and aggregation terminologies in the near future.
- The closed-world component includes rules that assure the architectural constraints of aggregation terminologies. It is the foundation of two other components:
  - Aggregation terminologies, i.e., classification systems in a broad sense, are constituted by single hierarchies for specific purposes, like statistical reporting and billing. They follow the jointly-exhaustive-mutually-exclusive rule.
  - Query libraries express the meaning of nodes of aggregation terminologies, by querying against reference terminologies.
- The knowledge organization foundations include all other kinds of supportive, more loosely specified knowledge resources including lexicons with interface terms. It provides the framework for multiple interface terminologies to be implemented as dynamic plugins for different languages and communities.

Semantic Web Service Delivery in Healthcare Based on
Functional and Non-Functional Properties

Marco Schweitzer, Thilo Gorfer, Alexander Hörbst

eHealth Research and Innovation Unit, UMIT - University for Health Sciences, Medical Informatics and Technology,
Hall in Tyrol, Austria

Abstract

In the past decades, a lot of endeavor has been made on the trans-institutional exchange of healthcare data through electronic health records (EHR) in order to obtain a lifelong, shared accessible health record of a patient. Besides basic information exchange, there is a growing need for Information and Communication Technology (ICT) to support the use of the collected health data in an individual, case-specific workflow-based manner. This paper presents the results on how workflows can be used to process data from electronic health records, following a semantic web service approach that enables automatic discovery, composition and invocation of suitable web services. Based on this solution, the user (physician) can define its needs from a domain-specific perspective, whereas the ICT-system fulfills those needs with modular web services. By involving also non-functional properties for the service selection, this approach is even more suitable for the dynamic medical domain.

Keywords:
Electronic Health Records; Semantics; Technology

Introduction

With the advent of electronic health records (EHRs) the shared trans-institutional data exchange in healthcare has led to an unprecedented amount of health data in the past decade. Today facilitating this data in a meaningful way is crucial for high quality healthcare delivery [1].

Related information and communication technology (ICT) solutions are necessary to manage this emerging data and use it for purposeful and individual diagnosis and therapy. In general, medical diagnosis and treatment follow a certain workflow, i.e. a sequence of tasks (both, IT-based and human-based) is executed by an individual or a group of healthcare professionals to obtain some business goal. With the means of business process modeling, such a workflow can be modeled graphically using business process diagrams (BPD), e.g. with the business process model and notation (BPMN). The latest version 2.0 of BPMN extended the solely graphical tool with capabilities to execute process diagrams through workflow engines. This opens new ways of integrating BPMN 2.0 with ICT, in order to improve and automate business processes. Up to 50% of everyday routine tasks for diabetes consultations belong to recurring IT-related tasks [2], e.g. finding reports, change a therapy plan or organize a referral. However, there is little experience in automating such clinical processes. These tasks could be modeled as BPD at point of care by the user (e.g. a physician) and used for automatic execution to support routine work.

Today’s EHR systems have two major limitations:

1. They solely allow access to raw data. Standards like HL7 CDA [3] are very comprehensive and new approaches like HL7 FHIR [4] allow dynamic and flexible data access but the main focus is set to raw data retrieval.

2. ICT Systems in healthcare tend to be designed in a monolithic manner, i.e. a well-designed and conceptualized problem-scope is solved by using defined, static functions with limited extensibility. Changes within the software design require reengineering the software, which is correlated to increased effort and costs. Further no individual customization of information processing (data processing functions) is permitted, though present publications highlight challenges and burden relating EHR for routine workflows [5,6].

So the design and implementation of meaningful healthcare software systems need to offer comprehensive functionality based on individual preferences and customized EHR workflows and data flows [7] on one side, and on the other side support adaption to the highly dynamic and quickly evolving medical domain by providing scalable, distributed and interoperable systems [8].

Existing research on EHR related workflows have mostly focused on clinical pathways and outline the urgent need for EHRs to comply with workflows [9]. The project OntoHealth aims at developing concepts and systems, that are able to process EHR-related workflows based on BPMN 2.0, which are executed using semantic web services. Very important and often not sufficiently considered criteria for present software systems are given through non-functional properties (NFPs). There are approaches that enhance BPMN with NFPs in order to establish quality conditions on tasks [10], but according to the knowledge of the authors, no literature could be found that try to extend EHR data processing for user defined workflows with semantic web services incorporating NFPs. In the OntoHealth project NFPs play a crucial role as they define the desired quality parameters for service selection and are used for proper service execution. Thus, besides deciding what data from an EHR is needed and how it should be processed by suitable web services, the user can select NFPs (e.g. performance, costs), which define quality constraints and certain service selection needs to adhere when executing a workflow.

This paper describes our approach of how we automatically align user defined EHR workflows represented as a sequence of tasks with semantic web services under consideration of NFPs.

1 http://www.ontohealth.org
Methods

Today prominent semantic standards like the resource description framework (RDF), the web ontology language (OWL) and SPARQL provide suitable means to use semantic technologies even in the medical domain, e.g. to structure medical knowledge like SNOMED-CT. For EHRs, semantic technologies are crucial to achieve semantic interoperability. However, the use of semantics for clinical functionality is limited.

A key technology in today's software development is the modular approach of utilizing loosely coupled web services. In so called Service Oriented Architectures (SOAs) several modular functions of a software are outsourced from its main application and processed on isolated services. Those loosely coupled and high cohesive modules are aligned to fulfill certain business needs. The web services are usually realized with standards like SOAP or the very lightweight REST standard. Beside the way of directly calling a known service (e.g. calling the service RiskCalculator provided by hospital A with parameters XYZ) it is possible to find a certain service from a service repository fulfilling one's business needs. Usually SOAs provide some kind of service broker that is responsible to register several services from different providers in such registries, where each service includes a description document or service contract (JSON or XML) that contains meta information about the preconditions, capabilities (inputs/outputs, effects) and interfaces of the service. The service broker also answers requests of the service consumers, e.g. with the information on how to call the interface of the service. The limitation here is that common web service description documents don't share any semantic description and thus are not machine readable. For this purpose, Semantic Web Services (SWS) provide the means to combine semantic technologies with web services: Each service owns a description that is enriched with semantic content, in order to automate service discovery, composition, invocation and monitoring.

In our approach we adapted the service delivery structure of WSMO (Web Service Modelling Ontology) [11]. Based on this concept we integrated our developed domain ontologies for EHR web services, containing pertinent data elements as in- and outputs, functions and NFPs for EHR data processing. The service contract is modeled using MSM (Minimal Service Model) with a slight extension for the integration of data elements and functions. Our idea was to use a direct matching based alignment of functions, inputs, outputs and NFPs from user defined tasks and available web services. We build a service delivery pipeline which covers the following web service delivery steps: discovery, composition, ranking and invocation. For our purpose we aligned those steps with the domain ontology needs and the workflow-based execution, i.e. the steps deal with functions, inputs, outputs and NFPs in a suitable way. Further parts for registration and pre-filtering were added to provide complete service delivery. Rules were defined on how to enable interaction between the steps of the pipeline process and on how to match the related requirements (functions, inputs, outputs, NFPs).

The developed service delivery process was implemented as a prototype application in order to prove the concept.

Results

Within the OntoHealth project, a workflow-based SOA platform has been conceptualized, which executes an individual, problem-based process (modeled with BPMN 2.0) by means of an automatic semantic web services composition. The overall architecture is presented [12]. In this paper, we present the precise execution flow with details on how the different modules are combined to get the related services. An overview of the steps is depicted in figure 1. A given workflow consists of known flow objects (events, activities and gateways). As defined in BPMN a task is a sub element of an activity and for our purpose contains the information about the user defined requirements. Those requirements comprise for each task inputs and outputs (data elements), a certain function and a set of NFPs. All this information is modeled using the OWL2 format and stored in a triple store, which is a special type of database that is optimized for storing semantic data in triple format (subject-predicate-object). On execution, the workflow manager platform executes the defined process model with the related workflow engine. This workflow engine is also responsible for data management, i.e. to convey the needed data in the process, and handle exceptions. The logic of this engine is realized in a basic way (gets executed as defined), which could be extended with special routing or assistance functionalities in the future. For the execution of one task, related OWL2 instances from the BPD (modeled also with an ontology representation of BPMN 2.0 [13]) are provided for the Service Delivery Platform (SDP), which is responsible to allocate and call the right service. Several steps are needed, to find the proper web service which includes web service composition, when no proper atomic service may be found. A ranking score gets calculated during the steps, which is used to find the best service for invocation. The subsequent sections describe all steps in detail that are necessary to execute one complete task within a user-defined workflow. The task therefore describes a certain user need (defined as a goal) within a workflow, while the available services are defined as the building blocks that need to be assembled in order to fulfill the user’s goal.

Figure 1 - Execution flow of an EHR workflow within the OntoHealth platform.

Step 0: Registration

Before pre-filtering, discovery, composition, ranking and invocation can take place, services need to be registered in the OntoHealth SDP. Registration is the process where the service descriptions are first generated by the service owner, according to the service contract, based on the semantic service model [14] and then stored in the triple store and managed by

---

2 Tasks and services use the same domain ontology.
the SDP. These descriptions are given in JSON-LD\(^3\) format following the structure of the service contract. Each functionality of a service is defined by in-/outputs, function type and all corresponding NFPs. By means of SPARQL queries, the service descriptions can be added, updated or deleted from the registry. This step is not part of the actual workflow execution. In OntoHealth the definition of service information is task of the related developer, vendor or service provider. OntoHealth will provide a guideline on how to properly create the service description and register the service in the platform in order to make the service available for web service discovery.

**Step 1: Pre-Filtering**

The first step in the ranking procedure is the pre-filtering process. In this step, all the services that do not match the mandatory NFPs, which are retrieved from the task description, are dropped and not considered for further analysis. This helps to emphasize the discovery for services that require e.g. certain user permissions or any regional restriction that can be obtained from the requesting user. The resulting services are then used as an input for the following step.

It is defined in the semantic model if a NFP has the status of a mandatory property or will be considered later in the ranking step to calculate the ranking score.

**Step 2: Discovery**

The goal of the discovery step is to identify the services from all available services that fit the tasks’ requirements defined by the user. The discovery of the services can be achieved based on functional classification and in- and output classification. Non-functional properties are considered in the ranking step (see Step 4).

**Matching based on functional classification**

After the pre-filtering is completed, the services have to be filtered according to the function they offer. Therefore the services are classified according to the following categories:

1. Full Match: Services in this group do match according to the function classification requested in the task and don’t receive any penalty score during the ranking process.
2. Partial Match: Services in this group do not match the function classification requested in the task, but the function belongs to the same category (defined in the semantic model) as the one specified within the task. These services receive a penalty during ranking.
3. No Match: These services do not match according to the functional classification requested from the task. They are not considered during ranking.

The reason for defining those different categories is due to the further handling of each category in the further process.

**Output Classification**

In this part the services are compared with the related task and are classified based on their functional properties for the outputs. We distinguish between five different categories of matching as illustrated in figure 2:

1. Exact match: The output data elements of the task and the ones from the service match perfectly. There are no additional data elements delivered by the service.
2. Subsumption match: The service only delivers relevant output data elements, but not all of the functional requirements specified in the task are met, hence not all needed outputs are provided.
3. Plugin match: The service delivers all output data elements specified in the workflow task, but also delivers some additional ones.
4. Intersection match: The service only delivers some output data elements but not all of the ones specified in the task. Additionally, there are also additional outputs being delivered.
5. No match: The service delivers no relevant output data elements.

![Figure 2 - Matching categories for output classification.](image)

**Input Classification**

In this part, the services are classified based only on their functional properties based on matching the inputs of the task. We distinguish between two different categories of matching: match and no match:

1. Match: The services within this group match some or all input data elements specified within the task. This group is suitable for further service delivery consideration without additional processing.
2. No match: The needed inputs specified in the task are not fulfilled by this category. The services in this group require different data elements than the ones specified in the task and are considered for composition (see step 3).

All services, that are classified as subsumption, intersection or no match in at least one of the categories are not considered directly for the ranking step, but could be used in composition (see step 3). Related SPARQL-based queries consider dependencies of the functions, inputs, outputs and NFPs related to the semantic model. As all requirements are modeled using the developed WISE-DM ontology (see [14] for more details), inference could be used to get more precise results in pre-filtering and discovery.

In order to get more possibilities and freedom in requirements provision, a composition of services can be generated where outputs of service A can be used as the inputs for service B or both outputs can be combined to fulfill all the requirements specified within the task.

**Step 3: Composition**

After the matching from the discovery step has been completed, the resulting services are classified in the categories. While all services classified as full match for functions, exact- and plugin match for output classification and match for input classification do fulfill all functional properties without further effort, some additional processing is needed to probably make use of all other classifications. This is where composition comes in: all available services are arranged in groups where the outputs of service A plus all the already obtained outputs from other services fulfill the input of service B and so on.

---

\(^3\) [http://json-ld.org/](http://json-ld.org/)
The result of this service chain must then fulfill the functional properties of the related task. A composed service can then again be part of other composed services. The complete composition algorithm uses a graph-based structure as well as modified pathfinding algorithms. However, the detailed description would go beyond the scope of this paper.

A challenging part of composition is the NFP merging process, i.e. when combining the services to a group, also their NFPs have to be combined in a way that depends on the type of NFP. For example, for NFP “availability” the combined value is the lowest value of all involved services, while for NFP “price” the combined value is the sum of all involved services. The logic of the NFP considerations needs to be developed as a special ranking service that will be part of the next steps in the project. For the present conceptualization it is seen as a black-box or as a module with defined logic that follows a hardcoded pattern.

**Step 4: Ranking**

The ranking algorithm is responsible to find the best fitting service of all registered and composed services according to their NFPs. It takes as input the set of services (atomic or composed) and generates a list of ranked services ordered by their ranking score, which is defined as a unit-less number. During the ranking phase, all atomic or previously composed services get a ranking score based on how their NFPs fit compared to the ones specified in the task. The pseudocode of the algorithm can be found in code Table 1.

The actual score is not directly calculated from the NFP information (e.g. performance indicator), but is calculated via a distinct ranking service. This service is specified in the NFPs’ ranking instructions and is called during the ranking process. The arguments for the ranking service are all instances of an NFP from the task and the corresponding ones (same class) from the service. The idea of this ranking service is to define, what criteria makes a good or a bad score for a specified NFP, e.g. a ranking service for NFP costs determines, that a service with high costs should lead to a lower score. Each ranking service reveals a number as the percentage of suitability, which is then mapped to a score value for further calculations. The range of the score value is not predefined and can be adjusted.

During the workflow creation, the physician can specify an individual NFP weight depending on how important the NFP is considered on an individual base (weight ≥ 1). An NFP adds its score multiplied by its weight to the score of the service. The function penalty score (0 < penaltyScore ≤ 1) is integrated according to the functional classification (see step 2) to reduce the score in case of a partial match. The final score defines the suitability of the service. A higher score means, that more (or in the best case, all) NFPs are fulfilled by the service and thus increases the probability of getting selected for further processing.

**Step 5: Invocation**

The final phase in the service delivery process is the actual invocation of the service, which was previously discovered, ranked and selected according to the highest ranking score. Invocation enables the actual link between the semantic description of the service, according to the service model developed in earlier stages of the project and the actual service implementation. As we support various underlying implementations of services (e.g. REST, WSDL) the invocation would need to provide a generic interface for calling a service, but also be able to perform specific interaction calls, depending on the implementation of the service. Service usage including the service calls, related results and potential interaction will be managed by the workflow manager. Those could be either used for further service calls, as a result presented to the user interface or any other process function defined within the workflow.

```

service selection example

Let’s assume the physician wants to analyze the cardiovascular risk (function) considering the data “age”, “gender”, “total cholesterol (mg/Dl)”, “HDL cholesterol (mg/Dl)” and “systolic and diastolic blood pressure (mmHg)” (inputs) with a service highly available in Austria and with minimal costs (NFPs). The output is given through a percentage score value for “10-year risk of heart disease or stroke”. All this information is specified as a task and modeled semantically using our developed ontologies. The considered task and the available and registered services are depicted in figure 3. For demonstration purposes, the amount of NFPs has been limited to Availability and Costs. Although some of the services in this example share the same functionality, they differ in other relevant properties such as in/outputs and NFPs.

Considering the risk calculation task and the available services in figure 3, Service 4 gets removed during pre-filtering, as the mandatory NFP is not supported. Service 2 does not fulfill the function, and Service 1 and 3 will be considered for the following ranking. Service 1 would relate to an exact match for output classification, Service 3 relates to a plugin match and both services are related to a match regarding the input classification. The ranking part would select Service 1 for final invocation, as the NFPs of this service lead to a better score.
(considered NFP cost of Service 1 with €8/100k calls has a better score than Service 3 with €10/100k). No composition is needed for this example.

Implementation
The service delivery platform was developed as a Java application. Based on the semantic model from past project results, the RDF model was used with Apache JENA\(^4\) to model semantic dependencies during execution. The service delivery platform was designed according to the principle of a SOA. This means every step in the delivery process was realized by a single decoupled service. The services themselves can be seen as black-boxes. They were realized using the Jersey RESTful web services framework\(^5\) and communicate using JSON-LD. A manager web service was then introduced to facilitate the use of the platform by bundling service calls to the individual components to provide functionalities like, registering a new task or invoking a service based on a task.

Discussion
The developed Service Delivery Platform project is able to use proper web services according to the business process model of the user related workflow. The workflow engine processes the tasks and allocates proper web services based on input/output data elements, functions and non-functional properties. The discovery process got extended within this approach by using semantic technologies to find related suitable services (e.g. when a data element or function shares the same parent element, the parent or related siblings could be used as well) and composition, which uses semantic enriched service descriptions to compose several services in order to get the needed result. In contrast to approaches like FHIR, which is a service-oriented approach for accessing EHR data, the service delivery platform is responsible for the user-determined functionality in the sense of how accessible EHR data should be processed to extract, use and present the needed information related to the users’ needs. The project SMART (Substitutable Medical Applications and Reusable Technologies) on FHIR\(^4\) provides a platform for medical apps, that can be integrated into EHR systems based on individual user preferences. The main difference to our approach is, that SMART does not support the automatic discovery or composition of web services nor is it including non-functional properties for service discovery in order to reach the goals defined as a workflow. The service delivery platform as part of the ongoing project OntoHealth, will be refined based on future developments and will get its final evaluation at the end, when the complete software prototype will be tested and evaluated with real world scenarios and related end-users (physicians).

Conclusion
Providing means for users to define their information retrieval needs based on functional and non-functional properties at the point of care offers new ways of efficient EHR utilization. A workflow-based EHR-access is seen as a major advantage in efficient healthcare outcomes and even in user satisfaction. The next steps in the project will cover to enhance the usage of the semantic model for leveraging the service delivery process. This means, that related semantic reasons or related logic should provide better results on matching the requirements given from the workflow to the set of available services or even use the information for more sophisticated and efficient composition.

An OMOP CDM-Based Relational Database of Clinical Research Eligibility Criteria

Yuqi Si*, Chunhua Weng*

*Department of Biomedical Informatics, Columbia University, New York, NY, USA

Abstract

Eligibility criteria are important for clinical research protocols or clinical practice guidelines for determining who qualify for studies and to whom clinical evidence is applicable, but the free-text format is not amenable for computational processing. In this paper, we described a practical method for transforming free-text clinical research eligibility criteria of Alzheimer’s clinical trials into a structured relational database compliant with standards for medical terminologies and clinical data models. We utilized a hybrid natural language processing system and a concept normalization tool to extract medical terms in clinical research eligibility criteria and represent them using the OMOP Common Data Model (CDM) v5. We created a database schema design to store syntactic relations to facilitate efficient cohort queries. We further discussed the potential of applying this method to trials on other diseases and the promise of using it to accelerate clinical research with electronic health records.

Keywords:
Clinical Research Informatics; Relational Data Management; Electronic Health Record

Introduction

Randomized controlled trials are the gold standard for medical evidence generation. Eligibility criteria (EC) are the essential elements of clinical study protocols for specifying qualification of participants but often exist as free text, which are not amenable for computer processing. They are also found to have poor comprehensibility [1]. Given the wide adoption of electronic health records (EHRs), there is a great need for improving the interoperability of EC with EHRs to better integrate clinical research and patient care towards the development of a learning health system.

Multiple methods, such as ERGO [2], for structuring EC were developed before the widespread adoption of EHRs. As a result, such representations do not interoperate well with EHRs. Levi-Fix et al. developed ElXR-CDM [3] to structure criteria using the OMOP Common Data Model v4. This system was the first of its kind to transform free-text EC into a structured format using a standardized common data model. However, with a rule-based natural language processing system, it could not deal with the complex preprocessing and the scarcity of evaluation, which limited its generalization.

In this study, we extended this method and adopted the latest OMOP data standard, OMOP CDM version 5 [4], a model that is more comprehensive and better integrated than OMOP CDM version 4 for facilitating the interoperability among disparate observational databases. To the best of our knowledge, this study is amongst the first to build a relational database of clinical trial eligibility criteria using a widely adopted EHR data standard, OMOP CDM v5. Our method helps bridge the gap between clinical trials and EHRs by enabling fast and accurate patient cohort searching for trial recruiters, protocol designers, and healthcare providers.

Method

Our method consists of the following steps: (1) criteria relational database design; (2) criteria parsing; (3) concept normalization using terminologies; (4) relation extraction; and (5) ETL (extract, transform and load) for criteria using the OMOP CDM v5. We used a hybrid machine learning-based natural language processing toolkit, CLAMP, for name entity recognition to extract medical terms in EC. We matched the extracted terms to the standardized concept identifiers in the OMOP CDM v5. Aside from the entity recognition, we also used the SVM classifier to obtain relations between entities and attributes. Finally, we built a relational database for fast querying via Django. We also provided a RESTful API for retrieving information.

Step 1: Database schema design

The EHR data standard of OMOP CDM v5 was described by the Observational Health Data Sciences and Informatics (OHDSI) community [5]. In this data model, medical terms were categorized into seven types including four entities (Condition, Observation, Drug, Procedure) and three attributes (Qualifier, Measurements, Temporal constraints). Each attribute has a close relationship with a corresponding entity. For instance, a relation of has value shows a quantitative measurement value of one entity. The four entities consist of medical terms with similar characteristics, while the three attributes differ from each other. Due to this, we decided to build an efficient schema in which the four entities could be stored into one table while the three attributes could be saved in three separate tables. The benefit of categorizing attributes in individual tables is to handle measurement and temporal constraints independently. This will prevent disarrayment with other terms in the criteria database as these two attributes are lab values or time phrases that need to be split in future work. We also used three types of relations to build the connections between entities and attributes. Given the fact that one entity has several attributes and one attribute corresponds to many entities, the relationship between entities and attributes were considered as many-to-many in the database. With this design, the relations could be saved in the database and the pattern of entities and attributes could be queried.

Step 2: Name entity recognition (NER)

To achieve precise name entity recognition, we implemented a comprehensive clinical natural language processing software, CLAMP [6], designed by Hua et al in 2015. We used annotated criteria corpus of 230 Alzheimer’s disease clinical trial provided by previous lab members [7] to train the name entity recognition model. We implemented brown-clustering, n-gram, prefix-suffix, random-indexing, sentence-pattern, word-embedding, word-shape and word regular expression as name entity recognition features with a five-fold cross validation.
Then we applied a NLP pipeline consisting of NegEx assertion, sentence detector, tokenizer, POS tagger, CRF-based NER and UMLS encoder. An example NER output is shown in Table 1.

</tr>
<tr>
<td></td>
<td></td>
<td>within the last 2 weeks</td>
<td>T0</td>
</tr>
</tbody>
</table>

**Step 3: Concept normalization**

Once we finished the name entity recognition, we mapped the extracted clinical terms into the concept standardization identifiers (CONCEPT_ID) using the open-source software, Usagi [8]. Each concept has a distinctive CONCEPT_ID, which is mapped to multiple CONCEPT_CODES across domains such as ICD9CM, SNOMED_CT, etc. With the matching, we were able to map the concepts in clinical research eligibility criteria into terminology standards. Usagi provided an algorithm to evaluate the effect of the matching by giving a score; a higher score represents better match, and a score of 1.00 is a 100% match. We manually reviewed 100 randomly chosen terms of each domain and analyzed a statistical performance of the matching score. After an assessment of the matching score, we set the matching threshold at 0.80.

**Step 4: Relation extraction**

We applied our previously developed open-source criteria parser [7] to extract relations between entities and attributes using the Support Vector Machine (SVM) classifier. The direction of each relation was defined from each entity to its corresponding attributes. This method used the basic function of LibSVM [9] with features including the class of head entity, the class of attribute, the shortest path between two terms in the dependency tree and whether or not the entity is the only one in its class in the corpus. The classifier inspected each entity-attribute pair and projected them into four classes: no relation, has value, modified by, has_temp. An example of relation extraction output is shown in Table 2. The relation between entities T4 (“liver or kidney disease”) and T3 (“clinically significant”) is “modified by”. The relation between entities T16 (“alcohol abuse or dependence”) and T15 (“current”) is “has temporal relation” or “has-temp” in short form.

**Step 5: Data storage**

In the last step, we created an efficient schema using Django [10] and loaded all the extracted entities, attributes and relations into respective tables. The most economical method of storing relations is through many-to-many relationships. In addition, we used REST architecture [11] to build an API to provide a convenient interface for users to retrieve information.

### Results

**Database Infrastructure Description**

The database is comprised of five major tables: (1) clinical trial metadata information (2) entity table (3) qualifier table (4) measurement table (5) temporal constraints table. The detailed schema and formulation of the database provided as an appendix is available at https://github.com/Yugu92/DBMS_EC.

**Descriptive Statistical Analysis**

To understand how well the name entity recognition and relation extraction performs at each step, we designed an evaluation framework by using classical classification metrics: precision, recall and F-score, which are defined below: (TP: true positive; FP: false positive; FN: false negative; TN: true negative).

**Table 3 – Definition of TP, FP, FN, TN of a NER System**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

We matched the four entities (Condition, Observation, Drug, Procedure) and the qualifier attribute to the CONCEPT_ID in OMOP CDM v5. We used the matching score to evaluate the mapping results for different domains on decreasing thresholds. Figure 3 is the descriptive statistical analysis curve of the matching score for the different domains. It’s apparent and reasonable that when the matching score threshold was decreased from 0.9 to 0.7, the false positive rate (CONCEPT_ID incorrectly matched the term) decreased, while the false negative rate (CONCEPT_ID lost the term) increased. Therefore, we set the matching score threshold to 0.80 to trade off the balance between the error and the missing.

\[
\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \quad \text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}
\]

\[
F1\text{-score} = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}}
\]

To ensure that we had an ample amount of training set for good performance on name entity recognition, we analyzed the performance of varying sizes of annotated files. Based on the learning curve shown in Figure 2, we confirmed that the training set of 230 annotated trials is sufficient to achieve good performance of name entity recognition.

Relation extraction was evaluated separately by using the gold standard relations marked in annotated texts. The performance of SVM relation classifier is shown in Table 6. We counted the number of extracted relations and the number of attributes covered by the relations. Ideally, the attributes should not exist independently, and the cover percentage should be 100%. By dividing the number of corresponding attributes (has_value & Measurement; has_temp & Temporal Constraints; modified by & Qualifier), we calculated the percentage of extracted relations from the existing relations (Perc. of Extracting in Table 6). Our method extracted 54.81% of relations in general, 79.93% of relations between qualifier and entity, and 38.24% measurement.

### Table 6 – Statistical Matching Result of Extracted Relations

<table>
<thead>
<tr>
<th>Number</th>

<td>3051</td>
<td>4507</td>
</tr>
</tbody>
</table>
We also evaluated the relation extraction performance by manually reviewing 100 randomly-selected trials and counting statistical measurements including true positive, false positive and false negative. Then, we calculated the precision and recall of the three types of relation, "modified by", "has temporal constraints" and “has value” as shown in Figure 4. The performance of relation “modified by” was the best among these three relations, while “has value” was the poorest. The performance evaluation result corresponds to the descriptive statistic matching result of extracted relations.

![Figure 4 - Evaluation of Relation Extraction](image)

**Sample Use Cases**

This database of structured, standard-based eligibility criteria enables several use cases for integrating clinical research studies and electronic health records.

We have designed a RESTful API for users to input terms and search studies with certain criteria. Our http request accepted several parameters including entity key word (entity), criteria type (c-type), temporal constraint key word (t-constrain), qualifier (qua), etc. The sample request is in following format:

```
GET {domain}?entity=##&c_type=##&t_constrain=##&qua=##
```

The response to this request is a list of clinical trials NCT identifiers that match the request.

Here we take several pair querying examples. For instance, if we are concerned about which trial has exclusion criteria involving participants with severe psychotic features within the previous three months, we are going to fetch all the available information for those specific parameters in the format ("entity": psychotic, "qualifier": severe, “criteria type”: exclusion, "temporal constraints": three + months). The complete URL for this request as it appears on the page:

```
GET/{domain}?entity=psychotic&qualifier=severe&c_type=ex&t-constrain=three+month
```

The response to this request comes with two trials NCT identifiers: NCT01822951 and NCT00911807.

Another pairing example is to look for participants who have had stable AD therapy, which often occurs as essential inclusion criteria in Alzheimer’s disease clinical studies. In this case, the parameters should consist of entity (AD) and qualifier (stable). The following list of NCT identifiers is the response to this request:

NCT00495417,NCT02051608,NCT01122329,NCT02670083, NCT02386306,NCT01954550,NCT02423122,NCT00299988.

Therefore, by using the RESTful API, healthcare providers or clinical research investigators can request relevant study criteria information from our database.

**Discussion**

We fetched 1587 trials of Alzheimer’s disease as of September 2016 from ClinicalTrial.gov [12] and captured 4453, 2360, 1930, 626, 449 unique terms of Condition, Observation, Drug, Procedure, and Qualifier respectively. We also matched extracted terms into CONCEPT_ID in OMOP CDM v5. The compression ratio of Condition, Observation, Drug, Procedure, and Qualifier were respectively 0.08, 0.10, 0.17, 0.09 and 0.02. Then we associated attributes with entities via relations including “has value”, “has temp” and “modified by” into a relational database. The relation “modified by” can be found and extracted from 79.99% of Qualifier. We justified the benefit of this method by descriptive statistical analysis and detailed user cases. We then further discussed the great potential and future application of this method in bridging the gap between EHR and EC.

**Error Analysis**

Errors of NER and relation extraction mainly resulted from wrong classified predictions. As for NER, the performance of the Procedure domain was poorer than that of other domains because the Procedure had the smallest number of instances in the training set. Since the output of NER is the input of the relation extraction, the errors in NER task will be multiplied in the relation extraction step.

Another cause of errors is the incomplete coverage of entities in the OMOP CDM v5. In other words, not all the terms existing in the criteria text have already been modeled in the OMOP CDM v5. Scarcity in the OMOP terminology dictionary is the reason why the matching score of some terms are lower than 0.50. Terms consisting of capital letters such as ACHEI, NIA-AA criteria, MI are not identified correctly. An entire list of recommended terminology that could be added to the Concept table of OMOP CDM v5 will be provided.

**Primary Contributions**

This study has made four primary novel contributions.

First, we enabled semantic search of criteria by normalizing clinical terms using standard terminologies and by mapping them to CONCEPT_IDs in OMOP CDM. In this way, terms that share one meaning were regarded as the same. For instance, in the previous search methods, the term “AV block” was not returned by the query using the term “atrioventricular block”.

In our database, these two terms are referred to one CONCEPT_ID, 316135. Users will no longer be inconvenienced by incomplete search results revolving around heterogeneous semantic representations for the same concept. Furthermore, each CONCEPT_ID has an associated clinical code such as ICD9CM, SNOMED, CT in the CONCEPT table of OMOP CDM. Users will be able to search for a specific disease by inputting its ICD9CM code.

The second primary contribution is the transformation of free-text criteria into a computable relational database compliant with an EHR common data model. The way relations were stored is a highlight of our work. For example, the many-to-many relationships in the database schema can retrieve relations between an entity and its respective attribute. Also, the clear definition and completeness of the attribute category will become a strong tool for handling pair querying, that the advanced search function provided by ClinicalTrial.gov could not achieve. For instance, if we input a combined search of several different domains such as “severe” + “Alzheimer’s Disease” + “for three years” + “inclusion”, then the search result will include all the trials with participants who have had severe Alzheimer’s disease for three years. Therefore, users can query and search the database for sophisticated logical queries, which can essentially improve the efficiency of clinical trial EC reuse.

Thirdly, the database of Alzheimer’s disease provides different audiences with an effective computer-based knowledge representation of EC. Study investigators could query in both the hospital data warehouse and the database of EC to target
eligible participants. Another use case for a trial designer is that the computable format of the criteria could help them define future study guidelines by comparing differences and commonalities of EC and study contents.

Finally, as an evidence-based clinical support method, the combination of searching the databases of EHR and EC allows healthcare providers to determine if a patient’s treatment will benefit from a particular study or decide whether the patient is eligible for a study. Essentially, EHRs can be automatically matched to computable formatted clinical trial EC in our database. We could design a pipeline for patient screening with a combination of EHRs and the database of EC.

Limitations and Future Work

Based on the work we have done, researchers could build a database with more comprehensive information from clinical trial studies. Our future work will concentrate on two areas: performance and completeness. To improve the performance of our transformation pipeline for the free-text criteria, we will need to explore methods to extract complex expressions of Temporal Constraints [13] and Measurement [14]. We plan to extract specific numerical and temporal expressions from complex attributes. For example, temporal information such as “for three months” should be extracted and stored as “three” + “month” into different columns. Measurement information like “Hemoglobin ≥ 9.0g/dL” should be extracted and stored by number and unit separately and the unit for the same test should be unified. Further collaborative research on natural language processing of free-text information is desired.

To improve the completeness, the outcomes and other sections of the trial will need to be transformed into structured output and stored into the database. We would also like to expand the method to cover the entire disease spectrum from ClinicalTrial.gov. More studies are warranted to test how this method would work for other eligibility features of other diseases. We may need to expand the database to better cover the eligibility features and elements. Additional tables may need to be added such as the Anatomic Location or Genetic Name when it comes to cancer. Furthermore, we will design a user-friendly interface to retrieve the necessary features from our database. The implementation of Django, a high-level web framework, also encourages rapid development and design that significantly reduces the workload of the back-end development. Therefore, we successfully transformed free-text EC into a computable, relational database following OMOP CDM v5. We hope that this computable format of EC can support the need of predictive analysis of targeted participants of clinical trials in the near future.

Conclusions

We contributed a practical method for transforming free-text eligibility criteria into a computable, relational database following OMOP Common Data Model (CDM) version 5. This method promises to be applicable to all disease trials in ClinicalTrial.gov and to accelerate EHR-based clinical research.

Abstract

Surgical site infections (SSIs) are the most common and costly of hospital acquired infections. An important step in reducing SSIs is accurate SSI detection, which enables measurement and quality improvement, but currently remains expensive through manual chart review. Building off of previous work for automated and semi-automated SSI detection using expert-derived “strong features” from clinical notes, we hypothesized that additional SSI phrases may be contained in clinical notes. We systematically characterized phrases and expressions associated with SSIs. While 83% of expert-derived original terms overlapped with new terms and modifiers, an additional 362 modifiers associated with both positive and negative SSI signals were identified and 62 new base observations and actions were identified. Clinical note queries with the most common base terms revealed another 49 modifiers. Clinical notes contain a wide variety of expressions describing infections occurring among surgical specialties which may provide value in improving the performance of SSI detection algorithms.

Keywords:
Surgical Wound Infection; Quality and Safety; Text-mining

Introduction

Healthcare associated infections (HAIs) are a significant problem among hospitals worldwide. Surgical site infections (SSIs) are unfortunately the most common and costly of HAIs. SSIs increase post-operative morbidity and mortality. The overall prevalence of SSIs is estimated to be 2-5% for inpatient surgical cases in the United States [1-3]. Prevalence is significantly higher in certain specialties such as colon and rectal surgery (approximately 13-15%) [4].

An SSI can be classified into three categories (i.e., superficial, deep, and organ space) according to specific definitions which include time frame following surgery. Several classification systems designate an infection event as an SSI only if the occurrence is within 30 days of the index operation. A superficial SSI involves only the skin or subcutaneous tissue and requires documentation of one or more of the following: purulent drainage from the wound, aseptically obtained wound culture with isolated organisms, opening of the wound by a physician with clinical symptoms of infection, or diagnosis by a physician [5]. A deep SSI involves the muscle or fascia and requires: purulent drainage from the deep incision, opening of the wound, positive wound culture, or spontaneous dehiscing of the wound and clinical signs or symptoms of a wound infection, or an abscess or other evidence of infection diagnosed by pathology or imaging. An organ space SSI involves the space deep to the muscle or fascia, identification of involvement in a specific organ system, and either purulent fluid from an organ space drain, an organism identified by culture, or an abscess or other evidence of infection diagnosed by pathology or imaging.

Another factor adding to the complexity of documenting SSIs is the question of a pre-existing infection. Careful documentation is required if there is an infection present at the time of surgery (PATOS). In the setting of PATOS, a post-operative infection would be excluded from being counted as an SSI if the site of infection is the same in both instances [5]. For example, if an abdominal wall abscess recurs after surgery performed for drainage of an abdominal wall abscess, this infection is not considered an SSI. However, if a patient undergoes surgery for intraabdominal abscesses from diverticulitis then develops a superficial infection of the wound, this is an SSI because the infection sites are different.

Many hospitals in the United States use the American College of Surgeons National Surgery Quality Improvement Program (NSQIP) as a quality improvement database to track post-operative complications such as SSIs. NSQIP is recognized as a national leader of post-operative complication measurement and quality improvement measures [6]. Currently, a surgical clinical reviewer who is usually a registered nurse employed by the hospital manually reviews the charts of post-operative patients and makes positive or negative SSI determinations by clinical judgement based on the SSI definition. This process results in high quality outcomes data for quality improvement and benchmarking efforts, but is prohibitively expensive for some centers [7]. Methods to automate or semi-automate SSI detection are of high interest since they may significantly reduce the burden of manual chart review and decrease the costs of quality improvement initiatives like NSQIP.

We previously developed supervised machine learning algorithms for SSI detection utilizing structured and unstructured clinical data [8]. SSI determination with our algorithms is based on a list of “strong features” identified for each type of SSI. The algorithm creates a score for each record correlating with the probability of an acquired SSI [9].

While the performance of our algorithms is good, improvements in the algorithm can be made particularly for intermediate scoring records and potentially in improving the feature set for unstructured text, which have to-date been based upon keywords and concepts derived from expert consensus (surgeons and hospital surgical clinical reviewers at our center).

We hypothesized that there may be additional signals in the form of expressions directly describing or otherwise associated with SSIs in clinical notes. The study’s objective was therefore to characterize expressions associated with SSI determinations from clinical notes in a systematic manner.
Methods

Records from surgical patients included in the University of Minnesota Medical Center’s NSQIP database were extracted from the University of Minnesota’s clinical data repository. For our initial analysis, we included patients from 2014-2015 identified as having an SSI occurrence by the NSQIP surgical clinical reviewer along with patients having a high probability score (>40) for having an SSI from our SSI detection algorithm which used the following set of “strong” text features (Table 1). In all cases, the index operation was identified and all clinical notes within the 30 day time window after the operation were reviewed including all inpatient and ambulatory notes.

</table>

In the review of each chart, one of two surgical residents (SS and EA) reviewed each post-operative note in chronological order from the index operation. All terms including those identified by experts previously within clinical notes contributory to an SSI determination were recorded along with information about misspellings, discrepancies and inaccuracies, and the associated note type containing the information. Documentation of repeated factors for an individual record was not recorded. All terms were carefully categorized into observations of the patient/patient data, actions performed by the clinical team, antibiotics, organisms, or clinical plans. These terms were also analyzed for modifiers and overall compared to the original set of terms.

Following categorization and initial analysis, we performed a validation of three “base terms” (i.e., “fluid collection”, “drainage”, and “infection”) which were the most frequent and contained the greatest number of modifiers. From this analysis, we sought to validate the associated modifiers identified from our initial analysis. For this, we examined a separate cohort of patients with and without SSI (25 records each) from the year 2015. These were also patients within the the institution’s NSQIP database, but had not been assessed for SSI-related phrases. We utilized the Natural Language Processing-Patient Information Extraction for Research (NLP-PIER) clinical research clinical note search engine for each base term [10]. Each of the encountered modifiers within the search engine were recorded and added to our representation model in our evaluation where applicable.

Institutional review board approval was obtained and informed consent waived for this minimal risk study. Interrater reliability was assessed on 160 (ten percent) of SSI phrases by both physician-raters (SS and EA) to assess agreement on the whether the phrase was associated with SSI and whether the term was positive or negative (i.e., not indicating an SSI). Agreement was 100% for association with SSI and 0.94 with a kappa of 0.82 for positive or negative designation agreement.

Results

A total of 54 positive SSI patient cases from the NSQIP database (n=41) or with a high probability SSI score by algorithm (n=13) were reviewed. After reaching 45 patients, saturation of our corpus was assessed by tracking new terms. After assessing 9 additional patients, only 8 new terms were identified and our cohort was completed with 54 total patients. Demographics and surgical specialty of these patient cases are displayed in Table 2. The total number of notes reviewed was 3,232. Multiple surgical services were represented.

Overall, 1,536 distinct phrases were identified that were important for the designation of a SSI. There was a median of 25 (range 9-64) unique phrases identified in each chart. The majority of phrases 1,304 (85%) were identified from inpatient encounters. Outpatient encounters accounted for the remaining 15%, with 232 phrases. The majority of the SSI-related phrases were found in the progress notes of clinical teams following the patients in the hospital and is summarized in Table 3.

While most of SSI-related phrases had a positive correlation with an SSI occurrence, 161 (10%) phrases offered evidence against a surgical site infection (e.g., “no obvious purulence”, “improving of erythema”, “wound c/d”). These phrases “protective” of an SSI generally occurred in the early post-
operative period, or late in the course of the infection, signifying potential recovery.

**SSI-Related Base Term Classification**

Observations were categorized by isolating the “base term” that was being observed. There were 63 unique base terms that were recorded from review of 1,536 SSI-related phrases (Table 4).

There were a few “actions” found to be pertinent to SSIs in clinical notes. Sixteen unique verbs were found relating to SSIs. Most verbs were found in multiple tenses. These verbs (Table 5) were documented when used to explain procedures relevant to surgical site infections.

Directives of the clinical plan also included some phrases related to SSIs. Each group of phrases had some variability, but there were six main themes: computed tomography (CT) requests, wound culture/gram stain orders, specific wound care plan, consulting infectious disease (ID) and interventional radiology (IR), tentative plans for operative intervention, and antibiotic changes.

**Other SSI-Related Phrases**

Antibiotics were common SSI-related phrases included in the clinical note. Antibiotics comprised 241 (16%) of the recorded SSI-related phrases. The use of antibiotics was not consistent in the treatment of SSIs. Antibiotics were included in the analysis if started empirically (concern for SSI but no definitive evidence) or if being used to treat an SSI. There was a wide range of antibiotics used for treating SSIs due to the multiple organ systems represented by each different surgical service. Documentation in the clinical notes included both the trade and generic names of the antibiotics (Table 6). General terms, such as “antibiotics”, “IV antibiotics”, and “antibiosis” were also documented but are not included in Table 6.

Clinically significant organisms were documented in the clinical notes. These were recorded when associated with a wound or abscess culture (Table 7). Organisms comprised 111 (7%) of the total SSI-related terms. An organism isolated from a wound or abscess culture is sufficient on its own to diagnose an SSI [5]. Terms such as “gram positive cocci”, “lactose fermenting rods”, and “coagulase negative staphylococcus” were also recorded but not included in the table due to their generality in describing many infections.

Wound care items were commonly encountered terms. Types of dressings including: gauze, Kerlix, NuGauze, Aqualel, wet to dry, and xeroform were frequently documented as SSI-related terms. The most commonly encountered wound care item was “wound vac”.

SSI-associated abbreviations and acronyms were relatively uncommon, but repeated frequently. The recorded abbreviations are included in Table 8. They are grouped according to type of abbreviation.
Misspellings in the clinical notes relating to surgical site infections were infrequent. There were only 12 instances of misspelling found in SSI related terms. The most commonly misspelled word was “dehiscence”. Inaccuracies of documentation associated with SSIs also appeared to be rare. Although it is difficult to assess inaccuracies by solely a retrospective search of the clinical notes, only one obvious inaccuracy was discovered. A pelvic abscess was incorrectly documented in a telephone note.

**SSI Expressions in Notes Versus Original Expert Terms**

As demonstrated in Table 1, there were 43 unique phrases determined by expert consensus that were included in the original set of “strong features”. These original phrases can be broken down into 22 base terms (observations and actions) and 24 modifiers.

Overall, extraction of SSI signals from clinical notes resulted in an overlap of 17 base observations and actions (77%) with the original set of expert phrases with 5 terms from the original list not found in our corpus. There were 24 modifiers identified from the original features, with an overlap of 21 modifiers (88%). Only 3 modifiers were not found in our corpus. Combined, there was 83% overlap when accounting for both base terms and modifiers. One term in the original set, “antibiotics”, was categorized in our other SSI-related features. In addition, we identified 62 new terms from the corpus: 47 new base observations and 15 new actions. Eleven of these terms were in the top 25% of frequency in the 54 cases reviewed. All of our antibiotics, organisms, and abbreviations/acronyms were new compared with the original set.

**Modifiers of Base Terms & Validation of Modifiers**

Modifiers of the main SSI-related base terms (observations and actions) were extracted in analysis of each base term. Modifiers were also classified as evidence for an SSI diagnosis (positive) and against an SSI diagnosis (negative). Overall, there were 383 modifiers among all of the base terms. Only unique modifiers were recorded for each base term. Repeated modifiers were recorded only if used for different base terms. There was a wide range of modifiers per base term, with a median of 2 (range 0-49).

Three terms: “fluid collection”, “drainage”, and “infection” were tested with the NLP-PIER search engine on a new set of 25 patients with an SSI and 25 patients without an SSI in 2015 to validate the utility of the previously identified modifiers and to determine if there were additional modifiers associated with these base terms. From chart review, “fluid collection”, “drainage”, and “infection” had the most modifiers, with 32, 49, and 41 respectively. Only 49 new modifiers were encountered in this clinical note query of 50 patients (13 for “fluid collection”, 18 for “drainage”, and 18 for “infection”). Figure 1 is an example of a base term with its modifiers.

**Discussion**

Automated or semi-automated SSI detection has the potential to decrease present day manual abstraction required in most cases. While quality improvement registries such as NSQIP demonstrate tangible benefits to patient outcomes in hospitals in the private and public sectors [7-11], increased automation around outcome extraction for post-operative complications like SSIs could reduce cost barriers creating wider adoption. Our study demonstrated a number of important types of signals in clinical texts which we did not recognize previously with the assistance of expert consensus. This speaks to the variability of language used in our documentation of patient care, and it is likely that these findings can be leveraged to improve the performance of these algorithms.

The method used in this study was a two-step approach by first empirically analyzing the content of clinical notes in positive cases of SSI and then performing a validation of the base terms and associated modifiers to ensure good coverage of the identified modifiers. A previous study reported defining SSI patterns using two conceptual groups of terms in text-mining: bacteriology and surgery [12]. In our study, we discovered additional groups of SSI-related terms. We opted to classify our concepts into observations, actions, and plans related to SSIs. Our SSI-related observations were used to describe exam, laboratory, and imaging findings. SSI-related actions were used for procedures and tasks performed by clinicians. The clinical plan includes future tasks to be performed and next steps in SSI management. Other information related to SSIs included antibiotics, organisms, and wound care. We also observed abbreviations for many of these concepts.

We observed that antibiotics and organisms comprised 23% of total terms. These terms appear to have a relatively high sensitivity in detecting SSIs since only certain organisms and antibiotics tend to be associated with post-operative infections. Unfortunately, these same antibiotics and organisms can often
be found in infections not relevant to SSIs, resulting in a low specificity for SSI detection.

The original set of “strong features” identified by expert opinion included a portion of terms that could be used for SSI identification. Compared to our original set, 62 new base terms and 362 new modifiers were identified in chart review of patients with an SSI or a high probability score on the SSI algorithm. In addition to the base terms, there were six clinical plan categories as well as antibiotics, organisms, and abbreviations/abbreviations that could be leveraged for better SSI detection. While most modifiers were already discovered in the initial review of SSI cases, 49 additional new modifiers were identified through NLP-PIER searches which added to the robustness of the associated set of signals.

As expected, key data for the determination of SSIs is stored in the clinical notes. While structured data is useful for detecting SSIs, clinician judgement and physical examination remain key; significant, unique details about SSIs are only found within clinical notes. NLP and text-mining can be used to detect adverse events in clinical notes with better performance than manual review and other methods utilizing structured data for automated detection [13]. Recently, a text-mining approach using two categories was used to detect SSIs in a neurosurgery department [12]. Our findings demonstrate, however, that a constellation of terms is needed to determine the presence of an SSI. It is likely that improved discrimination for SSIs can be achieved by following for more complex phrases and/or base terms and their modifiers to capture more complex SSI semantics. Further organization including analysis of description groupings and locations may be useful in classifying terms for the identification of SSIs.

This project did not assess pre-operative risk factors and predictors of SSIs in surgical patients. By studying post-operative outcomes and improving outcome abstraction in surgical patients, we are building our knowledge of these risk factors and predictors. These risk factors have even more complexity, ranging from patient physical characteristics, past medical and surgical history, additional laboratory data, to operation-specific signals. With more data analysis, perhaps a future project could assess pre-operative clinical notes to develop a separate algorithm to predict SSI risk prior to or immediately following an operation.

Our study has several limitations including its relatively small sample size and the use of data from a single institution. Future work to validate these findings on a separate dataset including any regional variability of SSI language and additional variability associated with specialities with lower rates of SSI (e.g. neurosurgery or otorhinolaryngology) is needed.

Conclusions

The language behind SSIs is complex. There are many categories of terms that may contribute to an SSI determination, including observations, actions, clinical plans, antibiotics, and specific organisms. Empirical analysis of SSI cases was an effective method for uncovering the complexity of SSI-related expressions in clinical texts. These findings may provide value in improving the performance of SSI detection algorithms.

Abstract

In this research we aim to demonstrate that an ontology-based system can categorize potential drug-drug interaction (PDDI) evidence items into complex types based on a small set of simple questions. Such a method could increase the transparency and reliability of PDDI evidence evaluation, while also reducing the variations in content and seriousness ratings present in PDDI knowledge bases. We extended the DIDEO ontology with 44 formal evidence type definitions. We then manually annotated the evidence types of 30 evidence items. We tested an RDF/OWL representation of answers to a small number of simple questions about each of these 30 evidence items and showed that automatic inference can determine the detailed evidence types based on this small number of simpler questions. These results show proof-of-concept for a decision support infrastructure that frees the evidence evaluator from mastering relatively complex written evidence type definitions.

Introduction

While medication therapies are generally beneficial to a patient’s health, they can also result in harm. A recent review of epidemiologic studies published over a 14 year period found that 3.5% of hospital admissions are the result of an adverse drug reaction [1]. The United States Department of Health and Human Services recently stated that reducing the rate of adverse drug events should be a national priority [2]. Research on the safety of any given drug starts during its development and continues after marketing. During these phases, studies examine the potential for one drug to alter the pharmacokinetic properties (absorption, distribution, metabolism, or distribution) or clinical effect (pharmacodynamics) of another drug. The results of these studies can suggest PDDIs that might lead to preventable harm to patients without proper management [3].

The spectrum of study types used to research PDDIs is broad and complex. These include in vitro experiments, population pharmacokinetic analyses, randomized controlled clinical trials, and observational epidemiologic studies [4]. Data mining adverse event reports and case report evaluation can also be included because these are research activities that generate PDDI hypotheses [5]. Not only are there many different types of PDDI studies, there are also numerous considerations that can influence the validity of a given study [2,4]. The range and complexity of study designs and the resulting evidence types can make it very difficult to evaluate a body of evidence to determine if a PDDI exists. This difficulty might be an important factor influencing the large differences in content found in PDDI knowledge bases that are designed to help clinicians make management decisions [6,7]. Indeed, a more systematic approach to evaluating evidence for the existence of PDDIs was one of the recommendations put forth by a recent expert consensus conference series [8].

We believe that an ontology-based system can categorize PDDI evidence items into complex types based on a small set of simple questions, thereby reducing the cognitive load experienced by evidence evaluators. Our approach is to have a computer program infer the specific evidence type of a PDDI study based on simple data provided by the evidence evaluator. Here, we report our progress creating an infrastructure for this kind of decision support. We demonstrate a proof-of-concept for using an off the shelf OWL reasoner and formal evidence type definitions so that an evidence base curator only has to identify the study type at a high level (e.g., clinical study) and provide some simple design features (e.g., ‘randomization’). With this information, the OWL reasoner can efficiently and consistently infer the specific evidence type with which to tag the study (see Fig. 1).

Figure 1 – The steps taken to build the proof-of-concept for categorizing PDDI evidence.
Methods

DIDEO (https://github.com/DIDEO) is an OWL ontology developed to facilitate managing information about PDDIs from multiple sources (clinical studies, case studies, in vitro experiments, etc.). It is freely accessible from http://purl.obolibrary.org/obo/dideo.owl. The fundamental ontological commitments of DIDEO have been described in detail [9]. One key contribution of DIDEO is to provide OWL classes for evidence types (see Fig. 2).

The process creating the textual definitions for each evidence type has been previously reported [10]. For Step 1 of the current project, we wrote necessary and sufficient conditions (i.e.,

</table>

Next for Step 2, we created a dataset that would enable automated decision support for people who need to evaluate PDDI evidence items. As Table 1 shows, evidence definitions for more specific kinds of evidence can become fairly complicated. Decision support should simplify the cognitive load of a person evaluating an evidence item.

We developed a proof-of-concept system that was used to test whether an OWL reasoner and formal evidence type definitions can efficiently and consistently infer the specific evidence type from Table 1 based on basic evidence types (e.g., clinical study) and design features (e.g., ‘randomization’). Combining the evidence instance data with the OWL equivalent class axioms from DIDEO should enable an OWL reasoner to infer the specific evidence type of each instance. We tested this in Step 4 shown in Figure 1.

For Step 1 we used classes for the detailed evidence types shown in Table 1 in DIDEO (created in prior work) [11]. For Step 2, we drew on prior work [10] that had manually assigned a study type from Table 1: 30 publications were queried from the Drug Interaction Knowledge Base (http://dikb.org/), representing five publications for each of the six clinical study evidence types defined in DIDEO (see Table 2). Listing 1 shows the SPARQL query used to query a single evidence type from Table 2. The interested reader can modify the dikbEvidence:Evidence_type and PubMed identifier to retrieve any of the other items listed.

Listing 1. (Step 1) A query used to retrieve one of the 30 evidence types from the Drug Interaction Knowledge Base (https://dbmi-icode-01.dbmi.pitt.edu/dikb/snorql)

```
SELECT DISTINCT ?ev ?quote
WHERE {
  ?ev dikbEvidence:Evidence_type dikbEvidence:EV_PK_DDI_NR.
}
```

As part of Step 3 a questionnaire tool, previously developed for the CAFE project (https://cafe-trauma.com), was modified and used to manually enter high level type and simple design features for each study in Table 2 (see Fig. 3). We then exported RDF instances created by the tool for each evidence item. We put these into a single file for import into an RDF store. Our RDF store was the community version of the Stardog (http://stardog.com/) RDF store, which comes with a built-in

Figure 3 – (Step 3) The questionnaire tool used to enter high level type and simple design features for each study in Table 2.
OWL description logic reasoner. We loaded RDF file of evidence instance data along with following OWL files:
- RO core: http://purl.obolibrary.org/obo/ro/releases/2016-09-02/core.owl
- RO BFO classes minimal:
  http://purl.obolibrary.org/obo/ro/releases/2016-09-02/bfo-classes-minimal.owl
- IAO: http://purl.obolibrary.org/obo/ia/2015-02-23/ia/ia.owl
- BFO (classes only)
  http://purl.obolibrary.org/obo/bfo/2014-05-03/classes-only.owl
- RO annotations:
  http://purl.obolibrary.org/obo/ro/releases/2016-09-02/annotations.owl

Finally for Step 4, we developed a set of competency questions and associated SPARQL queries (see Table 3) that could be implemented in an application similar to that shown in Figure 3 in order to provide automated support to evidence evaluators for determining an evidence item’s type. We tested that each SPARQL query ran successfully over the inferred RDF store.

**Results**

Table 4 shows the results of running the competency question SPARQL queries (see Table 3) over the inferred RDF store. Each evidence type classification corresponds exactly to the manual classification from Table 2, thereby validating the data model and OWL ontology while showing proof of concept that complex evidence type classification can be obtained from the answers to simple questions.

**Discussion**

DIDE now provides OWL classes for many of the evidence types within the PDDI domain of scientific discourse. The current work shows the feasibility of using these formal definitions to build decision support that helps evidence
evaluators to determine the specific types of studies or experiments they review. Instead of having to master complex written evidence type definitions, such as those shown in Table 1, evaluators will only need to answer a small number of simple questions about the study, such as those shown Figure 3. With that information, simple SPARQL queries can be run over an inferred RDF dataset similar to the one used in this study to return the specific evidence type as a URI from DIDEO. By simplifying the task of evidence type assignment, a team of curators should be able to produce more correct and consistent work over the many hundreds of evidence items they need to manage.

Conclusions

In this work we showed proof-of-concept for the technical infrastructure, showing that PDDI evidence item data we added into a triple store together with DIDEO evidence types enable an OWL reasoner to infer an evidence item’s specific type. In future work we plan to conduct a user study to test the hypothesis that this approach improves the correctness and consistency of evidence type assignment by evidence base curators. We also plan to extend the decision support to include questions that can be used to infer the quality of a study. We then plan to conduct a user study that compares interrater agreement between two groups of PDDI experts – one provided with evidence evaluation decision support, the other using their usual procedures. Based on our hypothesis, the group of participants given decision support should show much greater interrater agreement than the comparison group. We will also compare speed, ease, and user preference. If our hypothesis is shown to be true, it would be a promising step forward toward reducing the large differences in content found in PDDI knowledge bases that are designed to help clinicians make management decisions [6,7].

Evidence annotation is already a significant part of the biomedical enterprise, with computer-supported manual annotation used by an entire community and additional efforts to synthesize clinical research (e.g. Cochrane Reviews). We believe that approaches to simplify annotation processes, using incremental formalization and granular information, will be essential for increasing the availability of searchable (and in some cases algorithmically-synthesized) information. Generalizations of the work presented in this paper have the potential to greatly increase the impact of the curation enterprise.

A Method for Constructing a New Extensible Nomenclature for Clinical Coding Practices in Sub-Saharan Africa

Sven Van Laere, Marc Nyssen, Frank Verbeke

Department of Public Health (GEWE), Research Group of Biostatistics and Medical Informatics (BISI), Vrije Universiteit Brussel (VUB), Laarbeeklaan 103, 1090 Brussels, Belgium

Abstract

Clinical coding is a requirement to provide valuable data for billing, epidemiology and health care resource allocation. In sub-Saharan Africa, we observe a growing awareness of the need for coding of clinical data, not only in health insurances, but also in governments and the hospitals. Presently, coding systems in sub-Saharan Africa are often used for billing purposes. In this paper we consider the use of a nomenclature to also have a clinical impact. Often coding systems are assumed to be complex and too extensive to be used in daily practice. Here, we present a method for constructing a new nomenclature based on existing coding systems by considering a minimal subset in the sub-Saharan region. Evaluation of completeness will be done nationally using the requirements of national registries. The nomenclature requires an extension character for dealing with codes that have to be used for multiple registries. Hospitals will benefit most by using this extension character.

Keywords:
Clinical Coding; Names; Africa South of the Sahara

Introduction

Medical coding systems have shown their relevance in health information management (HIM) systems. Clinical coding is an integral part of HIM practice which provides valuable data for health care quality evaluation, health care resource allocation, health services research, medical billing, public health programming and Case-Mix/DRG funding.[1]

In sub-Saharan Africa, several countries use their own coding system by (1) setting up their own code system, (2) using an in-house designed code system based on another reference terminology, or (3) by making use of an existing code system. However, to the best of our knowledge, there is little literature about clinical coding in sub-Saharan Africa. The may be due to limited available capacity and resources to carry out comprehensive and significantly sound community assessments.[2]

Moreover, sub-Saharan countries often lack the structure and technologies to provide data. For this purpose, open-source hospital information systems such as OpenClinic GA [3] may help. A study in 19 African health facilities [4] demonstrated that by applying this software, structured reporting improved dramatically.

If we look towards interoperability between countries, still a lot can be done, since every health facility reports information in a different way. Moreover, the complex structures of existing coding systems limit the use of them. The idea of a new nomenclature for the sub-Saharan region that is extensible for a country or as more specialized hospital rise.

The word nomenclature has to be used with care in the context of sub-Saharan Africa. By the word “nomenclature”, usually they understand: “a coding system to provide codes that are used in invoices, to specify the health services that were provided for particular patients”. We define nomenclature in a broader way, also taking into account the clinical definition of health services.

In this paper we will present a way to build this new nomenclature for sub-Saharan Africa, based on existing nomenclatures.

Methods

In nomenclature construction, it is key to have a clear goal. For example, the existing Anatomical Therapeutic Chemical (ATC) classification is used as a tool to register drug utilization in order to improve the quality of drug use [5]. Our purpose is to see what is necessary per sub-Saharan country and to find a common subset between these countries (see Fig. 1).

We will start from the lists containing all health services that are necessary for billing purposes. This means we will at least include codes of existing procedure classifications. The Current Procedural Terminology (CPT), International Classification of Health Interventions (ICHI) and NOMESCO Classification for Surgical Procedures (NCSP) can help in providing these specifications.

However, not only the billing aspect of procedures are of interest in an electronic medical record. To provide more granularity compared to what is often used, we will also include codes for medication and lab results. Possible terminologies to include are respectively ATC and the Logical Observation Identifiers Names and Codes (LOINC). The idea is to design a new nomenclature of codes, at least including the

![Figure 1: Idea of constructing a minimal subset of concepts (colored part) necessary to represent medical data](image-url)
topics mentioned above, in which it is possible to refer to the original code used. To enable traceability, we will use following structure:

\[\text{PREFIX}.\text{CODE}[.\text{XXX}]\]

where \text{PREFIX} indicates a reference to the original terminology, \text{CODE} refers to the internal code of the code system that represents a clinical idea and an optional \text{XXX} part will refer to an index, necessary for capturing more granularity.

This last \text{XXX} part will enable the handling of codes that are not provided by the minimal subset, but that are necessary on a national or even more local (hospital) basis. This extensibility is one of the key aspects of this sub-Saharan nomenclature.

How do we know when this extension feature will be needed? For this evaluation on a national basis, we will make use of the information that is required to be provided by the hospitals for reporting purposes to the national registers. The data elements in the reporting requirements will be used as an evaluation source.

Three scenarios can occur in this evaluation part (see Fig. 2):

- **Scenario A**: If there is a 1-1 mapping from the newly constructed nomenclature to the national requirement, no problem will arise. Each new concept that is used, can be used to fill up the register regarding this concept.

- **Scenario B**: If there is a N-1 mapping from our new nomenclature to the national registry, it means two (or more) concepts will be used to fill up the national register data.

- **Scenario C**: If there is a 1-N mapping from the new sub-Saharan nomenclature towards the requirements of a national register, it is necessary to provide an extension. This extension will then split up the newly generated code into multiple parts using the \text{XXX} part, until we obtain at least one concept per national register requirement.

First we will evaluate this regarding national requirements. This extension of course can also be used on a more local basis, for example in an African hospital specialized for a particular health care service.

**Nomenclatures**

In this part we will briefly list up the code systems that can be of interest for the creation of this nomenclature. We need concepts dealing with procedures in which CPT, ICHI and NCSP. We also include the ATC and LOINC classifications for registering respectively medication and laboratory information.

**ATC**

ATC stands for Anatomical Therapeutic Chemical and is a classification system used for medication.[5] It classifies substances based on the organ or system on which they operate and their therapeutic, pharmacological and chemical properties and is maintained by the World Health Organization (WHO). Moreover, the ATC system also includes “defined daily doses” (DDDs) for many drugs, indicating the usual dose used per day. The classification uses the representation of the concept identifier to classify medication at five different levels: (1) anatomic main group; (2) therapeutic subgroup; (3) pharmacological subgroup; (4) chemical subgroup and (5) chemical substance.

**CPT**

The Current Procedural Terminology (CPT) is a medical code set for uniform communication about services and procedures specifying which services health care providers have performed on the patient.[6] This terminology is maintained by the American Medical Association through the CPT Editorial Panel. Governments can use CPT for tracking the prevalence and value of procedures. Each CPT code is 5 characters long and may be numeric or alphanumeric, depending on which category the CPT code is classified. CPT codes are divided into 3 categories based on their usage.

**ICHI Alpha 2015**

The International Classification of Health Interventions (ICHI) is a system of classifying procedure codes, maintained by WHO.[7] ICHI was originally designed to replace the International Classification of Procedures in Medicine (ICPM). The classification is built around three axes: the target (the entity on which the Action is carried out), the performed action (a deed performed by an actor to a target) and the means (the processes and methods by which the ‘action’ is carried out). Extension codes are provided to allow users to describe more detail about the intervention in addition to the relevant ICHI code.

**LOINC**

The Logical Observation Identifiers Names and Codes (LOINC) provides universal identifiers for laboratory and other clinical observations.[8] This classification is maintained by the Regenstrief Institute. LOINC codes are composed by 5 or 6 parts that are separated by a colon: (1) component/analyte, (2) property observed, (3) timing of measurement, (4) type of sample, (5) scale of measurement, and if relevant (6) the method of the measurement.

**NCSP**

The NOMESCO Classification of Surgical Procedures (NCSP) is a classification for surgical procedures, maintained by Nordic Centre for Classifications in Health Care.[9] It is based on the traditions of the surgical profession in the Nordic countries. A NCSP code consists of three alphabetic characters (positions 1-3 of the code) and two numeric characters (positions 4-5 of the code). The alphanumeric part refers the classification (i.e. chapter) to which the code belongs and the numeric part refers to the specific procedure within the procedure group, including surgical technique and precise anatomical location.

**Discussion**

In sub-Saharan Africa many actors are willing to improve the health care system, especially the documentation of it. Not
only health insurance companies, but also ministries, public
and private hospitals are ready to improve documentation. Nowadays most of the health care actions still are documented
on paper patient charts or remain (partly) undocumented. When documentation is provided on these charts or in health
information systems (HIS), registration is often incomplete, inaccurate and/or performed in an untimely way.[10]
The reason for this, is that documentation schemes are just too
complex and too time-consuming (in the opinion of the man-
agement of a hospital and for the nursing staff). However, a
mental change in sub-Saharan Africa is progressing: they tend to see benefits of documenting.

In HIS used in sub-Saharan countries, documentation is often
used for billing purposes where each intervention that requires
several sub-actions is summarized into one general concept.
For example, the documentation of the concept “child-birth”
does not only include the hospitalization, but also procedures
and health services by various caregivers to help the patient in
delivering a baby. However, in most cases hospitals will pro-
vide an invoice only based on giving child birth.

It is important to stress that the documentation of these various
actions will lead to possible new insights regarding the func-
tioning of the hospital and/or the country’s health system.
Moreover, by documenting every step of the care process,
possible improvements with beneficiary outcome for the coun-
ty and/or hospital are possible. National institutes will be able to
provide epidemiologic summaries enabling them to im-
prove the health status of their country. Hospitals will be able to
calculate cost-benefit ratios based on what is documented
and may adapt their price system on their findings.

The aim of this paper is introduce a method for creating a new
extensible documentation system based on existing nomen-
clatures for the sub-Saharan part of Africa. The reason is an in-
creasing awareness for the need of proper coding principles.
Contrary to introducing a completely new coding system, we
will use existing coding systems. The benefit of reusing exist-
ing terminologies is that this terminology will require less
maintenance compared to a completely new terminology.

We will construct this nomenclature by calculating a common
subset of concepts over the sub-Saharan countries. After this,
an evaluation study is required to see if the new nomenclature
covers every aspect necessary. The idea of extensibility is essen-
tial to solve the problems cause by the different national
registry requirements in every country. To meet these re-
quirements it is possibly necessary to extend the new nomen-
clature so that codes that map onto multiple register require-
ments can be split up, in order to be more fine-grained.

Not only nation-wide this extensibility will give improve-
ments, but also hospitals can benefit from this characteristic of
this new nomenclature. Sometimes procedures are only exe-
cuted in particular hospitals. These procedure codes will then
not be part of the general nomenclature, but will be put in a
local extension.

Finally, we will enable interoperability between countries
using this nomenclature. The power of this terminology lies in
the origin of the common subset including only codes that are
necessary.

Conclusion

Sub-Saharan Africa is willing to improve the health care sys-
tems by investing in good documentation practices. This in-
creasing awareness grows both in nationwide institutions, as
well as inside the hospitals. Current terminology systems
appear to be complex and too extensive in use. We propose a
method for constructing a new nomenclature based upon exist-
ing terminologies. To cope with national and local differences
in sub-Saharan regions, this new nomenclature is made exten-
sible. For evaluating this nomenclature we will use the registry
information per country. When one code is necessary for
providing the required information for multiple national regis-
tries, an extension will be the solution for providing the coun-
try with the correct data. This nomenclature has the benefit of
being adaptable to both the needs of the hospitals and to the
needs of the countries.

Abstract
This study aims to identify subject content and trends in the medical informatics literature in order to shed light on the past, current, and future directions of diverse education and research activities. A list of 36 core medical informatics journals was compiled through expert consensus. We retrieved 60,862 articles from the U.S. National Library of Medicine’s MEDLINE database that were published by those journals from 1992 to 2015. A series of descriptive analyses were conducted to reveal the historical productivity of the journals, publications trends, and the subject content based on the Medical Subject Headings (MeSH) term frequencies and debut years. We found 73 core topics and 72 new topics of medical informatics within three relevant MeSH categories (informatics, techniques, and healthcare).

Keywords:
Medical Informatics; Publications; Medical Subject Headings

Introduction

Medical informatics (MI) is defined by the United States (U.S.) National Library of Medicine (NLM) as “the interdisciplinary study of the design, development, adoption, and application of IT-based innovations in healthcare services delivery, management, and planning” [1]. It emerged in the 1950s and has been an interdisciplinary domain for over half a century, involving applications of computer science, information science, engineering, social science, management science, among many others, in all fields of health and medicine [2]. Clinical informatics is now a medical subspecialty that allows physicians to practice clinical informatics in collaboration with other healthcare and information technology professionals to promote safe, efficient, and effective patient-centered care [3]. Today, over 80 U.S.-based academic institutions offer onsite or distance MI training programs [4].

Most published review articles in the MI domain have focused on specific subdomains or research topics, such as clinical decision support, natural language processing, and terminologies. Only a few prior studies have attempted to characterize the overall research activities in the MI literature [5]. To summarize the literature trends, these studies used Medical Subject Headings (MeSH), a comprehensive controlled vocabulary for indexing journal articles and books in the life sciences developed by NLM [6]. MeSH terms are assigned manually by professional indexers and the process can be assisted with automated approaches [7]. DeShazo et al. took the first step to use MeSH terms to analyze publication trends in the MI literature published between 1987 and 2006 [5]. Their study included all articles assigned any term in the MeSH “Medical Informatics” hierarchy as a major topic across all types of journals indexed by MEDLINE/PubMed.

To our best knowledge, no literature trend analysis across the overall MI field in the recent decade has been published. The focus of this paper is to describe the evolution of the field of MI in the recent two decades by conducting a trend analysis on research topics published in MI journals using MeSH descriptor terms. The aim of this study is to update the MI community about the most recent research trends from published MI literature. The results of this study will provide important insights for future educational, research and development directions. For example, our findings may be used to aid in the curriculum development for the MI training programs, core content updates for the MI subspecialty exam [8], as well as suggesting potential research funding areas.

Methods

We utilized a multi-step approach to identify informatics publications and research topic trends: (1) identify core MI journals, (2) form a query to retrieve articles from the MEDLINE database, (3) extract MeSH terms from retrieved articles, (4) select MeSH term categories, and (5) perform descriptive analysis to identify trends (see Figure 1).

Figure 1 – Methods Overview

Step 1: Identifying MI journals

In the MEDLINE database, there are approximately 26,000 journal records [9]. To identify MI publications, DeShazo searched MEDLINE for all documents assigned the term “Medical Informatics” in MeSH or any term in the “Medical Informatics” hierarchy as a Major Topic [5]. However, we found that this approach produces somewhat noisy results with a significant amount of non-relevant articles. For example, “databases, factual” is a descendant term in the MeSH Medical Informatics hierarchy. When one uses this term as a MeSH Major Topic to search MEDLINE, more than 29,000 articles are retrieved. However, many studies such as clinical trials, epidemiological studies, or economic analyses that used some sorts of databases may not necessarily be classified as “true” MI articles. Additionally, we also reviewed the 1200+ articles retrieved from the journal of “BMC Genomics” based on DeShazo’s query, the majority of the articles were not about MI studies per se, as this journal mainly focuses on genome-scale analysis, functional genomics, and proteomics. To account for this, we utilized a different approach by identifying MI “core” journals first. We
assume that the majority of MI topics are published in the “core” MI journals and topic trends in MI journals can serve as a proxy for the MI topic trends across journals in other fields.

In this study, we specifically include journals and articles related to clinical informatics, public health informatics, and nursing informatics that directly associate with patient care and population health. Although the broad biomedical informatics includes other important branches, such as bioinformatics and imaging informatics, journals focusing on these branches were not included in this analysis. For the purposes of this study, to define MI core journals, we examined whether the majority of the articles in a journal reflect the core content of clinical informatics as defined by Gardner et al. [8]. Some journals that cover those topics to a certain extent, but mainly fall into other domains, were excluded. These domains include: (1) biomedical engineering, physics, devices, images; (2) bioinformatics (except journal names containing ‘biomedical informatics’); and (3) general medical, nursing, and pharmacy journals.

We defined the inclusion and exclusion criteria and identified the core MI journals in two sub-steps: First, we started with a simple query to the MEDLINE/PubMed in November 2016 for retrieving all documents assigned any MeSH term in the following three MeSH hierarchies: “Medical Informatics”, “Public Health Informatics”, and “Nursing Informatics”. This query retrieved over 379,000 articles that were published in over 9,000 journals indexed by MEDLINE. The publication sources were sorted by the number of retrieved articles. Two MI researchers (LZ, MT) manually reviewed all journals with 50 or more relevant articles. For journals with less than 50 articles, or approximately 90% of publication sources, they used keyword search (e.g., informatics, information technology, and telemedicine) to identify MI journals. The two researchers separately reviewed the journal list and determined whether a source should be included or not. Disagreements were discussed and full consensus on MI journals was achieved. Second, we generated a list of MI journals by searching the NLM Catalog with the query “Medical Informatics [Broad Subject Term]”, which returned 91 journals indexed in MEDLINE. We then manually reviewed these 91 journals to identify MI journals. We found that many journals changed their names over the years. We merged different versions of journal names with the preferred name being the most recent. Finally, we compared and reconciled the journal lists generated by these two substeps.

Steps 2: MI Article Query

We formed a MEDLINE query based upon the identified core MI journals to retrieve all articles published in these journals between 1992 and 2015, as follows: MI_Journals AND "english" [language] AND 1992[PDAT]:2015[PDAT]. In this query, the MI_Journals refer to the journals from the previous step, where both the current and previous journal names were used. This expanded our query format to include the variations: (“Stud Health Technol Inform” [Journal] OR "AMIA Annu Symp Proc" [Journal] OR "Methods Inf Med" [Journal]...). With this query, we were able to plot the number of MI articles over the past 24 years to see the increasing rate of publications in the MI field.

Step 3: MeSH Term and Article Information Extraction

All of the information about the retrieved articles was stored in MEDLINE’s Extensible Markup Language (XML) formatted files. We downloaded related files through NLM e-utils and parsed those XML files using the Java DOM Parser to get each article’s identifying number (PMID), title, abstract, MeSH descriptor terms, and publication date. All extracted data was loaded into a local relational database.

Step 4: MeSH Category Selection

Each article is assigned as many MeSH terms as appropriate to cover the topics of the article. MeSH descriptor terms are organized in 16 major categories, (e.g., category L for Information Science and category N for Health Care) [6]. Each category is further divided into subcategories, and within each subcategory, descriptors are listed in a hierarchical structure. Each descriptor has a number that indicates its tree location, e.g., computing methodologies [L01.224] is in the Information Science [L01] subcategory of the L category. We obtained the tree location numbers for each MeSH term from MeSH RDF Linked Data [10].

In this paper, we restricted our analysis on the topic trends to focus on MeSH terms in the following three categories: Analytical, Diagnostic and Therapeutic Techniques and Equipment [E], Information Science [I], and Health Care [N], among which, L category was the main focus. We chose these three categories to investigate MI research trends regarding technology and healthcare in general. Although other MeSH categories (such as diseases, humanities, geographical) are also valuable to describe different aspects and characteristics of MI publications, they were not included in this analysis.

Step 5: Topic Trend Analysis

Detection of Core Topics: We consider a MeSH term as a core topic if it was frequently assigned to MI articles. We count the total number of publications for each individual MeSH term over the past 24 years without aggregating of the counts from its children concepts in the MeSH hierarchy. We sort the MeSH terms by the number of publications in each selected MeSH category. The top ranked MeSH terms were considered as core topics.

Detection of Trending New Topics: Novelties were defined as those MeSH terms that debut in recent years with increasing interests by the community reflected by an increasing number of indexed articles. The determination of a MeSH term as a trending topic is done through a combined consideration of three factors: debut year, rate of increase, and number of indexed articles before 2016. The debut year is defined as the year articles were published in the MeSH terminology. We only included those MeSH terms debuted in the recent 10 years. The rate of increase of a MeSH terms is calculated using the formula: a/b+b+1, where a is the number of articles indexed by the term and published in the past five years (2006-2010), and the number “1” is a parameter to handle the situation when some MeSH terms have zero indexed articles in years (2006 – 2010). After we obtained the debut year, rate of increase, and the total number of indexed articles for each MeSH term, we were able to assign three kinds of rankings to the MeSH terms based on how recent they debut, how large the rate of increase is, and how large the total number of indexed articles is. We then obtained a combined ranking number by sum of the three ranking scores. Thereafter, we ranked the MeSH terms with the combined ranking scores and manually picked those terms that were top ranked as novel topics.
Results

Journal Analysis

After combining the journals that were renamed during their lifespan, we selected 36 journals as core MI journals (see Figure 2). Of which, twelve journals have changed their names: “J Biomed Inform”, “Int J Med Inform”, “Inform Health Soc Care”, “Health Manag Technol”, “Comput Inform Nurs”, “AMIA Annu Symp Proc”, “IEEE J Biomed Health Inform”, “J Innov Health Inform”, “J Healthc Inf Manag”, “Top Health Inf Manage” and “J Inst Health Rec Inf Manag”.

Figure 2 – Core Medical Informatics Journals with Start and End Years and Total Number of Publications.

and “Telemed J E Health”. Figure 2 shows the start and end year of each journal, as well as the total number of publications as of 12/31/2015 indexed in MEDLINE/PubMed. The average number of articles per journal is 1,834 [range: 99-12096]. The average age of the journals is 23.7 years [range: 3-55]. In Figure 2, an end year of “2016” indicates that the journal is currently active. For example, “J Biomed Inform” started publishing in 1967 under the original name “Comput. Biomed. Res.”. It was renamed using the current title in 2001 and is still active in 2016. One fifth (8 out of 36) of the journals ceased publishing or indexing to MEDLINE during our study period (1992-2015). For example, a journal titled “MD Comput” is still active but the articles are no longer indexed in MEDLINE.

Publication trends

60,862 articles were retrieved from selected MI journals in 1992-2015 (see Figure 3). The increase in the volume of MI publications between 1996 and 2006 almost follows the exponential growth trend. However, a slight decrease was observed between 2006 and 2011. Between 2011 and 2015, the growth of the publication went back to its previous exponential trajectory.

Figure 3 – Publication Trends of MI Articles by Year

MeSH Analysis

We extracted a total 8,652 MeSH terms from retrieved articles, with an average of 8.3 MeSH terms per article [range: 1-32]. The MeSH terms were distributed in all 16 categories of MeSH descriptor hierarchy, except the category of Publication Characteristics [V]. Restricting the MeSH terms to the three categories resulted in 2,929 unique MeSH terms, among which, 1,295 were in E, 378 were in L, and 1,260 were in N, while some terms overlapping categories (see Table 1). Within category L, only 68 MeSH terms belong to the branches of “Medical Informatics”, “Public Health Informatics”, and “Nursing Informatics”. Among all of the Information Science MeSH terms, we show the top 50 MeSH terms in Figure 4 sorted by the total number of indexed articles, the top 5 being: computerized medical records systems, algorithms, software, internet, and user-computer interface. The growth along every 6 years is also shown in Figure 4. Figure 5 shows trending new topics that debuted in the last decade with increasing research interests in the MI community, including: social media, mobile application, health information exchange, and cloud computing. Besides the L category, we also detected a list of core and trending new topics in the E and N categories (see Table 1).

Discussion

We identified 36 core informatics journals with over 60,000 MI articles published in the last two decades. The dissemination of MI research is currently occurring at an exponential pace. In addition, new MI journals are becoming increasingly more specialized. For example, some of the most recent MI journals include: “Telemed J E Health” (2000) focusing on publications around provision of telemedicine or telehealth; “Inform Primary Care” (2003) focusing specifically on primary care settings; and “Appl Clin Inform” (2009) providing a venue for publications focused on applied MI projects and studies.

Although we used a different set of MI articles compared to DeShazo’s work, the publication trends look similar in terms of exponential growth of publication numbers over the past 40 years. One caveat still remains – no growth was observed between 2006 and 2011, compared to the previous and following periods. One possibility is the effect of the financial crisis around 2007-2008 and the great recession in world market during the late 2000s and early 2010s.
In the past two decades, the field of medical informatics has undergone significant changes. This evolution can be traced through the analysis of publications in the field, which have been categorized into two main categories: Core and New topics. These categories have been further divided into E (Analytical, Diagnostic and Therapeutic Techniques and Equipment) and N (Health Care, Core = core medical informatics topics, New = New trending topics).

The Core topics include areas such as Electronic Health Records, Models, Theoretical, Models, Statistical, and Reproducibility of Results; Surveys and Questionnaires; Delivery of Health Care; Confidentiality; Efficiency, Organizational; and Attitude of Health Personnel; Pilot Projects; Models, Statistical; Organizational Case Studies; Remote Consultation; Medical Records; Quality Assurance, Health Care; and Organizational Innovation; Practice Guidelines as Topic; Evaluation Studies as Topic; Patient Satisfaction; Quality of Health Care; Forms and Records Control; and Patient Education as Topic.

New topics, on the other hand, have expanded to include areas such as Health Records, Personal (2008); Precision Medicine (2008); Early Detection of Cancer (2009); Actigraphy (2010); Genome-Wide Association Study (2009); Accelerometry (2012); Brain-Computer Interfaces (2009); Clinical Alarms (2009); Health Smart Cards (2015); Drug Repositioning (2010); Clinical Knowledge Management (2010); Decision-Making (2015); Epidemiological Monitoring (2012); Medication Adherence (2008).

This prioritization is driven by the need to improve healthcare delivery, enhance clinical outcomes, and optimize resource allocation. The adoption of electronic health records (EHRs) and the expansion of internet-based technologies have been pivotal in this transformation. For instance, the implementation of EHRs has led to increased efficiency and patient safety, as evidenced by the reported reduction in medical errors and improved patient outcomes.

In conclusion, the shift towards more advanced technologies and data-driven approaches in medical informatics reflects a broader trend towards personalized and evidence-based care. The continuous evolution of the field is driven by the interplay of technological advancements, regulatory requirements, and societal needs. As such, the field of medical informatics remains dynamic and poised for further innovation.
topics that show a decreasing number of publications in recent years (e.g., computer or information systems, microcomputers, and computer communication networks). This might indicate that more specific MeSH terms (along with newly added ones) were used to index articles rather than using broader terms, such as computer or information systems. 

Alternatively, this might indicate outdated terms with only infrequent use today (e.g., microcomputers referring to “small computers using microprocessor chips”) [13]. Overall, comparing the core topics extracted from the MI articles in the L and E categories, the majority of the terms were mentioned as part of the core content defined by Gardner et al. [8].

Our approach also detected new trending topics that have appeared only in the recent years. The most frequent new topic was the data mining, introduced in 2009 with almost 1,000 publications before the end of 2015. The second most frequent new topic was machine learning (including support vector machines). With the volume of health related data information growing exponentially, it is not surprising that new tools, such as data mining or machine learning are increasingly applied to process these data. Other literature also supports our findings on the increasing application of machine learning and data mining in healthcare [14–16]. Other frequent new topics in information science include concepts related to new technologies (e.g., wireless, smartphone, sensor, and mobile), as one might expect. In agreement with other literature [17,18], we found an increasing research focus on social media and related knowledge exploration techniques (e.g., crowdsourcing and pharmacovigilance) in healthcare. In terms of Analytic, Diagnostic and Therapeutic Techniques, electronic/personal health records are important tools to support analytics and statistical modeling, both of which show large increased interests to the MI community. In addition, recent advances in genetic testing and other molecular or cellular analysis gave birth to new topics such as precision medicine and genome-wide association study. In terms of topics in Health Care, two groups of trending topics were identified: (1) patient-centered care, which is indicated by the topics such as patient participation, patient preference, patient satisfaction, patient handoff, and health literacy; (2) medical safety, which is reflected by the trending terms like patient safety, medication reconciliation, medication adherence, and clinical alarms.

This study has several limitations: First, we collected articles from a set of selected MI journals. We could have missed MI articles published in journals in other fields, such as medicine, nursing, public health, library science, computer science, and engineering. However, articles published in a non-MI journal may not truly be MI, although it was assigned a MeSH term in the MI hierarchy. For example, “databases, fractal” is a MeSH term in the MI hierarchy and it can be assigned to many non-MI articles that used databases in their studies. As our study includes core MI journals, we believe that our findings capture the mainstream topics in the MI field. Second, using MeSH as part of our search and analysis strategy can be problematic. The MeSH terms may not totally reflect diverse topics in the domain of MI. The MeSH indexes can be subjective, although they were assigned by trained subject matter experts. Also, the addition of new MeSH terms often belatedly follows the actual research trend. Although these new MeSH terms may be assigned to literature retrospectively, our trend analysis based on MeSH may be chronologically behind the real trend. Third, our study does not include analyses of journal’s impact factors and other bibliometrics, such as citations. Lastly, we focused on the MeSH term analysis over the last 24 years; the patterns of the trending and emerging topics detected in this study could be easily outdated as time passes.

Conclusions

We used MeSH terms to describe ongoing and emerging trends in MI publications. Our results indicate that over the past two decades, the body of MI literature has grown at an almost exponential pace. Our analysis indicates that while some popular topics in MI publications remain stable throughout the years (e.g., software, artificial intelligence), new topics also emerged in the past few years (e.g. data mining, social media). Our findings can be used to examine the existing MI educational programs (in terms of content coverage) and suggest new research avenues (e.g., emerging topics such as crowdsourcing).

Abstract

Patient falls are a common safety event type that impairs the healthcare quality. Patient falls are the most common safety events resulting in adverse patient outcomes and imposing significant costs, become a great burden to society. Patient safety organizations (PSOs) have listed patient falls as one of the top patient safety events [1]; 92% of inhospital falls are preventable [2]. Efforts such as prevention and assessment tools as well as reporting systems have been developed to reduce the recurrence of patient falls in the U.S. Prevention and assessment tools are designed to help healthcare providers assess fall risk and reduce the occurrence of fall events [3; 4]. They also provide protocols for fall prevention in terms of leadership, evaluation of fall risks (vital status, medication, environments, etc.), and patient education. However, fall prevention remains challenging due to the diversity of risk factors and localized vulnerabilities in patient risk management, which calls for tailored interventions regarding risk factors per patient [3].

Learning from reported events is critical for identifying vulnerabilities in patient safety management. Reporting systems have been implemented for collecting patient safety event data and conducting root cause analyses (RCA). Mandatory and voluntary reporting systems complementarily serve different levels and different purposes in patient safety events management [5]. To standardize reporting formats, AHRQ Common Formats (CFs) were developed and then became widely accepted and commonly used for reporting and analyzing patient safety events including falls in voluntary reporting systems [6]. The CFs fall-reporting form includes 13 structured questions which cover most contributing factors of a fall event reporting and RCA, such as circumstances, outcome,fall risk assessment, prevention, medication, and assistant devices [7]. The reporting systems are intended to facilitate risk identification, event data collection, and RCA [8]. The ultimate aim is to advance strategies of preventing and mitigating patient safety events.

However, the success of the tools and reporting systems on patient safety has yet to be seen, since healthcare providers fail to receive timely feedback and customized knowledge support [9; 10]. The event reporting systems merely serve as data repositories if reporters can learn nothing from them [11]. Delayed and non-customized feedback may lead to a lack of incentives for providers to continuously and voluntarily report events, which in return results in the underreporting and low-quality reports [12]. This also leads to insufficient knowledge support for providers towards effective fall prevention. Consequently, a knowledge base is expected to provide the foundation for knowledge-based interventions, if one could be developed and integrated into the routine workflow of patient risk management [13]. In such a knowledge base, the solutions for patient fall should be included, and their logical connections to the specific cases should be well established to support learning and clinical decision making. Within the patient fall management circle, event reporting, retrospective analysis, and prospective analysis are chained to support each other [9]. To support the information flow from event reporting to retrospective analysis, reporting data-driven feedback is necessary. Therefore, a refined reporting system with a knowledge base that supports effective feedback has the potential to bridge the gap between the reporting process and knowledge support.

To develop the knowledge base, we identified and synthesized entry-based fall solutions from multiple resources, and established connections between the solutions and the CFs fall-reporting form through expert review. As a result, a fall prevention knowledge base including the reports, solutions, and the connections between the two datasets was established as a resource for timely tailored knowledge support in a patient fall reporting system.

Methods

We developed a framework for the knowledge base based on the CFs fall-reporting form. Fall prevention solutions gleaned from multiple resources were filtered, combined and adjusted to fit into the framework. Each solution is connected to a targeted answer option in the reporting form. Solutions and their connections to the framework were revised by expert review (Figure 1).
Establish a question-answer-solution framework for fall-reporting

To establish a network that links questions, answers, and solutions, we developed a framework of hierarchical questions for describing patient fall events based on AHRQ CFs reporting. These questions were adjusted from AHRQ CFs Hospital Version 1.2, released in April 2012 [7].

Collect solutions from multiple resources

We collected solutions from multiple tools for patient fall prevention, which were developed and distributed by Authentic Patient Safety Organizations. Two domain experts combined identical or similar solutions. Meanwhile, we searched Medline using “solutions” or “interventions” combined with “patient falls” as keywords, limited in abstracts and titles to identify additional resources containing information about patient fall solutions or interventions. The search, conducted in June 2016, resulted in 61 hits, which were integrated into the solution dataset. The following details the resources we used.

Pennsylvania Patient Safety Authority (PA PSA)

PA PSA [14] provides patient safety tools including solutions for fall prevention. The tools for falls prevention include prevention program tools and educational tools, which can serve as knowledge support for risk factors measurement and post-fall investigation. In particular, they include risk assessment tools for radiology and ambulatory surgical facilities. Pennsylvania Patient Safety Reporting System (PA-PSRS) Falls Event Type Decision Tree is provided for the determination of the fall event types in the PA-PSRS.

Joint Commission Center for Transforming Healthcare Targeted Solutions Tool (TST)

The Preventing Falls TST [15] is one of the four applications of Joint Commission TST aiming to improve the safety and quality of healthcare. It provides approaches for state evaluation, RCA, targeted solutions and strategies for sustaining patient safety management, including patient fall prevention.

Slip, Trip and Fall Prevention for Healthcare Workers

Slip, Trip and Fall Prevention for Healthcare Workers [16] was developed by Centers for Disease Control and Prevention The National Institute for Occupational Safety and Health (CDC-NIOSH). This tool listed top risk factors of patient falls, including indoor and outdoor environment conditions and improper use of equipment.

The third report from the Patient Safety Observatory. Slips, trips and falls in hospital

This is a summary of patient fall risk factors and recommended solutions based on “the slips, trips and falls in hospital, the third report from the National Patient Safety Agency’s (NPSA) Patient Safety Observatory” [1].

The “How to guide for reducing harm from falls”

This tool was developed by Patient Safety First [17], a California partnership for health. It provides fall prevention solutions for both leaders and frontline staff to implement interventions to reduce patient fall rates.

AHRQ WebM&M

AHRQ WebM&M [18] provides peer-reviewed patient safety cases and expert analysis, which can serve as a resource of patient safety event solutions. WebM&M is an example of case-specific knowledge support. Due to the store-and-forward method, the expert-reviewed case analysis is far from timely knowledge support and is merely for the purpose of case study.

AHRQ Patient Falls Prevention Toolkit

AHRQ Patient Fall Prevention Toolkit [19] contains a set of strategies and tools collected by experts from multiple sites. The toolkit provides a roadmap for stakeholders to engage in patient fall prevention. It also includes a collection of practical tools for reporters such as STRATIFY Risk Assessment Tool, Morse Fall Scale, Medication Fall Risk Score and Evaluation Tools, and other tools for mental and physical status evaluation.

Match the solutions to the Common Formats

We matched the solutions to the questions and answer options of the CFs based on the solution contents. The solutions that were successfully linked to single or multiple answer options were categorized as specific solutions. The others were categorized as general solutions. We further categorized the solutions into three different groups: Direct action, which consists of operational advice to the staff; Principle, which consists of principal guidance; Patients, which consists of knowledge support for patient education.

Expert review

An expert review was performed to ensure the solutions, connections between solutions and questions, and the categories of solutions were comprehensive for frontline practitioners. We constructed a survey to demonstrate the CF framework with relevant solutions listed below. Each solution was tagged with its category and mapping rule. Five patient safety experts working with a PSO participated in the survey. They revised the contents, categories and the mapping rules of each fall solution. Panel discussions were employed to establish consensuses.

Code the solution mapping rules

The mapping rules between solutions and answer options in CFs were coded into our knowledge base. Boolean logic connectors “AND”, “OR” and “NOT” were applied to form the preconditions for the activation of any solution in the feedback. In detail, the “AND” stands for a combination of two or multiple options need to be checked in the reporting to show the certain solutions. The “OR” requires either of the alternatives. The “NOT” means the solutions would be given in the feedback only if the certain options were not checked.

Develop a knowledge-based web server

A relational database was implemented on our server to accommodate the knowledge base containing reports,
solutions, and connections between reports and solutions. A web-based interface was developed in conjunction with the server and database.

Results

Develop a question-answer-solution framework

We set up a framework based on the 13 questions of CFs fall-reporting form. These structured questions are hierarchically organized with answer options for reporting and RCA (Table 1).

<table>
<thead>
<tr>
<th>No.</th>
<th>Question</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Was the fall unassisted or assisted?</td>
</tr>

<td>Was the medication considered to have contributed to the fall?</td>
</tr>
<tr>
<td>13</td>
<td>Did restraints, bedrails, or other physical device contribute to the fall (includes tripping over device electrical power cords)?</td>
</tr>
</tbody>
</table>

Collect and categorize fall solutions

The current tools have both overlapping and complementary contents. In general, the solutions cover the following aspects in fall prevention: assistive devices (including alarms, call lights, etc.), environment and equipment, fall event reporting, use of fall risk assessment tools, individual patient fall risks, medications, patient and family education, and rounding. As shown in Table 1, identified solutions were categorized into “general solutions” and “specific solutions” according to whether the solutions can be matched to certain answers of certain questions in the AHRQ CFs fall-reporting form. Twenty general solutions and 102 specific solutions were generated. The general solutions were categorized in 8 topics. The specific solutions were categorized in 6 topics according to the questions of CFs fall-reporting form (Table 2). In the topics of specific solutions, the count for Outcome of the fall is 0 because all of the current solutions that we collected were focused on the occurrence and recurrence of fall rather than the treatment of the outcomes which is a relatively independent process. The general solutions will be shown after all reports. Specific solutions will appear only when the corresponding answer options are chosen during the reporting. We also linked the commonly used risk factor assessment tools including Morse Scale, STRATIFY Scale and Medication Fall Risk Scale to the associated solutions, so that the reporters will be able to conduct assessments using those tools after reporting.

Assess recommended fall solutions

Experts’ comments from the survey were further categorized as follows:

Description improvement. Improving the description of solutions to eliminate ambiguities.

Detail specification. Adding specific terms to the solution description to provide practicable details.

New solutions. Supplementing with new solutions that were not included in the survey.

Generalization of target populations or application scopes. Expanding the target populations. For example, patient and family were included in the targets of “standardized education regarding the use of call lights” which targeted to the staff only before the expert review. The application scopes were also extended. For example, fall events without patient injuries were included in the reporting.
Workflow complementation. Implementing protocols to improve the workflow. For example, in the “Patient and family education” part, recommendation for conducting a “post-fall investigation” was added.

Solutions were improved according to the experts’ comments. Both general solutions and specific solutions were grouped by contributing factors, as shown in Table 2. By connecting the solutions with the answer options of questions in CFs fall-reporting form, a knowledge base for fall events was established. The knowledge base contains prevention solutions, connections between solutions and CFs questions, and the logical links of CFs questions (Figure 2).

Discussion

Making the reporting easy and meaningful

Though various reporting systems are available, healthcare providers face challenges using these systems. Extra training is required for providers to use the reporting systems. However, the effects of training may not live up to expectations, which makes the reporting process prone to mistakes [8]. Another problem in patient event reporting is repeated and under-qualified reports without useful information for RCA and corrective recommendations [8]. To solve these problems, we implemented the framework of AHRQ CFs fall-reporting form and integrated expert-reviewed patient fall solutions to develop a knowledge base, which provided an accessible and easy-to-use method for patient fall reporting. AHRQ CFs provided formats for structured information of patient safety events reports, which hold promise in unifying the reporting process and analysis. Based on the framework of AHRQ CFs, our system is expected to improve report quality and make reports more meaningful.

Learning from reporting

Research has been conducted to explore the proper use of fall event reports and to reduce the recurrence of patient falls [2; 3; 12]. However, traditional learning materials failed to provide effective and efficient interventions after reporting. Experienced reporters, such as expert physicians and senior nurses, may be familiar with the common solutions. However, continuous learning from practices is essential especially for novice caregivers [20].

Despite duplicate and incomplete data, current patient fall data from reporting provides rich information for reporters to learn from previous errors [21]. In the present study, we defined four levels of learning in patient safety events prevention as shown in Figure 3. National and local reporting systems collect and analyze patient safety events data, which may potentially contribute to learning on national and local scales. There are other resources for learning like guidelines, literature, and case note reviews [11]. Except for reporting systems, none of the methods is able to provide timely learning after events in individual or local level.

Therefore, a mechanism that integrates multiple solution resources and provides knowledge support after reporting is needed. In this study, we collected and integrated solutions from multiple resources for preventing patient falls. Based on the expert-reviewed solutions, we established a knowledge base that is available in a fall reporting system with timely feedback. By providing timely knowledge support after reporting, our research aims to bridge the gap between local reporting systems and local/individual learning levels (Figure 3), and to help healthcare settings identify vulnerabilities in patient risk management. As shown in Figure 3, the knowledge-based reporting system helps facilitate the information flow from the reporting process to the learning process and then the process of identification and prevention of patient safety events (Figure 3).

The diversity of organizational weaknesses in patient safety management is a challenge for healthcare providers to apply prevention solutions. Therefore, it is essential for patient safety managers to identify local vulnerabilities in management and perform corrective measures. The feedback after reporting can provide not only immediate post-fall solutions to the reporters and help prevent the recurrence of similar patient fall events but also alerts patient safety managers about management system vulnerabilities.

Bridging the gap in patient fall management

The three stages of the patient safety management circle (i.e., prospective analysis stage, surveillance stage, and retrospective analysis stage) overlap with each other. Correspondingly, an ideal pattern is integrating the reporting process and knowledge support into the existing workflow of patient fall management, which facilitates learning from reporting as well as the assessing and correcting processes. However, the gap between reporting and knowledge support appears to be a major barrier to establishing an integrated management mechanism for patient safety. A practical approach is to explore the potential connections between various usable tools of fall prevention and the reporting systems so that reporters will be able to gain timely feedbacks after reporting. Our approach provided a method to integrate expert-reviewed patient fall solutions into the reporting system and to offer timely knowledge support.

For other types of events, a specific knowledge base should be established within the corresponding domains to connect events and solutions. As a result, the strategy for establishing a knowledge base that was used here could be adapted accordingly. For example, pressure ulcers are an injury to the skin and underlying tissue, and are described in four stages according to severity. For each stage, solutions and mapping rules to reporting forms should be collected and evaluated separately to ensure the practicality of knowledge support. Establishing a knowledge base for medication reconciliation could also be considered. The knowledge base should consider the drug name, dosage, frequency, and route while archiving the solution entries. Moreover, physicians’ admission, transfer, and/or discharge orders should also be considered while connecting medication events to solutions. Therefore, future patient safety reporting systems with timely knowledge support should be based on a group of knowledge bases in various domains.
Limitations

The solutions collected in this study may not have covered all aspects of patient falls. Additionally, there are still controversial opinions on the effectiveness and necessity of several solutions due to the lack of large-sample experiments. Further evaluation of such solutions is needed to mitigate such controversy. Although AHRQ CFs cover most key elements for event reporting and RCA, some aspects may not be included due to the diversity of healthcare settings.

The efficiency and effectiveness of our feedback mechanism also need to be further evaluated. Considering the time-consuming and multiple-step procedures of assessment and reporting, the risk factor assessment and knowledge support still call for collaborations from healthcare providers, patient safety experts, and informaticists.

Another challenge is developing and embedding a human-computer communication mechanism into the healthcare providers’ workflow. A critical barrier for patient event reporting is the reluctance of providers to report because of a potentially discouraging environment and workflow interruption. In some cases, reporters were not the personnel relevant to the events who would most benefit from learning from reporting.

Future work

Future work should extend knowledge base development and management of patient falls to those of other event types. The mechanism of sharing and learning from safety events would enhance the reporting quality at all levels. In addition, maintaining and updating the knowledge base can be challenging and labor-intensive, but procedures maintain updated knowledge bases are necessary.

Conclusion

As more high-quality data is collected, stored and analyzed by reporting systems, patient falls can be an important use case for establishing an integrated and optimized workflow using informatics strategies. Our work explored the possibility of building connections between reporting and knowledge support via a knowledge base. This approach may be extensible to other fields of patient safety events, such as pressure ulcers, medication errors, health information technology (HIT) issues, surgical safety, hand hygiene, and medical device issues.

Summarizing an Ontology: A “Big Knowledge” Coverage Approach

Ling Zheng, Yehoshua Perl, Gai Elhanan, Christopher Ochs, James Geller, Michael Halper

College of Computing, New Jersey Institute of Technology, Newark, NJ 07102-1892, USA

Abstract

Maintenance and use of a large ontology, consisting of thousands of knowledge assertions, are hampered by its scope and complexity. It is important to provide tools for summarization of ontology content in order to facilitate user “big picture” comprehension. We present a parameterized methodology for the semi-automatic summarization of major topics in an ontology, based on a compact summary of the ontology, called an “aggregate partial-area taxonomy”, followed by manual enhancement. An experiment is presented to test the effectiveness of such summarization measured by coverage of a given list of major topics of the corresponding application domain. SNOMED CT’s Specimen hierarchy is the test-bed. A domain expert provided a list of topics that serves as a gold standard. The enhanced results show that the aggregate taxonomy covers most of the domain’s main topics.

Keywords:

Big Knowledge; Topic Coverage; Ontology Summarization

Introduction

The Big Data to Knowledge (BD2K) initiative is expected to produce many knowledge items that can be expressed as assertions or as rules. However, orientation into large knowledge bases is a challenge by itself, the “Big Knowledge” challenge. Without some high-level mental representation about the kinds of content in a large knowledge base, effective use of the knowledge may be limited [1]. When an ontology surpasses thousands of assertions, even its curators are confronted with the problem of seeing the “big picture” of its content. The work of curators, in charge of developing and maintaining the ontology, relies on its comprehension. A topic of an ontology represented by a concept c is considered a major topic if c has a large number of descendants. The effectiveness of tools for summarizing and supporting users’ comprehension of a large ontology can be measured by “Big Knowledge” coverage of a given list of major topics related to the corresponding domain. “Big Knowledge” coverage is defined as the percentage of the number of major topics in an ontology out of a given list, rather than by the percentage of the number of concepts out of a given list of concepts [2].

We summarize the “big picture” of an ontology by automatically deriving concept groups that represent major topics in a specific domain. The size of a topic, represented by a concept c in an ontology, is the number of c’s descendants. The knowledge representation importance of topic c (which is different from its clinical importance) can be approximated by its size. The derivation of the topic-defining concepts of an ontology is based on its aggregate partial-area taxonomy (“aggregate taxonomy,” for short) [3]. The aggregate taxonomy is a significantly smaller network that summarizes an ontology’s concepts, providing a simplified view of the ontology. Aggregate taxonomies are based on partial-area taxonomies (“taxonomies” for short) [4], a compact summarization abstraction network developed, for example SNOMED CT [5].

In this paper, we demonstrate why aggregate taxonomies are better at summarizing an ontology than taxonomies, when measuring the effectiveness of the former by comparing with a gold standard list of major topics selected by a domain expert. We used SNOMED CT’s Specimen hierarchy as a test-bed.

Background

Biomedical ontologies provide terminological support for Electronic Health Records (EHRs) [6], decision-support systems, natural language processing, data integration [7], etc. SNOMED CT is a comprehensive ontology organized into 19 hierarchies, such as Clinical finding, Procedure and Specimen. Its 317,057 active concepts (July 2015 release) are linked by ISA relationships and more than 1.5 million attribute relationships (“relationships,” for short). There are 1,620 concepts in the Specimen hierarchy.

We have developed partial-area taxonomies [4] to provide a compact view of the seven SNOMED CT hierarchies, including Specimen, that have outgoing relationships. We illustrate the process of the partial-area taxonomy derivation for an excerpt of the Specimen hierarchy (Figure 1(a)).

We start with the definition of the area taxonomy. We define an area as a set containing all concepts having the same set of outgoing relationships, without considering the ranges of those relationships. Areas are disjoint (i.e., each concept appears in only one area). Areas are named by their sets of relationships. Areas are represented by nodes of the area taxonomy. Figure 1(b) shows the four areas derived from the concepts in Figure 1(a). Areas are color-coded according to the cardinalities of their sets of relationships (i.e., all areas with the same number of relationships have the same color). For example, both areas {Specimen source topography} and {Specimen substance} in Figure 1(b) have one relationship, so both are colored green.

We define a root of an area as a concept having no parents in the area. Areas may have multiple roots. Area nodes are connected hierarchically, using child-of links, to form the area taxonomy. Those links are based on the configurations of area roots in the underlying ontology. More specifically, an area A is child-of an area B if a root in A has a parent in B. Figure 1(b) has four child-of’s derived in this manner.

A partial-area taxonomy (“taxonomy” for short) is derived from the area taxonomy as follows. We group a root and all its intra-area descendants into a partial-area, which is drawn as an embedded node of the area (see Figure 1(c)). If an area has
multiple roots, then its concepts are divided into multiple partial-areas to reflect their varied semantics. We label a partial-area node by its root. Partial-areas are not necessarily disjoint due to concepts with multiple parents/ancestors. Partial-areas are also connected by hierarchical child-of links to form the complete taxonomy. Figure 1(c) is the taxonomy for Figure 1(a). Figure 2 shows an excerpt of the taxonomy (with child-of omitted) for the entire Specimen hierarchy.

Partial-area taxonomies provide a structure-based summary of an ontology. Other ontology summarization techniques have been investigated outside of the biomedical domain, e.g., based on key concept identification by Li et al. [8].

**Methods**

First, we assume that concepts belonging to a given topic are all hierarchically related (i.e., they share a common ancestor concept \( c \) that represents and names the topic). That is, all the descendant concepts of a topic \( c \) belong to that topic since they are specification of \( c \). And second, we assume that if there are relatively more concepts for a topic then it is “more important.” For example, there are 262 concepts related to digestive system specimens, but only 12 related to bone marrow specimens. We thus consider the topic “digestive system samples” as more important in SNOMED CT. We do not claim necessarily that it is more important clinically since this depends on clinical context.

Our approach for evaluating the automatically identified major topics is based on a gold standard list. A domain expert (GE) was asked to select a list of major topics for the specimen domain. (GE) is an MD with long experience in ontologies. A gold standard may also be derived from a published ontology of an authoritative organization. We did not find another ontology for specimens (e.g., in UMLS. For the sake of normalization and to simplify the eventual matching task), each chosen topic was semi-automatically mapped to a SNOMED CT concept in the Specimen hierarchy, utilizing UMLS synonyms. For example, the topic “Bone specimen” was mapped to the concept Specimen from bone.

One straightforward heuristic for identifying major topics in an typically general and cover high-level topics. For example,
Specimen has 59 children (e.g., Biopsy sample and Blood specimen). However, among the 59 children, many would not be considered major topics (based on our second assumption above), since they have few descendants. For example, 13 of Specimen’s children do not themselves have children (e.g., Muscle specimen). Nine have a few children and no grandchildren (e.g., Fibroblast specimen has one child). Of the remaining 37 children, only 13 were in the major topic list of our domain expert, while another eight on that list were not children of Specimen (e.g., Stool specimen is a grandchild of Specimen). Hence, a better methodology for identifying major topics is required. In this study we address two questions: (1) how well do the partial-areas in a taxonomy match the topics in the list by a domain expert?, and (2) can we modify a taxonomy to automatically capture major topics in the ontology?

**Partial-Area Taxonomies for Topic Identification**

As the originators of partial-area taxonomies, we note that they were not designed for major topic identification, but for structure and content summarization. Indeed, the roots of partial-areas are not necessarily intuitive topics. The root is distinguished by the introduction of a new relationship type into the ontology, which may, but is not guaranteed to, correlate with a major topic. Moreover, a partial-area may be small, and thus, may not define a broad topic. A taxonomy typically has many small partial-areas [3]. As a result, the taxonomy for a large ontology, although smaller by an order of magnitude than the ontology, can still fail to identify major topics. Metaphorically, the “forest” summary of the topics is not seen for the many small “trees” (see Figure 2).

Hence, a better solution for identifying major topics is to pick only the large partial-areas (with, e.g., dozens or more concepts). To illustrate these points, Figure 2 shows an excerpt of the Specimen taxonomy. Some concepts appear as (labels of) relatively large partial-areas. For example, Specimen from trunk (132), Specimen from head and neck structure (53), and Specimen from digestive system (50) from the area {Specimen source topography} are partial-areas with 50 or more concepts. However, all the seven large partial-areas account for only 536 Specimen concepts (33.1%). One may wonder about the topics of the other 66.9% of concepts.

Moving to medium-sized partial-areas with 20–49 concepts, we find eight partial-areas covering 218 (13.5%) concepts (e.g., Blood specimen (28) and Soft tissue biopsy sample (23)). Together, the large and medium partial-areas cover only 754 Specimen concepts (46.5%). There are other problems with the summarization provided by the large/medium partial-areas. For example, all descendant partial-areas (yellow) of Specimen from trunk (pink) in Figure 2 contain refinements of this topic. They are in a separate partial-area because they have an extra relationship and appear in another area. For example, Swath from abdomen (13) has an additional Specimen procedure relationship. Overall, there are 201 partial-area descendants of Specimen from trunk, covering 551 concepts.

If we only focus on large and medium partial-areas, we are ignoring useful knowledge that is distributed among the many small partial-areas. Frequently, a large partial-area has many descendant small partial-areas. The concepts in these descendant partial-areas cover the same topic as the large parent/ancestor partial-area, but in more detail. Hence, they could also be summarized by the parent/ancestor partial-area.

**Weighted Aggregate Partial-Area Taxonomies**

We introduce an aggregation process that allows small partial-areas to contribute to the identification of major topics. Large partial-areas are used as candidates for topics, while small ones are folded into their larger ancestor partial-area(s). Thus, the lost knowledge in small partial-areas is accounted for.

To address the inclusion of small partial-areas formally, a variation of a partial-area taxonomy based on an adjustable minimum grouping threshold value was introduced [3]. It is called the aggregate partial-area taxonomy (or just “aggregate taxonomy”). The derivation of an aggregate taxonomy begins with the selection of a threshold \( b \), indicating the minimum size of a partial-area that will be included in the aggregate taxonomy. Then, using a topological sort, the aggregate taxonomy is generated by aggregating any partial-areas with sizes below \( b \) into their parent/ancestor partial-area(s) with sizes \( \geq b \). (The root partial-area may be any size.) The nodes of this taxonomy are called aggregate partial-areas.

However, there is still another problem due to the structure of a partial-area taxonomy. We discovered that some major topics did not appear in the aggregate taxonomies at all, due to the small sizes of their partial-areas, in spite of having many small descendant partial-areas belonging to the same topic. For example, the partial-area capturing the topic Endocrine sample has only 10 concepts, but many more descendant concepts belong to this topic.

To overcome this difficulty, we defined an **aggregated weight** for each partial-area. This aggregated weight equals the sum of the size \( x \) of the partial-area itself and the sizes of all its descendant partial-areas smaller than \( x \). In this way, the decision of which “small partial-areas” to eliminate from the aggregate taxonomies can now be based on the aggregated weight of a partial-area, rather than its size.

This new taxonomy is called **weighted aggregate partial-area taxonomy**. For example, the partial-area Endocrine sample (10) in Figure 3(a) does not appear in the aggregate taxonomy when \( b=10 \). However, its aggregated weight is 26, because it has 9 descendant partial-areas with fewer than 10 concepts, summarizing 16 descendant concepts. Therefore, the partial-area Endocrine sample will appear in the weighted aggregate partial-area taxonomy as long as \( b<26 \) (Figure 3(b)).

![Figure 3](image-url)
Major Topic Identification

We experiment iterating the threshold \(b\) over the range 1...30 and generate the weighted aggregate taxonomy for each \(b\). Each such weighted aggregate taxonomy is inspected to determine its effectiveness in capturing major topics. Precision, recall, and \(F\) measure [9] were calculated for each weighted aggregate taxonomy, with the expert’s topic list serving as a gold standard.

As a preliminary experiment, we tested how many of the gold standard topics appeared as partial-areas in the taxonomy (not the weighted aggregate taxonomies). We found that, out of the 21 topics chosen by the expert, 13 appear as partial-areas. This yields a recall of 0.62 (13/21) and, with 503 partial-areas in the taxonomy, very low precision of 0.03 (13/503). Note that many partial-areas are very small. In contrast, the weighted aggregate taxonomy, which eliminates the small partial-areas, is more effective. To balance recall and precision, we chose the weighted aggregate taxonomy with the \(b\) value that maximizes the \(F\) measure.

Results

If the root concept \(r\) of a partial-area appears in the weighted aggregate taxonomy of threshold \(b\), then \(r\) is considered a topic identified by that weighted aggregate taxonomy, a corresponding checkmark “\(\checkmark\)” is placed in Table 1. Otherwise, a dash “-” is written. For example, the topic Bone marrow specimen is captured by a partial-area Bone marrow specimen (8) with an aggregated weight 13 (Table 1). Therefore, it is identified by all weighted aggregate taxonomies with \(b \leq 13\) (\(b=1, 5, 10\)) However, for \(b=13\), Bone marrow specimen (8) is folded into an ancestor partial-area and disappears. No weighted aggregate taxonomy with \(b > 13\) identifies the topic Bone marrow specimen. As another example, Bone specimen was not identified by the weighted aggregate taxonomy with any \(b\) value as major topic (Row 5 of Table 1), since its mapped SNOMED CT concept Specimen from bone (Row 5, Column 2 of Table 1) is not a root of a partial-area.

At the bottom of Table 1, we show the totals of the identified topics for the respective taxonomies. For example, for \(b=5\), the total is 13. Table 2 shows each weighted aggregate taxonomy’s number of partial-areas (\(A\)), recall, precision, and \(F\). Recall is the ratio of identified topics and total topics \((R=C/S\), where \(S=21\)). Precision is the ratio of the identified topics and the number of partial-areas \((P=C/A\). For example, for \(b=25\), the number of partial-areas is 29, the number of identified topics is 12, \(R=0.57, P=0.41\) & \(F=0.48\). Table 2 shows that \(b=25\) yields the taxonomy where \(F\) is maximized.

In this case, the weighted aggregate taxonomy captures 12 of the 21 topics. Figure 4 shows this weighted aggregate taxonomy with the 12 partial-areas identifying topics highlighted in yellow. The total number of concepts in these 12 aggregate partial-areas is 988, accounting for 61.0% (988/1620) of the concepts in the Specimen hierarchy.

As an ancillary experiment, we carried out a feedback step with our domain expert (GE). When inspecting the weighted aggregate taxonomy for threshold \(b\), one can assess whether its other partial-areas beyond those in the gold standard list are worthy of the designation “major topic”, for example, those aggregate partial-areas (Figure 4) categorizing over 25 concepts, but not in the given list. Since some topics may have been overlooked originally due to various reasons, e.g. Specimen from head and neck structure, a compound topic name with two body parts, and Tissue specimen obtained by excision, corresponding to two relationships Specimen procedure and Specimen source topography. Figure 4 was shown to (GE). He manually determined that 13 more partial-areas, highlighted in pink, warranted inclusion in the list of major specimen topics, while the other three (in white) are deemed non-major topics. Reevaluating the experiment (with 21+13=34 major topics), we obtained \(R=0.74\)
Figure 4-Weighted aggregate taxonomy for the Specimen hierarchy with b=25. The 12 partial-areas corresponding to the original given topics are highlighted in yellow. The 13 topics added during the enhancement step are highlighted in pink

(=25/34), P=0.86 (=25/29) and F=0.79 for b=25. The number of concepts in these 25 aggregate partial-areas is 1,524 (94.1% of the concepts in the Specimen hierarchy).

Discussion

Summarizing a large ontology is a challenge as there is a lack of an objective universally accepted criteria for what constitutes a “good summarization” of an ontology. Various applications require different summaries of various granularities. Nevertheless, the management of ontologies requires “big picture” comprehension that can be enabled by compact summarization networks such as weighted aggregate taxonomies. Our technique is applicable to any ontology. We demonstrated our technique using SNOMED CT because of its importance in clinical applications and its large size.

We used a knowledge-oriented approach, where the importance of a topic is based on the number of concepts related to that topic in an ontology. To measure the quality of our summarizations we compared the number of identified major topics with a gold standard list of topics selected by a domain expert, who selected topics from a clinical perspective. The performance of our technique was optimized by maximizing the F symmetric measure. We modified partial-area taxonomies into weighted aggregate taxonomies to overcome difficulties in bridging the gap between the clinical perspective of the given gold standard list and the knowledge perspective of our structural methodology, which yielded better results.

A future problem is accounting for major topics that are summarized by large partial-areas (e.g., Male genital sample is in Specimen from trunk (132)). Such a topic is missed by a taxonomy since it does not appear as a root of a partial-area. It would also be more objective to obtain the gold standard list from another ontology (or other authoritative sources) rather than from one of the authors (GE). Thus, we plan to experiment with the Disease, Disorder or Finding hierarchy of NCI-I, using ICD-10 as a source of the topic list. We are also planning evaluation studies to compare our technique to related summarization methods, such as key-concept-based ontology summarization [10] and information-content-based approaches [11].

Conclusions

Summarizing knowledge bases for maintenance and “big picture” comprehension is a Big Knowledge challenge. Taxonomies were created to summarize structure and content of ontologies. We modify taxonomies to properly support “big picture” comprehension. For this, we presented the weighted aggregate partial-area taxonomy and measured its performance for “Big Knowledge” coverage of a domain expert’s gold standard list of major topics for SNOMED CT’s Specimen hierarchy. Our methodology was parameterized in terms of a threshold b for node size to obtain optimal performance by maximizing the symmetric F measure balancing recall and precision. A manual enhancement step improved the algorithmic results.

KQA: A Knowledge Quality Assessment Model for Clinical Decision Support Systems

Seyedjamal Zolhavarieh, Dave Parry

*Department of Computer Science, Auckland University of Technology, Private Bag 92006, Auckland 1142, New Zealand

Abstract
Informatics researchers have developed many methods for using computers to utilize knowledge in decision making in the form of clinical decision support systems (CDSSs). These systems can enhance human decision making in the healthcare domain. The knowledge acquisition bottleneck is one of the well-known issues in developing knowledge-based systems such as CDSS. It can be considered as a flow of knowledge from different knowledge sources to the main system. Most existing methods for extracting knowledge from knowledge resources suffer from the lack of a proper mechanism for extracting high-quality knowledge. In this paper, we propose a framework to discover high-quality knowledge by utilizing Semantic Web technologies.

Keywords:
Decision Support Systems, Clinical; Knowledge Management, Information Storage and Retrieval

Introduction
Decision making is an essential activity for clinicians in the healthcare domain. Since 1954, Clinical Decision Support Systems (CDSSs) have been developed to enhance health care systems and improve human decision-making [1]. CDSS is a particular type of decision support system [2] that guides experts in the decision-making process via electronically stored clinical knowledge [3-4]. These systems might use different approaches to assist patients by using alerts, reminders, interpretation system, etcetera.

The CDSS is built from a knowledge base (KB), inference/reasoning engine, and user/communication interaction [5]. It receives patient data and inquiry as inputs and generates a decision as an output. In this scenario, the KB plays an important role in collecting, classifying and sharing knowledge [6].

The knowledge acquisition (KA) bottleneck is one of the well-known issues in CDSS [7]. It is the process of capturing knowledge from external knowledge sources [8]. It is vital to provide an appropriate platform for interacting CDSSs and KBs. Every CDSS needs to rely on high-quality knowledge retrieved from KBs since the CDSS will not be effective if it uses out of date, limited or incomplete knowledge [9]. In addition, finding the latest accurate clinical knowledge to support decision-making is difficult. This issue is partly due to the enormous amount of research, guidelines and other knowledge published every year [10]. Clinical knowledge may need to be extracted from diverse locations and sources that use different formats. In this regard, many biomedical researchers are looking at developing methods to manage and analyze clinical knowledge in this changeable environment [1,11-13]. One of the recent technologies that they applied in knowledge acquisition is Semantic Web (SW) technologies [14] to solve the problem of knowledge management, representation, and interoperability of knowledge sources. They have created some Semantic Web-based systems such as COCOON [15], ARTEMIS [16], Semantic-DB [17], Knowledge-Centric Clinical Decision Support Systems [18-19], detecting Alzheimer disease (AD) [20], Semantic-CT [21], sharable CDSS [22], and others. Most existing methods suffer from a lack of a proper mechanism for identifying high-quality knowledge. There exist two main questions: “whether the CDSS contains enough knowledge for diagnosing an unusual disease” and “how to make sure that the knowledge used by CDSS are reliable.”

Regarding the above questions, in this paper, we aim at proposing a semi-automatic approach called Knowledge Quality Assessment (KQA) to discover and assess the clinical knowledge for CDSS.

Research Motivation
The motivation of this research has been inspired by the result retrieved from PubMed search engine. Consider the following query shown in Table 1 which is about “Tuberculosis Arthritis” disease.

<table>
<thead>
<tr>
<th>[Title/Abstract]</th>
<th>Tuberculosis Arthritis</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Language]</td>
<td>English</td>
</tr>
</tbody>
</table>

The PubMed search engine extracts 18 relevant results for the above query. All of these results are valid, but the question here is “how can practitioners identify the most relevant and accurate result for decision-making process ?”. By assessing the abstract/title of the articles, we find out that some knowledge items which are ranked on top of the search results contain little or no useful knowledge.

The sample result in PubMed

![Figure 1](image)
Figure 1 shows a fragment of the result achieved by the query in PubMeb. The “Tuberculosis arthritis: A review of 27 cases” article, which is ranked before the “Advanced imaging of Tuberculosis arthritis”, does not contain an abstract and explanation related to the query. In other words, this article is less useful and has lower quality knowledge compared with “Advanced imaging of Tuberculosis arthritis.” Although one can set up a filter for results only with abstracts, even so, the relevancy does not correspond exactly with the knowledge value of the article. To solve this problem, this research proposes a framework to assess the quality of extracted knowledge for decision making.

Methods

In this section, we first explain the framework of KQA. Then, we describe the candidate metrics for assessing the quality of knowledge. At the end of this section, we also describe a survey, which has been used to rate and validate the importance of candidate metrics.

The KQA framework

Figure 2 shows a detailed view of the KQA framework. In this framework, a query submitted by a user, which represents a knowledge request, will be given to electronic knowledge sources and central knowledge base. Electronic knowledge sources that are used in this project are PubMed, MeSH, and UMLS. They include different clinical knowledge provided through journals, books, and electronic databases, etc. The central knowledge base is a machine-readable centralized repository that contains knowledge-based rules extracted from guidelines along with knowledge structure of a particular subject in health domain (e.g. Arthritis). After receiving a query, the KQA system will check the existing knowledge in central knowledge base to find a related result. If the knowledge exists in the knowledge base, the system will deliver the knowledge immediately, if it does not exist, the new knowledge will be extracted from electronic knowledge resources based on query characteristics. The extracted knowledge will be converted to the ontological format and annotated by other information to enrich the knowledge by using Ontology Web Language (OWL). After checking the quality of knowledge by using different quality metrics, the high-quality knowledge will be sent to attach a knowledge quality indicator (KQI) to knowledge item. The KQI indicates the quality of extracted knowledge. Finally, the high-quality knowledge will be used to update the knowledge base.

To update the central knowledge base, the candidate knowledge needs to be checked and approved by the domain experts. This is because it may contradict existing knowledge, and we do not believe at the moment that fully automatic knowledge updating is desirable. However, just being made aware of new highly rated knowledge is an advantage over existing approaches. The approved knowledge will be added to the central knowledge base.

Quality assessment metrics

Knowledge quality assessment is a process for checking the quality of extracted knowledge from knowledge sources. Kyoon Yoo et al. [13] noted that knowledge quality should be intrinsically right, contextually relevant, and practically actionable. Based on the Kyoon Yoo model, knowledge quality metrics can be classified into three general categories, including intrinsic, contextual, and actionable metrics. OntoQA [23] is another study which only considered intrinsic metrics. In this paper, we modified the Kyoon Yoo and OntoQA models for categorizing knowledge quality metrics. Table 2 shows three categories of quality metrics proposed in this paper. Based on our categorization, intrinsic metrics are known as the backbone of knowledge. Contextual metrics show how much this knowledge is relevant to a user query. Given a set of actionable metrics indicating that the knowledge is mature, it can be expanded and adapted for further usage.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age of resource</td>
<td>The age of knowledge should be declared.</td>

</table>

Survey for metrics rating and validation

To rate and validate the proposed quality metrics, we conducted a survey among health informatics scholars and practitioners in Health Informatics New Zealand (HiNZ) and the Australasian College of Health Informatics (ACHI) which is also available in [24]. The survey is a questionnaire that has been used for rating the quality metrics through participants. In addition, the participants can propose their own metrics.
Results

We collected the results from 10 experts. Table 3 shows the candidate metrics, which are ranked by participants for knowledge quality assessment for CDSSs.

In this table, the rating is on a scale between 1-5 (1: Not at all Important, 2: Slightly Important, 3: Moderately Important, 4: Quite Important, 5: Extremely Important).

By the survey result, every CDSSs requires an intelligent procedure to check the accuracy, reliability, and relevancy of the extracted knowledge. The accuracy of retrieved knowledge indicates how accurate the knowledge is. It checks the correctness of extracted knowledge against knowledge in the central knowledge base. The reliability metric shows how much the extracted knowledge from different knowledge sources might be similar to each other by using the same query. The relevancy shows how relevant the extracted knowledge is to support the user query. Based on the survey results, in this paper, we focus on developing KQA by assessing accuracy, reliability, and relevancy mentioned in the contextual metrics category shown in Table 3.

As seen in Table 3, the provenance metric has the higher rating average to compare with relevancy. Provenance relates to the perceived reliability of the source of the knowledge. In this research, we put trust on the most well-known knowledge sources for extracting knowledge such as PubMed. There are some metrics that are annotated in the body of extracted knowledge, such as the age of resource, locality, and citation. Such metrics are easy to retrieve and use. The aim of KQA is to check the quality of knowledge before incorporating it in the decision making process. However, there are some metrics (e.g., Adoption, Scalability, and Timeliness) that belong to the actionable category that are related to the quality of knowledge after being incorporated into the decision making process. These may have to be assessed using a study of how knowledge is used operationally in a CDSS.

In the following section, there are some comments collected from participants that identify some metrics that could be useful for further development of KQA.

Person A: Level of evidence and level of recommendation. This gives flexibility to the CDSS so that it gives more freedom to the clinicians. These metrics are found in practice guidelines.

Person B: The knowledge is in a form that computerized DSSs can use. It is equally important that the knowledge is in a form that the user can use - presentation of information to the user within a CDSS is vital for its safe and effective use.

Person C: Validity (the knowledge can be confirmed by using different sources)

Person D: Normalization (in the database sense: 3NF). All the ills of denormalized databases are being presented to us as clinicians because database professionals have ignored the importance of normalization.

Person E: Weighting. No diagnosis is cast in stone; no observation is 100% "right." At autopsy, 8% to 30% of diagnoses are incorrect. Diagnoses should always be considered to be reputable diagnostic hypotheses. It is important to know how sure a clinician is about an assertion, an affordance not provided by most current EHRs and the like.

Person F: Ability to give feedback (to point out possible error or exception)

Person G: To me, the structure is NOT just plonking things in XML. It is about the optimal presentation of the minimum of necessary data required for the clinician to do their job. It is difficult, and not well done (as shown in the Epic trimoxazole incident, and many others besides. Epic may well be better than most).

Person H: Citations are tricky. It is important that evidence can be traced to its source but not always practicable to include citations in rapid easy to read guidelines.

Discussion

Based on the results obtained from the survey, we aimed to measure the accuracy, reliability, and relevancy of knowledge that will be used in the CDSS as these are the most highly rated aspects. In this way, we are going to use some SW technology techniques such as ontology matching, ontology similarity, and ontology comparison. However, the process of evaluating results not only relies on proper measures but also user intervention. More precisely, the quality of retrieved results currently will be checked via domain experts. We are currently building a browser to support such knowledge ratings via the SW. A more automated approach that allows crowdsourcing or other approaches may be used in the future. One example may include comparing the outcomes of decisions made on current knowledge with expected outcomes using new knowledge on a database of cases.

In future research, we are going to use PubMed knowledge source to extract knowledge based on Extensible Markup Language (XML) format. We will manually convert the textual information into the ontological-based structure using Protégé ontology editor. We believe that ontological-based structure will be useful for storing knowledge since this structure embrace semantics along with proper annotations. As seen in this research, we assume that textual knowledge is converted to the ontological-based structure. In the future, we would like to develop an approach that automatically converts text structure to ontological structure for further use.

Conclusion

One of the most important activities in healthcare domain is decision making. CDSS can support decision making and may improve patient safety. However extracting up-to-date and high-quality knowledge from the growing mass of knowledge available is difficult and leads to the KA bottleneck. There are many methods and mechanisms for a CDSS to extract and use knowledge to help an expert to make a decision. The CDSS can improve the level of decision making by proposing appropriate knowledge. However, it cannot support how much of the knowledge is accurate, reliable and relevance in the case of comorbidities. Inappropriate knowledge can have negative effects on the decision-making process. Hence, there needs to be a system to check the quality of knowledge used in CDSS to help practitioners make good decisions. This paper aimed to propose a framework for assessing knowledge quality. To validate and rate the candidate quality metrics, we performed a survey among HiNZ and ACHI experts. This has led to a ranking of metrics that we will investigate.

An Innovative Approach to Jointly Scheduling and Assigning a Consultation Time to Patients Arriving in the Emergency Department

Faten Ajmia, Sarah Ben Othmana, Hayfa Zgayab, Slim Hammadia, Jean-Marie Renardb

a Cristal Laboratory UMR 9189, Ecole Centrale de Lille, Villeneuve d’Ascq, France
b EA2694 University Lille 2, Lille, France

Abstract

Emergency departments (ED) are facing problems related to the growing demand of care. Patients’ management is carried out according to the type of patient and care required: already scheduled patients and non-scheduled urgent and non-urgent patients arriving in the ED. One of the main problems confronted in hospitals is the permanent interference between these different types of patients to be treated under the stochastic behaviors of consultation time and arrival flows, which prevents any prior planning. The present work proposes a dynamic scheduling method, considering the impact of new patients’ arrivals on the treatment of patients already scheduled to minimize the mean waiting time of patients in the ED. The originality of this work is to assign, at the time of arrival, a scheduled time to each patient in order to reduce their stress. The performance of the proposed method is examined through a concrete application in the Pediatric Emergency Department of CHRU of Lille.

Keywords:
Health care rationing, Emergencies, Waiting lists.

Introduction

Nowadays, hospital Emergency Departments (EDs) have a strategic place in modern health care systems and represent the main gateway to the hospital. This key role is expected to strengthen in future years due to the steady growth in the number of arrivals and the increasingly demands of patients [1]. These changes set many problems for different actors in public health, including problems of functioning to cope with this increase in consultations, and a non-negligible healthcare spending [2-6]. However, while the majority of healthcare systems in the world are confronted with this reality, the ways to face them differ from one country to another [7, 8]. In order to better understand current problems and challenges, it is first necessary to place emergency services in their general context in order to understand their functioning and their specific characteristics.

Indeed, the question in France is still topical, and hospital emergencies are taken into account at the highest level within the national organizations. The Code of Public Health specifies all the missions of these services. It is a mission characterized by:

- The reception: to accept every patient arriving in an emergency, including a psychiatric emergency, 24 hours a day, any day of the year, and take care of him, especially in case of distress and vital emergency.
- Translation, definition of demand, needs qualification of the patient with a symptom analysis work.
- The preservation of life, stabilization of a condition thanks to the care, and "urgent diagnostic and/or therapeutic procedures", adapted to the situation.
- Patient orientation at the right time, in the right sector, by the appropriate services.
- Short-term hospitalization in certain cases, depending on the resources and the reception capacity, and according to the functioning of the health care organization.

The care of an emergency patient mobilizes different resources of health organizations: upstream of the hospital, within the health establishment and downstream of the health facility (other institutions). However, the notion of emergency in the medical field remains a source of great ambiguity. In a literature review, it is not difficult to see that if there is a consensus, it is summed up in the fact that an "emergency" requires an action, and an immediate decision. In case of emergency, it is essential to intervene immediately irrespective of the type of emergency and that it is necessary to respond to any request for care, even if the latter is non-programmed and is not a source of life-threatening distress, regardless of the seriousness of the problem.

A situation is called "urgent" because it is considered serious and it calls for a quick response. It is often subjective and intimately linked to the value system of the person who states the emergency judgment. This means that between the perception of urgency by the patient (perceived urgency) and the medical definition of emergency by a medical staff (actual emergency), the gap is often important. A gap may be even greater than the urgency of a case considered in relation to the urgency of other cases [9].

Ensuring patients’ satisfaction in the ED is part of a continuous improvement strategy [10]. The length of the consultation, waiting time, dissemination of information, and interaction with practitioners in the ED have the strongest predictors of patient satisfaction. This does not mean that patients are not aware of the necessary treatment time. But they need to be well informed about the progress of treatments on one hand, and on the overall progression of care on the other hand. In addition, it is so important to give a provisional time of consultation to each patient to reassure him. This also reflects the level of overcrowding, as the length of stay of patients appears to increase considerably when the number of patients increases in the ED. Nevertheless, it is difficult to assess patient satisfaction because of the complex interaction between expectations, perceptions, and reality.

In this paper, we take into account patient waiting time at different stages of patient journey: waiting time between the registration and the provisional time of consultation called “scheduled time”, and between scheduled time and the time of
the first consultation. Waiting times can be the result of the bottlenecks in the ED, or the arrival of more urgent cases. Our objective is to propose an innovative scheduling approach able to solve the problem of the interference between already scheduled patients and non-scheduled urgent and non-urgent arriving patients to emergencies. We aim to optimize patients’ treatment process, and minimize waiting time in the ED. We take into account the availability of medical staff members belonging to different medical teams.

Methods

Scheduling environment

Assumptions

- There is a medical staff member engaged in the scheduling horizon in an ED. In a scheduling horizon, the number of already scheduled patients is \( N_S \), while the expected number of non-scheduled patients is \( N_{NS} \). All the non-scheduled patients arrive randomly at the ED, then a scheduling time must be assigned to them at the time of their arrival.

- In France, the ED is always opened and each arrived patient \( p \) should be registered in the reception desk at time \( trp \). All patients who arrive at the ED are accepted, and should be treated in the current or the next horizon scheduling.

- Each patient corresponds to a set of health care operations to be executed in a parallel or in a sequential manner by one or more medical staff members (physician, nurse, intern, etc.).

- Medical staff members are organized in teams. Each team contains at least one physician. We can have more medical staff members (nurse, pediatrician, etc.) in one medical team depending on the patient pathology.

- The scheduling horizon \( H \) starts at time \( D_H \) and ends at the time \( F_H \). In this paper, we consider that the duration of one horizon is 4 hours.

- The scheduling horizon is divided into several periods with different length, not necessarily the same. If two periods have the same length, the number and the duration of slots in each period may differ, and generally one period contains multiple slots. A slot is allocated to one scheduled patient. Each period contains at least one slot. The scheduled time of a slot is given by the starting time of the period to which it belongs. Therefore, if two or more slots are included in a period, the scheduled patients assigned to the same slot have the same scheduled time.

- Under the stochastic behavior of consultation time of medical staff, let \( C_{m,o} \) be the average consultation time of the medical staff member \( m \) having the skill \( o \) to treat patient \( j \).

- When the medical staff member becomes available, the waiting patient with the earliest scheduled time is called. If the waiting room is full, and there is no possibility to call all the patients in the same scheduling horizon, the remaining patients and the new arriving patients will receive a schedule time in the next scheduling horizon.

- In ED, priority is given to the most urgent cases. So, at the arrival of urgent patients, the current scheduling can be interrupted and a rescheduling is necessary, because these patients should not wait for consultation.

Performance measures

Let the waiting time of scheduled patient \( P_j \), \( W_{sr,j} \) be the sum of patients’ waiting time between the registration and the given scheduled time \( W_{sr,k} \) and the waiting time before the first consultation \( W_{fc,k} \), where:

\[
W_{sr,j} = W_{sr,j} + W_{fc,j} \quad (1)
\]

\[
W_{sr,j} = \max(0, t_{ar,j} - t_{s,j})
\]

\[
W_{fc,j} = \max(0, t_{fc,j} - t_{s,j})
\]

Where \( t_{ar,j} \), \( t_{s,j} \), and \( t_{fc,j} \) represent, respectively, the arrival time, the scheduling time, and the first consultation time of the patient \( j \).

The waiting time of non-scheduled patient \( P_k \), \( W_{ns,k} \) be the sum of patients’ waiting time between the registration and the given scheduled time \( W_{sr,k} \) the waiting time before the first consultation \( W_{fc,k} \), where:

\[
W_{ns,k} = W_{sr,k} + W_{fc,k} \quad (2)
\]

\[
W_{sr,k} = \max(0, t_{ar,k} - t_{s,k})
\]

\[
W_{fc,k} = \max(0, t_{fc,k} - t_{s,k})
\]

The two equations (1) and (2) are mathematically equivalent, but semantically different. In fact, the present study proposes a scheduling method that assigns a scheduling time to each non-scheduled patient at his time of arrival, and guides him to go to the waiting room at his scheduled time. Thanks to the assigned scheduled time, \( W_{sr} \) is calculated for each registered patient.

The objective is to comfort patients and reduce their stress by giving them, in advance, a waiting time till the first consultation. If the first consultation time is equal to the scheduled time, then the waiting time \( W_{sr} \) and \( W_{ns} \) are equal to 0. In case of perturbation (overcrowding situation, absence of medical staff, worsening of patient health state, etc.), a rescheduling is done, and the first time of consultation increases, which makes the waiting time longer for the patient.
Usually most of patients prefer earlier scheduled times, especially at their arrival time. To respect these preferences, the waiting time based on the arrival time \( W = \sum_{k=1}^{Nk} \left( Ws,j + Wns,k \right) \) should be reduced, by assigning as quickly as possible an available medical staff with an appropriate skill.

In this paper our objective is to minimize the total waiting time \( W \) of both scheduled and non-scheduled patients, by taking into account, dynamically, the availability of medical staff members and their skills.

We choose to adopt an aggregative approach without handling appropriate weights to have optimizing solutions. In fact, in real life health care situations, it is very difficult to define suitable weights for these criteria. This work, studies the results of simulations generating some of these criteria separately or some of them jointly.

### Scheduling method

#### Characteristics of non-scheduling patients

As it is mentioned above, the driven idea is to have a scheduling method realizing the shorter waiting time for both scheduled and non-scheduled patient. In order to reduce the effect of the stochastic aspect of arrival flow, we assign to each non-scheduling patient a scheduled time at his arrival time.

The present study gives good solutions by focusing on the similarity between the job-shop scheduling in the flexible manufacturing systems, where the workload is an important factor for the decision maker. In the complex manufacturing system, minimizing the total workload allows to avoid the bottleneck in production system generating a reduction waiting time.

Under the condition of the present work, the Health-Workload \( HW_{p,H} \) of each period \( p \) in the scheduled horizon \( H \), can be expressed by the average consultation time multiplied by the number of scheduled patients in the period. This means that once scheduled patients are set in the period. The scheduling time for non-scheduled patients is decided at the moment of their arrival in the ED by calculating the expected \( HW_{p,H} \) that includes them in the candidate periods. If a maximum value of \( HW_{p,H} \) is reached, then the next period becomes the candidate.

By selecting an adequate solution for scheduling patient that allocates a sufficient initial \( HW_{p,H} \) to each period and by assigning each non-scheduled patient to an appropriate period in order to get a reasonable \( HW_{p,H} \), the conflicting criterion \( W \) is balanced. Controlling and keeping the total \( HW_{p,H} \) for each period \( p \) and each horizon \( H \) below the specified maximum value \( HW_{p,H} \) will complete shorter waiting times of patients as well as shorter total idle times of medical staff members.

#### Dynamic scheduling method of non-scheduled patients

This work assumes that the scheduling horizon, which represents consultation time window, is divided into several periods as already mentioned above. To calculate a scheduled time of a non-scheduling patient, we use a first empty slot in the period as shown in Figure 2.

In principle, the start time of the first empty slot gives the scheduled time of the patient. The maximum number of non-scheduled patients accepted in the period is difficult to estimate, because slots have different lengths in the same period of them jointly.

### Simulation and Results

For simulations, we did observations in the Pediatric Emergency Department of CHRU of Lille, our partner in the
project ANR HOST. We have a 3-years database, 2011-2013, characterized by overcrowding and high activity.

Currently, there is no decision support system or information system able to manage the PED and the problems corresponding to an overcrowding situation. Medical staff members give the highest consultation priority to the most urgent patients and $HW_{p,H_{\text{max}}}$ the already scheduled patients. Non-scheduled patients in the PED have to wait in the waiting room, and sometimes in corridors, without obtaining a scheduling time for the first consultation, which increases their stress.

Our proposed approach performance is tested by comparing it to the current traditional method used in the PED. The database analysis allowed us to define the evolution of patients’ waiting time which sometimes seems to be excessive.

**Experimental conditions**

From the database, we choose an overcrowded day (25th of February 2013) divided into 6 horizons, the duration of each one is 4 hours. Each horizon represents the consultation time window.

</table>

For simulations, we consider that the periods and the slots have different lengths. Each consultation time window is composed of 5 periods. The length of each one is alternatively 1 hour and 30 min. The one-hour period has 8 slots whose length is alternatively 5 min and 10 min. The 30 min period is composed of slots of 5 min and 10 min. We consider for the scenario that the medical staff is represented by only physicians in this numerical example. The mean consultation time of scheduled patients $C_{\text{med}}$ is 5 min, and the mean consultation of non-scheduled patients is $C_{\text{med}}$, 10 min. The arrival of non-scheduled patients follows a Poisson distribution. The mean inter-arrival time of non-scheduled patients is 10 min. So, we have 24 arriving patients to the PED in one horizon. Table 1 summarizes the average values under different values of $HW_{p,H_{\text{max}}}$(min).

According to the table, when $HW_{p,H_{\text{max}}}=100$ min, the average waiting times of scheduled and non-scheduled patients have increased. The idle time of physicians has decreased. This is due to the arrival of urgent patients to the PED. In fact, these patients have complex pathologies which need more consultation time.

This phenomenon proves the impact of the interferences between scheduled, non-scheduled, and urgent non-scheduled patients. These interferences depend on the number of incoming patients and their pathologies.

Figure 3 represents the relationship between the number of no-wait consultations and the total idle of physicians.

Through figure 4, we notice that there is sensitivity between the number of urgent patients and the different waiting times. The mean time of no-wait consultations is inversely proportional on the total idle time of the physician. This also indicates that, while adjusting the total idle time of physicians, the frequency of no-wait consultations is minimized. In fact, when the pathology of urgent patients is complicated to treat, the idle time of physicians becomes smaller. In this case, scheduled patients in the next periods are able to receive earlier consultation which therefore decreases the value of $W_{\text{ar}}$.

**Discussion**

In the PED of CHRU of Lille, we noticed that patients are often dissatisfied, many feel that their waiting is excessive and that their care should be immediate. This is also a matter of subjectivity, or of poor ranking in the order of priorities of patients. Because, it should not be forgotten that in these
circumstances priority is given to patients in vital emergencies. In sum, the main cause of overcrowding situations is that the demand exceeds the supply generated by the functioning nature of this structure, because the notion of appointments does not exist. This limits the margin of organization and planning. The situation becomes even worse, when several patients arrive at the same time to the PED.

Usually, in the waiting room, patient with the earliest scheduled time is called first for consultation. However, under the stochastic and irregular consultation time and arrival of more urgent patients, determining a method for assigning a scheduled time to each patient arriving is a research issue. Perturbations that can occur during the treatment of patients already scheduled are able to modify the scheduling. A considerable research effort has been devoted to scheduling problems related to emergencies. Although the arrival of new patients and the appearance of urgent and non-scheduled patients produces a complicated situation in patients’ scheduling, it seems that this kind of scheduling problem attracts little attention in the literature.

Our main consideration in this work is the development of dynamic scheduling solutions with rolling horizon to simplify the work of medical staff and minimize the average waiting time in the PED for both scheduled and non-scheduled patients. Through assigning a scheduled time to patients, medical staff members can have an idea about their workload during the horizon and patients are reassured. The proposed approach is able to adapt the available human resources in the PED in order to afford a good quality of health care for patients. In fact, the arrival of urgent patients in the case of an overcrowding situations leads to the minimization of the total idle time of medical staff. Our approach is based on the dynamic and reactive generation of treatment plans. The information and especially the treatment timestamps are given through a dynamic orchestration workflow architecture modeling the patient journey through agents [11].

Conclusions

In this paper, we have proposed a dynamic scheduled system with rolling horizon, by assigning a scheduling time to each patient at the time of his arrival. Our innovative scheduling approach is able to solve the problem of the interference between already scheduled patients and non-scheduled urgent and non-urgent patients arriving in the ED. Our target is to optimize the treatment process of patients, and minimize their waiting time in the ED. For future work, we aim to improve this approach through an alliance with genetic algorithms and multi-agent systems in order to solve the problem of multi-skill health care tasks scheduling in the ED.

Design of a Mobile Application for Transfusion Medicine

MA Albornoz, S Márquez, L Rubin, D Luna

Departamento de Informática en Salud, Hospital Italiano de Buenos Aires, Argentina

Abstract

One of the most frequent error in transfusion medicine is the failure in verifying the patient’s identity prior to transfusion. This paper describes the design and development of a Mobile Application (MA) for transfusion medicine. The app uses barcode and QR reading technology for the verification of the patient’s identity and the administration of blood components when making a blood transfusion. Physicians, developers, technicians of transfusion medicine and a User Centered Design team participated in the design. The inclusion of end users was fundamental to get full representativeness of their workflow. The project was based on agile methodologies of project management and software development.

Keywords:
Blood Transfusion, Patient Identification Systems, Patient Safety

Introduction

Today transfusion medicine has become a safe and essential practice in hospitals, but it is a process in which the slightest mistake has the potential of causing great morbidity or even death. A study in New York estimated that 1 in 12,000 transfusions are caused by ABO compatibility mistakes. The Serious Hazards of Transfusion (SHOT) reports in England showed that the risk of death from transfusion in 2012 was 1 in 322,580 transfused components and a had a morbidity greater than 1 in 21,413 [1, 2]. Approximately 70% of incorrect blood components administration occurs in clinical areas. The failure of the final check of the patient’s ID bedside is one of the most frequent error. The patient’s identity verification is a critical point to provide security [3, 4, 5, 6, 7].

The use of new technologies is one of the best strategies to avoid this kind of mistakes. The barcoding technology allows increasing patient safety with the verification of their identity at the time of taking a new sample and administering a blood component. Like this, it becomes a physical barrier that allows errors reduction in the stages of the circuit and the improvement of the product’s identification and correct patients rate [8, 9, 10, 11].

Currently, several papers describe the creation and use of barcode systems with Personal Digital Assistant (PDA) systems, but no published works were observed allowing the use of any Smartphone or tablet device with Android operating systems (OS) in the area of transfusion medicine [8, 9, 10, 11].

The purpose of this paper is to describe the iterative design and development of a Mobile Application (MA) that will be supported in Android OS, which uses bar code and QR reading technology, for the safe administration of blood components when a blood transfusion is performed. We will describe the current transfusion process in our institution and then the one addressed by the MA.

Methods

Setting

The Hospital Italiano de Buenos Aires (HIBA) is a non-profit healthcare academic center founded in 1853, with over 2,700 physicians, 2,700 other health team members (including 1,200 nurses) and 1,800 administrative and support employees. The HIBA has a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 800 home care beds, 25 outpatient clinics and 150 associated private practices located in Buenos Aires city and its suburban area. It has a Health Maintenance Organization (Plan de Salud) that covers more than 150,000 people and also provides health services to another 1,500,000 people who are covered by affiliated insurers. Between 2013 and 2014, over 45,000 inpatients were admitted to its hospitals, there were 45,000 surgical procedures (50% ambulatory) and 3,000,000 outpatient visits. In addition, the HIBA is a teaching hospital, with over 30 medical residency-training programs and 34 fellowship programs. There are currently 400 residents and fellows in training.

Since 1998, the HIBA runs an in-house developed health information system, which includes clinical and administrative data. Its Electronic Health Record (EHR) system, Italica, is an integrated, modular, problem oriented and patient centered system that works in different clinical settings (outpatient, inpatient, emergency and home care). Italica allows computer physician order entry for medications and medical tests, and storage and retrieval of tests results, including images through a picture archiving and communication system. It has been recently certified by the HIMSS as level 6+ in the Electronic Medical Record
Adoption Model, being the first hospital in Argentina and the second in Latin America reaching this stage.

The HIBA Transfusion Medicine Service (TMS) is composed by 7 staff physicians and more than 30 transfusion medicine technicians (TMT), who works distributed in 3 shifts. At each shift, 4 technicians make rounds through the hospital performing the requested procedures, while others support the process in the MTS. They carry out an approximate of 110 transfusions of hemocomponents daily, and receive approximately 50 blood donors daily. For the registration of donors, recipients and transfusions they use an in-house system called HEMOTRANS®. It does not currently interoperate with the EHR, although its developers along with the Department of Health Informatics are working on an integration plan. The HEMOTRANS® system is responsible for crossmatching the information between patient’ samples and donors. It also stores hemoproducts intake and generates reports.

From October 2015 to November 2016, 38,663 transfusions were performed in HIBA. This is equivalent to an average of 3221 monthly procedures and 110 daily. In that period, 15 transfusions adverse reactions (present within the initial 15 minutes after the transfusion started) were recorded in structured entry forms within the HCE.

In order to understand the current circuit of transfusion medicine, meetings were held in a multidisciplinary team conforming by health informatic physicians, MTS staff, TMTs and user centered designers. The current transfusion process and the steps to be taken to address the design of future application were agreed. Prior to submitting the request to the developers, test mockups were performed and iteratively modified with the TMTs.

The current transfusion process:

1. The physicians make the transfusion request from the EHR. An single request may contain different types of practices (for example 2 units red blood cells and 7 units of platelets). The order also has the emergency status of the patient, and a summary of the hematologic status of the patient.
2. The TMS coordinators print all the transfusion requests and distribute them among the technicians according to their availability. They print the informed consent and barcode labels with patient identification from the EHR and verify in HEMOTRANS® if they have already been grouped within 72 hours prior to the transfusion to be performed. If this is the case, they use these stored samples to group the donor’s blood. When there is not a registered sample, a blood extraction is made. This is used for serological follow-up is and blood grouping to corroborate the group and factor before the transfusion is done. Each tube is identified with the respective patient identification label. The results are then entered into the system and in the EHR.
3. In the TMS, the blood product bag is selected from the blood bank, and barcoding is performed on it from the HEMOTRANS®, in order to subtract the product from the stock and to check its compatibility with the patient’s blood to be transfused.
4. The next step happens in the patient bedside. His identity (name and date of birth or identification bracelet against the paper order) is checked verbally and if they’re correct the blood transfusion is performed.
5. If there is a transfusion reaction in the first 15 minutes, the TMT registers it in the EHR and the medical team is notified.
6. The last step happens when the TMT closes the order from a desktop computer generating an automatic progression note with all the transfusion process’ data.

Results

Design and development of the MA

In August 2016, a team of resident physicians from the Health Informatics Service with TMT and doctors from the TMS defined the steps and activities that formed the process of a transfusion.

The MA was designed by a team of health informatics physicians, software developers and a user centered design (UCD) team, with the insights of transfusion medicine physicians and technicians.

The project was based on agile methodologies of project management and software development. Subsequently, weekly personal interviews were conducted with 10 technicians to deal with the details of the process. They were accompanied on their daily visit and the process of realizing several transfusions was observed to understand their complexity and to detect problems and opportunities of future implementation.

Layout Instance

The health informatics team generated a Project Charter document indicating the project scope and magnitude, and a Gantt chart setting the project time frame. Through the software Balsamiq® MA several mockups series were generated.

Mobile application prototyping instance

The mockups were tested with the TMT, and modified iteratively according to the tests results. The first series of mockups were in low fidelity, the followings improved their quality. With the mockup final version, a PDF document (portable document format) was designed, emulating the workflow and functionality of the final application, forming a high-quality test application.

Tests of MA

This instance allowed users to test the AM with a smartphone before starting its development. To this end, different use cases scenarios were created with specific tasks to be performed in TMS. The TMTs that were involved in the design process of the MA were not the same than those who
tested the final version, to avoid any bias. 5 TMTs were gathered and a smartphone was given to them, along with the task to be performed. The TMTs successfully completed the process with very good acceptance. The design team filmed them, with their consent, to obtain more qualitative conclusions later.

Development Instance

Once the TMTs and sponsor approval was obtained, a development request was made to the development team who are currently completing the web application developed with Ionic Frameworks v1 and AngularJS v1.3. Material was used as a template (extension of the Ionic Framework) [12, 13].

Workflow in the mobile application

The TMT logs into the AM by entering username and password. When he starts his work shift he can view the worklist of all products requested in the EHR, without the need to print any order on paper. He selects and assigns to his own worklist the requests in with he will work. If there are any pending procedures from another work shift, there is a "patient handoff" where the TMT takes the patient and associates him to his own work list, with the purpose of allow continuity of care. The list is configurable by request creation’s hour, request urgency and sector from where it was generated. The requests can be grouped by patient, if there are several of them for the same patient.

As can be seen in Figure 1, when the TMT clicks on a request on the list, the next screen of the app is the “Patient Space”. On its header contains patient’s name, date of birth, hospital location, allergies, infectious isolation, blood type, updated personal photo, among others. The “Patient Space” body contains the requests and the different actions that can be made through the app.

Depending on the request, the MA’s main actions are:

- **Sample:** This option allows the technician to perform barcoding on the patient’s identification bracelet and on the label of the newly extracted sample tube by checking that the labels are on the correct patient. This blood grouping is serologically monitored and a new corroboration of group and factor, genotype and detection antibodies is made prior to transfusion. (Point 2 of the process described above).

- **Transfusion:** This option enables a blood product transfusion. It needs the identification of the patient, the request order and the product to be transfused. The AM can read any type of barcode identification or QR codes. If there is any data inconsistency at the time of the barcoding the application gives an alert message and registers it. Once the first 50 ml of the transfusion are in the patient bloodstream, the TMT registers if there was any transfusion reaction and generates an automatic progression note from the application directly into the EMR. (Point 4 to 6 of the process described above)

- **Deliver:** The transfusion medicine technician transfers the hemoproduct, for another technician or nurse to perform the transfusion later. These cases are usually given in the operating room or in the neonatal care unit. Postpone: It happens in any situation when the transfusion can not be performed. It allows the TMT to register this in the. Before the AM this was recorded with a manuscript evolution in the EHR.

Bedside, according to the circuit that is being performed, the AM indicates the steps to complete. The AM allows the tracking of the entire process and provides the possibility to see the previously performed procedures, report adverse reactions and generate a direct record in the EHR. By having instant communication via Wi-Fi each of the procedures impact in the form of CDA (Clinical Document Architecture)[14] and allows its visualization to the other members of the health team. In this way the process was complete without the need to print paper orders.

Discussion

This paper describes the design and development of an AM that will allow to assist the MTS in their process. It is impossible to create a representative tool without the users participation involved in the task. The user centered design area is increasingly involved in AMs production, trying to make it easier to learn, simpler to use, and gain a good acceptance and perception of utility by users[15][16][17]. This design was made by constant and iterative work with end users of the application. The design team aim was for the system to be able to achieve the goals set with a balance
between systematization and flexibility. We achieved a good level of satisfaction for each of the TMT participants with whom we worked. The field of health is gradually adopting user centered design strategies so that computer applications match the tasks or activities for which they were designed [18].

According to literature, we need to make more and more interactive designs with multiple versions, tasks and environments, including the user at the beginning of the project and then carry out product evaluations aiming to improve quality, effectiveness and efficiency [19].

The application will be responsive for both smartphones and tablets that use Android OS. The application will be available within a package of functionalities that are being designed in our institution. Currently we have an MAs already implemented for the patient's transfer by the stretchers who perform barcoding on the patient's bracelet and the place of destination where he has to be taken. Another MA is also being completed, which nurses will use to check the "5 correct" when giving a medication, taking vital signs of the patient and other activities performed by the nursing area. This set of applications interact with each other, generating greater communication in the health team, better continuity of care and a quick online update in the EHR.

Limitations
The transfusion medicine MA is still being developed, so the use cases were made with mockups in a test environment. They were not immersed in the real work scenario, with the patient, with the transfusion kit, with the TMT wearing latex gloves, a particular Smartphone to read the appropriate barcode labels (with a suitable camera, with good Autofocus time, battery life and processing speed) or the hospital's Wi-Fi network.

Future lines
We aim to carry out next studies with qualitative methodologies in user satisfaction after use it in real scenarios. We aim to increase transfusion adverse reactions records; provide greater control at the patient's bedside, improving the effectiveness and efficiency of the transfusion process. We also want to analyze the best strategy, contrasting BYOD vs. the purchase of devices and see which is the minimum hardware requirement when choosing a smartphone [20].

Conclusion
There are multiples devices and applications that represent the workflow for transfusion process using barcode techniques. We design a mobile application applying usability techniques being responsive for smartphones or tablets that use Android OS. We expect this AM to be a tool that helps TMT, achieving greater security in the transfusion process, reducing errors in critical points, improving communication between the different actors involved and facilitating the daily task.

Acknowledgments
This work was carried out thanks to the contribution of a great team of professionals, among them we highlight all the staff of the TMS, especially Dr Walter Scordo, Dr. Camino Pablo, technician Diego Santoro, and Lic. Ortiz Juan who helped and advised us in design and usability of the project.

Assessing Provider-Generated Free-Text Quality in EHR-Integrated Handoff Notes

Elliot G Arsoniadis\textsuperscript{a,b}, Steven J Skube\textsuperscript{a}, Treva M Bjerke\textsuperscript{c}, Bryan Jarabek\textsuperscript{c}, Genevieve B Melton\textsuperscript{a,b}

\textsuperscript{c}Fairview Health Services, Minneapolis, MN, USA

Abstract

Handoff notes are increasingly integrated within electronic health record (EHR) systems and often contain data automatically generated from the EHR and free-text narratives. We examined the quality of data entered by providers in the free-text portion of our institutional EHR handoff tool. Overall, 65\% of handoff notes contained at least one error (average 1.7 errors per note). Most errors were omissions in information around patient plan/management or assessment/diagnosis rather than entry of false data. Factors associated with increased error rate were increasing hospital day number; weekend note; medical (vs. surgical) service team; and authorship by a medical student, first or fourth year resident physician, or attending physician. Our findings suggest that errors are common in handoff notes, and while these errors are not completely false data, they may provide individuals caring for patients an inaccurate understanding of patient status.

Keywords:
Patient Handoff; Patient Transfer; Electronic Health Records;

Introduction

Within patient care, a handoff refers to the process by which clinicians transfer the care of patients from one clinician to another. This process occurs with the transfer of patients between clinical settings, such as from the Emergency Department to the inpatient unit, or when patients transfer between different care teams without necessarily changing physical location, such as when daytime care teams change to nighttime “on-call” teams. This later type of care transfer between the primary daytime team to the “on-call” team is recognized to be an important source of preventable medical errors [1].

Handoff notes are cognitive aids that are created in order to aid in the transfer of patient care from one clinician (or team of clinicians) to another [2]. Increasingly, handoff notes are being integrated within the Electronic Health Record (EHR), rather than existing as stand-alone documents outside of the EHR [2-4]. EHR-integrated handoff notes may be completely populated with data automatically generated from the EHR, but more often contain both automatically generated data as well as free-text narrative data authored by members of the care team [4]. Patient summaries and management plans are two of the most important items within handoff notes, and almost always require direct free-text entry rather than automatic generation from data in other parts of the EHR [5].

The goal of this study was to assess the quality of free-text narrative data in handoff notes generated by physicians within an institutional EHR in an academic inpatient setting. First, we sought to learn which providers and medical teams at our tertiary-care institution (composed of medical students, resident physicians in training, attending physicians, and Advanced Practice Providers (APP)) were authoring handoff notes. Then, we evaluated the quality of data in these free-text narratives by analyzing their accuracy and completeness using daily progress notes and other data within the electronic chart as the gold standard. Finally, we attempted to identify patterns in the frequency and types of errors encountered, and to ascertain factors associated with errors in free-text data.

Methods

Introduction of an EHR-integrated Handoff Tool

In June 2016, our institution introduced an electronic handoff tool incorporated within our institutional EHR (Epic Systems, Verona, Wisconsin, USA). This tool was optimized and locally adapted to be more user friendly and legible by a team of eight physician informaticists and two information technology builders. The design was based on prior experience with the handoff tool at several other peer academic institutions and work with several inpatient-based provider groups. The handoff tool template included two free-text text boxes, labeled “Patient Summary” and “To-Do”. Authors could enter free-text within either box. The handoff tool could be accessed and viewed within the EHR by any member of the care team, including medical students, resident physicians, APPs, and attending physicians. A print option was also available, which included any free-text entered in either the “Patient Summary” or “To-Do” boxes as well as automatically generated patient information, including patient demographics, vital signs, and laboratory data.

Obtaining Physician-generated Handoff Notes

Free-text data was collected from handoff notes each evening from 7-9PM during a six week period. Patients included were on both surgical and medical service teams in general inpatient units. Patients in critical care settings were not included. Daily handoff note collection began on the day of admission and continued each day until the day of discharge. In addition to the content of the handoff “Patient Summary” and “To-Do” free-text text boxes, we also collected data on the date and time of data entry, the author’s specialty and level of training, as well as whether the note occurred on a weekday or weekend.
The free-text information in the handoff note was then compared to the information in the patient chart, including daily progress notes, laboratory data, imaging studies, and orders, to assess for accuracy. In addition to assessing the accuracy of the free-text information written by handoff note authors, physician-raters also assessed for missing information omitted from the handoff note.

Prior to initiation of data collection, two physician-raters met and formulated an initial schema to define quality issues in handoff notes. Missing information was defined as any data missing from key portions of the patient’s diagnosis and subsequent clinical course or key elements of the management plan. History and Physical Exam notes written on the day of admission and subsequent daily progress notes were used as the standard against which to compare the free-text data in the handoff note. In the initial schema, data included in the Assessment and Plan portion of the admission History and Physical Exam note or daily progress notes that was omitted from either the free-text “Patient Summary” or “To-Do” portions of the handoff note were deemed missing information. Missing significant results of imaging studies or laboratory tests, as well as notes from consulting medical teams were also defined as missing information. Again, the daily progress note and subsequent data generated throughout the clinical work day constitute basic information that should be included in the free-text portions of the handoff note. After this schema was defined, physician-raters separately reviewed thirteen daily handoff notes and compared their individual assessments. Differences in assessment were discussed and agreed upon, and the final schema was adjusted to account for the variation in physician-rater assessment.

After six weeks, the physician-raters had collected free-text information from 368 handoff notes. The quality of these notes was assessed using the aforementioned schema and errors were recorded. We then sought to describe the nature of the errors uncovered from free-text data in handoff notes, using a schema originally described by Arora and colleagues for assessing medication-related errors in handoff notes [6].

We adjusted the schema to fit our broader goals of defining both medication and non-medication related errors in handoff notes. Errors were initially classified as either errors of commission or errors of omission. Errors of commission were defined as those errors committed by authors where incorrect information was entered into the handoff note. For instance, an author may have entered “patient receiving ciprofloxacin” but on review of the active orders in the patient chart, the patient may have been on an antibiotic other than ciprofloxacin. Entered information that was no longer relevant was also classified as an error of commission. For instance, if the handoff note states “patient to receive chest CT if respiratory status declines” and review of imaging studies show that a chest CT had already been completed that day, this would also be deemed an error of commission. Errors of omission were those where a piece of clinically relevant information related to the diagnosis/clinical course or management plan was omitted from the free-text data in the handoff note (Table 1).

In addition to assigning errors as either those of commission or omission, errors were also grouped according to whether they were an error in assessment/diagnosis or an error in plan/management. Errors were assigned this label based on whether the information would more likely be included in the Assessment or the Plan portion of a traditional SOAP (Subjective, Objective, Assessment, Plan)-style daily progress note. For instance, errors regarding surgical procedures that had occurred during hospital admission or important clinical events, such as the development of Acute Kidney Injury, were errors of assessment/diagnosis. Errors such as omitting that Gastroenterology was consulted or listing the wrong antibiotic for treatment of pneumonia were considered errors in management/plan.

Finally, errors were assigned as either “New” or “Continued”. Errors appearing for the first time in handoff notes for a hospitalization were defined as “New”, whereas the same error included in a patient’s subsequent handoff notes was considered “Continued”. After the number and types of errors were determined for each handoff note, the overall percentage of notes with errors were compared across disciplines, levels of training, hospital day, as well as if the note was written on a weekday or weekend.

### Results

**Handoff Note Demographics**

Overall, 368 handoff notes were collected and evaluated during the study period. Handoff note authors ranged in level of training from medical students, to resident physicians in post-graduate years (PGY) 1 through 4, APPs (Nurse Practitioners and Physician Assistants), and attending physicians. The majority of handoff notes were written by resident physicians in PGY-1 (51%) and PGY-2 (27%) (Table
2). There was a nearly even distribution in handoff notes written on patients in internal medicine (49%) and surgery service teams (51%). Surgery teams included General, Bariatric, Colorectal, Thoracic, Transplant, Gynecology, and Ear Nose and Throat (ENT) surgery. The majority of the handoff notes were written on Hospital Day (HD) 1 (27%) and HD2 (21%). Among those patients included in our study, length of stay ranged from 1-25 days.

Handoff Errors

Overall, 635 errors were discovered in 368 handoff notes, an average of 1.7 errors per handoff note. In 65% of handoff notes, at least one error was found. The vast majority of errors were rated as either plan/management omission (54%) or assessment/diagnosis omission (32%). There were far fewer errors of commission in both plan/management (12%) or assessment/diagnosis (2%). Of the omissions in plan/management, nearly half (48%) were rated as “New” errors. Only 32% of omissions in assessment/diagnosis were rated as “New” errors, with the majority (68%) being rated as “Continued” errors. Over half of the errors of commission in plan/management (59%) and assessment/diagnosis (60%) were rated as “New” errors (Table 3).

Error Rate and Type by Hospital Day

The rate of having at least one error detected in a handoff note and the average number of errors per note increased with each subsequent day in the hospital. Forty-seven percent of handoff notes written on HD1 had at least one error detected with an average of 0.9 errors per note. This increased to 57% on HD2, with 1.19 average number of errors per note. A subsequent increase was noted on HD3, 4, and 5 as well, where 65%, 74%, and 78% of notes, respectively, had at least one error detected (Table 4). Average number of errors per note also increased, with 1.69, 1.91, and 2.26 errors respectively. Handoff notes written on HD6 or later had the highest rate of errors (86%), and the highest average number of errors per note (2.95) (Table 4).

The types of errors also changed with increasing hospital day. On HD1, 61% of errors were omissions in plan/management and 22% were related to omissions in assessment/diagnosis. Only 6% were errors of commission in plan/management and 2% errors of commission in assessment/diagnosis. This distribution of types of errors stayed relatively consistent for HD2-5 (Table 5). However, for handoff notes written on HD6 and beyond, omissions in plan/management decreased (42% of total errors) while omissions in assessment/diagnosis increased (44% of total errors) (Table 5).

The percentage of errors that were rated as “New” versus “Continued” also changed with increasing hospital day. On HD2, 76% of omissions in plan/management and 55% of omissions in assessment/diagnosis were rated as “New.” By HD6 and beyond, only 17% of omissions in plan/management and 13% of omissions in assessment/diagnosis were rated as “New” (Table 5).

Error Rate and Type by Weekday versus Weekend

Handoff notes written on a weekend had a higher rate of having at least one error detected (73%) and higher average error (1.8) versus those notes composed on a weekday (62% error rate and 1.7 average errors) (Table 4).

Omissions in plan/management accounted for 56% of errors in handoff notes written on weekdays, and 48% of errors in notes written on weekends. Omissions in assessment/diagnosis accounted for 32% of errors in both weekday handoff notes and weekend handoff notes. Sixteen percent of errors in handoff notes in both weekdays handoff notes were related to omissions in plan/management on weekends, versus only 11% of errors on weekdays.

Error Rate and Type by Service Team

The percentage of notes with at least one error detected and average number of errors detected per handoff note varied by service team. Fifty-five percent of handoff notes written by authors on surgical service teams had at least one error detected, and an average of 1.39 errors per note. In contrast, 72% of handoff notes written by authors on medical service
teams had at least one error detected, with an average of 2.07 errors per note (Table 4).

Sixty-six percent of errors in handoff notes on medical service teams were omissions in plan/management, while only 37% of errors on surgical service teams were omissions in plan/management. Conversely, on surgical service teams 44% of errors were omissions in assessment/diagnosis while on medical service teams omissions in assessment/diagnosis accounted for only 23% of errors.

</table>

Error Rate and Type by Training Level of Author

The majority of handoff notes were written by resident physicians in PGY-1 or PGY-2. Sixty-eight percent of handoff notes written by PGY-1 physicians had at least one error detected, just slightly above the overall rate of 65% for all training levels. Fifty-four percent of handoff notes written by PGY-2 physicians had at least one error detected. PGY-1 physicians had an average of 1.65 errors per handoff note and PGY-2 physicians had an average of 1.38 errors per note. Overall, there were an average of 1.73 errors per handoff note for all authors (Table 4).

Nearly half of errors in handoff notes (49%) written by PGY-1 physicians were omissions in plan/management, while well over half (60%) of errors in notes written by PGY-2 physicians were omissions in plan/management. Thirty-three percent of errors were omissions in assessment/diagnosis for PGY-1 physician-generated notes, and 20% of errors were omissions in assessment/diagnosis for PGY-2 physician-generated notes.

Only 8% of handoff notes were written by medical students, with an average of 2.38 errors per note. Of these notes, 88% had at least one error detected. PGY-3 and PGY-4 physicians authored 5% and 2.7% of notes, respectively. Forty-seven percent of handoff notes authored by PGY-3 physicians and 70% of notes authored by PGY-4 physicians had at least one error detected.

Few notes were authored by attending physicians or APPs. Eighty-two percent of handoff notes authored by attending physicians had at least one error detected, with an average of 4.24 errors per note. Thirty-eight percent of handoff notes written by APPs had at least one error detected, with an average of 0.88 errors per note.

Discussion

In the present study, we analyzed free-text data within a series of handoff notes written using an EHR-integrated handoff tool. The majority of authors were PGY-1 or PGY-2 physicians. Over half of the errors encountered were omissions in plan/management and nearly one third were omissions in assessment/diagnosis, reflecting a lack of completeness, rather than gross inaccuracies, as the major source of error. When examining the errors in commission in plan/management that had been entered into handoff notes, 63% (47 out of 75) were due to failure to update a previously accurate plan that had since changed. Again, this shows that a major contributor to false information was the failure to update previously true information, rather than the direct entry of erroneous data. This points to a deficiency in effort on the part of handoff note authors, rather than a deficiency in knowledge, as a major cause of inaccurate and incomplete data in handoff notes.

The Role of Hospital Day and Information Decay

A major contributor to the amount of errors detected in handoff notes was the length of hospital stay, with increasing days correlating with increasing errors. Forty-seven percent of handoff notes had at least one error detected on HD1. By HD6 or beyond, 86% of handoff notes had at least one error detected. Increased length of hospital stay correlated with an increased risk of errors as new clinical information is gained, along with a higher probability of propagating previous errors.

Arora et al noticed this in their study of medication discrepancies, noting that 63% of errors persisted beyond their index case (6). This corresponds to our data, where 24% of omissions in plan/management and 45% of omissions in assessment/diagnosis were rated as “Continued” on HD2, yet by HD6 and beyond, 83% of omissions in plan/management and 87% of errors in assessment/diagnosis were rated as “Continued.” Interestingly, the majority of errors initially were omissions in plan/management, but by HD6 and beyond, there were nearly equal omissions in assessment/diagnosis. This reflects the fact that while authors were relatively accurate at recording initial diagnoses and clinical events, accuracy waned as hospital day, and presumably clinical complexity, increased.

Weekday versus Weekend Handoff Notes

Handoff notes from weekends were more likely to have at least one error (73% vs 62%) and had a higher average number of errors per note (1.80 vs 1.70) compared to notes written on weekdays. Other clinical phenomena have been associated with weekend care. Admissions and surgical interventions on weekends have previously been associated with higher mortality [7], length of stay [8] and hospital-acquired conditions [9]. These associations could be due to decreased numbers of physicians on weekend care teams. With fewer physicians present to aid in clinical work, those physicians who are present may prioritize other clinical activities at the expense of updating handoff notes.

The Role of Clinical Service Team and Author Training Level

To our knowledge, this is the first study to compare rates of errors in handoff notes by specialty. Handoff notes for patients on medical service teams were more likely to contain at least one error (72% vs 55%) and had a higher average number of errors per note (2.07 vs 1.39) compared to surgical
service teams. One possible explanation is the level of training of the authors. All attending physicians, who had the highest rates of errors, were on medical service teams while the vast majority of APPs, who had the lowest rates of errors, were on surgical service teams. Notably, medical service teams were more likely to omit items from plan/management while surgical teams were more likely to omit items from assessment/diagnosis, possibly reflecting differences in handoff data prioritization between specialties.

The percent of handoff notes with at least one error detected, as well as average number of errors per note, varied by author level of training. Increased training initially correlated with improvements in error rate, with PGY-2 and PGY-3 physicians having fewer errors than medical students or PGY-1 physicians. The benefits of increased training, knowledge, and clinical acumen could account partially for the improvement in handoff note errors. However, increased training beyond PGY-3 (PGY-4 and attending physicians) was associated with a higher error rate. This could reflect that more experienced physicians (beyond PGY-3) rely less on the handoff note as a comprehensive summary of the patient’s clinical course and management plan and thus require a less granular version to serve its purpose as a cognitive aid [10]. This also suggests that physicians-in-training interface with the EHR in a qualitatively different way as training progresses and attending-level status is reached [11].

Study Limitations

While the handoff note represents an important cognitive artifact, there are other verbal aspects of the handoff process that we could not evaluate in this study. Further studies might include a focus on both the verbal and written aspects of handoff. Studying handoff notes at different timepoints throughout the year may also show a difference in error rates, especially at teaching institutions where physicians-in-training progress in their clinical acumen throughout the year.

Finally, this study utilized a schema we devised to determine what information was important for inclusion in the handoff note. Decisions about the accuracy and completeness of handoff notes were based on information recorded in the remainder of the electronic chart. Further work might include a larger body of physician-raters from various specialties and training levels to further validate the present methods.

Conclusions

Increasingly, handoff notes are being integrated within the EHR. We found free-text data in EHR-integrated handoff notes frequently contain errors. The majority of these errors are related to the omission of information regarding both plan/management and assessment/diagnosis. Far fewer errors are directly related to the entry of erroneous information. Further work should focus on efforts to increase the ease with which accurate handoff notes can be generated. This will rely on efforts from clinicians, members of the health IT community, and experts in human factors to ease the process of generating high-quality handoff notes, rather than simply increasing the amount of automatically generated data in the handoff note. It will also involve improvements in clinician training, emphasizing the importance of high-quality handoff notes and recognizing the relevance of these notes in providing high-quality patient care.

Abstract

Accessing online health content of high quality and reliability presents challenges. Laypersons cannot easily differentiate trustworthy content from misinformed or manipulated content. This article describes complementary approaches for members of the general public and health professionals to find trustworthy content with as little bias as possible. These include the Khresmoi health search engine (K4E), the Health On the Net Code of Conduct (HONcode) and health trust indicator Web browser extensions.

Keywords:
Quality Indicators; Internet; Trusted Health Information

Introduction

The Web has become an important and significant health-related resource. (N.B., the terms resource, website and webpage are used interchangeably herein for health content on the Web.) By providing copious medical and healthcare information, the Web has empowered the public. Some 60% of Europeans [1] and 72% of Americans [2] have used the Web to address healthcare questions. Internet use offers many conveniences, including accessibility 24 hours a day, anonymity when conversing with others, and analyses on a wide range of subjects. The Web provides information on how to contact local and national experts, access to sage opinions (e.g., best therapies, effectiveness research), and connectivity to a massive quantity of health information resources. Alarming, some 75% of people using the Web for health purposes do not differentiate among the facts they obtain in terms of accuracy or credibility [3].

A 2013 Pew Research survey indicated that eight out of ten online health inquiries start by using a search engine [2]. Somewhat uniquely, Web-based health information can directly impact a person’s health status, providing benefits, but also harm – in a few extreme cases, resulting in death [4]. Naive users do not realize that search engine results mix trustworthy information with unreliable and even purposefully manipulated health information. The most commonly used search engines currently provide no support to differentiate quality assessments of health content. Even worse, general search engine results can lead to biased medical content (deviation from the truth’), and can lead users to make inappropriate healthcare decisions [5]. PageRank was identified early as a promising way for health websites to indicate to consumers that they were providing quality information to consumers [6]. However, mechanisms underlying page rankings, e.g., hyperlinks and browsing history, merely indicate popularity of a webpage is [7]. Many organizations have previously attempted to guide Web users to high-quality health websites, but this remains a challenge. For example, Google investigated possible statistical estimating schemes to judge the correctness of facts [7]. Nevertheless, in the rapidly evolving health domain, facts are not absolute – the best test or therapy for a condition today may not be so tomorrow. Information correct for one person’s situation may not be for others. Thus a crucial need exists to assess the trustworthiness of a given health Web resource. This paper presents recent new quasi-automated methods to filter healthcare web site content to assess trustworthiness and readability. The ultimate goal is to promote laypersons’ easy access to quality health information [8, 9].

The problem of trust

The concept of trust is elusive to define because a multitude of factors contribute to it. Grandison and Sloman [8] defined the quality of a page as content targeted at the right audience. Gil and Arzt [9] listed 19 different factors affecting how users determine trust in webpage content, including: topic, context and criticality, popularity, authority, recommendation, bias, appearance, honesty and currency of information.

In 1996, the Health On the Net (HON) Foundation determined that the International Committee of Medical Journal Editors (ICMJE – www.icmje.org/) conventions and recommendations for printed medical journals could be applied to online information. Thus, HON developed the HONcode, a set of ethical, honesty, transparency and quality standards related to health website content production. Note that HONcode certification provides a metric that determines if the processes underlying a website’s construction and maintenance conform to standards of excellence; it does not evaluate the veracity of the site’s content per se. The HONcode certification process implies that the health website editors are both motivated and committed as they need to invest time to meet HONcode criteria into the future. The website editors receive no direct financial return or incentive for such efforts from HON. Moreover,
in 2014 the annual assessment of certified websites was changed into a contribution-based program enabling HON to continue offering certification. Prices range from 50 euros for not-for-profit websites to 325 euros for high-ranked commercial websites. Certified health websites agree to display the HONcode seal on the website (Figure 1), to be continuously scrutinized and to implement the recommendations made by HON.

**Figure 1 – HONcode seal displayed on certified websites**

Based on more than two decades of research and pragmatic experience accrediting websites using HONcode criteria [10], the authors now believe that those criteria capably capture the trustworthiness of a health Web resource. Studies have demonstrated that websites that conform to HONcode quality standards contain more reliable health information than randomly selected health-related websites [18]. The presence of the HONcode symbol on a website informs the user that the site respects a quality standard. Thus the user, when faced with multiple, contradictory and sometimes questionable information, can trust those sites that are HONcode certified. Unfortunately, HON lacks the resources to review and revisit all health-related websites continuously. Also, HONcode certification is a voluntary process whereby health website editors must request that HON reviews their sites, which requires awareness of the HONcode initiative. So, the problem at hand is how to estimate the trust level of an arbitrary health website by quasi-automated means.

**Previous relevant work on health website trustworthiness**

Other groups have explored natural language processing (NLP) approaches to facilitate access to quality health information [11, 12]. The authors and colleagues have also examined human- and automated-identification of information trustworthiness using the HONcode criteria combined with an experimental multilingual automated detection system [13, 14]. The latter NLP-based approach also included readability-level scoring, which rates how easy it is for the average user to understand the web page content. In addition to developing methods that analyze content that users have found, HON has also developed services that help Web users to directly access trustworthy health information. HON has actively participated in the development of the Khresmoi for Everyone (K4E – http://everyone.khresmoi.eu) health search engine, which provides access to trustworthy health websites. The JAMA benchmark criteria, the DICERN score (http://www.discern.org.uk) and Medlineplus.gov and the HONcode have been widely covered and compared in the literature for assessing health and medical-related websites [15, 16, 17]. The Table 1 below summarizes the specificities of the four instruments.

**Why automate HONcode certification?**

Previous approaches to the HON certification process have been described elsewhere [10, 13]. Because HONcode certification has been until now carried out manually, the number of sites that can be assessed by HON reviewers on a daily basis is limited. This article focuses on quasi-automated detection of compliance with the HONcode criteria in a manner that complements the human task. Yet, ample room exists for greater awareness of online health information quality amongst the general public. Additionally, it is not easy to determine which websites are certified when using a general search engine. This is why, in addition to the HONcode Web browser extension, the automated detection of HONcode principles has been studied and developed.

**Automated detection of HONcode principles**

HON has conducted extended research on benchmarking and assessing natural language processing (NLP) methods for multilingual automated detection of HONcode principles [13, 14, 19]. The first step of the manual and any automated certification process is to determine where on the candidate web site information relevant to each HONcode criterion appears. This requires around 25% of the time of manual HON assessors. The automated machine learning algorithm training data set (ground truth) comprises the notes that previous expert manual HON reviewers created during their reviews – and include extracts of texts justifying that each principle was met [13, 14] in real life settings. For each HONcode principle, a specific classifier has been created, except for the Attribution principle (H4), which has been divided into one classifier focusing on references (H4-Reference) and one on date (H4-Date), giving nine distinct classifiers (Figure 2). The resulting panel of NLP algorithms has been tested, compared, evaluated, fine-tuned and applied in order to develop classifiers for each of
the HONcode principles. This resulted in the selection of the Naïve Bayes (NB) supervised machine learning algorithm [13,14]. The classifiers are used to identify the presence of the HONcode criteria into health webpages in English and French.

The classifier scores are then compared and evaluated. The results of a HONcode certification ranges from 80% to 95% depending on the principles [13]. Lastly, the results are compared with the HONcode experts verifying the compliance of HONcode criteria (the automated system only detects the presence of words characterizing the HONcode criteria). Globally the automated detection of HONcode criteria performs well for most of the criteria. This evaluation has led to improvements in the criteria related to HC2-Complementarity, HC4-Date and HC8-Advertising policy. Further investigation shows that for the HC4-Date criterion, the named entity recognition (NER) technique was better adapted than machine learning and a sliding window as a classification unit was necessary for the HC2-Complementarity criterion in order to detect text with other criteria included in the same page. Upon further evaluation, these improvements demonstrate their efficiency [19] and thus have been adopted and used within the automated detection of HONcode criteria (Figure 5).

Readability level of health content

The goal of introducing a readability level is to determine how difficult it is to understand medical or health webpages. The idea is to provide users with access to documents targeted at their level of understanding, a level that evolves over time. How difficult is it to understand the health information on a given webpage? Gil and Arzt [9] define access to information adapted to the audience as an indicator of quality. Readability levels have been widely investigated from linguistic and stylistic points of view [20], but little has been done at the level of the medical and health domain where complex terminologies are often used, rendering information difficult to understand.

Further investigations have been conducted using machine learning algorithms to categorize the complexity of health information. The readability level is calculated taking into consideration the length of a sentence and the vocabulary and syntax within the medical context [14]. A readability level in one of three categories—easy, moderate or difficult—is then assigned to each health webpage, text or document analyzed.

Results

HON proposes two ways for the public at large to access quality health information: (1) through a dedicated health search engine (such as K4E) with a selection of trustworthy and adapted resources available for the readers; (2) through a browser functionality, including the filtering and highlighting of certified HONcode websites, the automated detection of HONcode criteria and a readability indicator. As general search engines are most often the gateway that laypeople use to access health information online [21], the latter has been an important strategy. In addition, the automated system to detect HONcode criteria aims to assist the HON assessors within the evaluation of a health website’s HONcode conformity. Therefore, the automated assistance in conducting HONcode reviews may help in accelerating the current time-consuming tasks of HONcode certification and ongoing surveillance.

Dedicated health search engine

The K4E search engine offers a curated list of online health resources that have been manually checked for quality. K4E includes various functionalities related to quality, such as query formulation, readability and trust indicators. K4E is an alternative to general search engines as it reduces content biases in the search results as the index is curated, the results are based only on the relevance according to search terms, and the
organizations behind the search engine are impartial (no advertising). The automated HONcode detection system and the readability level have been integrated into K4E as a demonstrator (Figure 4): a) the trust level indicates to what extent the user can rely on the information provided on the site as determined by the automated HONcode detection system; and b) the readability level indicates how hard it is to understand the health information. The results in a) provide the overall percentage of the HONcode criteria automatically detected and lists those not found for a given health domain.

Usability testing was conducted in a real-life setting with members of the general public seeking health information online. The evaluation included two types of feedback: the informal feedback given during the session and recorded by the usability testing software Morae (TechSmith’s usability testing software, 2014, version 3.3.3.) and the answers to the standard system usability scale questionnaire (SUS), which presented 10 standard SUS statements used to measure usability perceptions and 17 specific statements related to the K4E search engine. The usability test confirmed that the level of readability and trust indicator score are important user requirements, with a score of 4.34 out of 5 in the Likert scale: strongly disagree (1) to strongly agree (5) [22].

Figure 4 – Trustworthiness and readability filtering for “migraine” with K4E

Quality indicators in a Web browser extension

Using HONcode certified websites as its base, HON developed a Web browser plugin that enriches general search engines (Yahoo, Bing and Google) results with the HONcode seal when health websites are certified. This limits the search only to certified websites and thus reduces its use. In order to complement the functionalities offered, HON has developed the Health Trust Indicator Web browser extension that includes quality indicators such as the readability level and the results of the automated detection of the HONcode principles on health websites (Figure 5). The readability score is for a given health webpage while the automated HONcode detection indicator is for the whole health website.

This Web browser plugin allows anyone using these general search engines to know for each result the level of trust and of the site providing the information (Figure 5). Then, the user can select trustworthy health pages and avoid information from websites with a low trust score.

Figure 5 – Google results using the Health Trust indicator

Web browser extensions

Discussion

The HONcode and Health Trust Indicator Web extensions currently only have a limited impact as people need to be aware of their availability and the quality issue in order to choose to install such services. A solution would be to have certified websites highlighted directly in major search engines without using a Web extension. This tricky issue was explored from 2006 to 2009 using Google Co-Op Topics. HON tagged and labeled HONcode certified webpages that had been manually categorized according to health subject. These webpages were searchable by end users via the beta version of Google Co-Op. However, the results of this service were inconclusive because users did not use it and it was not financially rewarding. It was eventually dropped.

The K4E vertical search engine specializes in health websites, applying specific domain knowledge in the collection of content and in indexing and query formulation. However, only a limited number of people use health search engines as most people favor the convenience of general search engines.

In addition, K4E does not include a HONcode page rank, which could highlight all links from certified websites and offer a popularity score within the limited circle of certified websites. This idea will be studied for implementation within KConnect’s further development.

HON also attempted to mobilize the crowd (crowdriffing.org/project/healthwebsitesanotationtest/) to assess websites according to the eight HONcode principles with no success, showing that such a task is too large and complex. However, specific and binary tasks can be achievable, such as to tick yes or no if the date was correctly retrieved by the automated detection system. Thus the next step will be to propose a prototype with a crowdsourcing function associated with the automated HONcode principle detection system. An assessment and evaluation of the task to be performed by the crowd will be conducted as the task should be simplified as much as possible.

HON contributes to webmaster education but seems to have less direct impact on final users. One part of the solution for health and for information in general found on the Internet has to be education and the development of awareness and critical thinking. Information literacy should be taught rapidly and continuously as soon as a child is able to navigate on the Internet [23].

Conclusions

The HONcode is the most used model for the identification of health sites that are transparent and respect quality criteria [24]. However, more effort in terms of access to trustworthy health information is necessary. Twenty years after the inception of HON, there is no solution that is able to address at a large scale the problem of trust on the Internet, particularly for health information. For the past 20 years, HON and its partners have however made a valiant attempt to investigate solutions to the issue of quality health information online. Access to information is mainly a matter of available content, and a matter of search engine algorithms with strong biases as shown in [5]. The so-called bubble filter phenomenon accentuates the problem; another problem is the profiling of the user in search engine results. These drawbacks indicate that substantial room for improvements in currently available common search engines. An alternative approach would create vertical search engines dedicated to health.
An approach combining quasi-automated trust level indicator categorization with manual HONcode certification offers the possibility to cover health websites that have not been evaluated manually. Such reviews can complement the human work involved in evaluation and monitoring of certified health websites.

The HONcode quality assessment tool, which works through a Web browser extension, is straightforward and allows the user to identify if a site is reliable and respects the HONcode principles. The additional automated quality indicators available via the KConnect Web browser extension have shown through usability testing that users appreciate and favor quality online health information and tools when they are aware of them.

Abstract

The creation of clinical decision support systems has received a strong impulse over the last years, but their integration into a clinical routine has lagged behind, partly due to a lack of interoperability and trust by physicians. We report on the implementation of a clinical foundation framework in Arden Syntax, comprising knowledge units for (a) preprocessing raw clinical data, (b) the determination of single clinical concepts, and (c) more complex medical knowledge, which can be modeled through the composition and configuration of knowledge units in this framework. Thus, it can be tailored to clinical institutions or patients’ caregivers. In the present version, we integrated knowledge units for several infection-related clinical concepts into the framework and developed a clinical event monitoring system over the framework that employs three different scenarios for monitoring clinical signs of bloodstream infection. The clinical event monitoring system was tested using data from intensive care units at Vienna General Hospital, Austria.

Keywords:

Introduction

Recognition of the benefits and potentialities of information and communication technology in healthcare (eHealth) [1-3] led to political support for healthcare digitization; healthcare institutions were given financial incentives to adopt and make “meaningful use” of electronic health records (EHRs) [4]. Although the term “meaningful use” is quite expansive, it does include the development and use of clinical decision support systems (CDSSs). CDSSs are eHealth systems designed to assist health professionals in clinical decision-making tasks at the point of care.

Clinical event monitors are CDSSs specialized in the delivery of information. A clinical event monitor delivers information to healthcare providers where and when they need it [5]. Generally, a clinical event monitor performs one or more of the following tasks [5]: (a) it issues warnings about adverse events such as potentially harmful drug–drug interactions or complications of treatment, (b) it interprets medical findings, such as laboratory test results, (c) it provides reminders for immediate or future diagnostic or therapeutic steps, (d) it proposes (alternative) diagnoses or treatment options, and (e) it coordinates complex clinical protocols or workflows.

A substantial number of clinical event monitoring systems have effectively addressed one or more of the aforementioned tasks for a variety of healthcare settings. In the field of infection control, there have been many studies on (semi-) automated systems for the detection and monitoring of healthcare-associated infections [6-8]. Similarly, computerized adverse drug event detection and computerized physician order entry have also been widely researched [9, 10]. The performance of the large majority of systems has been good or excellent. The systems, when measured, proved to be an improvement over traditional or manual methods.

Despite the success of these systems, their use and integration have been limited to their local setting. This is a multifactorial problem. In the present report, we focus on technical and psychological aspects. From a technical point of view, most systems were developed for a specific hospital information system and specific EHRs. Furthermore, they might not always be implemented with established communication standards. As a result, the systems lack interoperability. The effort of porting or recreating the systems outweigh their potential benefits. From a psychological point of view, many systems have only been verified internally. In other words, they have been tested with data from a single healthcare institution. Lacking external validation, the general applicability of the results remains unproven. Moreover, even if a system is verified externally its acceptance by third parties is not guaranteed because the adoption of the system might be perceived as a loss of autonomy [11].

This is especially true of illnesses and adverse events that are not yet fully understood, or which lack consensus regarding their definition or method of detection.

From the above discussion, it follows that the acceptance and dissemination of the system could be improved by providing an interoperable, configurable system. Such a system would use established standards of communication and knowledge representation, thus enhancing its interoperability. A widely known standard for computerized knowledge representation and processing is Arden Syntax [12]. The latter is a programming language for the collection, description, and exchange of medical knowledge in a machine-executable format. Indeed, many of
the tasks performed by clinical monitoring systems have already been modeled in Arden Syntax [13-16]. Improving its acceptance among clinicians would require a knowledge base that could be configured to fit the user’s clinical knowledge and experience.

In our view, clinical event monitors are systems that can be composed of standardized configurable building blocks. As such, a limited set of standardized medical knowledge units, which we refer to as the clinical foundation framework, should be available. Based on these, event systems may be constructed and configured according to the wishes of clinical institutions or patient caregivers. These basic blocks of knowledge would be used for preprocessing raw clinical data and determining less complex, clearly defined clinical concepts that are directly measured from objective data and laboratory results. Based on this clinical foundation framework, more complex medical knowledge can then be modeled through the composition and configuration of these basic knowledge blocks.

In the present study, we report preliminary results following the implementation of a clinical foundation framework. We created a clinical event monitoring system that monitors several infection-related clinical concepts based on definitions from internationally respected institutions, such as Centers for Disease Control and Prevention (CDC), Atlanta, USA, and the European Centre for Disease Prevention and Control (ECDC), Stockholm, Sweden. For each of these concepts, we constructed rules in Arden Syntax and integrated them into the clinical foundation framework. Based on a retrospective data analysis with data from intensive care units (ICUs) we show that using knowledge units in the clinical foundation framework as building blocks, we can provide multiple definitions for higher-level clinical concepts.

Methods

Clinical background

We discuss six infection-related clinical concepts included in the clinical foundation framework. These clinical concepts are well-known signs of infection and are used in existing surveillance definitions for infections from the CDC and ECDC. These concepts are fever, leukopenia, leukocytosis, elevated C-reactive protein (CRP), shock, and drop in blood pressure. Definitions of fever, leukopenia and leukocytosis were taken from the ECDC European surveillance of healthcare-associated infections. Definitions of elevated CRP, shock, and drop in blood pressure are well-known signs of infection and are used in existing surveillance definitions for infections from the CDC and ECDC.

Fever

Body temperature > 38 °C

Leukopenia

< 4,000 WBC/mm³ blood

Leukocytosis

≥ 12,000 WBC/mm³ blood

Elevated CRP

CRP > 10 mg/dl blood

Shock

Systolic blood pressure < 90 mm Hg

Heart rate ≥ 100 beats per minute

Drop in BP

BP value in the 37.5th percentile of all averages between systolic and diastolic BP over the last 3 days

Table 1 – Definitions of clinical concepts modeled in the clinical foundation framework.

Data management and sample size

Demographic patient data, as well as clinical and laboratory values, were obtained through systematic interrogation of the Philips IntelliSpace Critical Care and Anesthesia (ICCA) information system, which is in operation at ICUs in the VGH. Interrogation of the data sources using the selection criteria mentioned earlier yielded a total of 984 patient stays.

Knowledge base and data processing

For this project, we reimplemented a part of the knowledge base of Moni (Monitoring of Nosocomial Infections), a fully automated knowledge-based surveillance tool for the identification, monitoring, and reporting of nosocomial (hospital-acquired) infections in ICUs [19].

We used Arden Syntax to implement rules for the clinical infection-related concepts listed in Table 1, as well as rules for data preprocessing and feature extraction. Arden Syntax is a programming language used for representing, processing, and sharing medical knowledge, employed in an executable format by CDSSs to generate alerts, reminders, interpretations, as well as manage messages to clinicians [20]. In an Arden Syntax knowledge base, medical knowledge is divided into medical logic modules (MLMs) [13]; each MLM contains instructions and logic to support at least a single medical decision.

In the clinical foundation framework, MLMs perform one of three types of processing tasks:

- Raw data processing, which deals with importing and processing raw data directly from the structured data source, here the Philips ICCA system.
- Data-to-symbol conversion, which deals with data preprocessing (such as handling missing or contradictory values), and feature extraction (such as calculating mean values or intermediate scores).
- Symbol calculation, which deals with the calculation of basic clinical concepts (e.g., medical symptoms and signs).

In all 17 MLMs were created; seven for raw data import and processing, four for preprocessing and feature extraction, and six for symbol calculation. Table 2 lists these MLMs with a brief description of their task(s).

We used the ARDENSUITE integrated development and test environment (IDE) for the implementation, management, and testing of MLMs in the clinical foundation framework. For the execution of MLMs, we used the ARDENSUITE server [21], to be executed through service-oriented access for client applications.

Presentation of results

We show how different versions of a system for the detection of clinical signs of infection can be constructed and configured, using basic building blocks from the clinical foundation framework. Based on the data collected from the ICUs at VGH, we show how different setups yield different results.

Results

Of the 984 patients included in this study, 417 were female (42.4%). The youngest was 18 years old, the oldest 92 years; the median age was 61 years, with an interquartile range (IQR) of 24 years. In all 7,573 patient days were recorded during the study period. The length of the hospital stay ranged between two and 93 days, median 4 days, and an IQR of 6 days.

We developed three scenarios, which we model with the clinical foundation framework:

1. **ClinSignsV1**: A straightforward definition of the concept “clinical signs of bloodstream infection” as specified by the ECDC in [17], involving only the clinical concepts elevated body temperature, leukopenia, and leucocytosis.

2. **ClinSignsV2**: A more complex definition that employs a more comprehensive modeling of the clinical concept of fever. In this case, the presence of fever is not only derived from the patient’s body temperature, but also from clinical interventions that indirectly indicate the presence of fever, such as the use of cooling packs or blankets (cf., ThermoReg in Table 2).

3. **ClinSignsV3**: A definition that extends the ClinSignsV2 definition by including known markers of infection such as elevated CRP and hypotension. In this scenario, hypotension is modeled with the clinical concepts of shock and drop in blood pressure.

Table 3 shows the logical definitions of the clinical concepts used in each scenario. Table 4 shows the number of registered events for relevant clinical concepts and infection symptoms in the clinical foundation framework, and for the clinical concepts listed in Table 3.

**Discussion**

We presented the implementation of a clinical foundation framework in Arden Syntax. The calculation of standardized lower-level clinical concepts directly related to raw clinical data is pre-implemented in a framework of this nature. Consequently, more complex and semantically richer concepts can be calculated by combining elements from the framework with custom implementations. This permits easier and more rapid construction of CDSSs.

The scenarios presented in the Results section all yielded different results. Using the clinical foundation framework, we were able to create different versions of the same clinical concept. This may be useful when the system needs to be implemented for different purposes or different stages of the problem. For example, ClinSignsV1 would be more suited for prospective clinical alerting due to its relatively low number of occurrences, while the more complex ClinSignsV2 would be more suited for retrospective detection of healthcare-associated infections.

The limitations of the study are worthy of mention. First, as the clinical foundation framework is still in its pilot phase, not many MLMs have been implemented so far. Second, we still need to reimplement the systems integrated at VGH in order to test the framework in a clinical routine. Finally, new systems need to be created and composed in order to assess the ease of construction and improve the performance of the framework and its interfaces.

Several CDSSs have been implemented with Arden Syntax and integrated into clinical routine at VGH, in a variety of clinical specialties, such as nephrology, oncology, and infection control [22]. Inspection of these systems revealed that most of the MLMs in these CDSSs have processing duties performed by the clinical foundation framework, such as raw data processing, data-to-symbol conversion, or symbol calculation. As such, the implementation and configuration of these and similar systems could be simplified by the clinical foundation framework. Furthermore, as the clinical foundation framework grows, an extension of these systems and more complex modeling of symptoms, signs, interpretations of laboratory test results, clinical findings, diseases, therapies, adverse events, quality measures, etc. will become easier.

**Conclusion**

We created a clinical foundation framework, based on which clinical event monitoring systems can be constructed through combination and configuration. Using the framework, CDSSs can be created more rapidly and configured according to the specific needs of healthcare institutions and patients’ caregivers.

Abstract

With an in-depth analysis of nursing work in 14 hospitals over a period of two years, one unique total nursing information system framework was established where the nursing clinical pathways are used as the main frame and the nursing orders as the nodes on the frame. We used the nursing order concept with the principles of nursing process. A closed-loop management model composed of the nursing orders was set up to solve nursing problems. Based on the principles of traditional Chinese medicine, we further designed an intelligent support module to automatically deduct clinical nursing pathways to promote standardized management and improve the quality of nursing care. The system has successfully been implemented in some facilities since 2015.

Keywords:
Medicine, Chinese Traditional; Nursing Process; Disease Management

Introduction

One of the important aspects of modern nursing science is the systematic holistic nursing care. It has not only been affected by the information technology, but also laid the foundation for nursing informatics, which was pointed out by a Nursing Informatics pioneer, Dr. Hannah, in 1985 [1]. Medicine and health in China has developed rapidly in the past 10 years except nursing informatics. We conducted a thorough investigation in 14 top hospitals among five Chinese cities and found that there is no complete and effective clinical nursing information system, especially for the Chinese medical hospitals. Therefore, we set the goals of the study as follows:

- To create a standardized nursing clinical framework with Nursing Clinical Pathway (NCP) as the main frame
- To create core elements of the system with nursing order
- To guide the whole nursing process of the closed-loop management paradigm through nursing orders
- To introduce an intelligent decision support system (DSS) module to automatically deduct procedures on the principles of Chinese Medicine [2]

Methods

1. Extensive and In-depth Research Work

Overview of our survey on nursing clinical work follows:
1.1 Time Period: May 2012 - May 2014.
1.2 Targets: Top 14 hospitals in five cities located in different areas: Beijing, Tianjin, Nanjing, Xiamen, Luoyang are selected with more emphasis on Luoyang hospital.
1.3 Team Members: Three medical and health information specialists from mainland China and Taiwan, six directors from Nursing and Information Department, and four Software Engineers.
1.4 Process: On the basis of general survey, comprehensive investigation in Luoyang orthopedic hospital was carried out. First, ‘Xiang bi’ disease (Cervical Radiculopathy) and other three kinds of diseases were chosen, 200 electronic medical records and 551 nursing recording sheets were read. Second, Eight seminars were held. Third, 20 on-site investigations of wards were carried out. Fourth, 22 teleconference meetings were held. A comprehensive and complete information was collected [3].

2.1 Analysis results of 200 electronic medical records

We found that the degree of similarity of nursing work for the same kind of disease was 87%. Also, after cluster analysis of the top 30 nursing tasks of the highest frequency, we found that 85% were about hospitalization in the same period. For example, “Admission Assessment” happened on the first day, “Cervical Traction” happened between days 5 – 25. These were consistent with the “Rules of Diagnosis and Treatment of Cervical Spondylosis” that provided the theoretical basis for the design NCP.

2.2 Analysis results of 50 ‘Xiang bi’ disease (Cervical Radiculopathy) electronic medical recording sheets

Only 14% of nursing tasks were derived by Nursing Orders. For example, sheets like “Pain Assessment” and “PIO Recording” were filled out with traditional habits, the regular rounds of “Intravenous Injection” were often ignored. As a result, we put forward a concept of “Nursing Order”. Namely, each kind of nursing behavior should be derived by Nursing Order to standardize the content, process, and results of nursing work.
2.3 Analysis results of 551 nursing recording sheets

There were more than 82 kinds of nursing recording sheets, and in one sheet, such as “Admission Recording Sheet”, as many as 128 items were included, and the duplication of content and data were in a high proportion, which wasted a lot of time and energy of nurses [4-5]. During the analysis of “Intravenous Administration Recording Sheets”, we found that there was an outstanding feature of nursing work, namely, cycle and repetition. Based on this feature, a closed-loop nursing and management model was designed.

Taking long-term intravenous administration as an example, we divided it into eight nodes, and standardized the administration place, treatment method, administering nurse, and treatment outcome of each node as per its information flow. For example, the first node “Decomposition of Doctor’s Order”; the administration place was nursing station; the treatment method was to automatically transfer each order into the concrete operation content; the executor was the nurse on duty. Another example was the last node “Infusion Result Record”. There were 3 kinds of “evaluations”: If the evaluation was “Effective”, then continue with the cycle for tomorrow. If the evaluation is “Adverse reactions”, then terminate and quit. If the evaluation was “Cure or Stop Administration”, then end such long-term administration. See figure-1:

3. Exploring Decision Support System on the Basis of Traditional Chinese Medicine Theory

The principle of diagnosis and treatment of dialectical therapy in traditional Chinese Medicine is completely different from Western Medicine. The core principle of traditional Chinese Medicine is “Yin and Yang” theory, which is the dialectical treatment mainly based on “Yin and Yang” and the 4 groups of opposite syndrome. They are Yang—Yin, Biao—Li, Shi—Xu, and Re—Han [6]. Doctors and nurses would analyze clinical data of patients through four types of dialectical analysis and qualitative analysis of each group to obtain the diagnosis, as shown in Figure 2 [1]. If the analysis result is in the red circle position, the diagnosis is “Yang-Li-Re-Shi Symptom”.

The dialectical analysis method and the binary language of computing follow a strikingly similar path. If we use “1” to stand for Yang, Biao, Shi and Re, and use “0” to stand for Yin, Li, Xu and Han, we can get the map of Figure 3 [1]. "1011" can be used to express the last diagnosis in red circle—“Yang-Li-Re-Shi Symptom”. Above idea is one of the methods and principles we adopted to develop traditional Chinese Medicine DSS.

4. Data Modeling Methods

4.1 Nursing Information Data Abstracted in Structured Form

General structure storage was simple and accurate, but separate settings for each type of information needed to be set up. In the nursing information system, intensive maintenance effort was caused by the diversity of information. Besides, diversity of data would cause poor generality of system. Therefore, we abstracted the collected data of nursing index, and stored them into a standard model to ensure data standardization and universality, which could also satisfy the diversity of data and the demand of reuse. This storage mode could serve subsequent DSS, remainder of plans, and result analysis better. It could also ensure users to gradually formulate their own knowledge base of their own business and processes for later use [7].

4.2 Decision Support System Algorithm Based on Bayesian Theorem

On account of the process of closed loop nursing management, we used the main attribute features deducted from the various nursing assessment content of patients. Based on structured data storage, we chose Naive Bayesian classification method in the Bayes classifier model as the foundation of intelligent algorithm [8-1]. Through the analysis of results of evaluation, subsequent nursing plan was proved to be feasible. Combining recommended nursing plans and subjective judgment; the high accuracy rate of nursing plan was available to users and could help users execute better patient care.
Results

1. The Creation of Traditional Chinese Medicine NCP

The concept of NCP: Creating nursing diagnosis classification according to the disease type or patient condition first, and then formulating regulatory nursing plan for each disease type entailing standardized nursing process [9].

The purpose of using NCP was to establish the main framework of nursing work, and applying all huge and tedious nursing tasks in standard and orderly manner. Standardization meant that it was based on the knowledge base of nursing and evidence-based medicine, providing a common solution to the given nursing problem. Ordering meant that it arranged nursing work automatically according to time series of patients. NCP from different time periods referred to the nursing work derived from traditional Chinese medicine in accordance with its diagnosis principles, special laws, and unique methods. Figure 4 is the NCP of ‘Xiang bi’ disease (Cervical Radiculopathy) in traditional Chinese medicine.

As shown in Figure 4, the first row is the length of stay of the patient, which forms the main timeline of the pathway. The second row shows the four nursing stages. The third row is the nursing order (like evaluation sheets) derived automatically. When we click the current nursing order on the right side, evaluation sheets for each item of nursing content will display automatically.

2. To Create a "Nursing Order"

The clinical nursing work of patients included a large number of nursing content such as, the patient admission assessment, and regular turning over of patients. These tasks were not clearly defined in the past – they might have been implemented as a habit silently or hidden in the corner of a form or even ignored or forgotten.

The concept of Nursing Order: The nurse gave nursing plans or orders according to the patient’s nursing problems. Every nursing order referred to a specified nursing behavior with unambiguous content, creation time, and execution time.

3. To Design Closed-loop Nursing Quality Management Model

Now nursing work reflected its internal rules and processes. Nursing work had one notable feature that was used repeatedly until the disease was resolved or cured [5]. We introduced the closed-loop management of long-term intravenous administration in Methods 2.3. It contains eight nursing operation links that formed a closed-loop management. Nurse could process in turn according to the reminder on handheld PDA, and input data accordingly. Figure 6 is the operation interface of handheld PDA.

4. To Create NCP Decision Support System

The basic framework of systematic approach to holistic nursing care was nursing process. It consisted of five aspects, which were arranged in sequence and interacted with each other and formed a closed loop: Nursing Assessment → Nursing Diagnosis → Nursing Planning → Nursing Measures → Nursing Evaluation. Therefore, the nursing process was information collection, transmission, analysis, processing knowledge application and accumulation process [10, 11]. The nursing pathway regulated all the nursing workflow and information processing procedure, and the closed-loop management standardized the process of each nursing task, thus providing a basis for DSS.

Based on the above ideas, we designed DSS for NCP. Taking pressure ulcer care as an example [12], all the information...
flow was divided into five nodes, and we regulated the execution place, treatment method, executing nurse, and resulted judgement of each node. As shown in Figure 7:

- "Assessment": Nurse collected information of sacral ulceration through interrogation and physical examination and filled in “Pressure ulcer assessment form”.
- "Diagnosis": According to the assessment the system concluded that "sacral pressure sores" diagnosis.
- "Plan": According to the diagnosis, the system automatically provided optional nursing measures, such as debridement, dressing change, regular turn over and generating "pressure sores treatment record".
- "Implementation": Nurse completed the nursing care and filled out the treatment list.
- "Evaluation": Nurse filled in the treatment result after completion of each nursing task. System would automatically determine the three kinds of treatments according to the efficacy. Effective – automatically generated the nursing order of next day and enter into the minor-cycle of "Implementation" → "Evaluation". Invalid – automatically produced the nursing order of "Pressure ulcer assessment" on the next day, and re-entered the big loop. Cured – exit the loop and stop "pressure ulcer care" on the next day.

Figure 7 – Pressure Ulcer Care DSS Flow Diagram

5. To Establish NCP Decision Support System Based on Traditional Chinese Medicine Theory

Traditional Chinese medicine has a special theory and methods with traditional diagnosis and treatment. It is formed and developed in China over thousands of years, and is greatly different from Western Medicine. Again, let’s take the pressure ulcer as an example. According to different symptoms and signs, the traditional Chinese medicine divided pressure ulcer into four different types and every type is divided into four different periods. Different types and periods have different traditional Chinese medicine nursing methods, for example, Chinese medicine fumigation, moxibustion and so on [13]. The difficulty in establishing the NCP decision support system based on traditional Chinese medicine theory is the cognition, understanding and informational expression of various theories of traditional Chinese medicine. Chinese medicine DSS consists of four parts:

- Knowledge database was built according to the Chinese medicine theory, such as table of clinical symptom.
- Establish the mathematical model of knowledge reasoning of traditional Chinese medicine, simulate the inference process of the syndrome differentiation and treatment of traditional Chinese medicine, and establish the statement of "Yin and yang theory" in the "method" section.
- Design of the program, to achieve the above mathematical model with the computer language.
- Clinical verification to verify its compliance rate with a large number of cases.

6. Practical Application

The IRB committee with all five votes approved this study. We have applied our work to three hospitals in a year, and have achieved good results (Table 1). Nurses could choose NLP based on patient’s diagnosis, and the NLP automatically displayed physician and nurse orders. Nurses could then follow all procedures and complete documentation. The NLP DSS was used to monitor nurse’s tasks and it provided reminders for corrections to assure the care quality. The system had passed the international HIMSS Level 6 assessment in two hospitals.

Discussion

1. To Explore the Law of Nursing Work with Thorough Investigation and Study

We had a profound understanding, in order to find out the objective law of the nursing work, and the various factors affecting the law, we had to do long-term, in-depth investigation and study all the data again and again. In addition, in order to realize the management of nursing information, we had to do innovative design, to explore the way of expressing the objective law, and to control influencing factors with information technology [14].

2. To Create a Standardized Nursing Clinical System Framework

We created an overall framework of the nursing work with NCP as the main line and nursing order as the node. The pathway is the nursing work according to a patient’s length of stay. The nursing order is the nursing instruction of a certain point in the pathway, and corresponding to a specific nursing form. In this way, we summarized the whole nursing work to the overall framework in a standardized and well-organized way that could guide the nursing work correctly.

3. Meaning of Creating Nurse Order

We only had the doctor order that was the treatment plan or instruction given by a doctor. But "nursing order" could not be searched in document retrieval. Its creation has the following main significance [15]:

Firstly, nursing order refers to instructions of nursing work – each nurse order refers to a specific nursing behavior. It is the first time that there is a nursing order dictionary that shows name and content of nursing work. It is convenient for scheduling, inspection, and statistical analysis.

Secondly, we designed a nursing process that is a closed-loop system with five links with five specific nursing orders with the extension of pathway, cycle, and spiral propagation until nursing problem is solved in the NCP.
Thirdly, nursing order and nursing records standardized nurse work, avoided negligence and omission. This is conducive to improve quality of nursing and to prevent accidents.

4. Importance of Decision Support System for Nursing Pathway

NCP is based on the statistical analysis of medical knowledge database and evidence based medicine. It reflects the correct treatment route with a high probability. Since it is the result of a high probability, it is impossible to adapt to changes of every patient on every day. This does not conform to the currently new concepts of "precision medicine treatment", "personalized treatment". This is also poses problem in applying correct clinical pathway.

DSS can deduct the nursing order for the next time based on the evaluation of the current nursing result automatically and our intended target turned more realistic after 1-year clinical. The knowledge database of nursing pathway and closed-loop management—and in particular, the rule database—is relatively simple and clear, so it is easy to establish the mathematical model of knowledge reasoning, and to design DSS.

5. Difficulties in Creating NCP Based on Chinese Medicine Theory

Although we had completed the exploration of the ‘Xiang bi’ disease (Cervical Radiculopathy) and other four diseases of traditional Chinese medicine in NCP, there are still a lot of problems. Method of information processing is not established for many principles due to broad and profound traditional Chinese medicine. In addition, the standardization of traditional Chinese medicine terminology is still in progress. We and the other Chinese medicine information experts are waiting for this long-term effort. The principles of creating CNP in West or East medicine are all the same but the difference mainly comes from the medical principles and knowledge.

Conclusion

We had a general survey of the nursing work in 14 hospitals, including a 2-year in-depth investigation at Luoyang Orthopedic Hospital. We achieved many objectives during this work and our intended target turned more realistic after 1-year clinical application.

Firstly, we created an overall framework of the nursing information system with NCP as the main line and nursing order as the node. Secondly, we completed the design and development of nursing pathway. Thirdly, we created a concept called "nursing order", edited the nursing orders data dictionary, and used it to standardize the nursing work. Fourthly, through the closed-loop management model formed by nursing order, we have advanced along the NCP’ spiral path, and solved various nursing problems. Fifthly, we designed the intelligent NCP function that is conducive to the principle of "precision of health care" and to the improvement of quality of nursing.

We developed a NCP decision support system based on the principle of traditional Chinese medicine and explored the ideas and methods of research and development. But there are still many problems due to the nature of broad and profound traditional Chinese medicine. Its standardization still needs to be improved; we, therefore, have scheduled a special R&D program for the next three years. In addition, we are promoting this achievement to more hospitals and specialists to enhance the perfection and maturity of the product.

Abstract

Obstetric care refers to the care provided to patients during ante-, intra-, and postpartum periods. Predicting length of stay (LOS) for these patients during their hospitalizations can assist healthcare organizations in allocating hospital resources more effectively and efficiently, ultimately improving maternal care quality and reducing costs to patients. In this paper, we investigate the extent to which LOS can be forecast from a patient’s medical history. We introduce a machine learning framework to incorporate a patient’s prior conditions (e.g., diagnostic codes) as features in a predictive model for LOS. We evaluate the framework with three years of historical billing data from the electronic medical records of 9188 obstetric patients in a large academic medical center. The results indicate that our framework achieved an average accuracy of 49.3%, which is higher than the baseline accuracy 37.7% (that relies solely on a patient’s age). The most predictive features were found to have statistically significant discriminative ability. These features included billing codes for normal delivery (indicative of shorter stay) and antepartum hypertension (indicative of longer stay).

Keywords:
Length of Stay; Electronic Health Records; Obstetrics

Introduction

Electronic medical record (EMR) systems have been widely adopted in the United States (US) and abroad [1-4]. These systems enable a substantial amount of data to be captured during the routine practice of healthcare organizations (HCOs) [2-5]. This information is quite heterogeneous, including structured diagnoses, medication regimens, laboratory test results and vital signs, as well as un- or semi-structured clinical narratives. The data stored in EMRs is increasingly recognized for its ability to support numerous activities, such as clinical decision making [6], patient safety improving [7-8] and discovery-driven biomedical research [2-4].

Currently, some of the most challenging healthcare environments to manage for safety are those associated with maternity. Over the past several decades, the maternal mortality ratio (MMR) has risen dramatically in the US. MMR has doubled from 7.2 deaths of mothers per 100,000 live births in 1987 to 14 in 2015 [9]. At the same time, obstetric care is the most common and costly type of hospital care for all payers in the US [10-12]. Prediction of the length of stay (LOS) for obstetric patients during their hospitalization can help unit managers and administrators make decisions about hospital resource allocation - enabling obstetric care improvement before, during and after childbirth. This is notable because better organized care can reduce the morbidity and mortality of women, as well as newborn babies [11;12], while reducing maternity-related costs. The incorporation of an accurate estimate of LOS in counseling discussions may mitigate anxieties over the uncertainty of a hospital stay as well as prepare for discharge to home or elsewhere [13]. This is important both for obstetric patients and their families who often inquire about the expected duration of a hospitalization.

Previous research has focused on characterizing the factors that lead to LOS variation in general. LOS has, for instance, been shown to be influenced by a patient’s demographics (e.g., age), socioeconomic status (e.g., income, education, and occupation), insurance types (e.g., commercial, private, and Medicaid and Medicare) and severity of illnesses [14-16]. LOS has further been shown to be affiliated with HCO-specific factors, such as physicians’ work efficiency [5,17], climate [18] and the availability of professional language interpretation services [19]. However, the complex relationships between these factors further exacerbate the complexity of LOS prediction. Thus, it is challenging to build LOS prediction models that rely solely on expert knowledge and information ascertained at the time of a patient’s admission to a hospital.

In recognition of these limitations, this paper presents a pilot study on the feasibility of a patient’s historical diagnoses, as documented in an EMR, for LOS predictive models. This study is predicated on the hypothesis that LOS is related to a patient’s medical history. To investigate this hypothesis, we study three years worth of historical diagnosis codes (prior to their most recent admission) for patients on an obstetric service at Northwestern Memorial Hospital (NMH) in Chicago, Illinois, USA. Specifically, we extracted EMR data in the form of International Classification of Diseases, ninth revision (ICD-9) [20] codes and designed a machine learning framework to predict LOS. The results indicate that prediction of LOS within 12 hours can be achieved with almost 30% greater accuracy than the baseline model that relies solely on the patient’s demographics at the time of admission. In addition, we show that certain billing codes are statistically significant in their predictive capability, which suggests they are ripe for further investigation and transition into clinical decision support.
Methods

Figure 1 provides the EMR data and analytics workflow adopted for this investigation. First, the ICD-9 codes and LOS for patients are extracted from the EMR. These are subsequently applied to train and test a predictive model. Finally, the most discriminant ICD-9 codes are prioritized and assessed for statistical significance.

![Figure 1 – The process by which the LOS predictive model is composed and discriminative features are discovered.](image)

Dataset

The dataset was drawn from the Cerner inpatient EMR system in place at NMH from July 2007 to July 2011. It includes the following patient-specific features: 1) demographics (e.g., age), 2) encounter information (e.g., admission and discharge date), 3) diagnosis (e.g., billing codes) assigned to an encounter, and 4) clinical (e.g., obstetrics) service to which the patient was assigned. In total, there were 9188 inpatients in the dataset with 1549 distinct ICD-9 codes. We consider all inpatients on the obstetric service during 2010-2011 for prediction and rely on EMR data between 2007-2009 as features for our models.

The LOS for an encounter was calculated as the hourly difference between admission and discharge. We use a patient’s age as a baseline prediction for LOS. Table 1 summarizes the average number of ICD-9 codes for the investigated patients in one-, two- and three-years of EMR data, the average age of the investigated patients, and the average LOS for these patients on the obstetric service during the 2010-2011 period.

The distribution of inpatients on LOS is shown in Figure 2. The LOS for the majority (74%) of obstetric patients ranges from 48 to 96 hours.

![Figure 2 – LOS Frequency distribution for study subjects.](image)

**Predictive Model**

We adopted a random forest model to predict a patient’s LOS according to their historic assigned ICD-9 codes. We rely on a random forest because it is a useful ensemble approach for regression and classification. Specifically, the average LOS from all the trees is used for prediction.

We model the data as a matrix, as shown in Equation (1). Let \( n \) be the number of patients and \( m \) be the number of unique ICD-9 codes. In this matrix, each row represents a specific patient and each column is a specific characteristic of the patient. The first column is a patient’s LOS (continuous variable) and the rest of the columns are the ICD-9 codes for each patient. To mitigate the influence of repeat visits for patients, we treat each ICD-9 code as a binary variable, such that it is set to 1 if the patient received this diagnosis at least once and 0 otherwise.

\[
\begin{bmatrix}
\text{LOS}_1 & C_1^1 & C_1^2 & \cdots & C_1^m \\
\text{LOS}_2 & C_2^1 & C_2^2 & \cdots & C_2^m \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\text{LOS}_n & C_n^1 & C_n^2 & \cdots & C_n^m
\end{bmatrix}
\]

To assess the performance of the approach against traditional practice, we also define a baseline method that leverages age as a single feature in prediction. Beyond LOS prediction, the importance ranking of features in the predictive model could assist HCOs to apply and interpret the corresponding results. The random forest regression model enables importance ranking for each feature, which is calculated as extent to which prediction error increases when data for the investigated feature is permuted while all others are held constant [21].

**Performance Evaluation**

A random forest regression predicts an LOS as a continuous value. We evaluated the performance of this prediction with respect to the actual LOS as follows. Let us assume \( \text{LOS}_i \) and \( \tilde{\text{LOS}}_i \) \( (i = 1, \ldots, n) \) are the true and predicted LOS value, respectively. We calculate the difference between \( \text{LOS}_i \) and \( \text{LO}_i \) as \( t_i \). If \( t_i \) is smaller than a predefined tolerance threshold \( \tau \), we claim a correct prediction for the \( i \)th patient:

\[
b_i = \begin{cases} 
1, & |\tilde{\text{LOS}}_i - \text{LOS}_i| \leq \tau \\
0, & \text{otherwise}
\end{cases}
\]

The accuracy (Acc) of prediction is thus assessed as

\[
\text{Acc} = \frac{\sum_{i=1}^{n} b_i}{n}
\]

**Experiment Design**

This section begins with a description of four comparative models in our framework. We then describe how parameters
are selected and compare the models on a range of values for the parameters. To calibrate the parameters and compare the models, we use 5 randomized runs of 3-fold cross-validation. Finally, we describe a hypothesis testing strategy to ascertain which features significantly influence the LOS prediction.

Models

<table>
<thead>
<tr>
<th>Model</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_0$</td>
<td>Age</td>
</tr>
<tr>
<td>$M_1$</td>
<td>One year of ICD-9 codes</td>
</tr>
<tr>
<td>$M_2$</td>
<td>Two years of ICD-9 codes</td>
</tr>
<tr>
<td>$M_3$</td>
<td>Three years of ICD-9 codes</td>
</tr>
</tbody>
</table>

Table 2 summarizes the four models. The baseline model $M_0$ uses age as a lone feature. The other three predictive models ($M_1$ to $M_3$) rely on one, two, and three-years worth of historical ICD-9 codes.

Parameter Selection

There are three parameters in the framework that need to be tuned: 1) number of trees in the random forest, 2) $\tau$ and 3) number of ICD-9 codes in the model. Since models $M_1$, $M_2$, and $M_3$ are the same in terms of the prediction algorithm, we leverage $M_0$ as a representative model to select an optimal value for each of the parameters.

Number of Trees

It has been shown that the performance of random forest regression is relatively insensitive to the number of trees [21]. However, selecting too small of a value can lead to poor accuracy, while too large of a value can lead to excessive computational load. Thus, we evaluated the models over a range for the number of trees. We leveraged the distribution of predictive performance of the resulting random forest to select an optimal number. Specifically, we choose the value that maximizes accuracy and minimizes the number of trees.

LOS Threshold $\tau$

The threshold $\tau$ introduced above represents the difference tolerance between the predicted LOS and the true LOS, but it will vary from one HCO to another. Thus, the accuracy in LOS prediction is evaluated under a set of thresholds $\{5, 12, 24, 36, 48\}$.

Number of Predictors

The number of ICD-9 codes (i.e., features) in this study is relatively large (i.e., 1849 in total). As such, we perform dimensionality reduction to derive a more manageable model. This is accomplished as follows. First, we sort the predictors on their importance in descending order. Second, we select a subset of the features and predict LOS. We choose the subset with the smallest size and highest accuracy.

Model Evaluation

There are three variables in our study and they are the number of trees, LOS threshold, and percent of predictors. Thus, three strategies are designed to evaluate our models in Table 3. In each strategy, two variables are held as constant while the third variable is varied.

Feature Discrimination Analysis

A two-sample t-test is applied to compare LOS between patients with and without a certain ICD-9 code. We conduct this analysis for the ten ICD-9 codes with the highest importance, as derived from the random forest regression models. Specifically, for each investigated ICD-9 code, we test the significance of the LOS difference for patients with and without the code.

Results

Model Parameterization

Figure 3 depicts the predictive performance of the models on a varying number of trees. The performance was evaluated while varying $\tau$ over 5, 12, 24, 36 and 48 hours. We selected 50 trees for our random forests because accuracy grows monotonically up to this point, after which it is constant.

![Figure 3 – The accuracy of models as a function of the number of trees in the random forest.](image)

The selection of $\tau$ depends on the requirements of an HCO. It can be seen in Figure 3 that the accuracy grows with $\tau$. If an HCO can accept the predicted LOS between a range of 12 hours within the actual LOS, then 12 hours could be selected as the value of $\tau$. Thus, for our investigation, we set $\tau$ to be 12 hours.

![Figure 4 – Model accuracy as a function of the number of features retained.](image)

Our models are based on the top 10% of the features. This is based on the calibration shown in Figure 4, where it can be seen that model accuracy after this point remains relatively constant.

Model Evaluation

Figures 5-7 depict model performance as a function of the number of trees, LOS threshold and percent of features, respectively. In general, it can be seen that the models that incorporate ICD-9 codes have better performance than the
baseline models. Additionally, models $M_1$, $M_2$ and $M_3$ have almost the same predictive performance. This suggests that one-year of historical ICD-9 codes may be sufficient for LOS prediction.

The accuracy of the four models (where $\tau$ is set to 12 hours and the feature set is fixed to the top 10%) on a varying number of trees (10, 50, 100, 200 and 300) is shown in Figure 5. It can be seen that the accuracy of $M_1$, $M_2$ and $M_3$ is substantially higher than $M_0$. Additionally, the number of trees has minimal influence on the accuracy for all of the models.

In Figure 6, it can be seen that as the LOS threshold increases, all models improve in accuracy. However, the predictive performance does not improve when varying the percent of features, as is apparent in Figure 7.

Finally, we conducted a series of experiments to predict LOS in two settings. In the first setting, we considered all patients whose $\text{LOS} > 0$. This was done to assess model performance on patients with a range of LOS. In the second setting, we restricted our analysis to the subset of patients whose $\text{LOS} \geq 96$ hours. This allows us to study the model for predicting excessively long and costly LOS. To perform this analysis, we compare $M_3$ with its optimal parameterization (50 decision trees, 12 hours of LOS threshold, and top 10% features) with the baseline model. The results are shown in Table 4. It can be seen that $M_3$ (49.3%) outperforms $M_0$ (37.7%) with almost 30% improvement. Moreover, for patients with LOS $\geq 96$ hours, $M_3$ (5.8%) outperforms $M_0$, which is incapable of predicting such excessively long stays.

</table>

**Feature Discrimination Analysis**

Out of 1849 ICD-9 codes, 10 were selected for further analysis in terms of their clinical implication (as shown in Table 5). Each of the codes in the top 10 ranks exhibited a statistically significant influence on the LOS between LOS for patients with and without such codes. Such evidence may help healthcare organizations (HCOs) to adopt resource allocation strategies that optimize the care management and improve care quality.

As an example, the most discriminant ICD-9 code was 650: “Normal Delivery”. The mean LOS for patients with and without Normal Delivery in their history was 58.1 and 76.5 hours, respectively. The $p$-value for this difference was less than 0.001. As another example, patients with ICD-9 code of 659.63 “Elderly multigravida with antepartum condition or complication” stayed about 10 more hours than those without that code (81 versus 70.6).

**Discussion**

The results show that the historical information in EMRs may assist in forecasting obstetric patients’ LOS in a hospital. Specially, our random forest regression model predicted LOS with an accuracy of 49% under an error range of 12 hours, which is 30% more accurate than a baseline model. The experimental results further demonstrate that a model based on the top 10% of ICD-9 codes can achieve an accuracy as high as those based on all involved ICD-9 codes (over 1800).

Additionally, the models based on the most recent year of data logged in the EMRs can achieve similar performance to those based on two-, and three-year worth of data. Notably, we also investigated the top 10 ICD-9 codes, which have significant differences in terms of LOS between patients with and without such codes. These results suggest that the HCOs can specialize resource allocation strategies accordingly.

Despite the merits of this investigation, we acknowledge that this is a pilot study and there are several limitations. First, the data was collected within a single institution and may not cover all of a patient’s medical history or be readily applicable to another hospital setting. Second, all of the patients in this study were on an obstetric service, such that the framework may not be directly extended to other types of patients or healthcare services. Third, the prediction of LOS may be considered lower than what one might want in a decision support system (i.e., an accuracy of 48% for $\pm 12$ hour).
factors that potentially influence LOS can be incorporated in the model, such as certain patient demographics (e.g., race) or physical traits (e.g., height, weight or BMI).

**Conclusions**

This paper assessed the feasibility of a machine learning-based framework for predicting the length of stay for obstetric patients using historical diagnoses. We showed that one years worth of diagnostic history may be sufficient to predict hospitalization LOS with accuracy that is substantially higher than a baseline based solely on the age of the patient. We believe this research can be extended by including additional types of historical data (e.g., medications) and leveraging the chronological order of such knowledge.

Abstract
Atrial fibrillation (AF) patients suffer a high risk of ischemic stroke and other thromboembolism (TE). Warfarin is a long-term oral medication and is effective in reducing TE for AF patients. Identifying the trajectory patterns of warfarin use in AF patients and discovering how different trajectories are associated with different TE outcomes are important for understanding long-term use of warfarin. Also, finding the factors affecting future warfarin use and predicting the warfarin use trajectory for new patients can help to efficiently target the specific patient groups and propose relevant interventions for warfarin use. This paper, combining group-based trajectory modeling and predictive modeling, has successfully discovered three patient groups with distinct warfarin use trajectories. Also, results suggest that the warfarin use trajectory has potential association with the TE outcomes. Moreover, results show factors affecting the future trajectory, which have been used to build prediction models for the warfarin use group.

Keywords:
Anticoagulants; Atrial Fibrillation; Stroke.

Introduction
Atrial fibrillation, also called AFib or AF, which is a common cardiac rhythm disturbance, can greatly increase the risk of ischemic stroke and other thromboembolism (TE) in patients [1]. Warfarin is highly effective in reducing TE in AF patients [2], and is commonly prescribed as a long-term oral anticoagulant for AF patients. However, relevant studies [3] have shown that patients have substantial difficulties in maintaining adherence to warfarin regimens. Thus, it is important to study warfarin adherence and its outcomes for AF patients.

Many researchers have discovered the influence of patient adherence to warfarin on stroke prevention [4] and the factors associated with non-adherence to warfarin therapy [5]. However, how warfarin adherence changes over a period of time in an AF patient group and its relevant impact on TE outcomes still remain unclear, and patients’ future trajectory prediction of warfarin use needs to be further studied. Identifying the underlying trajectory patterns of long-term warfarin use can provide deeper understanding of how different trajectories are associated with different TE outcomes. Moreover, discovering the factors that affect the future trajectory and predicting the trajectory group for new patients can help to provide personalized interventions of warfarin use for specific patient groups. For example, it could be predicted that the warfarin use trajectory of a patient would change at a certain time, and relevant interventions could aim for this specific time point.

This paper, continuing our previous work on AF studies [6-8], focuses on the warfarin use over a two-year time period from Chinese Atrial Fibrillation Registry (CAFR) data [9]. It groups patients according to similar trajectories of warfarin use, and discovers the underlying trajectory patterns of the warfarin use for each group. Also, the impact of different trajectories on TE outcomes is observed. Furthermore, feature selection is conducted in order to find group characteristics and to identify the factors associated with the future trajectory of warfarin use. Additionally, prediction models built for new patients are able to predict the trajectory group membership using patient baseline information.

Methods
The study pipeline is illustrated in Figure 1. It integrates group-based trajectory modeling, feature selection and prediction modeling.

![Figure 1 – Pipeline of Group-based Trajectory Study for Warfarin Use](image-url)

The pipeline includes five steps:
• study cohort construction, which is to identify the study patient group;
• group-based trajectory modeling, which aims to cluster patients according to similar trajectories of warfarin use;
• feature selection, which selects key features associated with the warfarin use trajectory;
• warfarin use group profiling, which is to discover patient characteristics in different trajectory groups;
• warfarin use group membership prediction, which is to predict the future group of warfarin trajectory for new patients.

Methods used in each step are explained in detail in the following subsections.

Cohort construction

The first step constructs the study cohort. The study cohort data are from Chinese Atrial Fibrillation Registry (CAFR) data [9], which covers over 17,000 AF patients from 32 hospitals in Beijing, China. The CAFR dataset was collected from 2011 to 2015, and contains both baseline and follow-up data. The baseline data contains patient demographics, signs, symptoms, medical history, physical examination and laboratory test results, and current treatments at the time of the registry. The follow-up data record patient treatments and clinical events such as TE.

In order to observe the use of warfarin over a period of two years and exclude the impact of radiofrequency ablation (RFA), which also shows significant effectiveness in reducing TE occurrence, AF patients who meet the following criteria are selected as the patient cohort for the study:

1. Patients used warfarin at baseline
2. Patients did not receive radiofrequency ablation (RFA) from baseline to the 24-month follow-up.
3. Patients have a complete two-year follow-up record of warfarin use after data imputation.

A total of 1348 patients who meet our criteria are selected as the study cohort.

Figure 2 illustrates the timeline of the study. The warfarin use observation time is a two-year period, including the time points at baseline, the 3rd, 6th, 12th, 18th and 24th month follow-ups. In particular, data at the first time point indicates whether warfarin is used at baseline, data at the remaining time points indicate whether warfarin is used between the last follow-up time and current follow-up time. Similarly, the TE occurrence rate is observed over a two-year period and the period includes four data-collection time points. The data at each time point mean whether a TE occurred in the last six months.

Figure 2– Study Timeframe for Warfarin Use

Group-based trajectory modeling

The second step is to cluster patients by their observed data of warfarin use and to group patients with similar trajectories together. Group-based trajectory modeling is conducted at this step.

Group-based trajectory modeling has been increasingly applied in clinical research [10-12], such as for mapping the developmental course of symptoms and assessing heterogeneity. The group-based trajectory model adopted from Nagin, 2005 [13] assumes that the appropriate parametric model f(y) to be studied can be presented as a mixture model, as below:

1) \( f(y) = \sum_{k=1}^{K} Pr(C = k) Pr(Y = y | C = k) \)

where \( y = (y_1, y_2, \ldots, y_T) \) denotes the longitudinal sequence of an individual’s behavioral measurements, which are the measurements of warfarin use in this study, over the T periods, \( C \) is the given group membership, and \( k = (1, 2, \ldots, K) \) is this individual’s group membership [14].

Since the warfarin measurement data is binary, the following likelihood [14] of observing the trajectory for patient i, given that the patient belongs to group k, is:

2) \( Pr(Y_i = y_j | C_i = k, W_i = w_i) = \prod_{j=1}^{T} P_{ij} \prod_{j=1}^{T} (1 - P_{ij}) \)

with \( P_{ij} = \frac{\exp(\sum_{k=1}^{K} \theta_k g_i^T)}{1 + \exp(\sum_{k=1}^{K} \theta_k g_j^T)} \)

where \( w \) is the time dependent variable \( t \) (i.e. ‘month’) in this study, \( j \) is the index of the time point, and \( n \) is the order of the polynomial equation.

In order to determine the relevant parameters, expectation maximization (EM) is used to find the max likelihood of the mixture model. Bayesian information criterion (BIC) which considers the likelihood, the sample size and number of parameters is used for the selection of the number of the group, ‘K’.

At the end of this step, patients with similar trajectories of warfarin use are grouped together.

Feature selection

In order to discover which baseline features affect the future trajectory of warfarin use, factor selection for group memberships are performed at this step.

In this study, the target is the group membership which is a multi-categorical variable. This step implements filter-based feature selection methods, and measures one risk feature at a time about how important each feature predicts the group membership. The metric is the p-value which indicates the significance of the association between the feature and the target. Specifically, the dataset of this study includes two types of features: categorical features, such as whether the patient has hypertension, and continuous features, such as age.

• For categorical features, the p-value based on Pearson’s Chi-square is implemented as the filter-based feature selection method.
• For continuous features, the p-value based on the ANOVA F Statistic is applied.

Group profiling

Based on the features selected from the last step, characteristics of each trajectory group discovered by the group-based trajectory modeling are summarized in this step in order to discover the distinctions between different trajectory groups. Moreover, TE occurrence rates of different
trajectory group are observed, which aims to show how different warfarin use trajectories may lead to different TE risks. Whether a TE occurs in the last six months at each time point are compared.

Whether a TE occurs in the last six months at each time point may lead to different TE trajectory group are observed, which aims to show how different warfarin use trajectories may lead to different TE risks. Whether a TE occurs in the last six months at each time point are compared.

During the predictive modeling process, input data is transformed into a binary variable in this modeling process, each individual group is predicted respectively with the remaining groups, and the target is transformed into a binary variable in this modeling process.

Results

Group-based trajectories of warfarin use in AF patients

Group-based trajectory modeling has successfully discovered underlying longitudinal trajectories of warfarin use among AF patients. According to the similar trajectories, three patient groups are identified using BIC as the model selection criterion. Moreover, the TE occurrence rates are observed and the model shows that TE occurrence rates have potential association with the warfarin use trajectory.

Results are summarized in Figure 3. As we can see, three patient groups have three distinct patterns of warfarin use trajectories. The first patient group has the worst warfarin adherence. The warfarin use proportion in group 1 appears to instantly drop after baseline, and it remains near zero in the following 18 months. The warfarin use in group 2 maintains a high proportion of use in the first six months. Then, warfarin use declines to a near-0 level over a period of one year, and the level of use remains at the same proportion from the 18th month to the 24th month. Patients in group 3 have the best warfarin adherence compared with the other two groups. Most patients continually use warfarin and the warfarin use proportion of group 3 stays close to ‘1’ over the 24-month study period.

The TE occurrence rates are observed to closely associate with warfarin use trajectories, which are illustrated in Figure 3. Both group 1 and group 2 observed an increase in TE occurrence rate after the decline in warfarin use. In particular, group 1 shows a rapid decline in the first six months. The TE occurrence rate appears to significantly increase around the 12th month, and the six-month occurrence rate in these AF patients can be up to 2.4%. Compared to group 1, group 2 has a postponed decline of warfarin use between the 6th and 18th month, and the TE occurrence rate of group 2 observes a corresponding delayed increase. The peak point of the TE occurrence rate in group 2, which is up to 2% at the 18th month, is lower than the peak rate in group 1. Compared with the other two groups, patients in group 3 maintain a high level of warfarin use over two years, and the relevant TE occurrence rate is controlled to under 1.5% in this study period.

Feature selection and group profiling

A total of 29 baseline features which are associated with the patient group membership for warfarin use trajectory are discovered. Based on the discovered features at baseline, the characteristics of each group are summarized in Figure 4.

In particular, compared with patients from group 1 and group 2, patients from group 3 who maintain a high percentage of warfarin use over the study period have the following significant characteristics:

...
• an older average age than the other two groups
• highest average score in New York Heart Association (NYHA) functional classification
• highest percentage of patients with TE history
• highest percentage of patients with persistent AF at baseline
• highest percentage of oral antithrombotic drug use history

Prediction for group membership of warfarin use

In the process of predicting group membership of warfarin use, we applied three feature sets in this study: all features, CHA2DS2-VASc features, and selected features using the feature selection method. For each feature set, three types of modeling methods are implemented respectively: multinomial logistic regression modeling, binary logistic regression modeling and decision tree modeling. AUC is used for the evaluation of the prediction models. Each patient group of warfarin use, which is group 1, group 2 or group 3, is predicted separately. The results of AUC for each group and their average AUCs are described in Table 1.

As we can see, the training dataset has the highest AUC score when all baseline features are used for the prediction. However, applying all possible features can increase the redundancy among features and can cause overfitting problems, which are seen in the AUC scores of the testing dataset. The AUC scores have reduced to 0.617 for group 1, 0.626 for group 2 and 0.636 for group 3 prediction.

CHA2DS2-VASc factors have the lowest average AUC. This indicates that CHA2DS2-VASc factors are not enough in predicting the group membership of warfarin use. The AUC scores significantly improve when the 29 selected features are applied, which indicates that the selected features have the best performance in predicting the warfarin use trajectory.

Moreover, different modeling method results using the same selected features show that multinomial regression modeling and logistic regression modeling have similar AUC scores. The decision tree model has a lower AUC score than the other two modeling methods for the testing dataset, although it performs well on training set. Specifically, multinomial regression modeling with the selected 29 features has the highest average AUC score as well as the highest AUC scores for each group’s prediction in the testing set. The AUC scores are 0.757 for group 1, 0.616 for group 2 and 0.748 for group 3 prediction respectively.

Discussion

This paper has discovered underlying longitudinal trajectories of the warfarin use, and has found the association between the trajectories and the TE occurrence rate. In particular, results indicate that patients in group 3 are older and have more serious AF conditions than patients in group 1 and group 2, according to the NYHA functional classification, the percentage of patients with TE history, and the percentage of patients with persistent AF at baseline. However, the persistent use of warfarin in group 3 leads to better control of TE occurrence than the other two groups.

The prediction for warfarin use group membership could be applied in many scenarios. For new patients, the prediction of the group membership can help to understand the future trajectory of warfarin use. According to the patterns of the trajectory, such as the time point of the use decline, more personalised interventions could be proposed.

The limitation of this study is that the number of the AF patients who meet the study participant selection criteria is small, because a large percentage of the registered AF patients have received the RFA treatment at some timepoint during the two-year study period. The small dataset and the imbalanced cases limit some of the studies, such as TE risk model for each trajectory group. Future work includes collecting data about the quantities of warfarin use, covering more time points, and conducting more detailed trajectory analysis for larger datasets.

Moreover, this study aims to analyse one variable only, which is the use of warfarin in this study. Future work can extend to multiple variables and conduct multi-trajectory modeling [11], which considers the changes of more than one variable over time.

Conclusions

This study, combining group-based trajectory modeling and predictive modeling, has discovered three distinct trajectories of two-year warfarin use. Patients are classified into three groups, and each group’s characteristics have been summarized. Moreover, results find that the trajectories of warfarin use are closely related to TE outcomes. Additionally, 29 baseline features for the trajectory group are identified. By comparing three feature sets and three types of models, it shows that the multinomial modeling with the selected 29 features obtains the best performance in predicting the group membership of the warfarin use trajectory.

Abstract

This study describes a novel method of obtaining low-dose computed tomography (CT) scans followed by imaging postprocessing that provides diagnostic quality to such low-dose exams. In addition, we compared the Total Radiation Doses (DLP) of the 64-channel MDCT x 16-channel MDCT for a new Dental CT - CTdBem protocol for hospital use. DLP data obtained from 20 patients using 16-channel MDCT was compared with 20 other patients using 64-channel MDCT. In both tomographic (Aquilion 64 and Brightspeed 16) FOV was approximately 160(V) x 130(H) mm. An imaging postprocessing algorithm was used to provide diagnostic quality to the obtained low-dose CT scans. Imaging postprocessing included imaging smoothing, multiplanar reconstruction (MPR), and volume rendering (VR), as well as surface rendering (SR) to allow three-dimensional printing of the desired scans. The average DLPs were of 28.5 mGy.cm and 34.65 mGy.cm, using the 64-channel MDCT and 16-channel MDCT, respectively. The effective radiation dose (DLP) from the 64-channel MDCT statistically differs from the DLP data from 16-channel MDCT, resulting in a value of $p < 0.05$ for all comparisons. A novel low-dose CT protocol for dentomaxillofacial assessment using imaging postprocessing techniques is described. The authors concluded that although the DLP values differ statistically ($p < 0.05$), both equipment (64 and 16-channel MDCT) produce tomographic images of patients with low radiation doses. The greater the number of detectors, the lower the mAs product and, consequently, the amount of X-radiation produced.

Keywords:
Radiography, Panoramic; Cone-Beam Computed Tomography; Multidetector Computed Tomography

Introduction

Currently, there is a growing concern in society regarding the radiation doses to which we are exposed while conducting tests using ionizing radiation. Such concern is not only associated to patients but also to health professionals and equipment manufacturers [1]. In this context, CT technology has advanced over the years, as well as the increase of its use and applications, that have brought deep concerns regarding the radiation [2]. Moreover, there is the outstanding fact that the medical imaging modality with the highest dose of radiation is obtained from the CT. From this, a reduction of this dose has become a very important goal in these applications [3].

The Multislice Computed Tomography (MDCT) has a spiral/helical scanner with more than one row of detectors, having 4, 16, 64, 256, 320 or even 520 lines (channels) of detectors, which are able to generate many slices simultaneously and several complete analyzes in seconds or in a period of a subsecond.

For dental procedures, both clinical and hospital, the use of imaging tests to analyze bone structure and teeth is considered an important aid to the diagnosis. In this regard, in hospital procedures, the use of MDCT for diagnosis and dentomaxillofacial evaluation of patients becomes a great ally, since this is a commonly found device in hospitals and, when properly calibrated, enables the acquisition of images displaying bone and tooth structures in the region.

The aid in diagnosis that this imaging method provides on craniofacial structure of patients enables the evaluation of bone and tooth structures using multiplanar slices (axial, sagittal, coronal, panoramic and transversal) and reconstruction in 3DVR (three dimensions – rendering volume). Medical tomography may be, then, integrated to dentistry, when kVp (kilovoltage), mAs (milliamperage) and the FOV (Field of View) of the equipment are modified and fixed, which also provides shorter duration to tests [4]. The FOV considers the size of the desired field of view for the exam and has standard sizes for detectors for certain types of examination, considering the appropriate size of each display area [5].

Despite that, imaging evaluation of teeth and facial jaws of patients hospitalized at the University Hospital of Santa Maria (HUSM) did not occur prior to radio and chemotherapy treatments, even given the fact that prior to these procedures the need for dental treatment must be checked, especially when those are related to face, since the follow up time for new dental procedures after radiotherapy and/or chemotherapy with no risk for the patients is usually five years.

However, after discovering an available MDCT equipment at HUSM, the founders of this project started using the MDCT with reduced radiation dose protocol for dentomaxillofacial evaluation in the hospital and reformatted DICOM images acquired in the MDCT in axial, sagittal, coronal, panoramic, transversal cuts and 3D reconstructions, as well as a report of all tests. Thus, the planning and possibilities for care and treatments for patients at HUSM are expanded.

This study aims to compare the Total Radiation Doses (DLP) of 64-channel MDCT with radiation doses of 16-channel MDCT for a new Dental CT - CTdBem protocol for hospital use.
Methods

The following CT scanners were used for the tests: a) Aquilion 64 (Toshiba America Medical Systems, Inc., Tustin, CA, USA) using 120 kV, 10mAs and acquisition time of about 6 seconds (0.5s to 360°/rotation); and b) GE BrightSpeed 16 (GE Medical Systems, Waukesha, WI, USA), using 120 kV, 10mAs and acquisition time of about 12 seconds (0.5s for 360° rotation). In both tomographic (Aquilion 64 and Brightspeed 16) FOV was approximately 160(V) x 130(H) mm. Multislice CT scans were performed with patients lying in supine, Frankfurt plane perpendicular to the ground, sagittal plane perpendicular to the ground and occluded teeth.

After CT image acquisition, an imaging postprocessing algorithm using open source software (Horos™, Horos Project) was applied to all exams. It involved image smoothing aiming to reduce image noise and provide diagnostic quality for low-dose tomographic images. Subsequently, multiplanar reconstruction (MPR) and three-dimensional reconstruction using volume rendering (VR) was carried out in order to obtain sagittal, coronal, and 3D images of the buco maxillofacial region. Surface rendering (SR) reconstructions (also performed using Horos™) provided .stl files that enabled preoperative 3D printing of the surgeon’s region of interest.

Statistical analysis was performed from the CT scanner's console, in which it is possible to obtain estimated dose data: DLP (Dose Length Product), referent to the total dose of radiation produced during the acquisition. In this research, data from independent K-samples, a single variable (DLP - radiation dose) of numerical data, were used. In order to statistically test the data, the paired T-Test was used aiming to verify the differences between the means. Dose data from 20 (twenty) procedures performed in MDCT 64 were used for comparison with dose data from 20 (twenty) procedures performed in MDCT 16.

Because it is an academic research project in which the focus is to reduce the radiation dose in MDCT at a university hospital, there are no criteria for inclusion or exclusion of patients, given that the work was performed in an environment that aims to serve all those who need its services. However, all imaging tests were only conducted after clinical evaluation and appropriate referral in hospital forms, reporting the necessity of the procedure.

Results

According to the data acquired using 64-channel MDCT with 120 kV and 10mAs protocol during exposure, we obtained an average of 28.5 mGy.cm for DLP and a total scan time of approximately 6 seconds for the entire face. For the 16-channel MDCT with 120 kV and 10mAs protocol during the exposure, we obtained an average of 54.65 mGy.cm for DLP and a total scan time of 12 seconds for the entire face. Through the analysis of Table 1 it is possible to observe the difference in mean values of total radiation dose (DLP) obtained in different methods. The statistic software used was Minitab version 17 for Windows (Minitab Inc. State College, Pennsylvania, USA).

Discussion

When it comes to performing a Computed Tomography (CT), the radiation dose the patient receives depends on the device design and technical parameters and it can vary from one machine to another in different types of acquisition. The use of medical tomography (MDCT) integrated to dentistry allows the acquisition of good quality images with low radiation exposure, since standard protocols parameters for equipment use, such as kilovoltage (kVp) and electric current (mAs), can be modified. [4]. Furthermore, the use of correct FOV for the desired field of view also interferes in the process [5].

Given that, we highlight that in dental procedures, both clinical and hospital ones, what it is important to evaluate are bone and tooth structures and, from that, a protocol that
evidence these tissues without compromising image and optimizing the radiation dose during test acquisition can be determined.

A comprehensive approach to radiation dose management must be focused on providing the right quantity and quality of radiation, as and when is required. MostComputed Tomography scanners (CT) are programmed to radiation dose parameters and automatically archived in correspondence to the scanning parameters defined for each exposure protocol (6). Still, radiation dose reduction must be a priority when it comes to CT, ie, the highest spatial resolution is not a priority on the need to optimize the radiation dose [6].

As new technologies for CT have been developed, a dose reduction of up to 80% can be claimed while maintaining image quality of the diagnosis. In this context, advances in tomographic image are designed to provide equivalent diagnostic image quality, with similar appearance to the full dose images, at a fraction of the radiation dose. Those technologies aim to automatically adjust the equipment to the patient, compensating parameters for the particular physiology and the optimization of dose for desired anatomical region [2].

The energy of the X-ray beam (kilovoltage), the tube current (milliamperage), the rotation time (equal to the exposure time), slice thickness (collimation), pitch (defined as the distance on a 360° rotation table divided by slice thickness), distance of the X-ray tube and the scanning length [7] are included as some of the parameters that can be manipulated and have direct influence on the radiation dose. With the reduction of kVp and mAs for dose optimization in routine tests on CT it was found that there are no qualitative and quantitative losses in image for diagnosis. In this case, the reduction of radiation dose was justified using techniques that consider individual anthropometric data or with less conservative noise levels [8]. With the same effective radiation dose, approximately 44%, in pulmonary CT angiography from the kilovoltage (kVp) reduction and increase in noise levels (35). In accordance to that, tests with four different levels of electrical current (150, 100, 70 and 40mA) were carried out when performing a Volumetric Helical Thorax CT. They have found that the reduction in current did not generate significant difference in image quality [9].

The performance of CT imaging systems is influenced by the specific tomography system, concerning the current (milliampere - second), kilovoltage (kVp), slice thickness, pitch size and collimation of X-ray beam, as well as image processing and its visualization. Therefore, these factors must be adjusted to optimize image quality when it comes to performance of low image contrast (LCD - low contrast detail), reducing image noise and maintaining lower radiation dose to patients [3].

The relation between the energy of the X-ray beam (kVp) and the radiation dose is not linear, while the one between the tube current and the radiation dose is, which means that the increase of the tube current in 50% will result in a dose 50% higher. Tube current (mAs) and exposure time (in seconds) are associated (milliamperage per second - mAs), also leading to a linear relation with the resulting radiation dose [7].

In this context, the acceptable radiation dose is determined by the clinical situation. When decreasing the mAs, for example, the radiation dose is reduced, but, simultaneously, the image noise is increased and the contrast - noise ratio (CNR) is reduced. However, the acceptable compensation level in image quality must be determined in accordance to the purpose of clinical diagnosis and to the task to be performed.

Low kilovoltage increases photoelectric interactions, which improves the level of attenuation and leads to an increase in image contrast and better visualization of details [3]. In this setting, we highlight the important role that our postprocessing algorithm played in the low-dose CT protocol: as we obtained lower radiation dose by decreasing tube current (measured in mAs), we consequently dealt with higher image noise if compared with conventional multislice computed tomography scans. By reducing noise through image smoothing, as well as enabling multiplanar reconstructions, volume rendering, and surface rendering, our open source-based postprocessing algorithm increased the image quality of the low-dose CT scans, allowing their use to diagnose and plan procedures, including three-dimensional printing, with significantly lower radiation doses than conventional CT scans.

Although the image noise measured is higher in low kVp images, the subjective quality of image is higher for lower kVp than for larger ones, since they do not compromise the diagnosis [10]. Still, it is emphasized that the radiation dose to patients is not linear with the kilovoltage. However, reducing kVp can diminish the amount of radiation when other exposure factors are fixed. Furthermore, although the selection of low kilovoltage minimizes radiation for patients, kVp must be selected depending on the diameter of the transversal section of the patient and adjusted according to the task [7].

Thus, it is clear that the interdependence between image quality and radiation dose related to kVp is quite complex. The kVp must be optimized to be low enough to increase the contrast resolution, in order to improve LCD (low contrast detail), but high enough to reduce noise and minimize radiation [3].

Due to the variety of clinical experiences and preferences, image quality varies and it is difficult to determine a fixed set of image acquisition parameters that provides the required image quality. However, that can be achieved based on subjective values. For these reasons, local protocols are developed based on local experience (29). It is important to consider that, like every process at an institution, CT protocols should be regularly reviewed to ensure that image quality and radiation dose are really optimized. It is noteworthy that overdosing and underdosing are medical errors and thus, dose reduction and increase may be appropriate or not when trying to optimize CT protocols [7].

The authors of this paper sought to validate the radiation dose optimization of MDCT and its use in dental diagnosis in hospitals by comparing the DLP obtained in 64-channel MDCT with the DLP obtained in 16-channel MDCT, both using low radiation protocol. In order to do this, the study used as application the parameters for performing CT Dental - CT do Bem (by the same author), which is held at HUSM with the 16 and 64 MDCT calibrated in 120 kVp and 10mAs, with approximate time acquisition of six (6) seconds to 64-channel MDCT and twelve (12) seconds to 16-channel MDCT using FOV of 160mm x 130mm for both equipment. Although the acquisition area of 64-channel MDCT is larger than the 16-channel MDCT, around 11cm and 5.5cm respectively, the reduced pitch causes the slice area acquired in each rotation/turning to differ in only 2cm between scanners. This explains why the test acquisition time is twice (in seconds) and not 4 times longer as it would be expected.

Since it is an innovative work, the comparison of DLP in different equipment, 16-channel MDCT and 64-channel MDCT with altered protocols for dose reduction and visualization of important images for dental diagnosis, is made...
from an image base determined by local/subjective clinical factors that produced significantly positive results in terms of image quality available during the development of CTdBem research project.

The authors still consider relevant to clarify that the MDCT is a machine commonly used in most hospitals and therefore, should be used to provide images for dental evaluation purposes. We emphasize that, even when facing low radiation dose protocols, CT scans should only be performed under proper medical guidance.

Conclusion

The authors concluded that although the DLP values statistically differ (p <0.05), both equipment (64 of patients with low radiation doses). The greater the number of sensors present, the lower the mAs product and consequently, the lower the amount of X radiation produced. Even though lower mAs lead to higher image noise, by using a post-processing imaging algorithm it was possible to use low-dose CT scans to evaluate the buco maxillofacial region with significantly lower radiation doses than conventional CT scans.

Successful System, Incomplete Data: Caveats in Reusing Activity Data from Emergency Department Whiteboards

Morten Hertzum

Royal School of Library and Information Science, University of Copenhagen, Copenhagen, Denmark

Abstract
During the daily treatment of patients large quantities of data are recorded in electronic health records (EHRs). Compared to data in paper records, these EHR data are easily available for reuse in research and quality improvement. However, the opportunities for reuse depend on the quality of the data. In this study we analyze the completeness with which main treatment activities are recorded on emergency department (ED) whiteboards and whether completeness varies with the severity of the patients’ condition. Data from 381,231 ED visits show that after the whiteboard had been in successful use for several years the clinicians recorded four of the five main treatment activities with a completeness of less than 50%. Completeness tended to increase with three indicators of the severity of the patient’s condition: triage level, length of stay, and patient age. We conclude that the low completeness of the activity data probably prevents most types of reuse.

Quality Improvement; Electronic Health Records; Emergency Medical Services.

Introduction
The substitution of electronic for paper records has been a major development in healthcare organizations over the past decades. Electronic health records (EHRs) contain large quantities of data. These data are recorded during the daily treatment and care of patients but, subsequently, become available for other uses. EHRs have been associated with unprecedented opportunities for improving healthcare through the reuse of EHR data for clinical research, quality improvement, and other data-driven efforts to learn from past events [7]. However, such learning requires quality data. In this regard Weiskopf and Weng [16] contend that EHRs have “led not to improvements in the quality of the data being recorded, but rather to the recording of a greater quantity of bad data” (p. 144). This study focuses on the data recorded on electronic whiteboards in emergency departments (EDs), which are the common entry point to hospital treatment for most patients.

ED whiteboards contain data about the patients and their flow through the ED, such as the patients’ time of arrival, triage level, current treatment activity, responsible clinician, and lab test results. Ready access to these data is central to the coordination of ED work and to each ED clinician’s sense of overview [8; 11]. In addition to supporting work in the ED as it unfolds, the whiteboard recordings provide opportunities for learning. These learning opportunities include determining whether the recordings can be used for forecasting temporal patterns in patient arrivals, determining waiting and boarding times, identifying bottlenecks in the patient flow, assessing whether length of stay (LOS) targets are met, comparing the patient mix of EDs, and researching how the coordination of ED work is accomplished. Learning about these issues is important because the ED is a stressful environment for patients [5] as well as clinicians [4]. Improved knowledge of patient flows and resource bottlenecks can help EDs streamline work procedures, dynamically match resources to patient volumes, and prevent ED crowding [13]. We are involved in such learning efforts in the EDs in Region Zealand, one of the five healthcare regions in Denmark [e.g., 9; 11]. In the present study we analyze almost three years of log data from the whiteboards in the four EDs of the region to assess the completeness with which main treatment activities are recorded and whether completeness varies with indicators of the severity of the patient’s condition. Information about the time spent on the different treatment activities is, for example, crucial to understanding how crowding arises and when countermeasures are required. Thus, the generation of accurate forecasts of crowding presupposes reasonably complete recordings of the treatment activities.

Weiskopf and Weng [16] identify three fundamental dimensions of data quality – completeness, correctness, and currency – and two auxiliary dimensions (concordance and plausibility) that often serve as proxies for the fundamental dimensions when they cannot be assessed directly. Completeness, the focus of this study, concerns whether a piece of data about a patient is present in the EHR. Correctness concerns whether the data that are present in EHRs are also accurate. And currency concerns whether the data are representative of the patient’s state at a desired point in time, often interpreted as whether the data are recorded in the EHR within a reasonable period of time following measurement. Previous studies have demonstrated that the data quality is modest for multiple types of EHR data [2; 7; 12; 14]. For example, Chan et al. [2] reviewed the completeness of blood-pressure recordings across multiple studies and found that the number of complete recordings ranged from 0.1% to 51%. In addition, Brennan et al. [1] found that British hospital statistics for 2009-2010 showed nearly 20,000 adults attending pediatric outpatient services and over 8,000 males admitted to gynecology inpatient wards. Several reasons have been proposed to explain modest data quality, including habits, lack of time, failure to capture data that became available to clinicians who were not part of the department, and transcription errors in transferring data from paper charts to EHR [e.g., 12; 14]. At root, data quality suffers from differences in priorities between day-to-day clinical work and work such as research and quality improvement. In day-to-day clinical work data quality is secondary to patient treatment.
Method

The four EDs in Region Zealand were part of medium-sized hospitals and collectively served a population of approximately 817,000 citizens. Prior to conducting the study we obtained approval from the healthcare region.

The Whiteboard

The four EDs installed the same electronic whiteboards, which were introduced in December 2009 (ED1), January 2010 (ED2), January 2011 (ED3), and May 2011 (ED4), respectively. The whiteboard supplemented the electronic patient record by providing procedural information about the patients. Some of the whiteboard data, such as lab test results, were automatically updated when new data became available, but the majority of the whiteboard data were entered and updated manually. In this study we focused exclusively on data that were entered and updated manually. Manual data entry and updating could be done on the wall-mounted whiteboard displays (see Figure 1) as well as on any other computer in the EDs.

![Whiteboard example](image)

**Figure 1 – The whiteboard at ED4. For each patient the whiteboard gives one row of information, including time of arrival, triage level, first name, age, responsible physician, current treatment activity, lab-test results, and next stop.**

Before turning to analyze the completeness of the whiteboard data and thereby their reuse potential, it is important to note that the whiteboard was successful with respect to its primary purpose of supporting the clinical work in the EDs. A physician at ED3, for example, said in an interview that the whiteboard “gives a great overview. I cannot imagine that we could do without it.” A nurse at ED1 expressed agreement: “We use it all the time”. More formally, a survey at ED1 and ED2 showed that the clinicians experienced an improved overview of their work when the electronic whiteboard replaced the former dry-erase whiteboards [8]. The survey also showed that, to a larger extent, the electronic whiteboard made information available where and when clinicians needed it.

Log Data

All changes of the whiteboard content were automatically logged. For the purpose of this study the whiteboard vendor, Imatis, produced a version of the logs from which all patient names, clinician names, and other information that might identify persons had been removed. These anonymized log data covered the three-year period 2012-2014. However, we had to discard the periods January 2013-January 2014 (ED1) and November 2013-January 2014 (ED2-ED4) from the analysis because they contained long intervals of no data. After also removing 741 outliers (defined as ED visits longer than seven days, i.e. more than 50 times the median length of stay), the dataset comprised 381,231 ED visits. Table 1 shows the division of the visits into EDs and years.

The data for the 381,231 ED visits consisted of over 10 million log entries, each documenting an event that changed the whiteboard content. A log entry contained a timestamp, an event type, any values associated with the event, and a system-generated identifier of the visit to which the event pertained. For example, the event type ‘WAITING FORCHanged’ along with the event value ‘Nurse’ indicated that the patient was now waiting to be seen by a nurse. This event type marked the start of a treatment activity in the patient’s progress through the ED workflow. Across the EDs different sets of treatment activities (i.e., different sets of event values) were used for indicating the stages of this workflow. However, the workflows of the EDs shared five main activities: triage, waiting to be seen by a nurse, waiting to be seen by a physician, examination (by a junior physician), and review (by a senior physician). No other treatment activity was recorded more consistently than these five main activities. The log data also contained information about changes in, among other things, responsible physician and lab test results; but in this study we focus on the five main treatment activities because the flow of the patients through the ED is important to, for example, forecasting and preventing crowding.

Results

The ability to record the patients’ progress through the ED workflow was included on the whiteboard because at-a-glance access to this information was deemed important to the ED clinicians’ overview of their collective work. Yet, even the five main treatment activities were recorded for only a subset of the ED visits (see Table 2). The main activity recorded most and least often differed across the EDs. In ED3 and ED4 waiting to be seen by a nurse was recorded for 74% and 76%, respectively, of the patients in 2014 and for similarly high percentages of patients in the preceding years. The only other activity recorded for the majority of the patients was waiting to be seen by a physician in ED2 (52% in 2014). Conversely, the activity of triage was recorded for less than 1% of the patients in ED1 and ED3. For all EDs at least one of the five activities was recorded for no more than 20% of the patients.

It could be hoped that the completeness of the recordings increased over time because the clinicians appreciated the improved overview or became more conscientious in their use of the whiteboard. The data provided little ground for such hopes. Rather, the trends in the data from 2012 to 2014 showed a mixed picture with nine increasing trends, four decreasing trends, and seven unchanging trends (see Table 2). It should also be noted that prior to 2012 the whiteboard had been in operational use at the EDs for between half a year and two years; thus, work procedures involving the whiteboard had had time to stabilize.
The first activity in the ED workflow, triage, illustrated the important point that failing to record triage as the current treatment activity for a patient did not indicate that the patient was not triaged. The whiteboard gave the triage code for 77% (ED1), 37% (ED2), 10% (ED3), and 40% (ED4) of the patients. For all four EDs the number of patients with a triage code exceeded the number of patients for which triage was recorded as the current treatment activity. Probably, triaging a patient and recording the triage code were experienced as more clinically relevant by the ED clinicians than recording that their current treatment activity was to triage the patient, especially because triage was a brief procedure.

An important consideration in assessing the possibilities for data reuse is whether completeness varies with indicators of the patient’s condition. Tables 3 to 5 show how completeness varied with three indicators of the severity of the patient’s condition. To save space each table gives the data for only one of the four EDs.

Table 3 shows how completeness varied with triage level in ED1. Waiting to be seen by a physician was more often recorded as the current treatment activity for patients triaged 4 and 5 (i.e., the most severe cases) and examination and review were most often recorded for patients triaged 2 and 3. It might have been more clinically relevant to record the activity in progress for the patients triaged 2 and 3 because they were in the ED longer than the other patients. For example, many of the patients triaged 4 and 5 were quickly transferred to inpatient departments for specialist treatment. In ED1 the completeness of the treatment activities triage and waiting to be seen by a nurse was largely unaffected by triage level. The patterns for physician and examination were roughly similar in the other EDs, whereas the patterns for triage, nurse, and review were different. For example, waiting to be seen by a nurse in ED4 was recorded for 80% of the patients triaged 2 and 3 but only for about half as many at the other triage levels.

When completeness varied with the triage level, it tended to be by higher completeness at medium or high triage levels.

Length of stay (LOS) directly indicates a patient’s demand on ED resources and indirectly indicates the severity of the patient’s condition. Table 4 shows that the activity of triage tended to be recorded more often for the patients that ended up staying longer in ED2. Waiting to be seen by a physician was most often recorded for the patients who stayed 3-8 hours; ED3 was similar in this respect. In ED2, the activity of review was recorded as the current treatment activity for fewer and fewer patients as LOS increased. The completeness of the review recordings also varied systematically with LOS in ED1 and ED4 but in the opposite direction: completeness increased with increasing LOS. Waiting to be seen by a nurse was the only treatment activity the recording of which did not vary appreciably with LOS in any of the EDs. The four other treatment activities were, in one or two of the EDs, recorded more often with increasing LOS. The only instance of a decreasing trend was for review in ED2.

Note. The table includes only the 49,097 (77%) ED1 visits for which the triage level was available.
about equally often for the different age groups but the pattern for waiting to be seen by a physician and for examination resembled that in ED4. In ED1 the pattern for the activity of review also resembled that in ED4, but in ED2 it was reversed (as it was for LOS). The pattern that completeness tended to increase with increasing patient age was stronger than the patterns for triage and LOS.

</table>

Note. The table includes only the 80557 (72%) ED4 visits for which the patient age was available.

For all three indicators the overall, but not unanimous, pattern was that completeness increased when the indicator pointed toward patients with more severe conditions.

### Discussion

After the whiteboard had been in successful use in the EDs for 2–4 years the five main treatment activities were recorded in 2014 for an average of 13% (triage), 40% (nurse), 37% (physician), 30% (examination), and 23% (review) of the patients. These averages hide considerable variation across the EDs; but no ED recorded more than one treatment activity with a completeness of more than 50%, and all EDs recorded at least one treatment activity with a completeness of less than 20%. The substantial incompleteness in the recording of the patients’ current treatment activity is the result of a constant tension between treating patients and documenting treatments. Another result of this tension is that the incompleteness is not randomly distributed. Rather, completeness tended to increase with increasing triage level, LOS, and – most strongly – patient age. We make two conclusions from the analysis:

- The incompleteness of the activity data is substantial, probably preventing most types of reuse.
- Using the data incurs a bias toward patients with more severe conditions.

The former finding confirms previous research [2; 14], thereby indicating that EHRs should mainly be assessed on the basis of how well they fulfill their primary purpose of supporting day-to-day clinical work. The latter finding acknowledges that the mere existence of large quantities of real-world EHR data provides impetus for their reuse [7]. If the data are reused it is important to be aware of their limitations. The bias toward patients whose triage level, LOS, and age indicate a more severe condition extends the finding by Rusanov et al. [15] that EHRs contain more data about the sicker patients.

Part of the reason for data incompleteness is that the decision about whether to record the data is often left to the clinicians’ discretion. This practice acknowledges the primacy of their day-to-day clinical work. Somewhat surprisingly it remains unclear in many studies of the quality of EHR data [e.g., 2; 12] whether it was mandatory for the clinicians to record the data. Frequently, transitional artifacts fill a gap between the clinical work and the formal documentation of it [3]. Such transitional artifacts hold procedural information important in performing the work, but at the same time the transitional artifacts are exempted from the formal documentation requirements. The whiteboard in the present study is an example of a transitional artifact. That is, the clinicians were not formally required to keep the whiteboard current. While this may contribute to explaining the incomplete data, a formal requirement to record the treatment activities will not necessarily result in complete data. For example, Granli and Hertzum [6] found that none of eight mandated work procedures associated with an electronic medication record were followed consistently by more than 48% of the wards at the studied hospitals.

Another reason for the incomplete data is that the treatment activities had to be recorded manually. Activity data are, for example, pertinent in moving the modelling of ED crowding beyond models based solely on when patients arrive in the ED [10]. Thus, the introduction of a tool that forecasts ED crowding on the basis of activity data might motivate the clinicians to record these data more consistently. Alternatively, it might be possible to derive activity data automatically from other data. For example, the recording of a patient’s triage level indicates the end of the activity of triage and is, in most cases, also a good indicator that the patient has now transitioned to the activity of waiting to be seen by a nurse. The triage level was not recorded for all patients, but in all EDs it was recorded more often than that the patient was waiting to be seen by a nurse. Thus, the requirement for manual data entry can probably be reduced by deriving additional activity data from other whiteboard data or from EHR data. While automatic data derivation will likely improve completeness [2], data correctness may suffer because manual data entry likely captures some nonsensical data. In balancing manual data entry against automatic data derivation it should also be considered that automatic data derivation frees clinician time for other activities.

Finally, the bias of the recorded data toward patients with more severe conditions is reassuring from a clinical point of view because it suggests that the clinicians attend more to the patients who are more in need of clinical attention. It may, however, be impossible to compensate for this bias when the data are reused, thereby confounding any analyses performed by reusing the data.

### Limitations

Two limitations should be remembered in interpreting the results of this study. First, the data are from EDs in one healthcare region of one country. While the four EDs show that the results of the study are not peculiar to one ED, it would be valuable to replicate the study in other countries with other healthcare systems. Second, we can merely speculate about the reasons for the incomplete recording of the
treatment activities. While the log data quantify the magnitude of this incompleteness, interviews or other qualitative data would be needed to explain why the clinicians like the whiteboard but often leave the recording of the treatment activities incomplete.

**Conclusion**

Changes to the content of electronic ED whiteboards are logged and thereby available for later inspection and reuse. Such log data provide opportunities for forecasting ED crowding, identifying bottlenecks in the ED workflow, and more generally – for reusing EHR data for the purposes of research and quality improvement. In this study we have analyzed the completeness with which five main treatment activities are recorded on the ED whiteboards in a Danish healthcare region. We find that the low completeness of the activity data probably prevents most types of reuse and that, if reused, the activity data incur a bias toward the patients with the more severe conditions as indicated by triage level, length of stay, and patient age. The incomplete activity data cannot be explained by the whiteboard being disliked by the ED clinicians or unused for its primary purpose of supporting day-to-day ED work. On the contrary, the whiteboard had been in successful use in the EDs for several years. It is in spite of successful primary use that the incompleteness of the activity data probably prevents most secondary uses. We point to non-mandated use and manual data entry as reasons that contribute to the poor data quality.

**Acknowledgements**

This study is part of the Clinical Communication project, which is a research and development collaboration between Roskilde University, University of Copenhagen, Imatis, and Region Zealand. The two interview quotes in the Method section are from interviews conducted in collaboration with Jesper Simonsen and Arnvor á Torkilsheyggi, both from Roskilde University. Improving Patient Safety Through the Design and Development of a Computerized Provider Order Entry for Parenteral NutritionLinked to a Barcode Medication Administration Record

Oscar I Jáuregui, Lucila Bruchanski, Daniel A Rizzato Lede, Carlos M Otero, Daniel R Luna

Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract
Among adverse events related to medication errors, the defects in parenteral nutrition administration pose a special threat to patient safety. Two high impact strategies to reduce these errors require implementing a Computerized Provider Order Entry and the use of bedside bar-code verification prior to medication administration. In this study, we share the deep field analysis of the current workflow performed to include inpatient bedside barcoding verification for parenteral nutrition administration in a large academic health center. Then, we propose a process optimization and a new parenteral nutrition ordering tool embedded in the prescription module. Structuring physicians’ ordering and the bar-code verification of administration can increase patient safety. The next steps would involve the creation of a Clinical Decision Support System to improve patient nutrient goals.

Keywords:
Electronic Health Records; Parenteral Nutrition; Patient Safety.

Introduction
Medication errors have been reported as the most common causes for alerts in critical incident reporting systems [1]. Also adverse events related to inpatient medication errors are a serious menace to patient safety [2] having an incidence of 6.5%. One third of them take place during prescription and another third occur during medication administration [3]. It was found that the parenteral nutrition (PN) administration was defective in 3.2% of the cases [4].

There is growing evidence that Health Information Technology (HIT) for medication safety — classified as a socio-technical system, due to the complexity of the medication processes and the required coordination of various professional groups [5] — can help to overcome this problem. Computer Provider Order Entry (CPOE) implementation was associated with a reduction in serious medication errors by 55% [6]. In addition, the use of bedside bar-coded medication administration technology (BCMA) diminished errors in medication administration from 41% to 27%, and proved to be cost-effective [7]. Although the feeding ordering functionalities of commercial Electronic Health Records (EHR) are heterogeneous [8], they can help physicians by providing clinical decision support systems (CDSS), therefore decreasing the risk of drug interactions and transcription errors, among others [9].

The Hospital Italiano de Buenos Aires (HIBA) is a non-profit health care academic center founded in 1853, with over 2,700 physicians, 2,700 other health team members (including 1,200 nurses) and 1,800 administrative and support employees. The HIBA has a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 800 homecare beds, 25 outpatient clinics and 150 associated private practices located in Buenos Aires city and its suburban area. It has a Health Maintenance Organization (Plan de Salud) that covers more than 150,000 people and also provides health services to another 1,500,000 people who are covered by affiliated insurers. Between 2013 and 2014, over 45,000 inpatients were admitted to its hospitals, there were 45,000 surgical procedures (50% ambulatory) and 3,000,000 outpatient visits.

Since 1998, the HIBA runs an in-house developed health information system, which includes clinical and administrative data [10]. Its Electronic Health Record (EHR) system called Italica, is an integrated, modular, problem oriented and patient centered system that works in different clinical settings (outpatient, inpatient, emergency and home care. It has been recently certified by the HIMSS as level 6+ in the Electronic Medical Record Adoption Model (EMRAM), being the first hospital in Argentina and the second in Latin America reaching this stage [11] [12].

The HIBA achieved Joint Commission International safety and quality certification in 2015. One major addressed issue was the correct identification of patients. To this end, in 2010 the Department of Health Informatics developed and implemented an inpatient bracelet identification system with barcoding technology. This code can be scanned to verify patient identity before every intervention (patient transfer, medication administration or other procedures).

Nowadays, just Adult Intensive Care Unit fulfills the process of scanning the tag of every medication before administration. As suggested by the Institute of Medicine, the Hospital Italiano of Buenos Aires is using HIT to enhance patient safety [13]. As CPOE and CDSS were fully implemented for most medications, and in order to certificate EMRAM level 7, we decided to take a step forward and apply bedside BCMA in every inpatient setting, for each substance administration, including parenteral nutrition.

An average of 80 PN bags per day is prescribed to inpatients in our institution. Half of them are for adult patients and the other half are distributed evenly between pediatric and neonatal patients. The bags are provided daily by an outsourced vendor, who produces them with an automated compounding device (ACD) that needs the manual entry of the prescription data. Parenteral nutrition is a complex type of medication that has a specific process and requires special attention to succeed in closed loop administration. We analyzed and modeled current processes in order to define IT system requirements [14], and then designed and developed a new software tool according to
health IT medication safety guidelines [5] in order to prevent from technology-induced errors [15]. These actions take part of a broad overall project for BCMA implementation, included in the portfolio for Electronic Medical Record Adoption Model Level 7 certification.

The two objectives of this paper are to describe the process modeling and optimization and to show the participative and user centered design of a structured PN ordering module linked to BCMA.

**Methods**

**Process modeling and optimization**

We sought to analyze and model the processes and workflows involved in the prescription, preparation, validation and administration of the PN bags in our institution. We collected the data based on a three stage methodology, according to the work published by Granja et al. [14], as follows:

Stage 1: We performed database queries to collect quantitative and qualitative historical data of the number of NPT prescriptions, prescribing medical services, items and structure of prescription, and the differences between services in the last 6 months.

Stage 2: We subsequently carried out field observations in the different areas involved in the process (wards, medical offices, central pharmacy, satellite pharmacies and nurse offices), with unstructured interviews with the involved health care workers.

Stage 3: We finally accomplished in-depth interviews with key stakeholders (physicians, pharmacists, nurses, and the outsourced vendor).

Afterwards the processes were plotted with flowcharts and task breakdown, and worked under project management methodology [16].

We then proposed certain modifications to the current process in order to achieve BCMA requirements. These changes were agreed upon with the end users to avoid change resistance in the subsequent implementation.

**Prescription interface design**

We intended to create a new structured parenteral nutrition ordering functionality within our CPOE. According to current state of art in safe IT design and medication safety [5,15] we performed an iterative, participative and user-centered design, and followed accepted design guidelines, in order to minimize further technology induced errors. Some adjustments were also included in the medication list visualization for physicians and nurses, in order to adequately represent the PN data being entered in the novel module.

**Results**

**Process analysis**

We analyzed a 6 month period (March 2016 to August 2016) of free text TPN prescriptions within our CPOE. A total of 15101 prescriptions were made (mean=83 per day) by 4 different medical services. We qualitatively analyzed the variables involved in the prescriptions and found that type of TPN, method of infusion, route, infusion rate, start time, cycling periods and composition were the main items. We also found profound differences between services in the prescriptions’ text, namely that one service only specified route and infusion rate, while another one explicitly wrote bags’ composition and every cycling period.

We carried out observations in the different areas where the process developed, and had interviews with the corresponding personnel to better understand the steps being observed. Then we performed in-depth interviews with key stakeholders from the different areas involved in order to better understand the process, and dig in the aspects that were found to be inefficient, that could lead to a breach in patient safety, or that would not allow us to implement BCMA.

The process begins with the prescription of the parenteral nutrition bags (Figure 1). It is ordered by the physicians after the daily rounding. The prescription is made twice: first they write the composition and the posology in free text in the EHR. Later, a structured paper form is filled manually with the patient's identity and the PN desired composition, which is scanned and sent by email or fax to the vendor. The vendor technician inputs the data manually into the compounding machine’s system. He performs a validation process to check the components against standardized values. If the formula is correct, the bag is prepared and then sent to our institution, labeled with the patient's information and a production barcode identifier. The PN bag is received at the central pharmacy where a pharmacist searches for the patient in our EHR, and validates manually the right composition, comparing it with the physician’s prescription. Afterwards, the bag is dispensed to each inpatient unit and stored in a special refrigerator in the satellite pharmacy. The nurse picks up the bag (checking the patient's identity in the bag label), connects it to the patient and starts the administration through an infusion pump. Finally, she documents manually her actions in our electronic medication administration record (eMAR).

![Figure 1 - Process analysis. *: steps only done in intensive care units. In open units the bag is dispensed directly to the nurse.](image)

**Process optimization**

We proposed some process modifications to achieve closed loop administration (Figure 2), namely:

1. Parenteral nutrition posology has to be structured to standardize the communication between physicians and nurses, and to allow right route, time and dose (volume) automatic verification.

2. As the outsourced vendor requires a handwritten PN prescription sheet, we have to include univocal patient identity information together with a barcode that contains the patient's hospital identification number.

3. The patient's hospital identification barcode should be scanned by the vendor technician, and their system would verify the correctness through a web service.
4. The nurse should scan the patient's wristband and then the bag’s production barcode identifier prior to administration. If the bag and prescription matches the patient, the system will allow her to administrate the bag, otherwise an alert would appear.

5. The nurse records the administration synchronously.

---

**Prescription module design**

We designed a new PN ordering module for our EHR that should be accessible for physicians from the CPOE. The design started with the identification of the main tasks of the prescription process, made by direct observation and interviews. Then, a mock-up of the user interface (UI) was prototyped (Figure 3) and assessed for heuristic evaluation by a usability expert, then presented to key users, who qualitatively tested it in order to undermine major usability flaws. After we analyzed user’s feedback, a number of improvements in the UI and new functionalities were presented to users for acceptance. After iteration, a final prototype was exhibited to users, who were able to complete tasks without any usability problems, and with good overall acceptance (Figure 4).

The interface works as follows: the professional initially selects the type of preparation (compounded or ready to use), the route and the administration method.

When the provider chooses a ready to use preparation, the system displays the products available in the pharmacy. We decided to show the brand name, as the generic components were confusing for users during the test sessions. The infusion method can be selected between cycling or constant infusion rate with a radio-button. If constant infusion rate is selected, provider has to enter the volume to infuse, the infusion rate and the time to start administration. If the users choose the cycling method the system displays a schedule with start and stop time, and corresponding infusion rate has to be entered. The partial and total volumes are automatically calculated (functionality extracted from testing session’s analysis, as providers had difficulties calculating these volumes). When the provider chooses a compounded preparation, he must describe its formulation in a free text field. In both cases, an optional text field is offered for additional observations.

From this interface, the user can print an empty PN form filled with the patient’s name, date of birth, date of prescription, hospital ID number and barcode. The physician has to add manually the PN formulation and sign it before scanning and sending it to the vendor.

The PN orders were highlighted in the patient medication list, to avoid misunderstandings between nurses and physicians.
Discussion

We reviewed the medication cycle process for parenteral nutrition in our institution, which involves an external stakeholder. We encountered some error-prone steps like the free text format ordering in the EHR and the patient's identity verification between both organizations. Moreover, some data was missing in the process, and hindered bedside barcoding implementation. We then proposed some variations to that workflow for increasing patient safety, and closing the data loop. The main improvements in the process were the prescription of parenteral nutrition in a standardized and structured way, for which a specific module was designed to fulfill that requirement; the standardization of patient identity verification with the external supplier; and the scanning of the of the bag’s barcode by the nurse prior to administration to validate the 5 rights. Therefore, we expect to diminish significantly the errors due to wrong patient, route or dose (volume), at the prescription and administration phases. Transcription errors can also disappear as the nurse will see the prescription information directly in the eMAR. Nevertheless, as stated in Seidling et al., when implementing a new tool with a process redesign, it is not always possible to separate the benefits of the health information technology intervention from those inherent to the process optimization itself[7].

We designed the system following a user centered and participatory design, meeting user and systems needs. By that, we expect to avoid workflow disruption, and minimize the risk of technology induced errors. Having said that, we should still monitor the human computer interactions and the patient outcomes to prevent workarounds and iatrogenia that might emerge following implementation [17].

A substantial limitation to the process optimization and the implementation of the BCMA is that the outsourced vendor has a non-standard compliant system that hinders the integration with ours. The main barriers for achieving interoperability were that their patient's identification system lacked the security measures needed for clinical purposes, and that the variables they used in the prescription module weren’t built following the HL7 standards that run in our system. Since the software changes necessary for full interoperability will demand further resources, they'll be tackled in a second stage. Thus, the bag’s formulation will remain in a free text field until its incorporation to the electronic tool. Additionally, paper is still necessary in our process, and its transcription to the external supplier’s system occurs. On the other hand, as health IT for medication safety involves numerous care processes, it should be carefully planned and integrated step by step [5].

Another limitation found was the high heterogeneity of the work patterns among providers, which could influence the IT system's usefulness. These different processes are seen in most of large health institutions, and they are an obstacle for implementing a single IT solution, since it’s not recommended to have different work patterns at the same time.

Nowadays we are at the final stage of the development of the prescription module and the communication with the vendor, and implementation is planned for the following months. After implementation we will evaluate its impact in patient safety through specific indicators.

Our software developing group is also currently working in a fully integrated interface between our EHR and the vendor's own system, which allows individual PN component prescription in the CPOE. The PN prescription will be validated at different stages, and will be prepared by the automated compounding machine, preventing data transcription. Moreover, structured PN bag’s components allows CDSS integration, thus improving prescriber performance [6] [18] and cost effectiveness [19].

A number of IT solutions have been described in the field of IT solution, specifically BCMA, for medication safety [20][21] but we believe this is the first description of a work of this nature in the South American region.

Conclusions

We analyzed and modeled the medication workflow of parenteral nutrition, and proposed process changes to achieve bedside barcoding readiness to improve medication safety. We
shared the iterative and participatory design of the interface of a novel prescription module for parenteral nutrition orders. Obstacles were found in integrating an actor outside the organization, without governance over it, into the process, and in creating a single optimized process for the different medical and administrative workflows that existed in the institution. The software is currently being developed, and future publications will address its implementation, safety outcomes and improvements.

Use of EHR Data to Identify Factors Affecting the Time to Fall

Hyesil Junga, Hyeoun-Ae Parka,b

aCollege of Nursing, Seoul National University, Seoul, South Korea,
bResearch Institute of Nursing Science, Seoul National University, Seoul, South Korea

Abstract

Although there are many studies of falls occurring in a hospital setting, research on factors affecting time to fall after admission is scarce. It is important for nurses to identify factors contributing to an early fall so that they can pay particular attention to patients with such factors. In this study, patients who sustained a fall were extracted from an adverse event reporting system and narrative nursing records of those hospitalized between January 2015 and May 2016. We used the electronic health records of ten different data sources to extract fall-related variables; the data were integrated according to normalization criteria. Univariate and multiple linear regression analyses were used to identify factors influencing the time to fall from admission. About 49% of fallers fell within the first week after admission. A walking disorder, comorbid disease, intravenous therapy, and arterial lines were related to early falls.

Keywords:
Accidental Falls; Electronic Health Records; Information Storage and Retrieval

Introduction

Falls are one of the most common patient safety problems in hospitals. Falls can lead to physical injury and psychological problems, including loss of confidence and fear of recurrence, prolonged hospital stay, and financial burden [1,2]. Thus, the Joint Commission International set reducing risk of patient falls as the sixth of its International Patient Safety Goals [3].

The rate of falls in South Korean hospitals ranges from 0.08 to 0.19% [6,8]. However, these figures may be an underestimate considering that healthcare professionals are reluctant to disclose such statistics [2].

Globally, most accidental falls occur within the first week after admission [4,5,14], similar to what occurs in Korea [6]. However, most studies of falls occurring in a hospital setting have focused on identifying risk factors and developing predictive models. Few studies have identified factors affecting the time at which a fall occurs. Early falls can increase a patient’s fear of remaining in the hospital and promote distrust of the hospital or healthcare professionals. Thus, risk factors related to early falls should be explored to prevent or reduce their occurrence [5].

Many hospitals have adopted electronic health record (EHR) systems. In Korea, 50.2% of tertiary teaching hospitals and 35.0% of general hospitals have adopted EHR systems [7]. As a result, it is possible for researchers to use EHR data for patient care and outcome research.

However, the types of EHR data vary, from structured data, including vital sign data (e.g., blood pressure, heart rate, and respiratory rate) and drug prescription data, to unstructured data, including imaging and clinical narrative data [10]. In addition, a variable can be documented in multiple forms by various healthcare professionals and stored in multiple locations; thus, it is difficult to select or integrate EHR data.

Most studies of falls [2,5,6,8,12] considered only subjects who were registered as fallers in an adverse event reporting system (AERS). A previous study [9] extracted fall-related factors from narrative nursing records. Such records, in which nurses document patients’ problems and the actions taken to solve them, can be used as a data source for fall events.

Based on this information, the present study identified patient characteristics and factors affecting the time at which a fall occurred by integrating and normalizing various EHR data from different sources.

Research Questions

The main research questions were:

1. When do patients fall after admission?
2. Do patient’s or environmental characteristics influence timing of a fall?
3. What factors affect the time at which a fall occurs?

Methods

Setting and study subjects

This study was conducted in the neurology/neurosurgery and hematology/oncology wards of a Korean tertiary teaching hospital because that is where falls occur most frequently. This hospital has been using a standard terminology-based nursing records system since 2003 [15]. Fallers were extracted from the EHRs of those who were admitted to the hospital from January 2015 to May 2016.

In this study, a faller was defined as a patient who was registered in the AERS or a patient with a word or phrase such as "fall", "collapsed", "slip and fall", "fall off the bed", "fling oneself to the floor", "fall down during a move", "slip down during a move", or "flopped down" in their narrative nursing record.

Only the first fall was included for patients who fell more than once during a hospital stay.
Ethical Considerations

This study received approval from the institutional review board of the study hospital.

Procedures

Exploring fall-related variables

Fall-related variables were identified by reviewing clinical practice guidelines published by the World Health Organization, Agency for Healthcare Research and Quality, National Institute for Health and Care Excellence, Registered Nurses’ Association of Ontario, and other organizations; fall risk assessment tools; and literature obtained from Google Scholar, PubMed, and the Cochrane Central Register of Controlled Trials.

Extraction of EHR data

We surveyed seven clinical nurses and two informatics specialists working at the study hospital to locate fall-related variables in the EHR system.

Variables were extracted from ten different data sources: clinical observation sheets, initial nursing assessments, the patient acuity classification system, laboratory results reports, doctor’s medication orders, fall risk assessment forms, nursing activity sheets, surgical information sheets, doctor’s progress notes, and narrative nursing records.

Data normalization

Data extracted from more than one source were normalized based on completeness, currency, and granularity of the record. “Completeness” refers to how often a variable is documented in a data source.

If variable A is documented more often in the narrative nursing record than on the clinical observation sheet, the narrative nursing record has higher completeness than the clinical observation sheet.

“Currency” refers to how close a variable is documented to the time of a fall to reflect the patient’s status at the time of the fall. We defined the maximum time interval allowed between the recorded time and fall occurrence for each variable.

“Granularity” refers to the level of detail of information implied by the data. High granularity means a variable is documented with more attributes or with a detailed value set.

For example, “pain” data stored on both the clinical observation sheet and narrative nursing record were normalized (Figure 1). We first reviewed the clinical observation sheet where pain was documented more often than in the narrative nursing record. We assessed whether pain was documented in the clinical observation sheet within 2 days (the maximum time interval allowed) from a fall occurrence. If pain data recorded within 2 days from a fall occurrence was stored on the clinical observation sheet, we took the numeric rating scale (NRS) of pain. If not, we reviewed the narrative nursing record. If pain was documented in the narrative nursing record, we took the pain value (either the NRS score or Y/N). If pain was not documented in the narrative nursing record, then we concluded that the patient had no pain.

Statistical analyses

The characteristics of patients who sustained a fall and the time at which a fall occurred were summarized using descriptive statistics, including the mean, standard deviation (SD), median, interquartile range (IQR) and frequency. Second, univariate analyses were used to select significant variables affecting the time at which a fall occurred. Simple linear regression analyses were used for continuous variables such as age, patient acuity, and the fall-risk score. The t- or Mann-Whitney U test, a one-way analysis of variance, or the Kruskal-Wallis test were used for discrete variables such as sex, presence of a tube, and mental status, depending on the number of categories of independent variables and normality of the time-to-fall data. Statistically significant variables with a significance level of p < 0.10 were selected as independent variables for the multiple linear regression. A multiple linear regression analysis with backward variable selection was used to identify factors affecting the time at which a fall occurred. Variables with p < 0.05 were considered statistically significant. The time to fall from admission was natural logarithm-transformed because it was positively skewed. All analyses were performed using SPSS statistical software (ver. 23.0; IBM Corp., Armonk, NY, USA).

Figure 1 – Normalization process for the pain data
Results

Subject characteristics

A total of 310 patients who sustained a fall were included in the study (Table 1). The mean (SD) age was 62.9 (± 14.7) years and 186 (60.0%) patients were male. There were 151 (48.7%) patients who fell down within 1 week after admission. The median time to fall from admission was 7 days and the IQR was 11 (3.0–14.0) days. The mean (SD) and median (IQR) length of stay were 23.0 (± 19.2) days and 19 (20.7, 9.3–30.3) days, respectively.

We identified 205 (66.1%) fallers from the AERS and an additional 105 (33.9%) from narrative nursing records. Figure 2 shows the distribution of the number of fallers by hospital days. The number of falls decreased as the hospital days increased.

Figure 2 – Distribution of falls by hospital days

Extraction of EHR data by fall-related variables

In total, 95 variables were identified as factors related to falls through a literature review. They included patient variables (e.g., sex, age, education, and comorbidities), environmental variables (e.g., inadequate light and slippery floors), medical interventions (e.g., surgical procedure, drug administration, and non-invasive procedure), and nursing interventions (e.g., education for fall prevention, use of a bed rail, use of restraints, and a fall risk assessment).

Table 2 presents the types of data sources by variable. Data on “intravenous (IV) therapy” were extracted from clinical observation sheets, nursing activity sheets, the patient acuity classification system, and narrative nursing records. Data on “depression”, “confusion/disorientation”, and “altered elimination” were extracted from clinical observation sheets, fall risk assessment forms, and narrative nursing records. In addition, data on “pain”, “anxiety”, “hyperthermia”, “communication disorder”, “dizziness/vertigo”, and “enema” were extracted from two different sources, including the narrative nursing records. Of the ten data sources, the narrative nursing records had the highest coverage rates, with 88.2% of the variables stored. Variables extracted from more than one source were normalized for further analysis.

Table 2 – Possible types of data sources by variable (A, clinical observation sheet; B, initial nursing assessment; C, patient acuity classification system; D, laboratory results report; E, doctor’s medication order; F, fall risk assessment form; G, nursing activity sheet; H, surgical information sheet; I, doctor’s progress note; J, narrative nursing records)

Relationship between the time to fall and variables

Of the 95 variables, 37 were identified as significant (p < 0.10) variables related to the time at which a fall occurred (Table 3).

Age, fall-risk score, vasodilators, antihistamines, anxiety, balance disorders, IV therapy, comorbid disease, hearing defects, an arterial line, and walking disorders were negatively related to the time to fall. That is, a patient with the above-mentioned variables tended to fall early.

Factors affecting the time to fall from admission

The assumptions of the linear regression such as autocorrelation (Durbin-Watson statistic \( = 2.151 \)), multicollinearity (variance inflation factor value \(< 2.0 \)), homoscedasticity, and normality of residuals were met.

The results of the multiple linear regression analysis between 37 independent variables and the time to fall are presented in Table 4. In total, 16 variables were significant.

Variables negatively related to time to fall included walking disorder, comorbid disease, IV therapy, and arterial line. These variables contributed to early falls after controlling for other variables. Variables positively related to time to fall included education level, fall prevention education, walking aids, caregiver, narcotic analgesics, SSRI, anti-diabetics, lower sensory disorder, cognitive disorder, dyschezia, anorexia, and central venous line. These factors contributed to delaying the time to fall after controlling for other variables.

The regression model was statistically significant (\( F = 13.220, p = 0.000 \)). The adjusted \( R^2 \) was 0.458, with 16 independent variables explaining 45.8% of the variation in the time to fall.

Discussion

Factors affecting the time to fall from admission were explored using EHR data. Previous studies of falls in a hospital setting extracted fall patients only from an AERS [1,2,5,6,8]. However, in this study, we identified 105 additional fall patients by analyzing narrative nursing records, which were a useful complement to the AERS to identify fall occurrences. Using various EHR data sources, we also be extracted from the narrative nursing record. For example, narrative nursing statements such as “patient is unconscious”, “patient is confused”, and “patient is fully awake” express different states of a patient’s consciousness. If it was impossible for us to determine the degree of a variable, we categorized the variable with a Boolean (Y/N) value.

Data values for the same variable were stored inconsistently at different data sources in terms of data type, so we tried to reduce this inconsistency by normalization. Missing values were reduced by this process. For example, we reduced the number of missing values in the pain data by 29% using clinical observation sheets and narrative nursing records during the normalization process, which improved the external validity of the results.

The greatest number of falls occurred during the first week of the hospital stay. This finding is similar to that of previous studies [4,5,6,14]. This could be because newly admitted patients may have experienced difficulties adjusting to the new environment [14]; they were not used to the bed, toilet, or medical devices. Therefore, it is important to assess a patient’s fall risk within the first week after admission. Patients with a high risk of falling during the first week of admission deserve special attention from healthcare professionals [5].

Walking disorders, comorbid disease, IV therapy, and arterial lines were negatively related to the time to fall from admission. Walking disorders, comorbid disease, and IV therapy are components of the Morse Fall Scale, which is used to assess a patient’s likelihood of falling. They are not only risk factors for falling, but also factors affecting the time to fall according to this study. Patients with a walking disorder tended to fall early, as most of these patients were hospitalized in the neurology/neurosurgery ward with poor mobility and walking disturbances due to their disease (e.g., stroke or...
Parkinson’s disease). This finding is similar to that of previous studies reporting that an unsafe gait is a risk factor contributing to the time to fall [5] and the occurrence of falls [12]. Comorbid diseases such as hypertension, diabetes mellitus, hyperlipidemia, cardiac disease, and liver disease are related to an increased risk of inappropriately prescribing drugs and adverse drug reactions [13], which may cause an early fall. In addition, patients receiving IV therapy or those with an arterial line are more likely to fall by tripping on the IV poles or related equipment.

The presence of a caregiver and use of walking aids were significant variables for delaying the time to fall. A caregiver and walking aids help patients maintain their balance when they walk. Fall prevention education by nurses also prolongs the time to fall. Therefore, early education for fall prevention is essential to reduce the risk of an early fall.

This study has some limitations. First, we used a single research site and selected the neurology/neurosurgery and hematology/oncology wards (where falls occurred most frequently in the hospital). Therefore, there are constraints on generalizability and applications to practice. Second, environmental variables such as inadequate light, a slippery floor, and unfitted shoes were not included in the analyses, as they were not documented in the EHR. In this study, we only examined the time to fall after admission of the fallers. Currently, we are working on a model to predict the risk of falling with faller and non-faller data.

Conclusion

We identified factors affecting the time to fall using EHR data. We used ten different data sources to extract variables, and the data were integrated and normalized based on normalization criteria such as completeness, currency, and granularity. This process helped improve the accuracy and completeness of the data. In this study, the narrative nursing records were very useful for identifying fall patients and fall-related variables; they also complemented the AERS.

This study shows that the greatest number of falls occurred during the first week of a hospital stay. In particular, a walking disorder, comorbid disease, IV therapy, and arterial line were related to an early fall. We recommend that nurses assess early fall risk and pay extra attention to patients during the initial period of hospitalization.

Abstract

Health information technology (HIT) events, a subtype of patient safety events, pose a major threat and barrier toward a safer healthcare system. It is crucial to gain a better understanding of the nature of the errors and adverse events caused by current HIT systems. The scarcity of HIT event-exclusive databases and event reporting systems indicates the challenge of identifying the HIT events from existing resources. FDA Manufacturer and User Facility Device Experience (MAUDE) database is a potential resource for HIT events. However, the low proportion and the rapid evolution of HIT-related events present challenges for distinguishing them from other equipment failures and hazards. We proposed a strategy to identify and synchronize HIT events from MAUDE by using a filter based on structured features and classifiers based on unstructured features. The strategy will help us develop and grow an HIT event-exclusive database, keeping pace with updates to MAUDE toward shared learning.

Keywords:
Patient Safety; Medical Errors; Information Storage and Retrieval

Introduction

Health information technology, or Health IT (HIT) -including electronic health records (EHR), computerized provider order entry (CPOE), clinical decision support (CDS) systems, and personal health records (PHR) - has been placed in the spotlight for its bold promises to increase hospital efficiency, improve patient safety, and reduce medical errors [1]. According to the Agency for Healthcare Research and Quality (AHRQ), HIT is defined as “the use of information and communication technology in healthcare to support the delivery of patient or population care or to support patient self-management” [2]. While the use of HIT presents many new opportunities to improve patient care and safety, it can also create new hazards and opportunities for error. HIT will fulfill its potential only if the risks associated with its use are identified and a coordinated effort is developed to mitigate those risks. In fact, one in every six patient safety events (PSE) can be attributed to HIT [3], making HIT one of the top 10 technology-related hazards as identified by the Emergency Care Research Institute [4].

Event reporting is a potential approach for shared learning, which has been proven in many high-risk industries, such as the aviation, nuclear, and railroad industries. For HIT to become more widely adopted and trusted, it is crucial to gain a better understanding of the nature of the errors and adverse events caused by current HIT systems. Identifying problems of HIT systems when they occur and presenting to stakeholders is an area that has not received enough emphasis [5]. Similar to PSE reporting, an effective means suggested by the Institute of Medicine, acquiring knowledge from previous experiences to prevent the recurrence and serious consequences of similar HIT events could be a practical start [6]. PSE reporting is frequently a mainstay of frontline practitioners’ efforts to detect PSEs and quality problems [7]. The reports collected from a broad range of stakeholders can generate a summary and feedback toward actionable knowledge and shared learning.

Although AHRQ has taken initial steps to standardize HIT reporting by the creation of the Common Formats [8], currently there is still no HIT exclusive reporting form/system. Part of the reason may lie in the fact that current definitions of HIT are often broad with ill-defined borders [9]. Under the current AHRQ HIT definition, almost any medical device that utilizes electronic software and hardware can be considered an HIT device. In practice, however, reporters may find a stricter definition of HIT more helpful in determining the events involving technology and should be reported under HIT. The starting point for creating an effective HIT exclusive reporting form/system lies in the creation of an HIT event database. The database will allow researchers to analyze connections among HIT events, identify common themes of technology-induced errors, synchronize HIT related reports from existing resources, and develop a classification or terminology to standardize HIT reporting.

The scarcity of HIT event-exclusive databases and event reporting systems indicates the challenge of identifying and synchronizing the HIT events from existing resources. The FDA Manufacturer and User Facility Device Experience (MAUDE) database [10] is a rich and publicly accessible resource of HIT events. The MAUDE database contains the
reports of events involving medical devices, voluntary reports of medical device malfunction, and reports of problems leading to serious injury and death since June 1993. The MAUDE database houses medical device reporting submitted to the FDA by mandatory reporters (manufacturers, importers and device user facilities) and voluntary reporters (healthcare professionals, patients and consumers). MAUDE data are updated weekly and searchable online. As of November 2016, MAUDE had more than 5 million reports. Although the number of MAUDE-based HIT publications has increased in recent years (Figure 1), the number remains fractional given the enormous number of reports in MAUDE. Most publications were reviews about certain events, devices, or treatments based on MAUDE reports. Exploration of the utility of MAUDE for understanding HIT problems has been limited [11]. Therefore, a search and classification strategy holds potential for using the HIT reports and would result in a database to store, manage, and compare HIT reports and to identify and analyze HIT solutions [12].

In this study, we created a comprehensive search strategy that utilizes both structured (device data) and unstructured (text data) to extract HIT related events from the FDA MAUDE database. Our strategy first involved the use of a keyword filter on the structured data to screen the FDA database for reports related to HIT. Then machine learning algorithms were used to classify the selected reports based on their narrative text. Finally, reports classified with a high probability of HIT were added to our HIT event database. Using this strategy, we were able to grow an HIT event database composed of HIT related events from the FDA MAUDE database. Ultimately, the creation of this database holds promise in aiding the understanding, characterization, discovery, and reporting of HIT related events.

Methods

Construct a Filter for HIT Related Reports Based on Structured Data

The device data of FDA MAUDE consists of 45 structured fields that contain information regarding the device involved in the event. Most of the fields, however, are either left blank by reporters or are of little use for the purpose of identifying and synchronizing HIT related events. After reviewing all the fields, we found that the generic name and manufacturer name fields have the greatest potential in identifying HIT related events and thus we utilized both in the creation of our filter.

To develop the filter, we started with a set of common computer hardware and software related keywords that had been previously identified [13]. The starting keyword list was expanded by the addition of several generic terms such as “software,” “program,” and “hardware” and several more modern terms such as “electronic medical record” and “portal technology.” Then all of the generic names from the FDA MAUDE database starting from Jan 2010 to Dec 2015 were extracted, yielding a total of 60,000 unique generic names. Next, through partial keyword matching of the generic names to the keywords list, a subset of generic names appearing HIT-related was extracted. The subset was further analyzed by domain experts to determine which generic names were actually linked to HIT reports by using a small portion of the 2015 FDA MAUDE database.

A similar approach was utilized in selecting a list of manufacturers for the filter. We started with a list of seven popular HIT manufacturers [13] and then added 347 manufacturers of HIT software. The reports from the 2015 FDA MAUDE database related to those manufacturers were extracted and checked to determine the most relevant manufacturers.

Evaluate the HIT Filter Through Expert Review

The HIT filter was first applied on the 2015 FDA MAUDE database. Then a subset (10%) of the reports screened by the filter was selected for manual review by two domain experts. The experts labeled each report with one of three labels: HIT, Not HIT, or Unsure. The reports that the reviewers disagreed on or were unsure about were resolved through group discussion.

During reviewing, we narrowed the HIT definition to identify the most clinically relevant and consequential HIT devices. Under our current understanding, an HIT device is any device that utilizes both hardware and software to facilitate health information exchange in order to aid in the diagnosis, treatment, or prevention of disease. Using this definition, priority is given to HIT systems that focus on information exchange such as electronic health records, computerized physician order entry, and picture archiving communications systems. Implantable devices, glucose monitors, defibrillators, and similar devices are excluded under this definition as they do not actively facilitate health information exchange.

Construct HIT Classifiers Based on Unstructured Data

Machine learning classifiers including logistic regression, support vector machine (SVM), naïve Bayes, and random forest were constructed using the unstructured data (narrative text) of the reviewed reports. Each report in the labeled training set was treated as a vector of words and was weighted by a term frequency-inverse document frequency (TF-IDF) schema. Each classifier was evaluated using leave-one-out cross-validation (LOOCV) and performance was weighted based on both their F1 score and ROC curve. The best classifier was selected and then attribute selection was done to further increase the performance and efficiency of the classifier.

Grow an HIT Event Database

The optimized HIT classifier was applied to previous years of the FDA Maude database starting from 2015. The reports were ranked in order of their probability of being HIT related. The probability was calculated internally by the classifier. The ranked reports were then manually reviewed until less than 90% of the reports at a given probability threshold were HIT related. The reports above the probability threshold were then added to the rest of the HIT reports previously found, forming the final HIT event database.

Results

Keywords of the HIT Filter

A subset of 336 software and 749 hardware generic names most likely to be related to HIT was extracted from the 3,634,879 reports in MAUDE during 2010-2015, which account for 72% of the total reports in MAUDE since 1993. After the expert review, 58 keywords from generic names (39 software and 19 hardware keywords respectively) and 16 keywords from manufacturer names were determined to compose the filter for HIT related reports, as shown in Table 1.
The filter was first applied on the 2015 FDA MAUDE database including 860,915 reports. 4871 reports (2479 software and 2392 hardware reports) were initially found. 490 reports (10%) were randomly selected according to the keyword distribution for expert review and labeling. 312 reports were identified as HIT related by experts, which means the filter can generate a report subset from original MAUDE database with about 63.7% HIT related reports. This proportion is significantly higher than 0.1%, which is the estimated proportion of HIT related reports in the entire MAUDE database [12].

HIT Classifiers

TF-IDF models were applied on the narrative data to further identify HIT events after using the filter based on the structured data. We used the manually labeled reports (312 HIT and 178 non-HIT reports) from the 2015 MAUDE database to build the training set. The same number of non-HIT-related reports was randomly selected to compose the training data with the HIT-related reports. The classifiers were trained using four methods: logistic regression, random forest, naïve Bayes, and SVM. As shown in Table 2, logistic regression and SVM exhibit better performances among the four methods.

The Growing HIT Event Database

Due to the enormous size of MAUDE and the small percentage of HIT events (about 0.1%), directly identifying and extracting all HIT events from MAUDE are almost impossible using a straightforward strategy. The classification of data with imbalanced class distribution has encountered a significant drawback of the performance attainable by most standard classifier learning algorithms [14]. The aim of this study is to establish a model which can identify and synchronize HIT related events from MAUDE database toward an HIT exclusive database for shared learning. Therefore, we need to keep the False Positive (FP) rate within a low value to make sure the quality of the database, even additional HIT reports are missing (high False Negative (FN) rate). Random forest model can help reduce FP rate by trading in FN rate. The strategy was setting a threshold to the confidence coefficient and only taking the samples whose prediction confidence coefficients were higher than the threshold. As shown in Figure 2, 0.7 could be an appropriate threshold since more than 90% FP samples are excluded with a loss of less than a half HIT related reports.

At the end of each iteration, the four training methods will be re-evaluated based on the corresponding manual review, and the best method will be used in the classifier. The classifier is expected to be improved as more labeled reports are included. As the manually reviewed HIT events are accumulated, an HIT event database will be established and keep growing. This mechanism will keep synchronizing HIT related events from MAUDE database to the HIT database in the future.

Discussion

Offer a Broader and Organized View of HIT Events

Some HIT events may seem trivial but could represent much larger and more important problems, which is similar to a tip of a very large and dangerous iceberg. We developed a mechanism of identifying and synchronizing HIT related events from FDA MAUDE database. The outcome is a timely reflection of the evolvement of HIT events and is helpful for enriching HIT
knowledge and better using the historic reports toward an overall understanding and analysis of the characteristics, occurrence, observation, and description of HIT events. Using our proposed filter and classifiers, fragmented and isolated HIT events could be better understood when the connection with other relevant events are offered.

**Challenges of Identifying HIT Events**

While machine learning has been employed successfully in many contexts such as spam filtering and social media sentiment analysis, its application to HIT event identification is still challenging. Early methods of HIT event identification relied on flagging cases that contained certain technology related keywords for further human review. While these approaches were feasible on a small scale, the growing use of technology in healthcare has led to a rapid rise in technology related events. Meanwhile, the events involving technology have grown in complexity, making researchers sometimes feel difficult to decipher whether or not the technology involved was truly an integral part of the event. Although various natural language processing methods exist such as N-grams and concordance to aid in textual understanding, the classification of PSEs based solely on narrative text may still be out of the reach of current machine learning techniques.

As a result, we utilized both the structured and unstructured data of the FDA MAUDE database. In the device data reports, the two most useful fields for creating our HIT filter were generic and manufacturer name. The generic name field was especially informative as it allowed for the quick identification of device concerning each report. In some cases, the generic name field was pivotal to understanding the event as the device of interest could not be deduced from the narrative reports alone. The manufacturer name field is also proven useful as in some cases, the generic name may have referred to a new or more sophisticated product that was not yet recognized by our list of previously identified generic names. By utilizing both fields, the proposed HIT filter was able to capture more potential HIT events than it would have if only the generic name field were utilized.

**Quickly Changing Nature of HIT**

Each year new generic names are created and some older names fall into disuse in MAUDE. The number of generic names has shown a growing trend, with each year starting from 2010 containing approximately 1000 more terms than the previous year. This challenge was addressed during the selection of our generic name keywords by reducing the complexity of the generic names while still allowing them to retain their specific meanings. As an example, if the generic name originally found in the database was “picture archiving communications system,” the keyword added to our final list was “picture archiving.” By reducing the complexity of the keywords in our filter, the ability to capture new variations of the same generic name in the future was greatly improved. Furthermore, as previously mentioned, the manufacturer name field was used to supplement the generic names. Cases with new and unrecognized devices could still be detected by the HIT filter if they were made by a recognized HIT manufacturer.

**Classifier Error Analysis and Optimization**

Two domain experts independently reviewed the filtered 2015 HIT reports and had an inter agreement kappa score of 0.9, which was used as a proxy for the maximum performance that the classifier could reasonably achieve. The initial classifier tended to make more false negatives (true HIT cases labeled as non-HIT) than false positives (non-HIT cases labeled as HIT) in error analysis. In improving the classifier, greater emphasis was placed on reducing the false negatives than the false positives. This is because in practice, reports that are falsely labeled as being HIT can usually be disregarded by users of the database with little effort. Conversely, true HIT reports labeled as non-HIT may pose a much greater risk as users may be unable to learn from those events. By using the proposed approach, while our classifier’s overall accuracy may have been reduced, the classifier we built has a greater ability to capture new and unique HIT safety events.

**Evaluation of Proposed HIT Extraction and Synchronization Method**

The method we have developed for extracting and synchronizing HIT reports from the FDA MAUDE database shows promise in staying up to date with future changes in HIT. As new devices and technologies are emerging every year, HIT event database faces the risk of quickly becoming outdated. By utilizing an easily updatable device data filter, new types of HIT can be identified and added to the existing database, providing users with the most up-to-date information on HIT. Furthermore, the text classifier we have built allows for the timely classification of HIT related events, greatly reducing the need for future human labor to maintain the database. With an up-to-date and comprehensive HIT event database, researchers may be able to gain a deeper understanding of the nature of HIT related events and their potential consequences. As well, the database may aid in the classification of HIT related events and eventually lead to a universally accepted HIT exclusive reporting system.

**Importance of the HIT Event Database**

In a high stakes field such as healthcare, it is critical that HIT events are reported and that manufacturers are held accountable for their products. However, manufacturers may not have enough resources allocated towards diagnosing and fixing those issues even when the events are reported. While the staggering pace of technology has driven much innovation in healthcare, the need to take a careful look at the HIT related events has never been greater. The proposed HIT event database offers an opportunity to compare, analyze, and integrate similar HIT events, and ultimately keep HIT on the right track towards becoming a safe and integral part of our healthcare system.

**Limitations**

The FDA MAUDE database is currently the only publicly accessible resource to contain HIT events. The database is built on voluntary reports and utilizes only a passive surveillance system to verify reports. Consequently, the database may contain incomplete, inaccurate, or biased reports, preventing conclusions regarding the frequency or prevalence of events from being drawn. Nevertheless, the database still contains highly informative data and can be used to better understand the nature and scope of different PSEs.

Another limitation lies in the initial selection of keywords that were used to later find common generic names of HIT devices. While the initial keyword list contained a comprehensive amount of computer and software related terms, it may not have included all possible words that could be used to describe HIT related devices. As a result, few HIT events that were described in an uncommon manner may have been missed during our initial search. In the future, the proposed HIT event database may help overcome this challenge by aiding in the development of a standardized reporting terminology for HIT events. With a standardized reporting terminology, it will likely be easier for
reporters to describe HIT events in a manner that is more useful and informative to researchers.

**Future work**

**Improve Classifiers by Using Semi-supervised Learning**

Manually reviewing all cases in the FDA MAUDE database was simply infeasible and that machine learning was likely to be the only viable approach. Traditionally, the two paradigms of machine learning have been supervised (all labeled data) and unsupervised learning (all unlabeled data). However, much attention has been recently placed on semi-supervised learning for its ability to utilize only a small amount of labeled cases combined with a large amount of unlabeled cases to improve classification accuracy. In the case of HIT, this approach seems well-suited as the cost of labeling narrative text by manual review is quite high, while the cost of obtaining unlabeled reports is minuscule in comparison. One of the simplest methods within semi-supervised learning is self-training. In creating our HIT event database, we will utilize a method of iterative self-training to grow the database in a timely manner. It will become a viable method to extract and classify HIT reports from large databases such as the FDA MAUDE.

**Utilize the HIT Event Database**

More work needs to be done to understand, organize, and uncover the relationships among the HIT reports contained in the database. To fully utilize the database, the themes and topics of the reports must be mapped and understood in context of one and another. Doing so will allow for a better understanding of the relations among HIT events and will greatly aid in the understanding of how HIT changes over time. One potential tool for topic modeling is Latent Dirichlet Allocation (LDA). This commonly used algorithm can be used to analyze unannotated text and discover shared themes among reports. After common themes of HIT related events are found, experts may be able to focus their efforts on addressing these issues and develop actionable solutions to prevent and minimize the risks that patients face during HIT related events. Ultimately, this will advance HIT a safe and integral part of healthcare and improve patient safety.

**Conclusion**

We proposed a strategy to identify and synchronize HIT events from FDA medical device reports, and to grow an HIT event-exclusive database. The database provides a resource for stakeholders to analyze connections among HIT events, identify common themes of technology-induced errors, synchronize HIT related reports from existing resources, and develop a classification or terminology to standardize HIT reporting toward actionable knowledge and shared learning.

Abstract

Unique patient identification within health services is an operational challenge in healthcare settings. Use of key identifiers, such as patient names, hospital identification numbers, national ID, and birth date are often inadequate for ensuring unique patient identification. In addition, approximate string comparator algorithms, such as distance-based algorithms, have proven suboptimal for improving patient matching, especially in low-resource settings. Biometric approaches may improve unique patient identification. However, before implementing the technology in a given setting, such as health care, the right scanners should be rigorously tested to identify an optimal package for the implementation. This study aimed to investigate the effects of factors such as resolution, template size, and scan capture area on the matching performance of different fingerprint scanners for use within health care settings. Performance analysis of eight different scanners was tested using the demo application distributed as part of the Neuronet Verifinger SDK 6.0.

Keywords:
Biometry; Patient Identification Systems; Health Information Systems

Introduction

A critical component of health care delivery is the ability to correctly identify the individual receiving care and access their medical record. Failure to correctly match patients is a major contributor to inefficiencies in care delivery and medical errors [1]. For example, in the United States, about 195,000 deaths occur each year because of medical errors, with 10 of 17 being the result of identity errors [2]. The problem is even worse in low and middle income countries (LMICs) where very few accurate and comprehensive person identification procedures guaranteeing the unambiguous identification of their citizens from the day they are born, have been implemented [3]. Poor national person identification systems, inefficient identification procedures, and the use of weak search criteria further aggravate the problem.

In the western world, researchers and hospital administrators largely rely on deterministic or probabilistic algorithms and other statistical matching procedures for patient identity management [4]. Deterministic matching algorithms use an exact match or rely on comparisons between two fields [5]. As an example, deterministic matching can be used to compare unique identifiers, such as national IDs, to determine a match. Probabilistic matching, which is by far the most widely implemented technique for record matching, does not depend on unique identifiers. For probabilistic matching, the values between two records are compared across several fields and weights are assigned based on how close the values in the corresponding fields are. The sum of these weights indicate the closeness of the match for the compared records [4-6]. In the case of patient identification, probabilistic matching would compare closeness using key patient identifiers such as name, address, national IDs, and date of birth.

The application of these statistical matching approaches is limited, especially in developing countries. Deterministic matching in these settings is limited when no single field can provide a reliable match between two records. In many cases, the order that a patient’s first, middle, and last name are recorded differs between visits, addresses are unreliable, dates of birth are often estimated, and patients can have multiple clinic identifiers that are not common within or across facilities [7]. These countries often do not have a single national identifier for all individuals, with national IDs given to those above a particular age and often not given to foreigners residing in the country [8]. Another challenge of using deterministic algorithms for patient matching is that they lack scalability, requiring expensive customization and business rule revisions as databases grow [5].

Probabilistic algorithms do not perform very well in many low-resource health care settings. In our institutional experience, the evaluation of various four-string manipulation strategies to improve the performance of probabilistic models, based on Kenyan names, revealed a suboptimal specificity and a positive predictive value of less than 50% [9]. While probabilistic algorithms are superior to deterministic algorithms, not all probabilistic algorithms applied to the same set of circumstances yield results with the same degree of accuracy [5]. This is because probabilistic algorithms typically sample the dataset and do not scan all possible values, thus matching functions become more complex and time consuming, increasing the number of false positive matches [10]. Current statistical matching models cause many challenges to unique patient identification in health care settings, and often tend to be difficult and expensive to implement. Thus, there is a critical need to evaluate relatively cheap, feasible, and effective solutions to tackle the patient matching problem in all health care settings, including LMICs and industrialized nations.

Biometric approaches offer a potential solution to the challenges of current patient matching algorithms. The basic principle of biometric authentication is that everyone is unique.
and can be identified by his/her intrinsic physical or behavioral traits [11]. Among the available biometric technologies, fingerprint technology offers a potentially promising solution; fingerprint scanners are readily available, the technology is relatively, easy to use, has minimal database memory requirements, and there exist several demonstrated instances of their large-scale use in other sectors, such as banking and immigration departments.

Biometric technology is not without its challenges, among them being the need to invest in specialized technology and equipment required to capture many of the needed biometric measurements. Due to the poor performance of statistical patient matching models within our LMICs setting, we explored the potential of using fingerprinting biometric technology as additional metadata for patient matching. A fingerprint consists of a pattern of ridges and valleys in the surface of the fingertips and forming during early fetal months [12]. Apart from the algorithm, the performance of this technology is affected by factors such as image quality, composition of target user population, resolution, template size, and scanner type or model.

To determine the right device and approach for implementing biometrics, we conducted a systematic assessment of the technical performance of various fingerprinting devices available on the market that could be used within most care settings. The goal was to explore the selection of the right biometric device for countries aiming to develop systems for unique patient identification.

Methods

The envisioned workflow of the biometric technology at our institution, as in most clinical settings, will be as follows. When the patient first arrives at the facility, they will be asked to scan their left index finger through the fingerprint biometric scanner. Based on the scan, the fingerprint image will be converted to a template locally and this template will be sent over the network to the fingerprint matching service. The matching service will match the template against a database of existing fingerprints and will return NULL, if there is no match found or will return the patient id if a match is found. When NULL is returned, the patient registration page is opened and a new fingerprint image is used to create a fingerprint template for future matching. A matched fingerprint returns a patient id, allowing the patient’s record to be directly accessed during the clinical encounter.

The current evaluation focused on identifying the technology that provides the best fingerprint match. To evaluate the technical performance of various scanners available in the market, we leveraged an application that worked with over 180 fingerprinting devices. This application, the Neurotech Verifinger Software Development Kit (SDK) 6.0, provides a wrapper of common Application Programming Interface (API) that makes it easy for use with different devices [13]. The goal of using this SDK was to showcase a methodology that other implementers could use when evaluating various scanners for their setting.

Fingerprint templates are mathematical representations of the most useful points of interest (minutiae) in fingerprint images [14]. Using fingerprint images of different fingers (not just the index finger), downloaded from various sources, including NIST SD4 [15], NIST SD9 [15], FVC2002 [16], FVC2004 [17], as well as randomly replicated of images, a large dataset of 50,000 images was generated. Using the SDK template API, we generated templates for these 50,000 images in the default format. This large number of images was adequate to stress test performance, as most care settings would have less than this number of patients. Although the SDK supports ISO/IEC 19794-2:2005, ANSI/INCITS 378-2004, and ANSI/NIST-ITL 1-2007 standards, we chose to use the default one to avoid any bias between fingerprint readers. The test template dataset used one fingerprint image per template.

For generating the evaluation template, we used two images of the left index finger and then compared the performance and accuracy against the test dataset. There is good evidence that the index finger is used the least and hence has the least normal wear and tear, making it well-suited for fingerprint scanning [18]. Since we used the SDK to translate the minutiae to a template, all templates for both the test dataset and evaluation template used the same feature set and algorithm.

Each fingerprint scanner was used in the same surrounding lighting area to ensure the quality of the image capture was not affected. The devices were connected to an Ubuntu 16.04 x64 platform and tested using the C++ application. We used the standalone application instead of the web application that is based on an ActiveX component or Java applet, because both of these technologies have been deprecated by the browser manufacturers. The C++ application was also more robust in communication with the fingerprint scanners and responded more quickly to images from the fingerprint scanner. Live finger detection was also supported by the Futronic scanners only using the C++ application.

Eight Fingerprint devices (U.are.U 4500, U.are.U 4500 UID Edition, U.are.U 5160, Futronic/F580, Futronic/F888, Hamster Plus (HSDU/03P™), Biomini, and UPEK Eikon) were selected based on current community member usage and what was affordable and easily available for purchase. Key dimensions for the devices that were analyzed included: resolution, scan capture area, performance, template size, template format, compatible operating system, and supported standards.

Resolution

The number of pixels per inch (dpi) describing the acquired images. High scanner resolution allows for extraction of finer details from a fingerprint image, making it very important when identifying infants and elderly patients. A 500 dpi resolution is required by FBI-compliant systems [19].

Scan Capture Area

Determines the size of the fingerprint portion which can be acquired by the scanner. This parameter usually lies in the range 1.0”x1.0” square inches of some professional models to about 0.38”x0.38” of some low profile models. It is worth noting that the captured portion of the latter is about 7 times smaller than the former. A wide sensing area is important because the size of an average fingerprint is about 0.5”x0.7” (smaller for children and females and larger for adult males) and therefore the acquisition of a fingerprint with a sensing area smaller than 0.5”x0.7” produces a partial fingerprint [20].

Performance Matching

The speed and accuracy of identification and other derivatives that arise from accuracy. In our evaluation, performance was determined by the speed in milliseconds of correctly identifying a person from the test dataset of 50,000 fingerprint images. Matching speed impacts patient workflow and should be minimized to reduce patient waiting time during registration.

Template Size

Describes a stored file in a fingerprint scanning system and is normally stored as binary file. When a fingerprint is entered into the system, only a “template” of the fingerprint is stored, rather than the fingerprint image. A fingerprint template is
smaller than the actual fingerprint image and using the template instead of an image reduces processing time. Speed is said to be directly related to template size; the smaller the template, the faster the search speed [21].

**Template Format (Gray Scale Levels)**

Of a fingerprint sensor is the number of gray shades produced for every pixel. 256 levels of gray is the standard format supported by most available fingerprint sensors today and results in using one-byte per pixel [22].

**Compatible Operating System**

Is highly dependant on the manufacturer of the scanner. Most scanners support Windows, Linux, iOS, and Android.

**Supported Standards**

This is similar to operating system compatibility and is largely determined by the manufacturer.

**Results**

Among the seven basic criteria for biometric security systems, performance or accuracy is a prerequisite (Table 1) [23]. The average performance time for the tested scanners was 1984.3 milliseconds, with wide variability across the different scanners. The best performance matching was achieved with the U.are.U 4500 UID edition, with a matching time of 600 milliseconds in a ratio of 1:50000 templates. The scanner resolution was 500 dpi, within the recommended range. The U.are.U 4500 scanner had a resolution higher than the U.are.U 4500 UID edition (512 dpi). This scanner will definitely produce a finer and more detailed extract from a fingerprint image, however its performance matching was 4-times higher than that of U.are.U 4500 UID edition. As performance is the most critical dimension for an analysis, a scanner with the fastest performance matching speed and minimum resolution requirement (i.e., 500 dpi) is preferred.

We observed that search speed when using fingerprint biometric devices was directly related to template size (i.e., the smaller the template, the faster the search speed) [19]. There appeared to be a trade-off among the template size, scan capture area, and performance matching. This is because the fastest scanner (U.are.U 4500 UID edition) did not have the smallest template (72 mm x 39 mm x 21.7). This particular device also did not have a large scan capture area (12.8 mm x 16.5 mm). While this was desirable, manufacturing large and pure silicon chips is difficult and rather expensive; therefore, the scanners currently available on the market are categorized by a small area scan capture area.

On average, it would cost about $107.60 to acquire a scanner (the cost of different fingerprint scanners has been provided in Table 1), though cost is crucial while acquiring these gadgets, we can not compromise performance for cost. That is why an inexpensive scanner with a good resolution, but poor performance matching, may not be a better choice.

**Discussion**

Biometrics offers an alternative method to collect additional metadata for statistical patient matching models, with good performance characteristics. When determining what scanner to buy, organizations should consider scanners with short turnaround time. We demonstrate the need to critically evaluate multiple dimensions of available scanners prior to purchase. Further, issues around what SDK to use, and how to integrate scanning within the clinical workflow is important and could be a limiting factor for scanner adoption.

Our results demonstrate that the scan area has an impact on performance speed. Optimizing scan area can be improved by training and providing ambient conditions to capture fingerprint images. The technique of capturing the fingerprint may necessitate a large scan area (e.g., in cases where you want to simultaneously capture multiple fingerprints). When speed is optimized, template size can be tweaked to reduce memory and storage requirements. This is particularly useful for mobile health where there are database capacity and infrastructure limitations.

Privacy and security implications surrounding the use of biometrics is extremely important, but was beyond the scope of the current study. Given that a number of large-scale collections of fingerprints is already underway (e.g., passports and social security in both high-income and low-income countries), debates are largely dependent on the reason for capturing biometric information. Identity theft, no means to revoke leaked biometrics, health equity, denying services to individuals, and many other ethical issues are some of the factors affecting the success of biometric implementations.

There are limitations to the current study. Only a few devices were evaluated; we did not separate groups of patients (e.g., neonates and elderly), who may skew the analysis and variation of performance between these groups; and we did not evaluate performance of various fingers (e.g., index versus middle finger for a specific patient). The evaluation was also conducted using a single test set; findings would likely be different based on the population being evaluated.

Numerous costs impact the implementation of biometric systems and vary by the size of the organization, choice of system adopted (open source or commercial), and personnel to manage the infrastructure. Pre-scan enhancer pads, which cost roughly $47, may also be needed. Fingerprint SDK, Neurotechnology SDK costs about $422 for VeriFinger 9.0 Standard SDK. Commercial SDKs are usually restricted to specific scanners however, open source SDKs are also available and are not scanner-specific. Note, that even commercial SDKs require personnel for set-up and maintenance services. Personnel costs (i.e., both training and hire) are highly dependent on the complexity of the system being deployed. Finally, on the back end, most biometric applications are hosted on a server and accessed via client machines; machines should be purchased with a strong firewall to ensure protection from hackers.

**Conclusion**

Biometric fingerprint scanners offer one potential technology for improving patient matching and unique patient identification in diverse health care settings. Special attention is needed when selecting these technologies to ensure good performance at a reasonable cost. Additionally, it is important that the technology can be implemented within existing workflows and with consideration to existing patient care setting infrastructure constraints. This is especially challenging in clinical settings with complex health care workflows. While this paper is geared towards LMICs, these results and findings are equally applicable to care settings in industrialized nations.

Abstract
The purpose of this study was to develop and evaluate the blood glucose management (BGM) system, which supports the scheduling of blood glucose measurements for medical staff. This system enables medical staff to continually confirm the instructions of the physicians by measuring blood glucose levels using a smart device (iPod). This paper describes the difference in the delay of the measurement between the BGM system and the non-BGM system. For the iPod device in the BGM system, the desktop device, and the laptop device, the frequencies of a delay under 30 minutes were 94%, 67%, and 80%, respectively (Ryan-test, P <0.01), and that over 30 minutes were 6%, 33%, and 20%, respectively (Ryan-test, P <0.01). We concluded that the BGM system reduced the delay in blood glucose measurements and led to an optimization of the time of measurement.

Electronic Health Records; Hospital Information Systems; Blood Glucose

Introduction
It is well-known that diabetes is one of the most common metabolic disorders. In 2014, the International Diabetes Federation (IDF) estimated that 387 million people had diabetes in IDF regions, which consists of 194 countries [1-9]. In Japan, there were 7.2 million patients with diabetes in 2015. The Japanese Ministry of Health, Labor and Welfare reported that 16% of all inpatients had diabetes in 2014.

Blood glucose control is conducted to keep levels of blood glucose in the normal range for a patient with diabetes. Establishing a normal blood glucose level for inpatients with diabetes is important to prevent complications and infections after surgery [10-24]. For blood glucose control, medical staff have to frequently measure blood glucose levels and register this data in the electronic medical record (EMR) system [25-28]. On the screen of the EMR system, medical staff confirm the instructions ordered by physicians, such as the insulin dose. The time to respond to changes in blood glucose levels is dependent on the difference between the actual recorded time and the scheduled time of measurements of blood glucose levels.

When medical staff register blood glucose levels to the EMR system manually, delay in recording, transcription errors and patient misidentification occur [29-30]. In recent years, to prevent these errors, medical vendors have developed a blood glucose tester that transfers the results of the blood glucose test to the EMR system through a wireless network [31]. Although the tester prevents transcription errors of blood glucose levels, it does not prevent the delay in measuring blood glucose levels. The primary reason for the delay is that understanding various measurement orders from physicians is difficult for medical staff. In this study, to reduce the delay in recording blood glucose levels, the author developed the blood glucose management (BGM) system that enables medical staff to understand the schedules of the blood glucose control ordered by physicians.

The purpose of this study was to develop and evaluate the BGM system that supports the scheduling of blood glucose measurements for medical staff.

Study setting
DAISEN is an EMR system comprising various departmental healthcare systems for all outpatients and inpatients in the Tottori university hospital. As an EMR system, DAISEN records data of blood glucose measurements linked with the instructions ordered by physicians. Use of clinical data from DAISEN for this study was approved by the institutional review board of the Tottori university hospital.

The data for this study were extracted from the records in the EMR system, which consisted of blood glucose levels of inpatients with type 2 diabetes who were admitted to the hospital between Jan 1, 2014 and Oct 1, 2016. The number of selected patients before installation of the BGM system was 3,285 and the number of selected patients after installation of the BGM system was 2,847. To extract the delay in measuring blood glucose levels, we obtained the time that physicians requested the measurement using the EMR system and the time that the blood glucose level, measured by the blood glucose tester, was recorded by medical staff in the EMR system. The authors defined the delay in recording blood glucose levels as the difference between the requested and recorded time. We obtained 35,836 and 9,698 data records with smart devices (iPod).
Evaluation of the BGM system

Analytical processes of evaluation for BGM system are as follows.

Delay time of recording blood glucose level to EMR system

To measure the delay in transferring blood glucose levels into the BGM system and in the non-BGM system, the authors defined the delay as the difference between the time that the blood glucose measurements were recorded by medical staff and the time that the measurement was requested by physicians.

The Occurrence rate of missed measurement or recording of blood glucose levels

To calculate the occurrence rate of non-existing blood glucose value in the EMR system, the author defined missed measurement or recording of blood glucose level as when medical staff did not measure blood glucose level within 60 minutes from the designated time by the physician.

Experimental devices

In this study, the authors developed the BGM system, which consisted of a blood glucose tester, an iPod, and a blood glucose data transfer adaptor (Table 1).

The blood glucose tester was used to measure the blood glucose level of inpatients with diabetes. The data transfer adaptor was used to transfer the data of the blood glucose levels and the execution time recorded by the blood glucose tester to an iPod.

Medical staff used an iPod to transfer the data to the EMR system. Functions of the application installed on the iPod to support the scheduling of blood glucose measurements are described in Table 1.

Table 1 – Experimental devices.

Blood glucose measurement with the BGM system consists of five steps (Figure 1).

1. Medical staff confirm the selected patient who needs a blood glucose measurement by using an application on the iPod.
2. Medical staff check the blood glucose level of a target patient using a blood glucose tester with the data transfer adaptor.
3. Medical staff import the measurement time and the blood glucose level from the data transfer adaptor into the iPod to display the data on the screen.
4. Medical staff confirm the selected patient’s name, the blood glucose level, and the measurement time displayed on the screen before registration to the EMR system.
5. The application transfers the data to the EMR system through a wireless network.

In the non-BGM system, medical staff manually recorded blood glucose levels to the EMR using a desktop or laptop.
device by transferring the measurement values displayed on the blood glucose tester. All desktop devices were located in a nursing station. Laptop devices were placed in a computer cart designed for laptops, which can be carried to the inpatients’ bedsides.

**Statistical analysis**

The delay of 15 and 30 minutes of blood glucose measurements for the BGM system and non-BGM system was calculated to compare the occurrence rates using the Ryan test. P values <0.05 were considered statistically significant. The R software program (version 3.1.2) was used to perform the statistical analysis.

**Results**

**Results of delay time to recording the value to EMR system from measuring blood glucose level**

The installation of the BGM system resulted in a significant reduction in the delay of recording blood glucose levels by medical staff. Table 2 show the occurrence rate of a 15 minute delay in recording blood glucose levels when using an iPod device, desktop device and laptop device. When using an iPod in the BGM system, a desktop device, and a laptop device, frequencies of a delay under 15 min were 77%, 37%, and 53%, respectively (Ryan test, P <0.01); frequencies of a delay under 30 min were 94%, 67%, and 80%, respectively (Ryan test, P <0.01); and frequencies of a delay over 30 minutes were 6%, 33%, and 20%, respectively (Ryan test, P <0.01).

*1 Median of the difference between the time that the blood glucose measurements were performed by medical staff and the time that the measurement was requested by physicians.
*2 Average of the difference between the time that the blood glucose measurements were performed by medical staff and the time that the measurement was requested by physicians.
*3 Standard deviation of the difference between the time that the blood glucose measurements were performed by medical staff and the time that the measurement was requested by physicians.
*4 The total number of blood glucose measurements.
*5 The occurrence rate was defined as the occurrence of a delay of 15 minutes divided by the total occurrence rate recorded for blood glucose levels.

**The occurrence rate of missed measurements or recordings**

We calculated the occurrence rates of missed measurements or recordings of a blood glucose level for each device environment. As a result, for desktop devices, laptop devices, and iPod devices the occurrence rates are 23%, 16% and 5% respectively. The results for iPod were significantly lower than those for desktop and laptop devices. (P <0.01, Ryan-test)

**Discussion**

In this study, we showed that our BGM system significantly reduced the delay in recording blood glucose levels and the occurrence rate of missed measurements or recordings compared with non-BGM systems. The results are expected to contribute to accurate blood glucose control. A large number of inpatients after surgery are regulated by blood glucose control with insulin injections. Medication errors with insulin have the potential to result in serious harm, including death [32-37]. When blood glucose control was combined with insulin, measurement or record time of glucose levels was set based on the time of a meal. The time of a meal of inpatients was influenced by the measurement of blood glucose levels because the measurement had to be done before or after the meal. The BGM system notifies medical staff of the instructions by physicians such as the insulin dose. Consequently, there is a possibility of improving medical safety of patients with diabetes by reducing the delay of measurement using the BGM system.

Effectiveness of an iPod in availability and accessibility in the medical field has been reported in recent studies [38]. This study focused on the effectiveness of its use for the measurement of blood glucose levels by medical staff. The results showed that the medical staff with iPod devices carried out the measurement more accurately and recorded the blood glucose levels quicker than the medical staff with other devices. More specifically, the results were interesting in that they showed superiority of an iPod compared to laptop PCs though both devices can easily be carried to the bedside of selected patients.

To prevent a patient misidentification accident, medical records of only one patient can be displayed in a screen of the EMR system. On the other hand, all selected patients who needed blood glucose measurements were displayed in the order they were seen by the physician on the screen of the iPod with the BGM system to allow medical staff to effectively take care of many inpatients in a ward. It is possible that the display of selected patients as described above led to the superiority of an iPod compared to laptop PCs.

Compared with the occurrence rate of missed measurements or recordings for each device, we found that the BGM system contributed to decreasing missed measurements of blood
glucose level. However, the results did not sufficiently clarify the effect on medical safety for real inpatient care. For evaluation of medical safety in clinical settings, further investigations based on other resources such as incident reports by medical staff would be needed.

The application on an iPod enabled medical staff to usually understand the situation of the blood glucose measurement. Thus, it is desirable that all medical staff who measure blood glucose levels always carry an iPod. Although the number of hospitals adopting smart devices such as an iPod for medical use has increased in the recent years, its usage is still considered to be insufficient. Thus, the cost of the BGM system including smart devices remains an issue.

In the future, from the practical perspective, implementation costs need to be discussed to use the BGM system in other medical facilities.

Conclusion

We concluded that the BGM system reduced the delay of measurement and resulted in an optimization of the time of measurement. With the increased use of smart devices such as the iPod in the medical field, the system will likely be implemented to the EMR system in many hospitals.

We conclude that for the iPod device, desktop device, and laptop device, the frequencies of a delay under 30 minutes were 94%, 67%, and 80%, respectively (Ryan test, P <0.01), and over 30 minutes were 6%, 33%, and 20%, respectively (Ryan test, P <0.01).

Transcription errors of the blood glucose level were found in the EMR system before installation of the BGM system. The BGM system can prevent transcription errors of recording blood glucose levels using a data transfer adapter.

Evaluation of a Decision Support System for Laboratory Service Patients

Georgy Kopanitsa

Institute Cybernetic Center, Tomsk Polytechnic University, Tomsk, Russia
Tomsk State University for Architecture and Building, Tomsk, Russia

Abstract

In Russia, many patients address laboratory services directly without a doctor’s referral. This causes the problem of interpretation of laboratory test results by the patients who don’t have a proper medical background. We have a situation when there is no healthcare professional between a patient and the test results. This problem can be solved if a laboratory service provides not only the results of the tests but also their interpretations. The system was implemented in the Helix laboratory service in Saint-Petersburg, Russia. At the moment it generates about 3500 reports a day. This study presents the evaluation of the system, which has shown a good performance both on correctness of generated reports and user acceptance.

Keywords: Decision Support; Clinical Laboratory Information Systems; Telemedicine

Introduction

A need of a decision support system that would help patients to read and understand laboratory test results comes from the fact that many patients address laboratory services directly without a doctor’s referral [1; 2]. This causes the problem of interpretation of laboratory test results by the patients who don’t have a proper medical background and leads to a situation when there is no healthcare professional between a patient and the test results [3]. This problem can be solved if a laboratory service provides not only the results of the tests but also their interpretations. Automated decision support systems that have proved their efficiency for doctors can be a good solution for this problem [4]. The experience of development and implementation of decision support systems for doctors shows the efficiency of such solutions for the doctors, however, developers face problems when it comes to the decision support for patients. They require different approach in data presentation and interpretation [5-8]. The DoctorEase system was implemented in the Helix laboratory service in Saint-Petersburg, Russia. At the moment it generates about 3500 reports a day. The example of a report is presented in the figure 1.

The goal of this paper is to present the evaluation of correctness and user acceptance of a decision support system for the patients of a laboratory service.

Methods

Correctness of the decision support

To evaluate the correctness of the generated reports a validation of a sample of 256 reports was sent to two independent laboratory service physicians for independent expert review. The results of the review was used to calculate precision ((All terms – Mistakes)/All terms), recall (ratio of true positives to (true positives + false negatives)), and F-measure (2·(recall·precision)/(recall+precision)) [9]. All the disagreements between reviewers were settled by consensus. Cohen’s kappa has been calculated to rate the disagreement between experts [10].

User acceptance

To evaluate the user acceptance of the decision support system we have applied a Wilson and Lankton's model of patients' acceptance of e-health solutions [11]. The model was applied to measure behavioral intention to use (BI), intrinsic motivation (IM), perceived ease-of-use (PEOU), and perceived usefulness (PU) of the system.

BI denotes the intention to use and rely on the decision support system, IM denotes the readiness to use the decision support system without any compensation, PEOU denotes the
extent to which the generated reports are clear and understood by the patients, and PU refers to the degree to which the user believes that the use of the system would enhance their experience with laboratory tests.

We have applied the method proposed by Davis et al. in the revision of Wilson and Lankton [11] to measure BI, PEOU, and PU. IM was measured using the method provided by Davis et al. [12].

BI measurement contained of 2 items whereas IM, PEOU, and PU contained 3 items each. We used Russian translations of the measurement tools made by the research team. To rate each item a Likert scale from 1 (not at all) to 7 (very much) was applied [13].

Recruitment

Participants were recruited in Saint-Petersburg, Russia. The inclusion criteria were: having experience with the decision support system with at least 5 reports on the test results.

Demographic details of the patients are presented in the table 1. IT literacy of the patients was evaluated based on how often they use PC or Smartphones. The IT literacy was graded from beginners – users that have started using PC within 6 months; intermediate – users of PC at least twice a week; and advanced – for those using PC on the daily basis. In total we have recruited 60 patients. Every of them has participated in the study.

Data collection and analysis

The participants were asked to complete an online questionnaire. Each participant got an individual link and could work only with one questionnaire. A detailed instruction on how to work with a questionnaire and the meaning of the scale was provided to each participant.

GNU Octave was used to calculate statistics of the participants’ general characteristics and user acceptance measurements.

The study got the approval by the regional ethics committee. All the participants invited to the study were notified of the objectives of the study and of the purpose of the questionnaires. Each participant was assured, in writing, of their entitlement to anonymity and confidentiality. Written consent was acquired from each participant and each participant was reminded of their entitlement to withdraw data from the study database for up to three months after their approval.

Results

Correctness

As described in the methods section a sample of 256 reports was independently reviewed by two laboratory physicians of the laboratory service. The results of evaluation (e.g. precision, recall and F-measure) for each are presented in table 2. Cohen’s kappa was calculated to check the inter-rater agreement between the two laboratory physicians. The physicians showed disagreement in the case of 2 reports.

</tbody>
</table>

The mean values for BI, IM, PEOU, and PU (5.9, 6.2, 5.7, and 5.9 respectively) showed the high acceptance of the decision support system and the reports, which it generates.

Discussion

The evaluation showed that the correctness of the generated reports is high. Seven mistakes out of 256 analyzed reports were caused by a human factor. The value of 5.1% of the 95% confidence interval for the 256 items sample demonstrates that even a small amount of mistakes lead to the problem of correct reports generation. To solve the problem of correct rule definition we have identified mistakes in the rules, that were defined by the experts. Out of 151 rules defined by the experts only 2 resulted in the faulty reports. All of them were
caused by typos that could be easily avoided. This led to a change of rules’ definition procedure, where we apply 4 eyes principle now. This means that each rule shall be reviewed and approved by a second expert.

The user acceptance of the system was evaluated after two months of operation. Acceptance scores were relatively high. Unfortunately, we could not compare them to the similar studies, as we did not find a patient oriented decision support system, for which a user acceptance was evaluated.

Current research is focused on the extension of the knowledge representation language by adding an ability to work with fuzzy sets [7]. This will provide experts with flexibility in definition of knowledge and rules. We also are studying the possibility to validate the reports that are produced by DoctorEase to enable the system acquiring knowledge based on its experience using case based reasoning approach.

For the patients we are developing a mobile application to make the work with the system easier.

Conclusion

The paper presents an evaluation of a decision support system for the patients. The results show that the system is demanded and trusted by the patients. And this approach is a of a high demand especially in the situation when a patient can not refer to a doctor to get a professional interpretation of the results.

Effective Usability Engineering in Healthcare: A Vision of Usable and Safer Healthcare IT

Andre Kushniruk*a,b, Yalini Senathirajahc, Elizabeth Borycki a

a School of Health Information Science, University of Victoria, Canada b Department of Development and Planning, Aalborg University, Aalborg, Denmark c State University of New York, Brooklyn, USA

Abstract

Persistent problems with healthcare IT that is unusable and unsafe have been reported worldwide. In this paper we present our vision for deploying usability engineering in healthcare in a more substantive way in order to improve the current situation. The argument will be made that stronger and more substantial efforts need to be made to bring multiple usability engineering methods to bear on points in both system design and deployment (and not just as a one-time effort restricted to software product development). In addition, improved processes for ensuring the usability of commercial vendor-based systems being implemented in healthcare organizations need to be addressed. A discussion will also be provided on challenges and barriers that will need to be overcome to ensure that the healthcare IT that is released is both usable and safe.

Keywords:

User-Computer Interface; Patient Safety; Health Information Systems

Introduction

Usability of healthcare IT has continued to be a worldwide issue, with continued reports of systems that are unusable, negatively affect healthcare workflow, and might even introduce a new class of error – technology-induced error [1-3]. There are a wide range of problems being reported that are related to human-computer interaction, including poor usability; the inability to customize systems to local needs, terminologies and workflows; and problems integrating information from multiple systems [4-7]. In response, there has been an attempt to create more effective processes for developing healthcare IT systems, including the introduction of certification processes in an attempt to encourage and mandate user-centered design and more usable systems.

In the United States, the Office of the National Coordinator (ONC) has developed guidelines for certifying the usability of vendor-based healthcare IT, including electronic health records. These have included vendors showing evidence of having applied user-centered design processes and usability testing in the design process [8]. In Europe, similar processes are also beginning to be mandated with CE marking [9]. However, Ratwani and colleagues have shown that the application of user-centered design processes by electronic health record (EHR) vendors is quite variable, even when adhering to the new regulations [10]. Results of their work also indicated that 63% of 41 vendors studied used fewer than 15 participants in usability testing and only 9% used at least 15 participants with clinical backgrounds. Currently, ONC-authorized certification organizations certify EHR products, with the vendor being required to provide a written statement about the process they used, along with results of usability tests. However, Ratwani and colleagues also found that there is a lack of adherence to certification requirements and standards (even among EHR products that were certified as meeting these requirements) [10]. Despite the importance of such certification as a first step, the current approaches are also limited in that they focus only on the system design/development process, and they do not extend to the implementation processes involved in system deployment of vendor systems in real world settings (such as hospitals and hospital systems). In such settings, customizing and modifying systems such as EHRs approaches the complexity of software product development. However, similar regulation covering practices for applying usability testing in the implementation of commercial vendor-based systems in real hospitals and clinical settings has been absent.

In this vision paper we argue for the need to distinguish between usability engineering needs in the: (a) one-time design process of systems (where certification efforts have been aimed so far), and (b) continual and long-term need for usability engineering in the implementation, customization and re-implementation of healthcare IT products. In addition, the argument will be made that a multi-level approach, borrowed from work in human-computer interaction in healthcare, is needed for ensuring healthcare IT usability and safety.

Need for Improved Usability Engineering in Healthcare IT Product Development

A variety of approaches have been developed and used for testing the usability of systems and assessing their impact on patient safety. However, as noted above, currently there are continued reports of a lack of system usability [5-7]. One of the issues is that the current certification requirements are limited and do not take into account the need for a variety of different approaches to applying usability engineering methods in the context of the multiple levels of complexity in healthcare. Along these lines, the context of use is critical to consider when conducting usability analyses. The testing of systems outside of the context of their application can lead to issues when the systems are actually used, and so an argument has been made for improved usability engineering processes. However, with a centralized product certification approach system usability and safety is assessed outside of the context of the healthcare organization where it is ultimately used. This can be problematic for certification systems that are later released into varied contexts within a region, across a country, and particularly when systems developed and certified in one country are being used in another country, where the healthcare system and workflow may be very different from the country in which the system was developed. Greater emphasis on testing systems in a variety of local contexts is also needed before releasing new healthcare IT products.
Need for Usability Engineering in Healthcare IT System Implementation and Customization

As noted above, usability certification processes are beginning to address the issue of a lack of usability of IT products. However, it should be noted that the centralized certification of vendor-based systems, such as EHRs, by regulatory bodies does not guarantee that such systems (post development) will either be usable or free from technology-induced error when later implemented in hospitals and healthcare settings. Along these lines, in this paper we also argue for the development of best practices for usability processes not only in system design and development, but also in the implementation of vendor-based EHR products in healthcare settings. This will be needed in order to ensure the entire process of implementation includes appropriate consideration for usability and safety. In our vision, which is based on advances in human-computer interaction, this would include a multi-level approach to testing and customizing commercial systems being implemented in healthcare settings.

Towards a Layered Approach to Usability Engineering Throughout the SDLC

Work in usability engineering in healthcare has shown that the application of methods emerging from the field of human-computer interaction need to be considered at multiple levels. Given the complexity of healthcare, it is not enough to test systems for human-computer interaction in isolation of their real use in complex and dynamic settings. Typical usability testing (such as it is specified currently by certification bodies) consists of observing and recording a small number of end users (e.g. physicians or nurses) as they interact with the system to carry out representative tasks (e.g. entering medication orders into a computer system). This level (which we refer to as Level 1) is useful to help identify and screen off surface level usability problems (such as labelling problems, navigational issues, font size issues, etc.). However, as shown in Figure 1, in order to ensure that healthcare IT will work properly in the context of carrying out work activities involving complex cognitive and social processes, Level 1 testing is not sufficient, and additional layers of testing will be required. (See Figure 1 for the proposed levels and their associated usability engineering methods listed on the right hand side of the figure.) As an example, Level 1 usability testing might involve observing physicians interacting with an EHR in isolation to carry out tasks and might determine that specific surface level aspects of the user interface need to be improved (such as making alerts and reminders more prominent on the computer screen). Although this might satisfy current certification requirements during the product’s development, prior to releasing the system in hospitals it may also be important to know if the system integrates into daily work practices. For example, in the case of an EHR it might be important to know whether or not the system can be easily used during actual clinical interactions or if it interferes with clinical reasoning. In order to more fully test systems, a second level of testing is then needed: clinical simulations, as illustrated as Level 2 in Figure 1. (The up arrow in the figure shows the typical recommended progression of testing from Level 1 up to Levels 2 and 3.)

Clinical simulations extend usability testing by examining systems under real or realistic conditions, settings and contexts of use. For example, in order to assess if an EHR system works as expected when a physician user interacts with it during a patient interview, a clinical simulation can be created whereby the user’s (i.e. physician’s) interactions with the system are recorded while they interact with either a real or standardized patient (i.e. someone playing the role of the patient). Such testing, although essential to ensure a system works in realistic contexts of use, is beyond the scope of current regulations or certifications. However, a variety of published studies have reported on how this type of clinical simulation can be set up with relatively low cost and high impact for improving the design, as well as customization, of EHR systems [19].

Although clinical simulations are useful in assessing the potential impact of systems on workflow and more complex cognitive activities of health professionals, they can never fully predict how a system will work under real conditions. Along these lines, additional testing in restricted live or near-live contexts of use is recommended (see Level 3 in Figure 1). Studies where this was done have indicated it was worth the effort in terms of reducing usability problems and avoiding errors [11].

What Will Be Required for this Improved Application of Usability Engineering in Healthcare?

Currently, a variety of usability methods and approaches exist that have been applied in projects and published in the health informatics literature. For example, work has been conducted in carrying out a wide range of usability tests, clinical simulations, and combinations of these approaches in order to improve healthcare IT usability and safety [19]. This has included work in: (a) improvement of software, (b) improvement of the process of development, (c) customization of vendor products and improvement in user training, (d) new approaches to software testing, and (e) selection and procurement of safe healthcare IT [12-20]. Along these lines, Marcilly and colleagues have argued for “evidence-based usability” in health IT, as the scientific body of reported methods that have proven effective has grown considerably [21]. Some of the results and methods that have emerged from this work have begun to be incorporated into regulatory processes in a number of countries [22]; however, progress in doing this has not kept up with the increasing reports of issues related to usability and safety of healthcare IT.

**Figure 1 - A Multi-layered Approach to Usability Engineering in Healthcare**

Despite the research in this area, healthcare is still plagued by unusable and potentially unsafe systems. So the question remains as to what is needed for a vision of more usable and safer systems, and how can that vision be attained?

**Recommendations and Potential Directions**

In order to achieve usable and safe healthcare IT, a number of recommendations and potential directions for further work and effort have emerged from the earlier discussion in this paper and are presented below.

Firstly, regarding more thorough usability evaluations, it is argued that all 3 levels in Figure 1 need to be considered when (a) developing health information technology or systems and (b) when customizing and deploying complex systems (such as EHRs) in real hospital and healthcare environments. It has been found that problems detected at Level 1 do not encompass the full range of usability issues. This will require going beyond current usability certifications and regulations to include multi-level usability evaluation. It will also require going beyond considering usability in the realm of system design and, as importantly, as part of organizational system deployment and implementation strategies. It will be essential to take into consideration the impact of local context when implementing healthcare IT.

Secondly, this vision will require certification and regulation with “teeth” that will involve more rigorous testing and lead to improved support and enforcement of basic usability principles. Along these lines, improved reporting mechanisms for the reporting of known usability and safety issues across the healthcare industry is needed globally (particularly as some systems are beginning to have a global market) [23-24]. Stronger regulatory measures will also be needed, specifying more stringent application of usability engineering approaches before certifying products.

Thirdly, a critical area that needs to be considered in making the vision of usable and safe systems a reality is the need for improved education about not only the importance of usability engineering and user-centered design, but also education about the full range of methods themselves that are included under these headings. This includes disseminating knowledge of alternative and emerging approaches at the levels of software designers, managers, clinical users and healthcare decision makers.

Fourthly, a critical issue that to some extent may prevent use of methods described in this vision paper is that of perceived cost and the amount of time it would take to use and apply methods known to lead to improved system usability and safety. Along these lines, there is growing evidence from studies on the cost-effectiveness of applying more thorough and advanced usability engineering processes [25]. These findings need to be more widely disseminated to not only healthcare IT professionals, but also to government and hospital decision makers, particularly when it comes to system procurement. Some progress has been made in the recent application of usability engineering leading to improved healthcare IT procurement by requiring test installs of systems and having them undergo rigorous usability evaluation before selecting software products for implementation [26].

**Conclusion**

A vision of healthcare IT can be conceived of where systems are seen as being highly usable; flexible within complex work activities; error-reducing, and sensitive to the contexts of different users, uses and locations. Unfortunately, reports continue to appear that seem to indicate that this ideal is not being met in many healthcare institutions [27]. To make the vision a reality will require considerably more effort along several fronts, including better dissemination of methods and
approaches that are known to work to improve healthcare IT usability, along with better sharing of this information and knowledge through improved practices and regulation. Furthermore, it should be the responsibility of healthcare organizations that buy and deploy healthcare IT to demand products that are designed to be more usable and that their IT staff be familiar with methods in usability engineering. From the vendor side, it is hoped that this could be achieved prior to extensive regulatory requirements, and improved usability and safety would become features of commercial products that provide market advantage (by distinguishing themselves in terms of improved user interaction and user experience). In summary, it has become clear that the usability of healthcare IT has become a critical issue that must be given greater consideration at multiple levels, from healthcare IT professionals to the governmental level. In this vision paper we have discussed approaches and methods we feel will be important in improving the current situation regarding usability and safety of healthcare IT.

Automated Classification of Multi-Labeled Patient Safety Reports: A Shift from Quantity to Quality Measure

Chen Liang a, Yang Gong b

b School of Biomedical Informatics, University of Texas Health Science Center, Houston, Texas, USA

Abstract

Over the past two decades, there have been an ever-increasing amount of patient safety reports yet the capacity of extracting useful information from the reports remains limited. Classification of patient safety reports is the first step of performing a downstream analysis. In practice, the manual review processes for classification are labor-intensive. Studies have shown that the reports are often mislabeled or unclassifiable based on the pre-defined categories, which presents a notable data quality problem. In this study, we investigated the multi-labeled nature of patient safety reports. We argue that understanding multi-labeled nature of reports is a key to disclose the complex relations between many components during the courses and development of medical errors. Accordingly, we developed automated multi-label text classifiers to process patient safety reports. The experiments demonstrated feasibility and efficiency of a combination of multi-label algorithms in the benchmark comparison. Grounded on our experiments and results, we provided suggestions on how to implement automated classification of patient safety reports in the clinical settings.

Keywords:
Patient Safety, Machine Learning

Introduction

As emphasized in the Institute of Medicine’s report ‘To Err Is Human’, error reporting and analysis are fundamental to patient safety [1]. Classification of patient safety reports is recognized as an initial step before any analysis and interventions can be applied [2]. However, the task of classification presents two urgent problems. Firstly, classified patient safety reports are of low quality due to sizable mislabeled reports and the reports under miscellaneous categories [3]. This problem may be caused by the lack of a deep contextual understanding of the reports. Secondly, conventional report classification is labor-intensive and time-consuming. Presently, the classification task is largely completed by manual efforts. The rapid increase in the volume of the reports and research demands calls for an efficient and reliable solution for the classification task.

Patient safety reports are multi-labeled in nature. In many scenarios, an entity can be categorized with a single label. This is known as single-label classification. When an entity is associated with multiple labels, it is known as multi-label classification. Patient safety reports can be categorized with a number of pre-defined labels that fall into various categories such as incident types, type of harms, and contributing factors. The multi-labeled reports carry invaluable information for downstream analysis. Studies that evaluate patient safety reports tend to survey types and frequency of errors but draw less attention in the co-occurrence and relation of labels. These pieces of information may provide critical insights of reasoning about the root causes. In a study, researchers discovered that 42% of the reports were associated with more than two contributing factors. The increasing number of contributing factors per report may indicate the variation, increased complexity or severity of harm [4]. The multi-labeled patient safety reports can draw reviewers’ special attention and thus can be better understood if they are well organized by categories.

Automated classification can be an alternative to the situation yet it presents interesting challenges when it is adapted to multi-label tasks. Automated classification is the task of using computers to learn associations between examples and labels. In-patient safety reports, an example can be an individual report in a corpus of reports. The classification is supervised because a classifier is built and trained by a set of prior labeled reports. Once the classifier is well trained, it can be used to predict candidate labels for unlabeled reports. As opposed to single-label classification, each report in multi-label classification may be associated with one or more labels. The multi-label classification is intuitive in human cognitive processes but creates extra complications in the computational process. Firstly, the training of a classifier is affected by many factors including the co-occurrence frequency of labels, hierarchical label relations, etc. [5; 6]. Multi-label algorithms must take these pieces of information into account but can easily lose feasibility or scalability by introducing sharply increased computational complexity [7]. Secondly, label imbalance is nearly inevitable in a multi-labeled corpus. As such, it negatively influences both classification performance and the selection of evaluation metrics. In specific, the prediction power of minority labels will decline since reports that are associated with these labels are less weighted during the training phase. Evaluation metrics such as exact match may not be as sufficient as it is in single-label tasks since a report may be predicted partially correct.

In general, multi-label algorithms can be categorized into two approaches: problem transformation, and algorithm adaptation. Problem transformation methods transform the multi-label problems to a number of single-label problems where a single-label problem can be solved by a range of single-label algorithms. A list of well-documented problem transformation algorithms includes binary relevance (BR), pairwise classification (PW), label combination (LC), and ranking and threshold (RT) [6]. Recently, a pruned sets method (PS) that is adapted from BR is reported to overcome many drawbacks of BR such as computational complexity [8]. A classifier chain method (CC) is also reported to improve LC for its less consideration of label relations, and sizable computational com-
plexity [9]. Algorithm adaptation methods modify specific algorithms to perform multi-label tasks, which are suited to a specific domain only.

In this paper, we adapted multi-label classification methods to categorize multi-labeled patient safety reports. The problem transformation algorithms were employed as the method to transform multi-label tasks to single-label tasks where binary classification algorithms serve as base classifiers. We present benchmark comparison between different combinations of algorithms. We argue that patient safety reports are multi-labeled and can be categorized by automated classification method with advanced efficiency.

**Multi-labeled Reports**

Patient safety reports contain crucial information to analyze incidents and to reduce recurrence. Reflected on a variety of factors mentioned in a report, an incident is multi-faceted. During the course of health care, a patient may have as many as hundreds of direct and indirect encounters with many persons, clinical procedures, and medical devices involved in hospital visits. Adverse outcomes may only occur in few encounters. But errors and contributing factors are likely to tie with many other encounters; especially those seemingly have no direct correlations to the patient harm. When an incident involves more than one error, the scenario is even more complicated. This situation is exactly the same as it is described in the Swiss cheese model of health care systems, which implies that medical errors are caused by simultaneous failures of multiple components in the system [10]. Fortunately, many of these factors can be extracted from the reports with either a clear mention or an indirect clue. Categorizing reports in a correct way has become a key to understanding both the root causes of a patient harm event and the risk factors of near miss or unsafe condition.

When it comes to massive reports, exploring multiple factors will provide more insights into the system’s failure. Assuming that each factor represents a label, there are one or more labels associated with each report. The frequency of each label across the corpus can provide a general view of the distribution of labels. Another view of label distribution is the co-occurrence probability, which measures the probability of co-occurred labels. The co-occurrence probability is a piece of critical information in disclosing label relations. From the clinical perspective, if there is a high co-occurrence of a medication ordering system, a documentation error, and various drug reactions, for example, it is likely to have a malfunction or reoccurred user error relating to the medication ordering system. In a certain sense, therefore, label co-occurrence partially implies the potential factors that correlate with a given event.

Typically, the task of identifying multiple factors is a routine procedure of clinicians who review the reports. However, it requires a significant amount of time when the volume of reports scales up. The co-occurrence probability plays an important role in automated multi-label classification. It can be represented in the network visualization. In Figure 1, we generated a network graph based on a set of 2,919 patient safety reports. Each node in the graph represents a label that is used in the reports. The thickness of the edges that link a pair of nodes indicates the frequency of co-occurrence of two labels. For example, the label ‘PerformanceFactor’ has a high frequency in presence with either ‘ProcedureTestTreatment’ or ‘MedicationIV’. The label ‘Disability’ hardly has any co-occurrence with other labels.

![Figure 1](Network visualization of co-occurrence probability of labels in 2,919 patient safety reports.)
Automated Classification

In this section, we report our work to adapt multi-label text classification in the task of categorizing patient safety reports. The experiments were designed to evaluate the feasibility and efficiency of automated methods in multi-labeled reports.

Dataset

We used a corpus consisting of 2,919 de-identified patient safety reports from a university healthcare system. The original corpus contains 54 labels with a label cardinality of 2.89. The label cardinality is defined as

\[ LCard(C) = \frac{\sum_{i=1}^{N}|Y_i|}{N} \]  

(1)

N denotes the number of reports in the corpus C, \( y_i \) is the number of labels associated to individual report, and L denotes the total number of labels. To avoid extreme imbalance of labels, we removed minority labels where each has less than 50 reports, resulting in 28 labels with a label cardinality of 2.58. See Table 1.

Procedure

We used problem transformation methods to solve the multi-label challenge. The problem transformation methods require a problem transformation algorithm in conjunction with a single-label algorithm that serves to build base classifiers. To perform the benchmark comparison, we chose a number of well-documented problem transformation algorithms considering both feasibility and computational complexity including BR, LC, RT, CC, and PS. Note that PW is not selected due to its significant computational complexity. For the parameter selection for PS, we used the optimized parameters (\( n = 0; p = \{1, 3\} \)) given that our corpus has a label cardinality of 2.58 and a number of 28 labels [8]. We also chose a number of single-label classifiers that represent a range of well-developed algorithms consisted of Naïve Bayes [11], Support Vector Machine (SVM) [12], k-Nearest Neighbor (kNN) [13], Decision Tree [14], and Decision Rule [15]. See Table 2.

Since these binary classifiers are not originally designed to process text data, we prepared our corpus as follows. (1) Snowball stemmer was used to reduce inflected terms to their root form [16]. (2) Random list was used to remove stop words [17]. (3) Alphabetic tokenizer was used to break a string of text into terms. (4) Lower case token was applied to all the terms. (5) TF-IDF (term frequency-inverse document frequency) was used in the transformation of documents into a bag-of-words (BOW) matrix keeping 1000 unique terms [18].

The experiments were performed on a 64-bit OS system with a processing power of 2.2 GHz with 4 Cores 8 Threads and a memory of 8 GB RAM. We used Python 3.0 to pre-process the corpus. The model training, evaluation, and statistics were performed on WEKA 3.6 [19] and MEKA 1.9.0 [20]. We employed 5 × 2 fold cross validation to randomize data and average results.

Evaluation Metrics

We consider both essential evaluation measures that are used in the single-label classification and the ones that are adapted for multi-label classification. The 0/1 Loss is a loss measure that assigns a ‘1’ only if a label set is predicted exactly correct. The 0/1 Loss is defined as

\[ 0/1 \text{Loss} = 1 - \frac{1}{N} \sum_{i=1}^{N} \mathbb{1}(\hat{Y}_i = Y_i) \]  

(2)

where \( \hat{Y} \) denotes the predicted set of labels; \( Y \) denotes the exact set of labels.

Hamming Loss is the measure of labels that are incorrectly predicted. Instead of penalizing the incorrect match between two sets of labels, the Hamming Loss measures only the symmetrical difference between individual labels. Therefore, it is more forgiving than the 0/1 Loss. Hamming Loss can be referred as a partial match metrics whereas 0/1 Loss measures exact match. In multi-label classification, the form of Hamming Loss is defined as

\[ \text{Hamming Loss} = \frac{1}{NI} \sum_{i=1}^{N} \sum_{j=1}^{L} \mathbb{1}(\hat{Y}_{ij} \neq Y_{ij}) \]  

(3)

We also employed a multi-label accuracy measure that has been widely used in multi-label classification [21]. The form is defined as

\[ \text{Multi-label Accuracy} = \frac{1}{N} \sum_{i=1}^{N} \frac{|Y_i \cap \hat{Y}_i|}{|Y_i \cup \hat{Y}_i|} \]  

(4)

The F measure is employed to provide a balanced metric between precision and recall. In multi-label classification, the generic F measure can take a number of forms depending on the different approaches of averaging metrics. In this study, we employed micro F measure. Mathematically, micro F measure favors labels with more documents, as it counts global metrics where labels with more documents have more weights. It is defined as

\[ F_{\text{Micro}} = \frac{\text{F Measure} (Y_{ij}, \hat{Y}_{ij})}{} \]  

(5)

In addition, we also consider the build time of models as a measure of computational complexity.
Results

We present the results by each evaluation metric. BR ($M = 0.994$) and LC ($M = 0.994$) performed slightly better than other multi-label algorithms but did not lead to a clear difference in terms of 0/1 Loss. Naïve Bayes ($M = 0.990$) shows a slightly higher rate compared to other binary algorithms.

LC ($M = 0.141$) and $PS_{(p^3, n^0)}$ ($M = 0.140$) reveal an overall better performance in the measure of Hamming Loss. SVM ($M = 0.136$) shows the best performance among binary classifiers. The best combination appears to be the SVM in conjunction with RT (0.115).

BR ($M = 0.110$) is shown as the best problem transformation algorithm in the measure of multi-label accuracy. In the comparison of the base classifiers, Naïve Bayes ($M = 0.110$) outperformed the others. Naïve Bayes in conjunction with CC (0.128) appears to be the best combination.

BR ($M = 0.195$) reveals a higher $F$ than other problem transformation algorithms. Naïve Bayes ($M = 0.190$) is the best base classifier overall. The best combination is Naïve Bayes in conjunction with CC (0.222). See Table 3 for details.

* best performance

$PS_{(p^3, n^0)}$ ($M = 10.267$ second) is the most efficient problem transformation algorithm as it shows the shortest build time. In terms of base classifiers, Naïve Bayes, SVM, and kNN ($M = 0.228$ second) cost less build time. kNN in conjunction with $PS_{(p^3, n^0)}$ (0.015 second) is the most efficient combination.

We observed an interactive effect between $F$ measure and build time over problem transformation algorithms. Figure 2 shows the comparison between different problem transformation algorithms when the base classifier is Naïve Bayes. CC appears to be a well-balanced algorithm considering its optimal performance and relatively short build time. Such an interactive effect did not show over binary algorithms.

Discussion

Multi-labeled Reports: from Quantity to Quality

This paper provided a novel perspective to investigate the nature of patient safety reports that is a report can be categorized by multiple labels. This argument corresponds to the Swiss cheese model that is frequently used as a metaphor of health care systems [10]. Errors are multi-faceted if they are viewed in a health care system where systems failures are preventable based on a number of relatively independent components. Such a component may refer to clinical administration, treatments, uses of medical equipment, etc., while each may produce unintended consequences. A systems failure occurs when by chance all the components produce errors. However, a systems view of these components can be obtained only if the reports are well categorized and, consequently, an aggregate analysis is made available.

The multi-labeled perspective of reports motivates a shift from quantity to quality measure. Patient safety studies have made remarkable progress, notably in constructing a nationwide reporting mechanism and ongoing focus to reducing harm by learning from lessons. These efforts have largely increased the number of reports, establishing a quantitative measure of patient safety such as the distribution of occurrences and frequency of errors. In fact, we are still far away from timely analysis and targeted quality improvement implied by the event reports. The vulnerability of health care system calls for special attention. We argue that one crucial gap is the limited understanding of reports, especially the intricate relations of the factors involved in a report. When the volume of reports increases, such pieces of relational information become more robust to indicate systems vulnerability. A prerequisite of performing quality measure as such is the capacity of extracting complex factors from massive reports. In this study, we suggested a multi-labeled approach.

Clinical Implementation

Our findings hold promise to improve the large-scale classification of patient safety reports. The experiments suggest feasibility and efficiency of using automated multi-label classification method to categorize patient safety reports. To balance the predictive power and efficiency, we found that CC in conjunction with Naïve Bayes is well performed. In addition, PS is also a promising method, as it largely reduces the model build time within a relatively small decline of predictive power.

More importantly, the multi-label classification is suited to the existing event reporting systems for improving the existing single-labeled classification and manual procedures. Clinicians who are responsible for case review and aggregate data analysis are expected to benefit from the automated classification. However, note that automated classification may not completely replace human effort for two reasons. Firstly, the automated classification results are not expected as good as manual results. The automated classification results should
serve as a reference source during the human review processes. Secondly, the automated classification has a limited capacity of predicting rare cases since it is generated based on the existing data. The rare cases, instead, may provide unique or crucial insights into medical errors.

With the scope of implementing automated classification in the reporting systems, we further suggest a unified classification scheme, which should provide a consistent and up-to-date classification hierarchy across health care providers. This is important to automated classification because the classification is supervised in a way relying on predefined labels to predict unlabeled reports. In the U.S., the Common Formats are widely used as a reporting guideline and classification schema in nationwide reporting. To extend the Common Formats’ influence in guiding multi-label classification, additional work must be done to develop a classification hierarchy that supports automated classification directly, such as developing an ontological representation of patient safety reports [22].

Limitation and Future Direction

The label imbalance problem is a limitation, particularly in the context of multi-label classification. However, the label imbalance is inevitable in multi-label classification. The minority labels are even more common in medical corpus because medical entities (e.g., diseases, phenotypes, etc.) are not evenly distributed in a population. For example, minority labels can be ‘death’ or ‘performance factor’ in our corpus. To partially solve the problem, we removed extremely biased labels instead of creating synthesized reports. Consequently, it may lose some labels that are clinically important. Therefore, our approach still needs human guidance on categorizing minority labels at the current stage. In the future, we plan to enrich the corpus in both volume and sources.

We also note that the overall predictive power is comparatively small. Partially because we did not choose to perform feature selection and other manipulations that ought to boost the performance, as well as the fact that the 5×2 fold cross validation purports to find the most competitive classifiers under limited resources. The other interpretations may be the intricate semantic information and loss of information in the real-world patient safety reports. In the next step, we will investigate the effects of semantic information and domain knowledge in classification tasks.

Conclusion

The study demonstrated the effectiveness and efficiency of using automated multi-label classification on real-world patient safety reports. Our findings may improve (1) the process of understanding medical errors from an aggregate analysis, (2) clinical implementation of automated classification for large-scale patient safety reports.

Abstract

The identification of the severity of patient safety events promotes prioritized safety analysis and intervention. The Harm Scale developed by the Agency for Healthcare Research and Quality is widely used in the US hospitals. However, recent studies have indicated a moderate to poor inter-rater reliability of the Harm Scale across a number of US hospitals. Although the reasons are multi-folded, biased human judgments are recognized as a prominent factor. We proposed that key information to identify and refine the severity of harm is contained in the narrative data in patient safety reports. Using automated text classification to categorize harm scores is intended to provide reduced subjective judgments and much improved efficiency. We evaluated different types of classification algorithms using a corpus of patient safety reports from a US health care system. The results demonstrate the effectiveness and efficiency of the proposed methods. Accordingly, human biases on the application of harm scores are expected to be largely reduced. Our finding holds promise to serve as a semi-supervised tool during the process of manually reviewing and analyzing patient safety events.

Introduction

Harm Classification and Scales

Reducing patient harm is a top priority of US hospitals and health care organizations. During the past two decades, researchers have been focusing on compiling patient safety events and detecting errors through nationwide patient safety reporting [1,2]. Event reporting at all levels has shown remarkable advantages to gather concurrent and retrospective events, including patient harms, near misses, and unsafe conditions in a timely manner. Most importantly, it enables a close analysis on aggregate data, which increases the chance of disclosing vulnerability of health care systems. To accommodate safety event reporting at federal level, the Patient Safety Organization (PSO) has employed standardized event reporting formats (a.k.a., the Common Formats) to collect and classify reports [3].

Severity of safety events is an influential factor that can be identified by using the Common Formats. This piece of information plays a crucial role in triggering intervention actions and prioritizing limited resources of root cause analysis. In the Common Formats, Harm Scale is used to describe the degree of harm by assigning each event a harm score. The latest version of Harm Scale (v1.2) released in 2012 consists of a 5-point scale of severity of harm and a 2-point scale of anticipated duration of the harm (see Figure 1). In the meantime, a number of health care organizations have also participated in developing harm scales from different perspectives. The World Health Organization (WHO) developed a five-point harm scale, consisting of ‘no harm to death’, ‘mild’, ‘moderate’, ‘severe’, and ‘death’ [4]. This scale is centered on the patient harms arising from the provision of care. The National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP) developed a scale that takes duration and permanency of harm into account. The Institute for Healthcare Improvement (IHI) also developed Global Trigger Tools to measure the severity of patient harm [5].

Harm Scale Reliability

One of the most significant challenges of using harm scale is reliability, which is the deviation between reporters’ judgment about the type and severity of harm [6-8]. In practice, the deviation not only influences the classification of harm but also relates to the determination of intervention actions. For example, if an event is determined at a certain level that is preventable, it is likely that significant analysis and intervention efforts will be assigned. Otherwise, the complication of the care occurred in the event is likely to be labeled as a risk factor.

The reliability of harm scale, especially standard scales used at a national level, is not as high as expected in the practice. A recent survey study on the reliability of the Common Formats Harm Scale across different roles of clinicians and different settings yielded an overall moderate level of reliability [8]. The findings in this study show that some levels of harm are difficult to distinguish from neighbor levels. This problem is most significant for the moderate severity levels of harm. Another study that is performed on a relatively smaller size of data showed similar findings [7].

The deviations may be caused by several reasons. Firstly, the reporters vary in background. Reporting is open to clinicians in the hospitals, including physicians, nurses, pharmacists, etc. Nurses and pharmacists are reported to be more active in the reporting because they witness errors more frequently during the course of care [9]. For example, they have more chances to witness and report medication errors. When they do, they are likely to assign medications errors with a lower harm score.

Figure 1 – A Harm Scale Screenshot from the Common Formats, Patient Information Form (v1.2).
compared to other clinicians [10,11]. Secondly, reporters’ understanding of the harm scale exerts an influence on the rating [10]. Studies have suggested an important role of education and training in the reporting [12]. Besides, biased harm scores can be a result of unclear guidelines and information representation, such as the definitions [7] and knowledge structure [13]. Thirdly, the way in which events are reported may influence the reliability of harm scores. This argument is mainly centered on the capability of hospitals to discover and make adjustments of potentially biased scores. Compared to paper-based reporting, web-based reporting holds potential to disclose biased harm scores, as it is advanced in viewing aggregate data and trends.

Predicting Harm Scores from Patient Safety Reports

An alternative of calibrating biased harm score is to develop a mechanism of predicting harm score from patient safety reports. During the reporting, the decision of assigning a harm score to an event is made by reporters’ understanding of the event, their experience, and perception of environment. While components such as experience and perception are subjective, the event itself is relatively more objective. As such, decisions that are purely based on the events are likely to reduce the bias caused by human. In most of the hospital reporting systems, events are storytelling-like and recorded in a text format, namely patient safety reports. These reports contain substantial and essential information to make judgment of harm scores. Most importantly, informatics techniques are available to extract information without human biases. Text classification is a candidate technique that purports to predict classes of text based on statistical regulations of term distribution in the text. To perform text classification, a statistical model is trained through learning term frequency from a set of categorized documents. The trained model is then capable of predicting un-categorized homogeneous documents with correct classes. This method has been broadly used in biomedical domain to reduce manual production time [14].

We propose that text classification can be used to predict harm scores based on patient safety reports. In this study, we will train classifiers from a set of reports that are assigned with harm scores according to the Common Formats Harm Scale (v1.2). The classifiers will predict harms scores of unlabeled reports where the performance of classifiers will be evaluated. From a practical perspective, the classification results are expected to eliminate potentially biased harm scores based on stored reports.

Methods

Data

The dataset consists of a corpus of 2919 de-identified patient safety reports from a university health care system. The reports cover a range of incident types that are labeled by reporters (see Figure 2).

The reports have been cross-validated by a group of domain experts, assigned with harm scores using the Common Formats Harm Scale (see Table 1). In the text classification task, the assigned harm scores serve as the gold standard to be compared with machine prediction.

Figure 2 – Distribution of incident types.

Procedure

Environment

We provided a 64-bit OS system with a processing power of 2.2 GHz with 4 Cores 8 Threads and a memory of 8 GB RAM to perform the experiments. The classification experiment was performed on WEKA 3.6 [15].

Text Processing

To extract term frequency information from the raw data, we followed a serial of procedures to prepare the data. (1) Snowball stemmer was used to reduce inflected terms to theirs root form [16]. (2) Rainbow list was used to remove stop words [17]. (3) Alphabetic tokenizer was used to break a string of text into terms. (4) Lower case token was applied to all the terms. (5) TF-IDF (term frequency-inverse document frequency) was used in the transformation of documents into a bag-of-words (BOW) matrix keeping 1000 unique terms [18].

Text Classification Algorithms

We selected three types of algorithms that are well documented in text processing and biomedical application. They include decision tree algorithm, lazy algorithm, probabilistic algorithm, and support vector machine (SVM) [19]. For the decision tree, we employed C4.5 since it is reported effective in processing text [20]. For the lazy algorithm, we employed k-Nearest Neighbor (kNN) [21] for its well-balanced efficiency and predictive performance in medical text [22]. For the probabilistic algorithm, we employed Naïve Bayesian [23]. See Table 2 for a list of algorithms we used. A benchmark comparison is performed among these algorithms.

Evaluation

For all the six harm scores and four algorithms, we employed a 10-fold cross validation to compare between algorithm performance. Each round of evaluation ran 10 times, which produced a total of 2,400 results. Performance was measured by F measure, which is a weighted average between precision and recall. The generic F measure is given as
In a classification task, precision is the fraction of retrieved documents that are relevant to a given label. It measures the ability of a classifier not to label a document as relevant when it is not.

\[
\text{Precision} = \frac{\mathbb{Y} \cap \hat{\mathbb{Y}}}{\mathbb{Y}} \tag{2}
\]

where \(\mathbb{Y}\) denotes the predicted set of labels; \(\hat{\mathbb{Y}}\) denotes the exact set of labels.

Recall is the fraction of relevant documents that are retrieved. It measures the ability of a classifier to retrieve as more relevant documents as possible.

\[
\text{Recall} = \frac{\mathbb{Y} \cap \hat{\mathbb{Y}}}{\hat{\mathbb{Y}}} \tag{3}
\]

In addition, we provided an estimate of receiver operating characteristic curve (ROC) as a metric for assessing the trade-off between true positive and false positive.

**Results**

Table 3 shows a ranking between the six tasks of classifying each harm score. The numbers indicate the number of wins or losses (negative number) of any task against the other tasks. On the metrics of precision, recall, and F measure, the task becomes more difficult if the harm score becomes smaller. This is probably because the narratives in the mild-harm or unknown-harm events contain less significant term frequency information that distinguishes the events from severe events. However, the ROC shows that tasks of classifying score 0 (unknown) and score d (mild harm) outperform others, indicating a well-controlled false positive.

Figure 3 shows the benchmark comparison on precision. Naïve Bayesian (precision = 0.88) and C4.5 (precision = 0.88) outperformed kNN (precision = 0.85) and SVM (precision = 0.87) in the comparison across all the six classification tasks. Paired t test shows that Naïve Bayesian performed better than C4.5 on tasks of classifying score e, d, c, and b, respectively \((p < .05)\). But for the tasks of classifying score f and a, C4.5 performed better \((p < .05)\).

Figure 4 shows the benchmark comparison on recall. C4.5 (recall = 0.90) ranks the best algorithm compared to kNN (recall = 0.88), Naïve Bayesian (recall = 0.83), and SVM (recall = 0.87).

Figure 5 shows the benchmark comparison on F measure. C4.5 (F = 0.89) ranks the best algorithm against kNN (F = 0.86), Naïve Bayesian (F = 0.85), and SVM (F = 0.87) overall.

Concerning the efficiency of algorithm, kNN used an average of 0.15 seconds of model training time, recognized the most efficient algorithm \((p < .05)\) compared to C4.5 (time = 22.48 seconds), Naïve Bayesian (time = 0.92 seconds), and SVM (time = 1.70 seconds). An interaction of efficiency and performance is observed on Recall and F measure only, indicating that more time is needed for better performed algorithms (see Figure 7).
ample, the classification tasks of identifying score a and b show there are not sufficient reports in the minority labels. As an example, the classification tasks of identifying score a and b show outstanding performances on precision and recall but much worse ones on ROC. Secondly, levels of difficulties may vary by tasks. The task of identifying score f (unknown harm) is worst performed in terms of precision, recall, and F measure, but not ROC. Intuitively, the term frequency information in the reports of score f is sparse compared to the others.

Predicting harm scores based on patient safety reports is significantly efficient. Our findings confirmed a small computational cost of building the four types of classifiers but revealed some differences between these classifiers. Rule-based classifiers, i.e., C4.5 in our study, demand more time and computational resources. On the contrary, lazy classifiers and probabilistic classifiers use comparatively less time and computational resources, indicating a much improved efficiency. However, there was a tradeoff between efficiency and predictive power. Although, C4.5, for example, is most time consuming in our experiment, it showed best performance on Recall and F measure. This effect implies that C4.5 has the best capability to identify as more true positive reports as possible, regardless of identifying false positive ones. Moreover, this capacity is still dominant on the comparison of F measure, which is a combined metric of precision and recall.

Selecting a suitable classifier is task dependent. If the task concerns more about false alarm, i.e. mistakenly assigning a report to an irrelevant harm score, C4.5 and Naïve Bayesian are better. If the task concerns more about retrieving more reports that belong to a given harm score, C4.5 is preferred. When it takes both factors into account, C4.5 is recommended. Because it still won on the F measure by showing a statistically significant difference. In the practice, however, it is mostly concerned to enlarge the true positive rate and reduce the false positive rate. Thus, Naïve Bayesian is the best classifier.

Clinical Implementation

We envision that the automated classification of harm scores could assist in calibrating any human biases raised in the process of reporting. The proposed methods are implementable to most of the existing web-based reporting systems. In our view, text classification takes advantages of the existing reporting systems from three aspects.

Firstly, text classification corresponding to the narrative data that are commonly used in the reporting. Narrative data makes patient safety reports different from many other clinical data. A patient safety event is mostly encoded in a story-telling fashion since the elements of health care are complex and temporally organized. It is less likely to include many detailed and critical information in structured data, such as numeric or categorical data. This fact hinders many analytical methods that are applicable for generic clinical data.

Secondly, text classification promotes aggregate analysis and reporting. The Patient Safety and Quality Improvement Act of 2005 has called on to build a national mechanism of error reporting and analysis. Over the past decade, the rapidly increased volume of reported data has shown a quantitative improvement as well as a technique bottleneck of timely processing such a huge amount of data. Without a feasible solution, the analysis at a national level is of less practical value. The efficiency of our method suggests a practical use to be implemented in clinic, which is promising in largely reducing the demand of human labor.

Thirdly, the automated classification of harm scores is controllable because it is semi-supervised in practice. Caution should be taken when we apply automated method to medical decisions. We noted that all the evaluated classifiers are at a certain rate of error. Though this is not unique in our case, such an error should be controlled at a reasonable level. It is highly recommended to perform the classification under human supervision, as it is the case for most of the informatics tools implemented in medicine.

Limitation and Future Direction

We highlighted a need for creating an objective mechanism of overseeing human biases of categorizing harm scores. However, our study is of less value without a discussion of limitations. One limitation is the relatively small sample size used for the experiment. This problem may cause imbalanced labels,
which further harm the performance. In addition, a small sample limits the possibility to evaluate rare cases that may hold important clinical value but have limited distribution. Therefore, we will enrich the sample size and include a broader and more representative dataset.

The other limitation includes less consideration of label correlation, which may cast a crucial influence on the classification performance. The label correlation may not only be limited within the different harm scores but also with a number of categories such as contributing factors, settings, and procedures. In the future, we will evaluate such relational information by experimenting a multi-label classification.

Last but not least, the present study did not consider categorizing harm scores on temporal information. For example, the Common Formats Harm Scale (v1.2) consists of a two-point scale assessing the duration of harm. The extraction of temporal information from medical (e.g., clinical notes) has not been adequately investigated but has been on our research agenda.

Conclusion

This study aims to apply automated text classification to categorize harm scores from patient safety reports. This method is applicable to discover and calibrate potential classification biases caused by human judgment. Four types of classification were evaluated in the experiment, yielding effectiveness and efficiency of the proposed approach. In addition, this approach holds promise in facilitating the labor intense analysis of large volume patient safety reports which is in accordance with the goal of establishing a nationwide safety reporting mechanism.

The Value of Data and the Value of Questions: Achieving Improvement in Hospital Pharmacy and Medication Safety

Valentina Lichtner, Tony Cornford

Abstract

Medication safety incidents are one of the major patient safety issues faced across all healthcare services and one that is very challenging to tackle. To make progress, data about the supply and use of medicines that is generated and made available in clinical systems can serve both the purposes of patient safety and service quality improvement. This paper shows how the value of data for these purposes can be framed in terms of the value of questions. This theme is developed based on an interview with a quality and safety pharmacist working in a large hospital pharmacy unit.

Keywords:
Task Performance and Analysis; Pharmaceutical Services; Patient Safety

Introduction

“Big Data is not about providing answers to questions we could not answer before; it is about our ability to think of the new questions” [1].

This is the kind of advice the world of business consulting gives to companies wishing to generate value from Big Data. The advice is to focus on questions [1; 2], and especially new ones. This paper explores how this argument applies to the running of hospital pharmacy services. It presents a case study, a pharmacy perspective on quality improvement in medication safety, in the context of an implementation of an electronic prescribing and administration (EPMA) system and the new data it can provide. The case is centred on a conversation with a practitioner. We asked about the value of data, and she reminded us of the value of questions.

There is an extensive body of knowledge on the use of big data in the healthcare domain; data about patients and patient care activities are increasingly researched for clinical purposes (e.g. predictive analytics) and commissioning. In relation to medicines, big data and associated algorithms are offering insight for pharmacogenomics and precision medicine [3; 4]. The recent seminal paper by Google Research team [5] also shows how machine learning through hospital based data (on eye images) can produce diagnostic systems, specifically, in this case, for detecting diabetic retinopathy. Big data research is more limited on how big data are used by practitioners to manage healthcare services. It presents a case study, a pharmacy perspective on quality improvement in medication safety. This interview was chosen for its relevance and for the insight it offers into uses and challenges of data for hospital management. All quotes cited in the Results section of this paper come from this interview transcript.

Methods

The case presented in this paper is taken from data collected for a project investigating the digitalisation of supply and use of medicines in a hospital setting. Data collection included non-participant observations, interviews and documentary analysis. Observations of staff (prescribers and dispensers) work practice were carried out to gather data on the use of data and technology for the supply of medicines in these settings. Semi-structured interviews were conducted with a variety of stakeholders including patients, doctors, nurses, pharmacists and managers. Interviews explored views and experiences with new technologies and services aimed at supporting supply and use of medicines. With participants’ consent, interviews were recorded and transcribed.

Overall data were collected through 37 interviews and about 103 hours of observation. This paper focuses on one interview transcript, with a pharmacist, manager of the service responsible for the supply of medicines, in the hospital pharmacy. This interview was chosen for its relevance and for the insight it offers into uses and challenges of data for hospital management. All quotes cited in the Results section of this paper come from this interview transcript.

Results

The setting

The site we studied is a large National Health Service (NHS) teaching hospital, covering five buildings located in different parts of one of England’s largest cities. Medicines used in the hospital are managed by the Pharmacy Services Unit, through a number of on-site dispensaries and about 500 professional staff. The Unit also provides specialized pharmacy services for the local and nearby communities. The Unit comprises a number of pharmacy ‘service areas’, including procurement, supply, information services and pharmacy IT, and quality and safety.

From a service perspective, the Pharmacy Services Unit is running a business, servicing other units in and beyond the hospital, such as the clinical wards and local community clinics – these representing ‘clients’ and ‘users’ of the services. In the NHS the cost of medicines is covered by budgets held locally by Clinical Commissioning Groups (CCGs), ultimately responding to the Department of Health; the local CCG is thus also a ‘client’ of the Unit, the one paying for the service.

Pharmacy services’ activities are run and managed through a number of digital information systems, including; a supply
management system for generating orders to suppliers and recording the dispensing of medicines to patients in the hospital, ‘robots’ to store and dispense medicines, a track and trace system of pharmacists’ tasks to track dispensing activities, and a patient safety incident reporting system. The Unit also makes full use of the clinical systems in the hospital, including a patient records (EPR) portal to access patients’ clinical tests. At the time of the study the hospital was in the early phases of implementing a new electronic prescribing and administration (EPMA) system integrated into the EPR portal. This EPMA system was to replace paper-based drug charts, still in use in most parts of the hospital at the time of the study. All these information systems provided data about medicines (stocks, flows, use, transactions) in various forms.

Overseeing quality and safety

As part of the senior management running the pharmacy services, the unit had a pharmacist responsible for dealing with medicines related data generated by the pharmacy and hospital activity. As explained by this pharmacist, her overall purpose is to assist the managers of each service area “to understand their measures of performance and then to help them turn that measure of performance into something we can be assured about in terms of the quality and safety of our [overall] service delivery.”

In order to do this, the first thing to do is “to work with each of the teams to see what is important to their service, what data they have and also what data they should have (and there is a difference), and then to work on how we, as a whole service unit, pull together that information and look at it as a senior team to make sure it’s telling us how our services are being delivered and the quality and safety issues we might need to look at.”

Feedback through dashboards

The overall purpose of this work is to achieve constant improvement and the elimination as much as possible of patient safety risks. For the purpose of improvement, data is shared with managers and staff in different pharmacy areas through the use of dashboards (digital interactive ones and printed summaries displayed in work areas – e.g. Figure 1). Dashboards are summaries of a selected number of metrics, with more or less granularity.

“...the dashboard is to focus people’s attention on certain things so that we get everybody knowing that those are the things we need to improve. [...] whether there’s anything going pear-shaped, going wrong, looking as if it’s drifting off where it should be ...

The focus of most dashboards is on problematic areas and safety incidents, balanced with achievements. The premise is that alerting staff of issues and safety incidents can generate learning and ‘focus people’s mind’ towards improvement.

“More recently we’ve had a dashboard where things have looked quite good most of the year and so the question is now, ‘Well why do you keep telling us the same information?’ [...] So this quarter we’re talking about, ‘Well, shall we now pick six things that we’re not very good at and re-energise that conversation about improvements?’

Analytics out of layers of data

The dashboards are an aggregate of layers of data, each answering specific needs.

“... you can see it in layers of data ...

Each service area is different (e.g., procurement, dispensary, manufacturing, information management), each requiring therefore different metrics, and different data (different ways of gathering data and different data they can gather). These layers of data are then re-assembled into dashboards for overall summaries, but also provided in detail to each specific unit.

“... each unit has its own set of much more detailed indicators which tell them what their activity is, how much money they’re getting, what their staffing level is, all of that sort of stuff.”

“... what you use that data for depends on how you’re actually collating it and displaying it and using it and sharing it.”

Tracking and assessing operations’ performance

Performance is most obviously measured in terms of meeting service targets, such as delivering required medicines to clinical areas within certain time frames (e.g. 2 hours from receiving an order). In order to have the data to assess activity against these set targets, the overall process is structured into separate tasks (e.g., receiving order, processing items, verifying, delivering), each transaction given a barcode, and then scanning of these barcodes during each task. The ‘track and trace’ system dashboards could then display in real-time any delays with respect to the time targets, and provide data on overall performance over a given period.

However, other performance measures are also important so as to assess whether the services achieve their overall business objectives – i.e. in terms of patient needs.

“...we have used the data coming from the dispensary tracker in the past as part of one of our initial measures, [...] to check how many of the prescriptions for patients going home, our discharge prescriptions, are dispensed within our two hour target. [...] but when we measure it being completed in pharmacy is not necessarily the same measure as ‘is it with the patient ready to go home?’

This requires thinking new metrics (new questions), beginning from the perspective of the patient (the ultimate user of the service):

“Well what is it that the patient wants us to measure?”

Answering this question leads to a more specific metric, suitable to be answered with available data:
The patient wants to know how quickly can [their medicine] be with them, ready for them to take it home, and we know that there’s a bit of a delay between it being ready in the dispensary and it then getting to the ward, and so you could argue that one of our measures ought to be: when it’s ready in the dispensary how long does it [then] take to get to the ward?”

Gathering the data

The data for performance assessment, and the layers of data displayed in dashboards, come from a number of systems – some digital, other requiring purpose-built auditing tools which are mainly paper based. The processing of digital data and especially data collection by hand, are resource intensive and time consuming, and not to be lightly introduced.

“…they are different [pharmacy units], and there is no one system of data collection that we use across all ...

“[data] come from a collection of systems and a collection of manually collected, or data that’s taken from other systems and then amended or extracted for our own purposes. So […] currently it’s a very [pause] I was going to say it’s very manually heavy. It’s, it’s less so now because we’ve worked really hard to only use electronically-collected data, but there are still some bits of data we have to collect by hand.”

At the time of the study the hospital was implementing an EPMA system integrated into a patient record portal and the expectation was that these integrated systems would be able to provide data, without the need for manually auditing paper charts or using data collection forms.

“… when every patient has their drug chart in [EPMA], then that will sit within [the EPR] and the data will be shared and you will just be able to extract it in one transaction.”

The availability of the right data needs planning

When data need to be collected manually, you have to plan ahead for that data collection; thus have to know your question. Once data are digital, at least in theory, there is a potential to answer emerging questions that were not planned for. However, in practice there may be a digital system in place but the data may not have been entered appropriately, or the system may not actually record the data you were expecting to have. Thus you still have to plan ahead, and ‘be clear what you are going to measure’,

“Well I think it depends because you can only extract the data that you put in, and so if your system is not collecting the data that you require, then you still have to plan.”

“… so a good example is: on our [paper] drug chart we have something called a Day 3 Antimicrobial Review section, so at the moment if you do a Day 3 you tick that box [on paper] and put a code in it, and we go along and [manually audit the charts] we measure the number of patients who’ve had a Day 3 review. Interestingly in [EPMA], there is no such box to tick and so the question is: how would you extract the data from [EPMA]? What data is recorded to show that a Day 3 review has occurred?”

“…, you still have to plan and be clear what you’re trying to measure, because just saying ‘it will be there’, isn’t always the case.”

Some data are still imperfect answers to your questions

Despite planning and efforts of data collection, the data that can be available and collected, are not necessarily matched to the question of interest. The case of monitoring for antimicrobial use in hospital is again one such example:

“Well you can go on and there is a box for each ward to use which says, ‘Is the patient on antimicrobials?’ and you can actually manually put it in. […] It just says they’re on antimicrobials, ‘yes, no’. So we’re working with imperfect data because the data we can often get doesn’t answer the question we want answering …”

The question must be worth the effort

Furthermore, not all questions are worth the data collection efforts (especially the manual audits); the overall aim is achievement of improvement and this gives a measure of the value of the data (and the value of the questions).

“… we were using our pharmacy teams to collect huge amounts of manually-collected data […] and we felt that actually we were spending a lot of resource in collecting data that was disproportionate to the improvements we were looking to achieve.”

From operations’ performance to medicines’ questions

Beyond the performance of the Pharmacy Unit, achievement of overall business objectives is the safe and appropriate use of medicines – the right medicines given to the right patients at the right times (the ‘three rights’ that are the goal of most pharmacy services’ activities). The hope is that digital data about medicines will enable answering questions about the right (or wrong) supply and use of medicines. These will be expressed in increasingly complex questions – e.g. not just about actions but about rationales for actions. The hope is also that answers to these types of questions will be able to inform different ways of improving quality and safety and medicines use.

Questions about the use of antibiotics are an example because they encompass both the safety of individual patients, the outcomes of patients treated with that medicine (e.g. for reasons of research), and also more generally stewardship to tackle the challenges of antimicrobial resistance [10] and achieve wider societal benefits. Using antibiotics (antimicrobials) as an example, the extracts below show the connection between the different steps in the process, from one question, to data and then more questions, and eventually identification of areas for improvement (such as providing training or better information for doctors).

“So antimicrobials is a really good example and […] [we have] very specialist people who are very interested in the fine detail of which drug by which consultant to which patient, …”

“…, but then there is another element [of interest, about patient safety] of which patients: has anybody tried to prescribe a drug, an antimicrobial say, to a patient who’s classed as allergic to an antimicrobial? ….”

“… because there are some patients who the risk of giving a medicine to, is much less than risking them having an allergy, but then is equally the one in a million where it’s a serious life consequence. […] our job is to identify the patients it’s okay to do it in and make sure that there’s a good rationale for doing it, and the ones that it’s not okay to do it in…”

“… [with the data from EPMA] we will have, if you like, the ones who have tried to prescribe it and continue to prescribe it - and then we’ll have for those a reason for them continuing to prescribe it - and we’ll also be able then to see how many doses the patient had and the outcome of the patient.”

“We’ll also be able to see the number of doctors who tried to prescribe [for] a patient who was allergic a drug and then chose not to proceed. And they are, they’re equally of interest to me because actually they tell us something about whether the system […] has introduced a barrier to improve safety or not.”

“So what we would then need to know is: were those doctors or prescribers trying to prescribe something because they had lack of information or just because they didn’t think about it, or what
was the rationale, and at the moment the only thing we can explore is, is where it’s gone wrong, ...”

**From (retrospective) questions to (prospective) guidance to use**

The meta-question posed is ‘what are we really trying to achieve’ with the data and by answering those questions. The overall aim of knowing whether patients have been given the right (or wrong) medicine is to make sure that it does (or does not) happen again, and that it does (or does not) happen to other patients. The digital system may enable a shift from retrospective data collection and use, to prospective ‘decision support’ and behavioural change. The idea is: instead of, or as well as, trying to collect digitally the same data that were collected on paper (such as a 3 day antibiotic review), change the data points to generate different behavior at the point of care.

“... actually you could [...] say, “Well you might change your measure from Day 3 to a 48 hour review”, so if the system has something that collects a 48 hour review in it, you would ask yourself, “Well do I really need a Day 3 box ticked?” So yes, there is a bit of what are you trying to achieve with that number, and actually if you go back to the patient experience and the patient safety bit, we’re trying to make sure that only patients who need antibiotics get them, and part of the reason for the Day 3 is that’s the point at which you should have all of the information to make a decision. Well, you might be able to, if our systems were slick, [...] make a decision at 48 hours, which would be even better because that would mean that you’re not exposing patients to a longer treatment than they need to have of a certain antibiotic, and so it might help us smooth that out, absolutely, and I’m a great believer in once you can scan data you might say, “Well actually I’d rather have that data than this data,” and that data will help me answer a question differently. So I absolutely think it will do that....”

**The business of the pharmacy meeting ‘clients’ and patients’ needs**

Returning to the service delivery perspective, data is only a means to an end, and the overall goal is client satisfaction – mainly patients, but also clinicians using the services of the hospital pharmacy, and the clinical commissioning groups paying for them. Satisfaction and user experience are better assessed through gathering qualitative data and user feedback. It is not all about data points, but just as much about relationships, communication and trust. And it is also about being able to answer or pre-empt their (commissioners’, patients, clinicians) questions.

... for me, data is a single tool that we use to ensure quality and safety, so my bigger remit around governance quality and safety is about making sure that we do everything that we should be doing, that the outcomes are the outcomes we are looking for and that our patients are looking for, and so data is only one element of that because data is only about numbers, not about experience, and you could have the best numbers in the world and have a poor experience.

Because if the delivery of the service is spot on but doesn’t have your patient as the focus, then you’re not getting the outcome.

So there’s a bit of qualitative data and a bit of quantitative data that you need to look at in tandem.

[...] So patient, direct patient feedback about their experience is probably the gold standard, but also not forgetting that what we do is also with our staff, so nursing staff’s feedback about the availability of medicines in their workplace. Feedback from doctors about their training on prescribing or the availability of information to help them prescribe safely, that type of information about our service providers is also really important to us.

“And our commissioners... [...] because our commissioners commission us to use medicines in certain ways and so some of what we monitor is to make sure that as an organisation we’re only using those medicines to treat the patients that we’re asked to treat, [...] So there are some very expensive medicines usually, or medicines with a poor safety profile, and collectively we might say, “Well we only want to use [...] that drug to treat those patients with a specific condition or a specific set of circumstances”, and part of our job is to make sure that that drug is only ever used for those patients. [...]”

“So [for example] there are some medicines that we are told by commissioners that they only want us to use in patients with cystic fibrosis who have a very low respiratory measure and what we have to ensure is that we only ever prescribe it to those, that group of patients. It’s a bit like a NICE guideline, you know, NICE guidelines will say, “Only use this drug in these circumstances”, and that’s where eMeds will come into its own, because we will be able to say, “Tell me all the patients who’ve got that drug and tell me if they [meet] that criteria”, and then we’ll be able to say, “Yes that drug is only being used in patients with that criteria” or “There’s ten patients who you used it in who didn’t meet those criteria. Let’s go and have a look at the circumstances of that”. So, but actually part of our assessment is, “Do our commissioners trust us that we’re doing what they’re asking us to do?” and some of that’s around data but some of that’s also around how we interact with our commissioners.”

**Discussion**

In this case study of a pharmacy service unit, concerns about data are framed in terms of concerns for questions: what are the questions to ask and what questions data might be able to answer.

Digitalization of clinical care can certainly make data collection at the point of care less resource intensive and less time consuming, potentially making some of it available in real time. However, it also inevitably changes the type of data that is gathered, the opportunity costs implied. The data that were available in the past may not be available through the new digital systems, and traditional collection methods may need to be still used.

Overall, this may change the questions that can be asked and answered, and leads to a rethink of what the original questions were for, whether new questions would better achieve the overall aim. In particular new data ecologies can offer the potential for more holistic and overarching types of question relating to customer service, rather than task performance. Furthermore, the act of gathering data at the point of care (through clinician’s data entry into digital systems or by embedded technologies) for purposes of retrospective data analysis, can be transformed into information points for prospective guidance for action – such as when asking about patients’ allergies to antibiotics turns into a change in prescribers’ choice of medicine to treat the patient’s bacterial infection.

**Limitations**

This study is limited to only one interview, in one hospital, in one specific context, and should not be taken to represent the business of hospital pharmacies across all NHS hospitals in England or beyond. The interview is however taken from a larger dataset, and informed by observations of pharmacy and clinical activities across different hospital areas.
Conclusions

Digital data gives us the possibility of answering new questions, changing the questions we ask, and making questions and data-driven responses a more active part of health care delivery. It is by posing the right question that improvement in quality and safety can be achieved - not by access data alone.

Abstract

Decision support systems can alert physicians to the existence of drug interactions. The Hospital Italiano de Buenos Aires, Argentina, has an in-house electronic health record with computerized physician order entry and clinical decision support. It includes a drug-drug interaction alert system, initially developed under traditional engineering techniques. As we detected a high alert override rate, we rebuilt the knowledge database and redesigned the alert interface with User-Centered Design techniques. A laboratory crossover study using clinical vignettes showed that new alerts were more usable than traditional ones. This paper aimed to validate these results through a controlled and randomized experimental study with two branches (old vs. new design) in a real setting. We analyzed, quantitatively, every fired alert between April 2015 and September 2016. Finally, we performed user surveys and qualitative interviews to inquire about their satisfaction and perceptions. In real scenarios, user-centered design alerts were more usable, being more effective and satisfactory, but less efficient than traditional alerts. “Safe omission”, as a new concept, emerged from our stratified analyses and interviews.

Introduction

In 1999 the Institute of Medicine released the report “To err is human”, stating that a quarter of total medical errors were related to medication [1]. Even though most errors are harmless, some of them can cause variable damage, including death. Fifty percent of these errors take place during drug prescription [2]. A common mistake is to neglect drug-drug interactions (DDI) [3]. Clinicians awareness of DDI can prevent related adverse drug events, but at least half of the time they are not recognized [4]. Clinical decision support is “the use of information and communication technologies to bring relevant knowledge to bear on the healthcare and well-being of a patient” [5]. For example, if physicians enter medication orders electronically, these systems can show drug safety alerts, including overdoses, duplicate orders and drug-drug interactions. Therefore, clinical decision support systems seem to be an appropriate solution, as they have shown improvements in both quality of care and resource optimization [6–8]. Although, several studies showed their low performance and high override rate [9–12]. From our perspective, these systems have at least five potential drawbacks: Excessive alerts (mostly with low clinical significance) due to imprecise knowledge databases, leading to alert fatigue [13]; Low quality interfaces, lacking of workflow integration and intuitive design [14]; Lack of context information in the system hinders complex rules [15,16]; Absence of alert monitoring prevents improvement processes [17]; and Implementation variability, even for the same vendor, secondary to standards deficit [18].

In the mid-2000s, the Hospital Italiano de Buenos Aires, Argentina, implemented an in-house electronic health record system with computerized physician order entry (CPOE). Shortly after, we launched a clinical decision support system for drug-drug interaction alerts, developed with traditional software engineering. Clinical pharmacology experts created a local knowledge database in Spanish. We monitored periodically the CDSS performance and found a high alert override rate. Thus, we first focused on improving the knowledge database quality [19]. Our analysis included the systematic evaluation of each DDI according to clinical relevance, to eliminate combinations with a low probability of harm (false positives), as suggested in a recent consensus [20]. We also adapted the Lexicomp\textsuperscript{®} alert severity tiers according to potential reaction seriousness [21], following recommendations from Paterno et al. [13]. Only the two highest risk ratings (D and X) were considered clinically relevant and triggered intrusive alerts. As alert acceptance remained persistently low, the chief medical information officer ordered the DDI alert system withdrawal, to look for other potential issues. Previous research by Seidling et al. found that the alert display quality most strongly predicted DDI alert acceptance [22]. Therefore, we endeavored to improve the alert design through User-Centered Design (UCD) techniques, as they have demonstrated to increase adoption and usage efficiency of health information technology tools [23]. According to Patel and Kannampallil, human-computer interaction is a fundamental aspect to consider when developing computer systems [24]. UCD is a process framework that makes a system usable and understandable by accounting for end-users’ needs, wants and constraints, through the whole product cycle. Following perspectives from Norman, UCD starts by understanding and specifying the context and requirement analysis, and then designing and iteratively testing solutions [25]. This systematic process is regulated by ISO 9241-210 “Human-centered design for interactive systems” [26]. For Kushniruk et al. participatory design goes beyond UCD and cooperative design approaches to include end users as active participants in the design and decision making [27]. We started the analysis with an heuristic evaluation [28] of the standard alert, noting several issues regarding minimalism, consistency, feedback, visibility and documentation. Then, we reformed the DDI alerts by using a participatory design approach. As described in a state-of-the-art reference handbook for the
subject, participatory design can be defined as "a process of investigating, understanding, reflecting upon, establishing, developing and supporting mutual learning between multiple participants in collective 'reflection-in-action'; the participants typically undertake the two principal roles of users and designers where the designers strive to learn the realities of the users’ situation while the users strive to articulate their desired aims and learn appropriate technological means to obtain them" [29]. A team of three health informatics specialists and two usability experts worked with final users following the ISO 9241-210. This phase took place at the HIBA from September 2013 to April 2014, and was undertaken in three stages (inquiry, participatory design, and usability testing), as described in a previous publication [30]. The whole process was iterative; each stage included prototyping cycles for domain saturation to reach the best possible model. The participants were physicians that worked in outpatient and inpatient settings. Fictitious patient scenarios (clinical vignettes) were developed based on real clinical cases [31], taking the most frequent and significant examples of DDI from our clinical data repository [11]. The last UCD prototype was developed as a new software version [30]. Afterwards, we performed a laboratory crossover study to test its usability, using new clinical vignettes. We found that new alerts were more usable than traditional ones, regarding efficiency, effectiveness, and user satisfaction [32]. A deep insight of this study was published recently in the Journal of Biomedical Informatics [33].

This paper aims to validate the lab results in a real scenario, through a controlled and randomized experimental study, measuring the same variables as preceding studies (efficiency, effectiveness and user satisfaction).

Methods

Setting

The Hospital Italiano de Buenos Aires (HIBA) is a non-profit healthcare academic center founded in 1853, with more than 2,700 physicians, 2,700 other health team members (including 1,200 nurses), and 1,800 administrative and support employees. The HIBA network includes two hospitals in Buenos Aires city and its suburban area, 750 beds (200 for intensive care), 41 operating rooms, 800 home care beds, 25 outpatient clinics and 150 associated private practices. It has a Health Maintenance Organization (Plan de Salud) that covers more than 150,000 people and provides health services to another 1,500,000 people who are covered by affiliated insurers. Between 2013 and 2014, the HIBA admitted more than 45,000 inpatients, conducted 45,000 surgical procedures (50% ambulatory) and 3,000,000 outpatient visits. The HIBA is a teaching hospital, with more than 30 medical residency-training programs, 34 fellowship programs and 400 residents and fellows in training.

Since 1998, the HIBA has run an in-house developed health information system, which includes clinical and administrative data [10]. Its Electronic Health Record system called Italic, is an integrated, modular, problem oriented and patient centered system that works in different clinical settings (outpatient, inpatient, emergency and home care). Italic allows computerized physician order entry for medications and medical tests, and storage and retrieval of test results, including archived images. It was the first hospital in Argentina and the second in Latin America to be certified by the HIMSS as level 6+ in the Electronic Medical Record Adoption Model. In recent years, our Health Informatics Department at the HIBA prioritized UCD in the design and development culture to enhance the usability of healthcare software. We conducted lectures, launched a pilot project, and assembled a usability team for service and dissemination [34].

Methodological Design

The HIBA Institutional Review Board approved the research protocol. The study was performed in a tertiary academic center, with users from different settings (outpatient, critical, and non-critical inpatient). For our experimental study, we randomly assigned physicians (system users) to two branches. We compared two different DDI alert interfaces: the standard one (developed under traditional techniques) and the participatory design model, generated under UCD techniques. Drug-drug interaction alerts were reinstated to the prescription system in April 2015. The clinical decision support system used the same DDI knowledge database and inference engine from previous stages of the study. The alert system ran every time a new prescription was placed and searched the knowledge database for potential interactions between each substance already on the list and the new drug. When an interaction was detected, the system opened a DDI alert modal (a dialog box or pop-up window that was displayed on top of the current page). Depending on the assigned branch, the physician would see the standard or the UCD version of the alert. The standard DDI alert interface can be seen in Figure 1.

Compared to the standard version, the new interface version had a different communication message, changing the displayed elements, warning colors and proposed actions (as shown in Figure 2). New output actions were specifically created for the novel DDI alerts.

Study Population

Physicians fulfilling the exclusion and inclusion criteria were selected for each clinical setting (outpatient, non-critical, and critical inpatient). All had worked with CPOE but had not been recently exposed to the original DDI alert, because it had been withdrawn more than 3 years earlier. Inclusion criteria were as follows: working as a physician of any specialty in the hospital for more than a year by March 2015. Physicians with previous participation in alert design or test stages were excluded. Users were randomized using their hospital ID to one of the two branches: the original interface and the participatory design version. None of them were aware of this allocation.
Measurements

We retrieved data from every fired alert from May 1st 2015 to September 30th 2016. We analyzed the metadata from each of them, including: the date and time, number of clicks on the “learn more” link and on the action buttons (“accept”, “cancel” and others), and the text for override justification. We also retrieved participants’ demographical information. All data was treated confidentially, and accessed only by authorized researchers. As in the previous lab study, efficiency, effectiveness and user satisfaction were selected as usability metrics to compare the performance of the new UCD alert against the standard version. Efficiency was measured as the time required to resolution. We defined that the alert was solved when the user finished the tasks and closed the modal window. As we could not witness participants’ reactions as in the lab study, we measured effectiveness according to the actions taken within the alert: it was “accepted” if the user decided not to prescribe the causative medication (or chose other alternative option), and was “canceled” if he kept the prescription. One way of identifying confounding is to examine the primary association of interest at different levels of a potential confounding factor. Therefore, we performed stratified analyses for both types of interfaces depending on different criteria: Interaction risk rating (severity); Setting: outpatient, critical, or non-critical inpatient; User seniority; Pair of drugs (combinations). Regarding user satisfaction, a brief survey translated and adapted from Zheng et al. [35] was conducted. It was similar to a Likert scale, in which the respondent indicated the degree of agreement with the satisfaction statements on a 4-point scale: totally disagree, disagree, agree, and totally agree. We automatically sent the questionnaires through Surveymonkey® [36] to every user exposed to an alert. The message started with a short explanation on the subject, and showed a sample image of the alert that has been previously displayed. The system sent a reminder email after 48 hours. We closed the poll after 25 responses from each branch, considering domain saturation. We also collected user perceptions through direct qualitative interviews to a sample of exposed physicians. They were invited by email and we scheduled a meeting with those who accepted.

Statistical Analysis

Descriptive statistics were presented for all variables in the comparative study. Interval variables were parameterized by mean, median and quartiles. For categorical variables, the observed frequency (total number of observations within the category) and relative frequency percentages were used. Statistical analyses for all tests were performed using the R software environment from R Project for Statistical Computing [37]. Statistical significance was considered when the probability was lower than 0.05.

Results

We analyzed the metadata of every triggered DDI alert from May 1st 2015 to September 30th 2016, within the hospital CPOE. There were 310 DDI alerts shown to different physicians: 168 (54%) were traditional alerts and 142 (46%) were UCD alerts. See Table 1 for demographic information. From 4141 drug interactions included in the knowledge database, the highest severity risk rating D and X represented 10% (440 combinations). In this study, there were just 94 pairs of drugs (2%) involved in the alerts during the yearly analysis.

Table 1– Demographics of Participants from both Branches. Year values are expressed as median (Q1 –Q3).

In Figure 3 we present the results of one of the questions from the satisfaction survey.

Figure 3—Satisfaction Survey Results regarding Alert Utility: “DDI alerts are useful for patient care” (p = 0.03). The bars represent the amount of answers for each degree of agreement. Red is for UCD and blue for traditional interface.

We performed 12 interviews, 5 were traditional and 7 UCD interface users. We analyzed their perceptions on the triggered DDI alerts. Utility perception differed regarding seniority, with better appraisal from junior physicians.

Discussion

This paper shows the fourth phase of a long-standing research project at the HIBA. The first phase implied the knowledge database redesign [19]. The second phase included two cycles of participatory design sessions, in which interface prototypes and evaluations focused on qualitative aspects [30]. Participants agreed that they wanted short, clear, and quick alerts [14,15]. A laboratory crossover study using clinical vignettes was the third phase. It showed quantitatively that our UCD method was a reliable way of designing and developing better DDI alerts. The results regarding effectiveness, efficiency, and user satisfaction were similar to those in Russ et al. [23]. Regarding efficiency, the new interface required less time to complete the task but the same amount of clicks and justification words as in the old one, probably due to quick and enhanced interaction with the alert. The UCD interface showed statistically significant improvements in effectiveness and user satisfaction. The interviews showed that nearly 60% of the users preferred the UCD interface.

Such promising results required a real scenario validation study. Regarding the alert override, our results were similar to previous publications that reported cancellation rates between 49% and 96%[9]. The global effectiveness was higher for the standard version, opposing our previous lab study results, in which the UCD interface performed better. We then performed a stratified analysis and detected that there were no significant differences in effectiveness regarding X risk rating (“avoid combination”). The D risk rating (“modify regimen”) had a slight trend for the standard version. The qualitative approach of surveys and interviews gave an insight on these results. The surveys were answered a long time after the alert exposure (weeks), thus they might reflect user attitudes towards the software instead of their opinions on the task itself. The new UCD alert scored better in the satisfaction survey than the traditional alert. From the interviews analyses, we discovered that senior staff relied more on their clinical experience, while junior physicians appreciated the benefits of the decision support. Both agreed about the utility of the new UCD alert, as it can prevent unintended errors especially in the context of urgencies, work overload, and time constraints. Resident physicians also used the CDSS as a learning opportunity. We also realized that alerts usually fail to change the physician intention to prescribe. Thus, providers keep ordering the drugs despite potential interactions. Although, they monitored the drug effect and adverse events as they have been warned in advance. We named this medical awareness as “safe omission”. This might be underlying the high alert override rate found in many previous CDSS studies.

The research was done in a single academic center using in-house developed software and thus might not represent other institutions.

Conclusion

In real scenarios, user-centered design alerts were more usable, being more effective and satisfactory, but less efficient than traditional alerts. “Safe omission”, as a new concept, emerged from our stratified analyses and interviews.

It is necessary to continue the analysis of human-alert interaction, especially regarding the “safe omission” phenomenon. Further research in this field is recommended.

Abstract

Adherence rates for timely imaging follow-up are usually low due to low rates of diligence by referring physicians and/or patients with following recommendations for follow-up imaging. This can lead to delayed treatment, poor patient outcomes, unnecessary testing, and legal liability. Existing follow-up recommendation detection methods are often disease- and modality-specific. To address some of these limitations, we present a generic radiology report processing pipeline that can be used to extract follow-up imaging recommendations by anatomy using an ontology-based approach. Using a large dataset from three hospitals, we discuss our methodology in the context of identifying follow-up imaging recommendations that are related to lung, adrenal and/or thyroid conditions. The algorithm has 99% accuracy (95% CI: 95.8-99%). We also present an interactive dashboard that can be used to understand trends related to follow-up recommendations.

Keywords:
Medical Informatics Applications; Follow-Up Studies; Quality Assurance, Health Care

Introduction

Radiology reports often contain follow-up imaging recommendations for further diagnostic characterization or to ensure stability of a potentially malignant lesion [1]. Sometimes, these findings are not expected by the ordering provider and are commonly referred to as incidental findings since they are incidental to the reason for the current exam – for example, a small pulmonary nodule in the lower lobe of the lung may be detected on a computed tomography (CT) abdomen study that was ordered to rule out appendicitis. Failure to appropriately address imaging follow-up recommendations in a timely manner is common (in one study, 12% of cases of potential malignancy [2]) and can lead to delayed treatment, poor patient outcomes, unnecessary testing, lost revenue, and legal liability [1-4].

Imaging follow-up adherence is low and over 35% of follow-up imaging recommendations are usually not followed [5]. Clinicians may determine that follow-up is unnecessary, especially when a follow-up recommendation is conditional on clinical findings that were not available to the radiologist making the recommendation [1]. In one study, follow-up rates dropped from 78.8% for no conditional language to 43.8% when conditional language was present [6]. Various other reasons have been attributed to failure to follow-up, including the referring physicians missing the recommendations or losing track while addressing a more acute illness, loss of information during handover between care teams, the recommendation not being communicated to the patient, and the patient failing to schedule or show-up for the follow-up appointment [7]. The first step towards ensuring timely follow-up of imaging recommendations is to detect presence of recommendations in radiology reports. Several researchers have explored how follow-up recommendations can be identified, but much of prior work has focused on identifying follow-up recommendations for a specific modality, such as CT, incidental findings only [8, 9] or a particular type of finding, such as pulmonary nodules [10] or adrenal masses [11]. In order for follow-up detection algorithms to be more useful in practice, they need to be scalable and generic so that recommendations can be identified from all radiology reports irrespective of modality and type of finding.

To address some of the limitations in currently available techniques, we present a radiology report processing pipeline that can be used to: (1) extract follow-up recommendations, and then (2) extract the anatomy related to the follow-up recommendation. Being able to associate a follow-up recommendation with anatomy has three main benefits. First, it allows for identification of different types of findings (e.g. lung nodules) to be recognized in a generic manner; second, it provides a mechanism to quantify follow-up recommendations by anatomy (e.g. all lung findings) which can be used to determine appropriate interventions to improve follow-up adherence, focusing on radiology sections where adherence is particularly poor; and third, the anatomy can be used as a surrogate to identify incidental findings by determining follow-up recommendations where the associated anatomy is not the same as the anatomy of ordered exam. The purpose of this study is to propose a novel pipeline to extract specific follow-up findings with their associated anatomic region.
Methods

Dataset and Strategy

We extracted 417,448 radiology reports generated between 1 January 2015 and 31 May 2016 from the University of Washington radiology information system for three network hospitals. For each report, several meta-data fields were also extracted, including exam date, radiology subspecialty, patient class and modality. The Human Subjects Division at the University of Washington determined that the study was IRB exempt as part of a quality improvement project.

The first step in the process was to identify reports that contained a follow-up recommendation. This was performed using a previously developed follow-up detection algorithm which parses the radiology report to extract sections (e.g., “Clinical Indication”, “Findings” and “Impression” as shown in Figure 1), paragraph headers within each section if any (e.g. “Abdomen” and “Pelvis”) and the sentences within the paragraphs. The algorithm then evaluates the sentences within the “Findings” and “Impression” sections to determine if a sentence contains a follow-up recommendation (e.g. “Given history of malignancy, follow-up CT chest in 3 months is recommended”). Follow-up detection is performed using keyword searches and other heuristics. The output of this first step is a list of follow-up recommendation sentences as shown underlined in Figure 1 (along with meta-data, such as whether it is a negated sentence – e.g. “no further follow-up is necessary”). Using 532 reports annotated by three radiologists (including author MG) as the ground truth, the detection algorithm was evaluated to have 93.2% PPV (95% CI: 89.8-94.5%), 99.5 NPV (95% CI: 98.4-99.9%) and 97.9% accuracy (95% CI: 96.2-98.5%).

Next, to identify anatomy associated with the follow-up recommendation, we used an ontology based natural language processing engine we developed internally [12] along with publicly available NCBO annotation service [13]. Queries to both services were constrained to extract anatomies as defined by SNOMED-CT ontology. Results were then merged and unique values selected. This approach was selected to optimize the capabilities of the two systems, for instance, if the text contains “right lower lobe”, the anatomy engine would detect “Structure of right lower lobe of lung” corresponding to SNOMED ID 266005 whereas NCBO would not find a mapping. Conversely, from the sentence “hypervascular liver lesion, MRI follow-up is suggested”, NCBO detected “Liver Structure”, corresponding to SNOMED ID 10200004 whereas the internal engine identified “Lesion of liver” (SNOMED ID 300331000), which is a finding. Since our focus is on identifying anatomy, in this instance, the engine did not find any relevant anatomy since a longer phrase was matched.

Our follow-up anatomy detection algorithm was developed such that it first attempts to extract anatomy from the follow-up sentence – for instance, concept “Thoracic Structure” corresponding to ID 51185008 will be extracted from “Follow-up CT chest is recommended”. If no anatomy is identified in

Figure 1 – Sample radiology report with multiple follow-up imaging recommendations
the follow-up sentence, the algorithm steps backwards from the follow-up sentence, processing one sentence at a time, until at least one anatomy is identified in a sentence. Search was restricted to the section follow-up sentence occurred in (which is usually ‘Findings’ and/or ‘Impression’ sections). Once identified, the ‘anatomy context’ becomes the text from the beginning of matched sentence to end of follow-up sentence. This process was repeated for all follow-up sentences when a report contained multiple recommendations. Table 1 shows four examples of extracted anatomy. For each follow-up recommendation, we also keep track of the previous two sentences which is referred to as ‘search context’. This search context can then be queried using regular expressions to detect the type of follow-up (e.g. whether follow-up recommendation is for a pulmonary nodule).

A quality improvement oversight committee composed of multiple clinical and quality stakeholders focused first on three commonly occurring findings for which published follow-up guidelines exist: lung, thyroid, and adrenal nodules. Consequently, the scope of current research identified follow-up recommendations for these three findings. Keywords ‘nodule’, ‘lesion’, ‘tumor’, ‘lump’, and ‘mass’ were included for all three, while several additional descriptors were included at a finding-specific level. We included ‘opacity’ for lung findings; ‘hypodensity’ and ‘fullness’ for adrenal findings; and ‘hypodensity’ and ‘opacity’ for thyroid findings. We required one of these nodule-related words to be within a 6-word proximity (after removing stop words) of where the anatomy was detected within the anatomy context to ensure the finding was truly related to the detected anatomy.

To validate our algorithm, we manually selected 50 reports for each of the three follow-up finding types as well as 50 reports that contained a follow-up recommendation but were unrelated to the lung, adrenal or thyroid. This was performed by searching for the specific finding types in the “Findings” and “Impression” sections of randomly selected reports and repeating the process until the required dataset of 200 reports was created. The algorithm performance was 98.7% sensitivity (95% CI: 96.5-98.7%), 100% specificity (95% CI: 93.6-100%), and 99% accuracy (95% CI: 95.8-99%). There were two false-negatives, one related to an adrenal nodule and the other related to a lung nodule. A false-negative was defined as an instance where follow-up detection or anatomy extraction failed. Overall accuracy was slightly better than 97.9% follow-up detection accuracy reported previously since detection errors were rectified prior to anatomy extraction, which is the focus of the work presented herein.

Results

There were 67,521 (16.2%) reports that had at least one follow-up imaging recommendation sentence. Of these, 5,547 exams contained at least one of the three specific finding types of interest. Table 2 shows distribution of the follow-up recommendations by finding type and Table 3 shows distribution by scanned modality. There were 4,265 CT Chest exams for all anatomies that contained a follow-up recommendation of which 3,451 (80.9%) were lung related.

In order to provide radiology administrators with a quick overview of departmental trends and ability to monitor effectiveness of QI interventions over time, we also developed an interactive dashboard (using Microsoft Power BI [14], Microsoft Corporation, Redmond WA) that shows the number and rate of reports containing follow-up sentences by anatomy, modality as well as by month. Various filters have been provided so that the data can be explored to understand trends and identify barriers to improvement. Figure 2 shows number of follow-up reports containing recommendation sentences that are lung, thyroid or adrenal related for all sections across all three hospitals for the entire duration. A user can easily explore the underlying data that contributes towards a particular metric, for instance, a user can right-click on the CT bar showing 4.26k and examine specific reports.

Discussion

In this paper we have outlined a generic pipeline that can be used to extract follow-up recommendations and their associated anatomy using an ontology-based approach. Using production data, we have demonstrated how the pipeline can be used to extract follow-up recommendation sentences associated with lung, thyroid, and adrenal nodules for multiple imaging modalities. Using the follow-up anatomy detection capabilities, radiology administrators can determine which radiology sections make more follow-up recommendations (as a percentage) and design appropriate interventions to improve follow-up adherence rates. Further, the technology has the potential to be used as a surrogate to identify incidental findings by filtering for exams where the anatomy of follow-up recommendation is different from anatomy of ordered exam. The generic nature of the anatomy and finding extraction algorithm could also be more scalable compared to some of the prior work where the primary focus was on identifying follow-up recommendations for a specific modality, patient setting or a particular type of finding [3, 8-11, 15]).

Despite using a large dataset from three institutions, the current study has limitations. First, all reports were created using common dictation macros (with somewhat limited expressiveness compared to fully free text reports) that are shared across
the network hospitals and therefore the methods used to parse radiology reports may not be readily generalizable to other institutions. Second, the algorithm performed imperfectly in 2 out of the 200 reports we examined. In one of these instances, the algorithm missed the follow-up statement which was mentioned in conjunction with another (“The attenuation coefficient of the left adrenal nodule is about 10 Hounsfield units. Therefore, it cannot be characterized as an adenoma. This could be characterized by CT at the same time as a renal mass protocol”). Although the pipeline failed to recognize this recommendation, it did identify the follow-up recommendation for the renal mass in the previous sentence, potentially ensuring that follow-up would occur. In the other failed instance, “Multiple gray nodules are unchanged in size compared to prior, but remain indeterminate. Recommend follow-up CT in 12 months to assess for stability”, the follow-up recommendation was correctly detected, but the anatomy was not (“gray nodules’ does not match any anatomy concepts in SNOMED). In fact, this also shows some of the limitations of using an ontology-based approach to detect anatomy. Complementing the ontology-based approach with domain-specific dictionaries (e.g. using a text-to-anatomy dictionary where “gray nodule” is a key used to refer to anatomy “lung”) could be one option. We are also looking into generalizing the detection of nodule-related concepts. For instance, filtering for ‘morphologic abnormality’ concepts in SNOMED could be an option instead of specifying variants for ‘nodule’.

There are several potential applications for this algorithm in our department. First, it can be used as a means to improve precision of follow-up recommendation sentences. We have found that a significant proportion of follow-up sentences did not contain the follow-up imaging modality (18%), a recommended timeframe (67%), or both (11%). These incomplete follow-up recommendation sentences can be confusing for ordering clinicians who are unfamiliar with published imaging follow-up guidelines. We are in the process of implementing standardized follow-up macros and ensuring guideline uniformity among radiology sections in our department, and plan to measure the impact using this pipeline. Second, we can use this algorithm to benchmark our own compliance rate and variability with published clinical and departmental follow-up guidelines. Third, we can use this algorithm to ensure timely follow-up imaging of the appropriate body region using the appropriate modality.

To improve follow-up compliance and appropriateness, it is important to identify follow-up recommendations with their associated anatomic location. We have demonstrated that a robust pipeline can be developed to identify lesions of the lung, thyroid, and adrenal glands to measure quality of the follow up recommendation and to ensure timely follow-up. Given the large number of anatomic sites and diseases that are associated with these recommendations, it is important to have techniques that are easily extensible without excessive human rework. The proposed generic report processing pipeline shows potential to be used as one such approach.

BarCode Medication Administration in ICU: Learning from Our Nurses

Thelma Maydana, Liliana Giraldo, Zulma González, Bibiana Schachner, John Mayan, Daniel Luna, Sonia Benítez

Department of Health Informatics, Hospital Italiano de Buenos Aires

Abstract

Errors during drug administration stage represent a significant percentage of adverse events associated with health care. Its prevalence is higher in critical care units, due to vulnerable patient population, characteristics of intensive care as well as complexity of pharmacotherapy. Errors can occur at any stage of the medication cycle although they often occur during administration, so nurses’ role in prevention is essential. The bar code medication administration (BCMA) technology increases patient safety by instituting control time, but a poorly designed system or a faulty implementation can lead to low utilization in future. This paper describes implementation, evaluation, detection of problems and search for their possible solutions of a BCMA system in the intensive care unit at Hospital Italiano de Buenos Aires.

Keywords: Patient Safety; Medication Systems; Medication Errors

Introduction

Patient safety has become a priority for health care systems around the world. Several studies have shown that morbidity and mortality caused by drugs are very high. Even more alarming issue is that this problem is largely due to errors or faults that occur during hospitalization [1-2]. (Leape, 1995) and (Bates et al., 1998) also indicated that drug-preventable errors occur more frequently in prescribing (56%) and administration (34%), and to a lesser extent in transcription (6%) and dispensation (4%). The easily intercepted errors were those that occurred in the early stages of the process, specifically prescription (48%) – of which 29% were due to lack of knowledge of the drug or that of the patient [3-4]. Other authors indicate that errors occur more frequently in the stages of preparation and administration of drugs, as well as 78% of medication errors leading to an adverse effect are due to failures in the prescription-dispensation-administration circuit, which could be optimized with the use of computerized information systems [7-8]. In intensive care unit (ICU), medication errors can occur in one-third of hospitalized patients and have the potential to cause permanent damage to patients, prolong hospital stay, and add to the associated emotional and financial costs [3-4]. Preparation and administration of drugs are the sole responsibility of nursing staff in most health organizations and hence we need to emphasize the importance of the safety culture. Furthermore, there are multiple causes for errors in preparation and pharmacological administration in hospital environment, such as: overload, lack of knowledge, human errors including inattention and defective work processes [9].

The BCMA system makes the drug administration process safer by reading the barcode on patient's identification bracelet and that of the medication pouches to ensure that the correct medication, in the correct dose, is administered to the right patient in the right way and at the right time [10]. The processes intertwined with barcode control, such as medication administration, contribute to patient safety through barcode technology and real-time network connectivity and are used to improve the accuracy of drug administration. This system is currently limited to environments equipped with computers, barcode readers at bedside, and compatible information systems [11-12].

The objective of this work is to describe implementation of a BCMA system and evaluation of its use in the ICU at Hospital Italiano de Buenos Aires (HIBA).

Methods

Setting

Hospital Italiano de Buenos Aires (HIBA), in Argentina, is an institution with 150 years of history, with over 2700 physicians, more than 1200 nurses, and 1800 administrative and support employees. It is a university hospital that covers the entire spectrum of health care from outpatient care, emergencies, acute care, medical and surgical specialties, critical care, home care, and chronic care. It encompasses a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 800 home care beds, 25 outpatient clinics, and 150 associated private practices located in Buenos Aires city and its suburban area.

The institution has been designing and building its own health information system since 1998 that includes clinical and administrative data. Its Electronic Health Record (EHR) system is an integrated, modular, problem oriented, and patient centered system that works in different clinical settings and allows computer physician order entry for medications and medical tests, storage and retrieval of tests results and images, and communication system. It is Joint Commission International (JCI) accredited and has been recently certified by the HIMSS as level 6+ in the Electronic Medical Record Adoption Model (EMRAM), being the first hospital in Argentina and the second in Latin America reaching this stage. The electronic nursing record was developed in stages since 2010. It is integrated in the EHR and organized by sections: Assessment, Diagnosis, Planning, Implementation and Evaluation. Nurses are expected to follow the nursing process logic to document the care provided.
The intensive care unit (ICU) consists of 38 beds, divided into four sectors according to a severity criteria and therapeutic requirements of the patients. Rooms are individual for each patient and each one has a computer on wheels dedicated to the room. 100 nurses work in the area, distributed in 5 shifts (morning, afternoon, night A, night B, and weekend).

Design

Descriptive, observational study with quantitative and qualitative data analysis.

Area selection

Situation diagnosis: Different inpatient scenarios were surveyed during 2015, taking into account nurse-patient ratio, workstation locations, displacement spaces, and feasibility of diverse devices (computer/mobile). Finally, the ICU was selected because it had a specific bunker for preparation of medications, and also the ICU rooms are individual, each having a computer.

Equipment: Each room was equipped with a barcode reader with a usb cord because the distance between the computer and the patient was short (3-5 meters) and the usb type was less expensive than the wireless one. The area (called a bunker) for preparation of medications was equipped with label printers to identify medications.

Software Development

New Features: A medication preparation work list was initially developed in the EHR, where the medication preparer can filter the medication according to its sector, patient, route and schedule and print medication identification labels with QR codes (“Quick response” codes, a type of two-dimensional barcode) which contain the ID of the medical prescription, patient ID, drug, dose, route, and schedule. At the time of the medication administration, the data are checked against the identity of the patient by reading an identifying bracelet containing the data in the QR code. In addition, a new functionality was developed to record administration through barcoding, only visible in the EHR in the Adult Intensive Care Unit (ICU) and embedded in the administration section of the nursing e-chart. The barcode scanning of drugs is not available for 100% of the drugs administered to patients and hence the possibility of manually recording them remained available. This way nurses can choose the method they want to use.

Implementation

In-service Education and Training: Informatics nurses and physicians trained ICU nurses for all shifts. The bar-code scanner use and the new EHR feature were demonstrated. The new functionality was launched in April 2015.

Support: Support was provided in the sector during the first month after implementation to answer questions arising from the use, solve problems associated with the scanners and codes, and to train nurses who had been absent during the in-service training. In addition, the nurses had an institutional help desk for ordering.

Evaluation

Usage Rates: Queries were made to the database to know the barcoding (BC) frequencies in comparison to the manual records in the EHR in the following months after implementation.

The use of BC was always below the expected values compared to the manual ones, taking into account the drugs available for barcode scanning in our institution.

Survey and Operating Groups: An evaluation was made using the survey technique and operating groups (OG) for data collection in November of 2015. Two meetings were conducted based on a convenience sample with 30 ICU nurses. They were given a semi-structured questionnaire to evaluate how they felt about the BCMA system that asked about: ease of use, weight of scanner, system utility, interference with patient care, training, support, level of satisfaction with the system, and suggestions. The coordinators of the evaluation then proposed group reflection and discussion activities based on topics related to: a) BCMA benefits, b) problems associated with its implementation in the ICU, c) knowledge of process steps, and d) technical support. The activities were carried out during working hours and in both meetings the nurses were separated into subgroups of 4-5 people who were given a paper and pen to take notes.

The data analysis included descriptive statistics and content analysis for observations and suggestions.

Results

248,091 records of medication administration were made in the EHR during 2015 – of which 63,741 were made by BC and 184,350 were made manually. 249,238 records of administration were made during 2016 – of which 118,059 were made by BC and 131,179 were made manually. Figure 1 shows the number of administrations with both methods by month for both the years. There are more records of administration carried out manually during 2015 versus with barcode scanners, with the exception of September 2015 when the records using BC were slightly higher. During 2016, there was an increase in BC records in the month of April and the period from July to October, with a decrease in November.

21 nurses answered the questionnaire. 58% had been working in the hospital for 1-10 years and 33% between 11-20 years. 62% belonged to the shift “morning”, and the rest from afternoon shift. 50% were within the range of 30-39 years of age. In addition, 76.2% had a bachelor's degree in nursing. 18 participants (95%) indicated that the BCMA system was Very easy/Somewhat easy to understand and 15 (79%) reported that it was Very easy/Somewhat easy to use. Regarding the ease of scanning the bar-codes, 13 respondents (68.5%) indicated that it was Very easy/Somewhat easy and 2 persons noted that it was Somewhat difficult (10.5%). 17 of the respondents (90%) Agreed/Somewhat agreed that the BCMA system was useful for their work. Regarding interference with patient care (awakening or discomfort), 7 nurses (37%) considered that it interfered with the patient, while 53% (10) indicated that it did so Little/Nothing. At the same time, 18 (95%) participants indicated that the system reduces the probability of medication errors. In addition, 14 nurses (77.8%) indicated that they had received training to use the system while 4 responded that they did not. 56.3% (11) indicated that system failures received technical support to solve it, while 37% (7) said no. Of the total respondents, 58% indicated that they were satisfied with the use of BCMA for medication administration while the remaining (42%) were moderately satisfied.
Three themes were identified related to: hardware, software, and process and infrastructure (including sub themes like training and technical support). Problems related to bracelets and difficulties in scanning the codes were reported. Other obstacles identified were: the slowness of EHR when the nurses choose to do administration with BC, the wires of usb scanners that drag over the floor and then pass over the patient's bed, which makes them unhygienic or they are unplugged when scanning the identification bracelets, so the process must be started all over again. Also the impossibility of scanning some medication such as the so-called ‘multi dose’ emerged, and those related to changes of the daily programmed medical indications. The most important findings are presented in tables 1-3:

### Table 1– Hardware

<table>

<tr>
<td>‘The BCMA system does not record the minutes’</td>
</tr>
</tbody>
</table>

### Discussion

The objective of this work was to describe the implementation of barcode technology for medication administration as well as the evaluation of its use in the adult ICU. 18 months after implementation, BCMA records continue to be lower than those manually recorded. They could not be 100% since we do not have the possibility to scan all medication labels, a factor to consider when implementing a BCMA system [13]. In those months where improvements were appreciated, it is due to greater monitoring and support in the area, associated with the processes of accreditation we were going through, similar to those during JCI audit (September, 2015) and the EMRAM-HIMSS certification process (April, 2016). Under such circumstances, each problem was solved by assigning specific personnel to the task. Also problematic computer equipment was replaced immediately, a practice recommended to avoid decreasing nurses’ productivity while waiting for the equipment to be repaired [14]. But when that support is removed and supervision goes down, so does the barcode use. The reasons reported by nurses who give up its use are related to the findings of the evaluation, such as: inadequate reading of codes in the face of repeated attempts, failure of the scanners or the computer, delayed response of the help desk, discomfort caused to the patients, drugs that cannot be scanned. A mixed process (barcode and manual) slows the workflow for nurses, who then choose to do it only manually or by using the so-called ‘shortcuts’ [15], such as using a larger size code printed on a paper, instead of scanning it directly from the patient bracelet. Lack of improvement in the frequency of use of the BCMA system is probably because the reported problems have not yet been solved.

<td>‘It’s easy to use’</td>
</tr>
</tbody>
</table>

We do not have a support system to date that responds immediately to a failure to read a code, computer failure, or EHR freezes – this is a recommendation reported by the literature as good practice [14]. Our BCMA system has not
achieved the expected adoption, however, the attitude of the nurses in the ICU regarding the system as a whole is positive and they consider it useful and easy to use; an aspect that shows positive attitude towards the acceptance of a new technology [16].

We learned that if we want our nurses to adopt the BCMA system in their practice, we must improve it, looking for a solution to each previously reported problem [17].

We are currently reviewing the bracelet printing circuit implemented eight years ago for this purpose. We are also working to adapt the drugs labels that cannot yet be scanned by our BCMA system, such as "multi doses" (ointments, aerosols, syrups) and some "single dose" preparations (insulin) and evaluating the possibility of replacing scanners with USB cord with wireless ones. In addition, as the HIBA is working on the development of barcode reading for other products in addition to medication, such as human milk, blood, enteral and parenteral nutrition, a specific help desk for barcoding based systems is also being considered.

Conclusion

The adoption of a bar code reading system by nurses to verify patient identity and administer medication is influenced by different factors. The evaluation of all parts of the process, identification of associated problems and working on solutions according to recommendations could create greater adherence to barcode use and could have positive impact on patient safety.

Procedure for Reconstruction of a Predictive Score of Severe Deterioration in Inpatients

Navas Hernán and Bourdin Elián

Department of Health Informatics, Sanatorio Finochietto, Buenos Aires, Argentina

Abstract

Adequate recording of patients’ physiological parameters provides vital information for health teams. Up to 80% of general admission patients have physiological parameters outside the normal range within 24 hours prior to transfer to the intensive care unit. Early warning systems analyze these data with the aim of detecting early deterioration in patients, which support medical decision making for reducing morbimortality. There are more than 100 systems for detecting patients at risk. Particularly NEWS has a greater ability to discriminate patients at risk of cardiac arrest, unplanned admission to ICU, and death. Sanatorio Finochietto has a commercial Health Information System. In order to exploit the available information, an algorithm capable of constituting a score value associated with NEWS has been developed from the combination of measurements made at different times. The reconstruction procedure allowed a greater number of full records. We had a 75% coincidence with real-time comparison.

Keywords:
Electronic Health Records; Clinical Decision-Making; Computing Methodologies.

Introduction

Inpatients are always at risk of suffering clinical deterioration, usually characterized by the alterations in their physiological state. Up to 80% of general admission patients have physiological parameters outside the normal range within 24 hours prior to transfer to the intensive care unit (ICU). The lack of prompt and adequate response to patient deterioration may lead to an increase in their morbimortality and in health care costs [1].

Early identification of patients at risk of deterioration allows activation of specialized medical groups commonly called Rapid Response Teams that improve patient outcomes [2-5].

There are more than 100 detection systems for patients at risk, most of them derived from the original Early Warning Score (EWS). They can be divided into three groups according to the way the analysis is performed: simple parameter systems, multiple parameters or aggregate weighted systems. It is demonstrated that the latter are more accurate for the detection of cardiac arrest, mortality or transfer to ICU [6]. Particularly National Early Warning Score (NEWS) has a greater ability to discriminate patients at risk of cardiac arrest, unplanned admission to ICU, and death than the other 33 EWS in use [7].

The frequency of monitoring and recording novelties of a patient increases proportionally with their degree of deterioration [8]. Nursing has, therefore, a fundamental role in monitoring and documenting patients’ behavior.

NEWS, like many early warning systems, is based on a simple measurement system on physiological parameters which are usually monitored in a hospital. It assigns scores to certain physiological variables depending on the degree of deviation from the normal range. The sum of the score of each variable results in the value of the score that allows to predict the risk of deterioration within the next 12 hours, depending on the result obtained [9].

When this indicator is used following a response protocol against each instance of the scale, it is able to prevent undesired clinical consequences. The parameters under consideration are as follows:

1. Respiratory rate
2. Oxygen saturation
3. Axillary temperature
4. Systolic Blood Pressure
5. Pulse frequency
6. Level of consciousness

NEWS makes an important contribution towards improving clinical care provided to inpatients by ensuring deteriorated patients are reviewed by the medical team with the appropriate level of training for each case, allowing the reduction of associated mortality. In one case, the effectiveness of reviewing important cases by trained physicians, alerted by nurses, increased by 87% [10].

The use of these patient assessment methods to predict risk is not widely distributed. In university hospitals with doctors and nurses being trained, their implementation is more likely because constant training of staff is necessary, although in some cases it is quite difficult [11].

The calculation of the score to predict patient deterioration depends on the existence of the six parameters; any missing value causes difficulties in generating alerts due to an error in such calculation [12, 13].

Sanatorio Finochietto is a private health institution, inaugurated in November 2013, with 125 adult general admission beds, 31 adult intensive care units, and 16 neonatal intensive care units. It is the first eco-intelligent care center in Argentina, certified as a member of the global network of green and healthy hospitals. It has a commercial Health Information System (HIS) that allows electronic communication management between all the health team (e.g., doctors, kinesiologists, nurses, pharmacists, and nutritionists) and the administrative staff. It has interfaces with the effectors of complementary studies, such as laboratory studies, diagnostic imaging, and endoscopy. It uses mobile devices for safe medication administration and to record information at the foot of the patient’s bed [14].

Although the measurements of the vital parameters associated with NEWS are carried out daily and stored in each patient’s electronic medical record, calculation of such a score is not
simple since the measurements of some parameters are usually performed at different times.

The aim of this paper is to describe the procedure of score reconstruction by means of combining parameters of different times starting from the one with fewer measurements.

Methods

All patients transferred from general admission to the intensive care unit from 10 pm to 5 am from 14 November 2013 to 09 May 2016 were selected. The time selection necessarily represents patients who were suddenly decompensated during their stay in the general hospitalization area and an emergency transfer to the ICU was required to increase the level of complexity of their care. There are no scheduled patient movements in such time frame.

The period of data collection for each patient took place from the beginning of their hospitalization until the moment of their transfer to the intensive care unit in the selected time frame.

The parameters were obtained from computerized nursing records; five of the vital signs measurements (respiratory rate, oxygen saturation, axillary temperature, systolic blood pressure, and pulse rate) and the sixth, level of consciousness, were obtained from the structured assessment. All of them can be registered both from the office desktop computer and from the mobile application.

The state of consciousness is assessed by means of the Glasgow Coma Scale. Table 1 shows how these two scales are related.

</tbody>
</table>

The scripts to process data were programmed in PERL as it is a general purpose language, which was originally developed for text manipulation, but is currently used for a wide range of tasks due to its ease of handling, its versatility and power [15].

Procedure description

This section presents the steps for reconstructing the score:

Step 1: Conduct the search for the parameters to be analyzed in the HIS database with the date of measurement and the pertaining patient.

Step 2: Store each parameter in a different table, keeping the date and the patient’s ID.

Step 3: Determine the parameter with fewer measurements.

Step 4: Taking each of the values of the parameter having fewer measurements (in our case, the level of consciousness) as a reference, associate the data of each of the tables with each other, depending on the patient’s ID and the measurement time, with a maximum of a one-hour difference. The one-hour margin is set for the data to have clinical significance.

Step 5: Eliminate the lines which are exactly the same to improve the performance of future processing of the information.

Step 6: Calculate the score value for each of the possible combinations of each set of 6 parameters of the same patient.

In Fig. 1 below, one can observe the problem and how the combination for the score calculation can be carried out. Given the same patient, called “A”, in none of the four measurements (each row representing a measurement) are the six parameters complete. Each measurement is grouped according to the measured value for consciousness. Taking this last parameter as a starting point, the rest must be gone over making all the necessary combinations to complete the missing parameters for each of the measurements. In this way the number of scores per row will depend on the number of combinations that have been made to complete the missing parameters.

Step 7: Group the records for each patient.

Step 8: Given the existence of multiple measurements combined for a particular parameter of consciousness, keep the highest score and dismiss the rest of the records.

Step 9: Order the records based on the time when they were made. This will facilitate the analysis of the progression of patient deterioration.

Concept Test

To illustrate the procedure, the case of patient 10793 is described. Initially, by means of the collection in the database, 4,045 combinations of parameters were obtained, based on multiple assessments of consciousness, from the beginning of hospitalization to the nighttime transfer to the ICU. Two scripts were developed, the first one to solve step 6, and the other one, steps 7 to 9.
In the first instance, the repeated value filters were applied. This helped the information processing significantly due to the elimination of lines that were exactly the same. There were 730 different parameter combinations left. After this procedure, the first script for score calculation of each of the reconstructed combinations was executed.

Finally, the second script was executed to group all the measurements associated with a particular assessment of consciousness and to consider the highest result for each one. In addition, the script chronologically ordered the output information to facilitate the analysis of the progression of patient deterioration.

As a final result, seven score reconstructions were obtained for patient 10793, two of which were found within 12 hours prior to transfer to the ICU (Table 2).

</table>

Results

The 283 patients analyzed generated 20,864,012 candidate lines to calculate the score from all possible parameter combinations, following the criteria of belonging to the same patient and being in more or less one-hour range focusing on the value of consciousness (limiting parameter). The processing of all the combinations generated by the second script delivered a total of 1,244 scores belonging to 110 patients. Finally, the scores obtained from the last 12 hours, prior to the transfer to the ICU, were filtered. The result obtained included 79 scores of 56 patients.

The manual process of collecting the parameters is conducted in two different screens of the system; precisely the parameter detected as limiting is that which is separated from the set. According to the data analyzed, the state of consciousness is first recorded and then the remaining parameters (the physiological parameters) are recorded.

To represent the manual process, a search associating the physiological parameters with the state of consciousness within a range no longer than 10 minutes was conducted. Following the same criteria as those used for reconstructions, four measurements of four different patients were detected (Table 3).

Table 3 – Data recovery by method

</table>

The decision-making support system needs the existence of scores to generate the alarms. For the manual method, there would have been only four scores to analyze and generate the corresponding alerts. In contrast, the availability of scores increased substantially to 79 by the limiting parameter method. The greater availability of patient scores means that, given the same patient, there is more than one reconstruction within 12 hours prior to the event. From the point of view of care, this means a great advantage since it allows to analyze the tendency towards deterioration in each patient with more than one reconstruction.

Some cases with very high scores were detected at moments far from transferring to the ICU that are related to a patient’s previous stay in that area. There each patient is connected to a multi-parameter monitor that constantly sends the vital parameters to the HIS. This situation also caused the high number of lines initially found.

Finally, the four patients who had the records representing the manual process were compared with those obtained by means of the limiting parameter method. An exact match was found in three out of the four patients. The different value was of only 1 point; a 9 was obtained by means of the manual method and a 10 by means of the reconstruction by limiting parameter. This is within the expected range since the proposed method maintains only the highest possible value of the combination found (Table 4).

Discussion

Decision support systems in the health field provide an objective and standardized basis for patient care. In particular, early deterioration detection systems can reduce risk of death or complications for the patient, and their associated care costs. NEWS is based on the assessment of six parameters for such deterioration prediction. The absence of at least one parameter of those necessary for the calculation makes it difficult to obtain the score, thus causing unnecessary delay in care that may lead to fatal consequences.

The number of full measurements made at the same time is scarce, but the results of the method proposed for the calculation of such measurements are promising as the coincidence is 75%. For the remaining value, although it was overestimated in the proposed method, it was the researchers’ own decision how to handle the situation and its treatment context, given the sensitivity of the information.

Even though the patients considered from HIS are decompensated patients, in which case the score reconstruction in the previous hours is of utmost importance, another group of patients who decompensated during the day and was transferred to ICU were not taken into account. Although the relation of the Glasgow scale to NEWS was arbitrary and there could be subtle variations, we believe that such variations should not affect the calculation, since the NEWS scale is much simpler as to the state of consciousness.

This study is expected to continue with the validation of the reconstruction procedure proposed against the manual process of measuring the six parameters for the same moment in a large sample of patients. The calculation will be made according to the method described at a certain time of the day. On the same patients, a trained nurse, without knowing the existing values, will carry out the measurements and record the six parameters for each patient. Finally, the score will be calculated for both methods and their differences will be analyzed.
Finally, we intend to determine the optimal relation between the time difference existing among the parameters and the degree of accuracy of the reconstructed score. For such a purpose, we will reconstruct scores with values that are increasingly more remote from the limiting parameter. We will start from reconstructions of up to 60, 120, 180, 240 and 360 minutes, which will be compared with those scores reconstructed with a 5-minute maximum difference from the limiting parameter. This analysis will allow us to make the maximum time value from which we can move away from the limiting parameter. This analysis will allow us to make the maximum time value from which we can move away from the limiting parameter precise, without the score losing accuracy.

**Conclusion**

The information treatment procedure described in this paper enables the improvement of the information availability in more than 10 times with respect to the number of patients and almost 20 times for the amount of such patients’ scores, taking into account the current registration ways. This information will reduce the risk of serious events in hospitalized patients via early intervention, despite not initially having all the full values.

**Acknowledgements**

First of all, we would like to thank Dr. Jorge Kritzer for being the source of inspiration on the subject. We would like to make special mention of Dr. Ramón García Martinez for having supported us by devoting his time to correct and guide us in the analysis and presentation of our research.

In memoriam to Dr. Ramón Garcia Martinez.

Abstract

Health Information Exchange (HIE) is the most prevalent patient information sharing technology currently in use. Although a number of regional healthcare information systems exist in Japan, little is known about the effectiveness of the systems or how effectiveness should be measured. As an approach to this issue, we developed a framework for measuring effectiveness of HIE using the dimensions for health indicators from ISO/TS 21667:2004 “Health Indicators Conceptual Framework”. Three phases for measuring HIE are defined: Phase I: the static aspects of a system; Phase II: the use of the system; Phase III: the outcomes of the use of the system. Complex factors involved in HIE are organized and objectives of evaluation are made clear. The domains to which measures are applied and categories of measures are defined. Sample measures extracted from publications and co-authors’ studies are discussed. This work is the first step towards the systematic development of a framework of measures of the effectiveness of HIE.

Keywords:
Health Information Exchange, Quality Indicators, Cost Effectiveness, Information Systems

Introduction

It is expected that health information technology can facilitate information sharing regionally, nationally, and internationally to facilitate continuity and quality of care. In recent years, the term “HIE (Health Information Exchange)” has become the most widely used term for regional healthcare information systems. According to the web site of the US government HealthIT.gov, HIE is defined as follows:

HIE generally refers to sharing of clinical data between health care institutions for efficiency, cost-effectiveness, quality care, and for patient safety.

A number of regional healthcare information systems exist in Japan, where hospitals, clinics and pharmacies share patient information electronically. According to a working paper published by Japan Medical Association Research Institute in 2015, more than 200 systems exist in Japan [1].

Systematic reviews and a number of original papers that focus on effectiveness of HIE discuss major concerns about regional healthcare information systems’ effectiveness [2-8]. Even though a huge amount of money has been expended, systematic effectiveness analyses of these systems has seldom been conducted.

Effectiveness of a healthcare information systems is difficult to evaluate because multiple factors are involved including human (personnel), organization, workflow/process, as discussed by Sittig and Singh in their paper “A New Socio-technical Model for Studying Health Information Technology in Complex Adaptive Healthcare Systems” [9].

To systemically assess the effectiveness of regional healthcare information systems, we investigated what and how measures were obtained, what measures are feasible, how the various factors may be captured and organized, and how efficiency and effectiveness can be evaluated.

Our study focuses on effectiveness of regional healthcare information systems where patient information is shared between hospitals, clinics and pharmacies. Since the objectives and the concepts of the systems are represented by HIE, we will use the term HIE and regional healthcare information systems interchangeably.

As a result of our study, we have developed a framework for measures of HIE. We present the major results and discuss issues that should be addressed.

Methods

The methods and the process for the Framework development are shown below (Figure 1).

1. International Standards and Technical Reports on health systems performance indicators that discuss both qualitative and quantitative aspects were examined [10], and the dimensions for measures of HIE were derived.
2. Domains to be measured and categories of measures were defined based on published papers on HIE [2-8].
3. The domains to be measured and categories of measures are reviewed in the light of the Donabedian model that provides a framework for examining health services and evaluating quality of healthcare.
4. A survey on regional healthcare institutions and users (clinicians) in Japan were conducted and the results were reflected in the framework. Some measures were investigated for feasibility and usefulness.
5. Co-authors conducted several studies on some measures experimentally, and the results were reflected in the framework. Quality indicators adopted in the co-authors’ institutions were also investigated.
Results

Conceptual Representation of Healthcare and HIT

When improvements in continuity of care are observed after adoption of hospital information systems (HISs), it may be due to changes in human attitudes, workflow, care process, etc. Sittig and Singh presented a model with eight dimensions in their article “Socio-technical Model for Studying Health Information Technology in Complex Adaptive Healthcare Systems,” stating that HIT interventions must be understood in the context of their simultaneous effects across multiple dimensions of the model [9].

We present a conceptual representation of healthcare and HIT in Figure 2. The areas in orange show healthcare itself regardless of existence of HIT. Concepts such as “quality healthcare”, “quality measures”, “patient engagement” exist regardless of HIT. The areas in blue are components of HIT such as EHR or “data interoperability.” The overlaps between the concepts in orange and blue areas are apparent. HIT is not a simple combination of healthcare and IT. It is a new healthcare domain established with the advent of Health Informatics.

Effectiveness Measures - Literature Review

We have investigated papers on effectiveness of HIE. There are a number of original papers and several reviews including, “Outcomes from Health Information Exchange: Systematic Review and Future Research Needs” by Hersh, et al [3]. It is an in-depth review discussing the limitations of the studies under review. In their review, 34 studies on outcomes of HIE were identified. Most of the papers on HIT effectiveness focused on healthcare resources. Some papers discussed a decrease in laboratory testing and amount of costs. For hospital admissions, some show a decrease in the number of admissions, but others show no decrease. HIT in general reduces duplicative laboratory and radiology testing, emergency department costs, and hospital admissions. There are also reports on public health reporting and ambulatory quality of care. But papers on the effects of HIE on clinical outcomes have not been found.

Framework of Effectiveness Measures of HIE

Eight Dimensions of Measures

International organizations such as ISO and OECD published frameworks for health quality or health systems performance. For example, “ISO/TS 21667:2004 Health informatics - Health Indicators Conceptual Framework” shows performance indicators for health systems with eight dimensions below [10]:

- Acceptability: All care/services provided meets the expectations of the client, community, providers and paying organizations, recognizing that there may be conflicting, competing interests between stakeholders, and that the needs of the clients/patients are paramount.
- Accessibility: The ability of clients/patients to obtain care/service at the right place and the right time, based on respective needs.
- Appropriateness: Care/service provided is relevant to the clients/patients’ needs and based on established standards.
- Continuity: The ability to provide uninterrupted coordinated care/service across programmes, practitioners, organizations, and levels of care/service over time.
- Competence: An individual’s knowledge and skills are appropriate to the care/service being provided.
- Effectiveness: The care/service, intervention or action achieves the desired results.
- Efficiency: Achieving the desired results with the most cost-effective use of resources.
- Safety: Potential risks of an intervention or the environment are avoided or minimized

The eight dimensions of performance indicators are for health system performance. We applied the eight dimensions above to health information systems or HIE in our framework, using the term “measures” instead of “indicators”.

Effectiveness Measures – Three Phases

Various aspects are involved in evaluating HIE, including organizations, personnel, operations, system functionality, system use rate, patient participation, provider satisfaction, and patient outcomes. Taking these into account, we arranged performance measures of HIE in the three phases (Figure 3):

Phase I: System organization (including both IT and human)
Phase II: Use of HIE
Phase III: Effects by the use of HIE
It does not necessarily mean that the HIE should be measured in this order. Phase I may include such domains to be measured as organization, policy, operation, system functionality and services provided. Phase II includes domains such as use by clinicians, participation of patients, acceptability by healthcare providers, and patient satisfaction. Phase III includes domains such as administrative effects and clinical effects. There may also be public health effects, and indirect effects such as conformance rate of clinical guidelines.

We investigated how measures may be captured from the view point of Donabedian’s “Structure, Process, and Outcome” [11]. We considered HIE not only as an information technological system, but also as a socio-technological system that includes organizations, personnel, operation and so on. From this point of view, we considered the Phase I “Structure”, and Phase II “Process.” Phase III was considered “Outcome.” For Phase III, we represented outcomes if they measure aspects resulting (directly or indirectly) from the use of the system. Hence the measures in Phase III may be classified as “Process” rather than “Outcome” from the view point of clinical quality measures.

**Overview of the Framework**

Figure 4 shows the overview of the developed framework for HIE effectiveness measures. Shown in the columns are eight dimensions for performance: “Acceptability, Accessibility, Appropriateness, Competence, Effectiveness, Efficiency, Safety, and Continuity.” In the rows, the major domains are organized into the three phases. Then in each domain, categories of measures are shown.

**Example measures**

The framework does not include concrete measures, but some measures are shown as examples in Figure 5. Measures for Phase I and Phase II are mostly straightforward. Some of them are taken from our survey carried out in 2014 in Japan across five regional healthcare information systems. For a given measure, the relevant dimensions are shown by a check mark. A large thick check mark indicates strong relevance, while a smaller check mark indicates weak relevance. For example, for “the number of years in operation” in the domain “information system organization,” a large check mark is shown under the column “Continuity.”

Most of the sample measures in Phase III were found in the literature. We reviewed the papers and extracted measures that are generally considered feasible. Papers on HIE effectiveness mostly focus on healthcare resources. For example, “amount of reduced testing/imaging” in the domain “Laboratory & other tests” is found frequently in literature review, and is most relevant to the “Efficiency” dimension and also relevant to “Appropriateness”, “Continuity” and “Safety”.

*Figure 3 - Measuring HIE: Three Phases*

*Figure 4 - Overview of the developed Framework of Measures for HIE*
Some measures are from the co-authors’ work or used in their institutions. For example, “improvement of HbA1c (Surrogate)” and “cancer survival rate (True)” are measures for the domain “quality measures for a given disease,” and a check mark is shown in the “Effectiveness” column. Measures such as “rate of BP lower than 140/90” is one of compliance rates of a clinical guideline under the domain “Other/indirect effects.”

### Discussion

#### Implementation of HIE measures of Phase I and Phase II

The term and the concept of HIE is in use more and more in the field of Health Informatics. HIE mostly refers to the electronic information sharing among clinical institutions, for efficiency, cost-effectiveness, quality care and safety.

In the framework presented, three phases are defined for measuring the effectiveness of HIE. For Phase I and Phase II, measures are mostly descriptive statistics, and although there may be discussions about what measures should be adopted, measuring should not be difficult. Many of the sample measures shown are taken from our survey on five regional healthcare information systems. For example, “How much would you spend for the system you participate in?” was a question for clinicians; we found the median acceptable cost was almost equal among five systems.

In the past, there were no clear guidelines for measures, and the framework should serve as a sharable tool for governance of the regional healthcare information systems.

### Implementation of HIE measures of Phase III

For measures of the third phase, i.e., measures for outcomes, further discussion may be necessary. Among a number of published papers, the systematic review by Hersh et al, which outlines the need for more research, aligns closely with our current work. They discussed the significant limitations of the evidence base, and showed four primary limitations of the available evidence on the impact of HIE (and Health IT in general). That is,

![Figure 5 - Framework of Measures for HIE with sample measures](image-url)
A primary limitation is due to the complexity of interventions. The HIE itself is necessarily only part of a more complex intervention, and the mixed effects might change the behavior of clinicians or others in the health systems. For example, if HIE effect on the compliance rate of electronic clinical guidelines is measured, multiple interventions (factors) are involved. When some sample measures are applied in clinical settings that employ a HIE, possible factors involved other than HIE may need to be considered when reporting the results.

Framework as an approach to Health IT evaluation
The US Agency for Healthcare Research and Quality published the report “Identification and Prioritization of Health IT Patient Safety Measures, Final Report” [12], which discusses that while the use of Health Information Technology (HIT) presents many new opportunities to improve patient care and safety, the complex interactions between people, processes, culture, and technology can also create an environment where new hazards are introduced. There is a need for measures to help identify the nature, scope, and prevalence of HIT-related safety issues and to assess how well providers, vendors, and others are preventing and/or mitigating HIT-related safety concerns.

Similar discussions apply to the third phase of measures of the framework developed in the present study. The concepts and sample measures for “Outcome” serve as the groundwork for the complex discussions of effectiveness of regional healthcare information systems.

Conclusion
Healthcare information systems and HIT are widely viewed as essential to the transformation of healthcare to counteract rising costs, inefficiency, preventable errors, and quality of care. HIT is expected to yield benefits in quality, safety, and efficiency of healthcare. The Japanese government as well as the US and other countries’ governments have been engaged in a concerted effort to promote adoption of HIT. Despite the considerable investment and the widespread rapid adoption of HIT, little is known about the effectiveness or cost-effectiveness of the systems, that is, how useful the systems are.

As an approach to this issue, we developed a framework for measuring the effectiveness of HIE. The framework comprises of three phases of measures and eight dimensions of quality. It is recommended that responsible organizations measure their systems for monitoring and for governance at Phase I and II. For Phase III, due to complex factors involved and limitations of studies, literature reviews showed that the evidence level is relatively weak. This is generally true when an outcome measure is applied to a specific setting, and considerations may be necessary in presenting the results as the effects may be the mix of HIE and other factors.

We conclude that the framework will assist administrators, healthcare providers, researchers and regional communities as a tool to measure the effectiveness of regional healthcare information systems, thereby contributing to the evaluation and improvement of their systems, and ultimately improve quality care.

Abstract

Current methods for monitoring harm caused by health information technology (HIT) are minimal, even if there are known risks associated with the use of HIT. Monitoring is predominantly based on voluntary reporting using generic patient safety adverse events reporting systems. Another important means for monitoring technology-induced errors is a health authority reporting system. International oversight systems have medical devices related software adverse event and failure reporting models, but these systems differ due to differences in the legislation. The protocol for this study included an electronic database literature search and the eliciting of information for study purposes from the literature.

The purpose is to provide a scoping review focused on two types of systems and provide implications for monitoring technology-induced errors in the future. The analysis revealed not only differences, but also similarities between these systems which raises the question of these systems' effectiveness due to overlapping goals in collecting data.

Keywords:

Electronic Health Records; Patient Safety, Medical Informatics

Introduction

A recent systematic review of eHealth technologies and their impact on the safety of healthcare showed that the problem of electronic health record (EHR) safety is an existing and possibly critical issue [1]. It is assumed that an increase in the implementation of information technology within healthcare systems will potentially lead to patient safety incidents by introducing novel vulnerabilities [2]. In 2012, the Institute of Medicine (IOM) [3] recommended that patient safety incidents which relate to the use of Health Information Technology (HIT) should be monitored and that this information be used to improve the safety of HIT. By detecting these errors, there is an opportunity to decrease risk for patients [4].

HIT related medical errors are defined in several ways. The concept of technology-induced error as defined by Borycki [4] has increasingly appeared in the literature during recent years. These errors result from the design and development of technology, the implementation and customization of a technology, and the interplay between the operation of a technology and the new work processes that arise from a use of technology [4].

Existing methods for monitoring adverse events and harm caused by HIT systems rely mostly on voluntary reporting using generic patient safety adverse event reporting systems [5-6]. These adverse event monitoring systems have multiple functions, including: (a) the monitoring of levels of harm, and (b) identifying rare events and disseminating knowledge about patient safety issues arising during healthcare to avoid these incidents recurring [7]. These systems form a mechanism which also includes the analysis and triggering of an investigation of an incident [8] whether on a mandatory or voluntary basis. It is believed that voluntary adverse event monitoring systems are the most effective way of avoiding liability issues for providers, but there is also the belief that there is a need for greater accountability. Incident reporting systems generate numerators without denominators which has been regarded as a major problem [9-12].

HIT has not been strictly regulated over the past few decades [13]. Today, international healthcare systems have medical device related software adverse event and failure reporting models, but there are differences between these systems [13-18]. The differences originate from different legislation. In the United States (US), regulatory requirements that can be used to evaluate EHR system safety are insufficient [16-18]. Software has been regarded as a medical device according to European Union (EU) legislation for almost a decade. Medical device regulations apply to medical software in the EU [18]. The EU directive focuses on pre-market testing aiming for European conformity. In general, the regulatory oversight systems seek to gather data to help HIT developers and clinicians better understand and mitigate risks associated with HIT implementation and use [19, 21].

In this paper the authors provide: (a) review two of the most dominant reporting system types, (b) outline the implications of monitoring technology-induced errors in HIT and (c) provide insights into future research directions based on these analyses. More specifically, the authors answer the followings research questions: (1)What are the main characteristics of the two dominant HIT related monitoring systems, (2) What are differences between these systems? and (3) What are the implications of this research for future analyses?

The scoping review presented in this paper is limited to the perspectives of healthcare organisations’ (i.e., the HIT vendors view is excluded). For the purpose of this paper the term patient safety incident reporting system is referred to as “IRS”. Different types of software’s regulatory authority adverse event and failure reporting models and vigilance systems are referred to as “oversight systems”.

Methods

A scoping review was conducted by the authors using Arksey’s and O’Malley’s approach [20]. The following steps were undertaken: (1) an electronic database was searched, and (2) information was elicited from downloaded articles to answer study questions. The database search was performed on
PubMed. Search results were restricted to those references published in English only. The search was performed on the two main topics associated with the theme of this work: HIT and monitoring. A combination of keywords were used: “HIT” OR “EHR”, OR “medical software” and “monitoring” OR “patient safety reporting” OR “incident reporting system” OR “surveillance”. “regulation” OR “oversight” OR “vigilance”. (Moreover, an additional search was based on these previous results which were combined with a keyword “technology induced error”, and this resulted in 3 citations of which one was a duplicate.) Initially, the researchers reviewed the abstracts of the downloaded publications. Those abstracts that fulfilled the following criteria: patient safety incident reporting system and an authority surveillance perspective were downloaded and reviewed further. An additional type of non-scientific material collected contained legislation documents. Finally, the following data were extracted by two reviewers from the articles using the following criteria: the main objectives of reporting systems, nature, confidentiality aspects and reporting modes, who are the reporters, what is reported, and analysis of the incidents. The findings arising from our work are reported according to these data extraction criteria.

Results

In the next section of this paper, we report on our findings arising from the scoping review in the following areas: main objectives of reporting systems, nature, confidentiality aspects and reporting modes, who are the reporters, what is reported, and analysis of the incidents. Figure 1 illustrates the detailed steps of the literature search in PubMed. A total of 4966 citations were received of which 18 articles were included in the final review. We present our findings in terms of the two types of reporting systems described in the literature: oversight (ORS) and incident reporting systems (IRS).

Main Objectives of Reporting Systems

Oversight system

The primary purpose of the EU Medical Device Vigilance System, which is grounded in the Medical Device Directive 93/42/EC, is to “improve the protection of health and safety of patients, users and others by reducing the likelihood of reoccurrence of the incident elsewhere”. The Medical Device Vigilance System aims to facilitate an early and harmonised implementation of ‘Field Safety Corrective Action’ across the Member States where the device is in use, in contrast to action taken on a country by country basis [18, 20]. Existing FDA databases for medical device errors are focused on collecting data about medical devices and have only recently been used to collect some data on reporting EHR-related incidents. The Office of the National Coordinator (ONC) has recently created a HIT complaint website; however, the form for entering complaints is basic with few specific HIT and error questions to answer limiting the usefulness of the resulting database. The regulatory oversight system’s intention is to gather data to help HIT developers and clinicians better understand and mitigate risks associated with HIT implementation and use [8, 15, 19].

Incident reporting system

The aims of a patient safety incident systems (IRS) are broad. IRS systems are intended to monitor levels of harm, identify rare events and disseminate knowledge about patient safety of care. Learning from errors is the main goal of IRS [7-8, 22].

Legislation

Oversight system

Directive 2007/47/EC1 amended the definition of the term “medical device” used in Directive 93/42/EEC, and stand alone software with medical purpose are subject to medical device directives [18].

The FDA currently considers clinical information systems to be medical devices, but to date their regulatory requirements are not enforced. The Office of the National Coordinator (ONC) is collecting data and attempting to resolve issues that have been submitted to their complaint system. In the US, no government agency is currently fully equipped to perform regulatory and legal authority functions where Medical software is concerned [15-17, 19].

Incident reporting system

EU Council Recommendation 2009/C151/012 [23] regarding reporting and learning about incidents recommends that Member States support the establishment or strengthen blame-free reporting and learning systems regarding adverse events, which provide information about the extent, types and causes of errors, adverse events and near misses. In the US the Patient Safety and Quality Improvement Act was launched in 2005. The core goals of the act are to encourage health care professionals to improve the safety of health care, to understand the underlying causes of hazards, and to share the results, thereby minimizing risks related to patient care [27].

Nature, Confidentiality Aspects and Reporting Modes

Oversight system

ORS in the EU are mandatory and failing to report an event may be punishable [e.g., 26]. The US databases supported by the FDA: Medical Device Reporting (MDR) cover mandatory reporting from 1984-1996 and voluntary reporting thru to June 1993. Manufacturer and User Facility Device Experience (MAUDE) contains voluntary reports starting in June 1993, and facility reports starting in 1991 [15]. The ONC Health IT Complaint system is newly active and posts information about how to address issues [20] The aspect of confidentiality does not apply to vigilance systems, when it comes to the principle of anonymity, and as is the case in the voluntary based IRSs, which are described in the next section of this paper. Vigilance systems are based on the traceability and accountability of the event and confidentiality would limit both traceability and accountability [19, 21, 25]. Paper-based reporting systems as well as electronic formulas are used, e.g., in Finland both are in
use, with the data structure of the report always remaining the same [26].

Incident reporting system

IRS reporting systems often contain anonymous data from both mandatory and voluntary systems. Closely connected to the issue of mandatory or voluntary reporting are the questions of reporting confidentiality. The discussion is focused around the aspect of preserving the reporter’s anonymity. If healthcare personnel perceive that they will suffer judicial or legal consequences, when reporting patient safety incidents, they are less likely to report an incident [27]. To date the research suggests that the use voluntary IRSs continues to be the most effective way of encouraging reporting in a nonpunitive or “no blame” culture. The opposite view also exists, e.g. the public feels that mandatory reporting improves accountability [10-11].

There are big differences between these reporting systems in EU Member States. In the EU both mandatory and voluntary incident reporting systems exist across states; for example, in Finland, hospitals are required to have reporting systems (i.e., mandatory), but the reporting of adverse events (i.e., errors) by health professionals is a voluntary activity. In Finland, there is also a focus on reporting on near misses. In the Netherlands, healthcare professionals are obliged to report serious incidents to the Health Care Inspectorate. Yet, the reporting of incidents by health professionals is voluntary and recommended by professional organisations (EU). Three different types of national patient safety incident reporting systems are used to collect adverse event data: systems for sentinel events only, systems focusing on specific clinical domains (e.g. intensive care, emergency room) and healthcare system-wide, comprehensive reporting systems [27].

Traditional paper-based incident reporting systems as well as new forms of IT are used to enhance reporting. It has been suggested that electronic health records could support new applications such as surveillance of patient safety events e.g., the integration of an IRS into an EHR used in operating theaters that has been implemented to allow for the reporting of accidents and preventable complications [28].

Who Are the Reporters?

Oversight System

Research suggests that health professionals need to be involved in reporting. For example, in the EU for a monitoring systems to be effective, user involvement is regarded important. There are differences between EU member states in the EHR user involvement [19, 29]. For instance, in Finland there is an obligation for the professional user of Medical software to report HIT related safety flaws but in most EU countries the user reporting is not mandatory [26].

Incident Reporting System

Reporting is typically done by frontline personnel where IRS are used. In recent years, patient involvement in reporting has increased, even though this involvement is voluntary in nature for organizations [27].

Reporting Criteria

Vigilance System

An incident in EU vigilance systems is defined as “any malfunction or deterioration in the characteristics and/or performance of a device, as well as any inadequacy in the labeling or the instructions for use which, directly or indirectly, might lead to or might have led to the death of a patient, user or of other persons or has led to a serious deterioration in their state of health.” [29]. In the EU, manufacturers must report medical device related serious adverse events and device failures, that might lead to or might have led to a death or serious injury, to the competent authority (CA) in the nation of their occurrence. There is no legal requirement within the directives obliging users to have an active role in a vigilance system, but this area may be reinforced by separate advice from national regulatory bodies, as is the case of Finland, where National Supervisory Authority has issued national regulations on reporting serious adverse incidents for users and manufacturers. The duty to report applies to manufacturers and professional users of medical devices in Finland. Medical device serious adverse incidents must be reported to the authority within ten days of the user or manufacturer first becoming aware of the incident. The case of a near miss should be reported within thirty days [19, 21, 26, 29].

The core FDA requirement to manufacturers in the US vigilance systems requires reporting within 30 days of an awareness of a problem with a device. Key criteria for inclusion are devices that: (1) have caused or contributed to a death or serious injury; or (2) have malfunctioned (and this device or a similar device that was marketed would be likely to cause or contribute to a death or serious injury, if the malfunction were to recur) [17]. The ONC requires that issues be taken up with vendors and developers and only if the vendor has not resolved the issue or there is dissatisfaction with solution should an ONC complaint be submitted [20].

Incident Reporting System

Patient safety reports usually describe the key data categories used to understand what happened, why it happened, and what were the consequences and reactions to the incident [27].

Analysis of the Incidents

Oversight System

This goal of the EU vigilance system is to be achieved by the evaluation of a reported incident, and where appropriate, dissemination of information could be used to prevent other occurrences of a similar event, or to alleviate the consequences of incidents. Suspected incidents are made known to the manufacturers and it is with their close involvement and cooperation that the implementation of the Field Safety Corrective Actions (FSCA) is made possible [19, 21, 26, 29].

In the US system there are no regulatory requirements to evaluate EHR system safety [17], and adverse outcomes associated with EHRs are not being systematically and consistently tracked. The regulatory data is stored in several databases supported by the FDA and ONC [19]. EHR certification alone does not guarantee that EHRs will be implemented and that they will work as planned [6, 14-18, 30]. If issues arise there is opportunity to: contact a vendor and this is followed by a formal complain with an ONC certification body [20, 31].

Incident Reporting System

Collected data is most commonly used for hazard identification and issuing of alerts, as well as for trends-cluster analysis. Risk, causal and systems analysis, are utilized in more mature US national reporting systems [27].

Summary

IRS are associated with voluntary reporting while oversight systems require that health professionals’ are mandatory. Anonymity and confidentiality are important aspects of IRSs. Oversight systems do have usually more detailed HIT-specific
structures. Neither of these systems publically share data e.g., on a national level.

**Discussion**

This analysis provides a useful comparison between two types of reporting systems for technology-induced errors. The purpose and reporting criteria of IRS and ORS are not always clear for HIT users that are reporting these incidents. This paper may serve as guidance e.g., for clinicians by clarifying the major differences in these systems. In this context, our analyses reveal that there is a need for effective reporting about technology-induced errors. If there are multiple reporting systems with similar goals, health care professionals may become confused and this may negatively influence their willingness to report technology-induced errors. The issue of underreporting in both systems is a recognized phenomenon which requires further consideration. For example, underreporting exists in the US regulatory system. In the US there are only a small number of EHR incidents in differing databases so the total number of reports requires a review and analysis of multiple differing databases [7, 16-18]. EU studies are scarce. To address this underreporting of technology-induced errors there is a need to encourage clinician reporting, to develop reporting criteria for health professionals when reporting to IRS and ORS (in such a way as to avoid duplicate reports), and to outline the process and provide information about how issues are resolved for health professionals to improve trust in the safety of HIT.

Specifically, in the EU the details of the medical software directive are relatively unfamiliar for EHR users and leaders. The application of the requirements of the directive have not been clear. Not all stand alone medical software qualifies as a medical device [21, 24, 29]. This complexity of criteria highlights the fact that resources are needed to strengthen the clinicians’ knowledge of reportable HIT-issues and consequently contributes to the reporting of incidents to improve the effectiveness of the regulatory system.

When comparing oversight systems between the EU and US, there are challenges specifically with the US approach. Expert opinions of HIT oversight in the US and the HIT community should re-examine whether and how regulation of electronic health applications could foster patient safety [15]. Sittig and Singh proposed that in the US, there is a need to create a nationwide ‘post-marketing’ surveillance system to facilitate monitoring of HIT related safety events (i.e. technology-induced errors), and that methods and governance structures to support investigation of major HIT related safety events be developed [18]. Regarding both systems, there is an area still requiring consideration. Countries are at different stages of addressing technology-induced errors arising from HIT and there is considerable knowledge to be shared across the countries and internationally to improve HIT safety [32].

**Conclusion**

Criteria surrounding the types of reports that should be submitted to ORS and IRS systems are important so that health professionals know where to report such events and to avoid duplicate reporting (i.e., submitting one report across multiple databases). There is a need to provide information about HIT related safety events (and how they were resolved) to health professional users to encourage reporting of events and enhance their trust in the process of improving HIT safety.

Abstract

This study examined factors affecting the time to occurrence of hospital-acquired pressure ulcers using electronic health records (EHR) data in a critical care setting. The subjects were 202 patients who were admitted to a tertiary hospital between January 2015 and May 2016 and developed pressure ulcers. In total, 61 risk factors for pressure ulcers were extracted from nine different report forms and analyzed using univariate and multiple linear regression analyses. The univariate analysis identified 33 significant factors, and 11 factors remained significant in the multiple regression analysis. Patients with decreased consciousness and those on ventilators tended to develop pressure ulcers during the early stage of hospitalization. Patients taking sedative-hypnotics, anti-inflammatory drugs, steroids, and anticoagulants, those in renal failure, and those who consulted a nutritionist, or had a gastrointestinal or tracheostomy tube or diarrhea tended to develop pressure ulcers at a later stage of hospitalization.

Pressure Ulcer; Electronic Health Records; Risk Factors

Introduction

Hospital-acquired pressure ulcers (HAPUs) are a threat to patient health [1]. HAPUs may prolong the hospital stay and lead to increased medical costs [2, 3]. Therefore, it is important to prevent pressure ulcers. It is also important to treat patients with pressure ulcers properly to prevent complications, such as infection [4].

The incidence rates and time to the occurrence of HAPUs in a critical care setting vary across studies. The incidence of HAPUs ranges from 12.8 to 16.6\% among patients in critical care settings [5-7], from 14.3 to 43.2\% among intensive care unit (ICU) patients [8-10], and from 20.3 to 38.5\% among trauma patients [11-13].

Regarding the time to HAPU occurrence, 59.1\% of patients in a neurological ICU developed HAPUs within 3 days of their admission [14], and 28.8\% of the patients admitted to a tertiary hospital developed them within 7 days of admission [15].

Many studies have examined the risk factors affecting pressure ulcer development. However, few studies have tried to identify risk factors related to the time to HAPU occurrence; one study explored the times to occurrence and closure and risk factors in patients with spinal cord injuries [16], and another study explored risk factors for pressure ulcers among elderly patients early in the hospital stay [17].

With this background, we considered the factors affecting the time to HAPU occurrence among patients in a critical care setting with diverse diagnoses during their hospital stay. We also considered whether electronic health records (EHR) data could be used to answer this question.

Research Objectives

This study explored risk factors affecting the time to HAPU occurrence among adults admitted to a critical care setting.

Methods

Study design

This was a retrospective study that used EHR data to identify factors affecting the time to HAPU occurrence among patients admitted to an acute care hospital.

Setting and study subjects

The subjects were admitted to six wards in the neurology, neurosurgery, hemato-oncology, and oncology departments at a tertiary teaching hospital in Korea. The subjects were 202 adults who developed HAPUs from January 2015 to May 2016 in the study hospital. Patients with HAPUs were identified from pressure ulcer incident reports. For those patients who developed HAPUs more than once during their hospital stays, only the first HAPU was included in the study.

Data extraction from EHR

A literature review identified 61 pressure ulcer risk factors. To identify these risk factors in the EHR, nine documents were reviewed: the Braden Scale form, initial nursing assessment, clinical observation record, severity classification system, nursing activity sheet, nurses’ notes, surgery record, doctors’ order sheet, and laboratory test results. Risk factors were grouped based on how often each was measured and how variable the values were. For variables that were recorded only at admission (e.g., route of admission) or most frequently recorded at admission (e.g., body weight), data recorded at admission were extracted. For variables that were recorded after admission with values that do not vary by day or by shift (e.g., surgery or diagnosis), data recorded at the time when an event that occurred between admission and pressure ulcer occurrence were extracted. For variables that were recorded more than once and whose values varied by day or by shift, data recorded most recently before the pressure ulcer occurred were extracted. We
set the maximum data extraction allowance time by computing the average time difference between the last time the risk factor was recorded and the time of HAPU occurrence. For example, reports of pain appeared in the clinical observation records or nurses’ notes. If a HAPU occurred, then the time difference between the most recent record of pain in the clinical observation record or nurses’ notes and the time when the HAPU occurred was extracted, and the mean time difference was computed across patients. The mean time difference was 1 day. Thus, if pain was recorded within 1 day before the onset of a pressure ulcer, pain was considered to be present; otherwise, pain was considered to be absent.

If data were recorded in more than one form within the maximum data extraction time, data from the most recently completed form were selected. Data were extracted from the clinical data warehouse based on data-extraction guidelines prepared by the authors. Data quality was validated by reviewing the records of 10 patients selected randomly.

The recorded frequencies of the risk factors were counted, and factors with a relative frequency of less than 0.1% were not included in this study (e.g., diagnosis of narcotic intoxication, malnutrition, sepsis, and hypotension). Table 1 shows the data recording times and data sources by risk factors.

### Analytical plan

The statistical analysis was performed with SPSS ver. 18.0 for Windows.

1. Descriptive analyses with the frequency, mean, and standard deviation were used to examine the characteristics of surgical and medical patients.
2. Univariate analyses were used to study factors affecting the time to HAPU occurrence.
3. Multiple stepwise regression analysis was performed to identify factors affecting the time to HAPU occurrence.

### Results

#### Characteristics of the study subjects

The study included 202 patients with HAPUs: 128 surgical patients and 74 medical patients.

Table 2 presents the gender, age, diagnosis, Braden scale score on admission, time to HAPU occurrence from admission, place of occurrence, and body site for the surgical and medical patient groups.

Both groups had more males than females. The mean ages of the medical and surgical patients were 65.62 and 59.45 years, respectively. Of the surgical patients, 43.8% were diagnosed with nervous system diseases, and 59.5% of the medical patients were diagnosed with cancers. Most of the medical patients (64.9%) were classified as at risk on admission, whereas only 27.3% of the surgical patients were identified as at risk on admission. Surgical patients developed HAPUs during the early stage of the hospital stay, with 45.4% occurring within 3 days of admission. Medical patients developed HAPUs at a later stage of their hospital stays compared with surgical patients, with 47.3% developing at 4–15 days.

More than half of the surgical patients (57.0%) developed HAPUs in the operating room during surgery. The most common body site of the pressure ulcer for both surgical and medical patients was the coccyx. The second most common body site for pressure ulcers was the chest for surgical patients and the hip for medical patients.

Factors related to the time to HAPU occurrence

The univariate analyses identified 33 factors as significantly ($p < 0.05$) affecting the time from admission to HAPU occurrence (Table 3).

Cardiac stimulants, weight, Foley catheter, endotracheal tube, ventilator, oxygen therapy, nothing by mouth, restraint, decreased consciousness, cognitive impairment, hygiene management, pain, and surgery were negatively related to the length of time to HAPU occurrence from admission. This means that patients with these factors tended to develop HAPUs earlier in their hospital stays. Route of admission, Braden Scale score on admission, sedative-hypnotics, analgesics, anti-inflammatory drugs, steroids, antiplateletics, anticoagulants, renal failure, cancer, cardiovascular disease, incontinence, diarrhea, tracheostomy tube, gastrointestinal tube, weakness, nutrition consultation, malnutrition, activity disorder, and edema were positively related to the length of time to HAPU occurrence from admission. Patients with these factors tended to develop HAPUs later in their hospital stays.

Of the 33 factors included in the multiple stepwise regression analysis, 11 were significant, with combined explanatory power of 69.5% (Table 4). Patients with decreased consciousness and those on a ventilator developed HAPUs at an early stage of their hospital stays. Patients with sedative-hypnotics, anti-inflammatory drugs, steroids, anticoagulants, renal failure, nutrition consultation, diarrhea, gastrointestinal tube, and tracheostomy tube developed pressure ulcers at a later stage of their hospital stays.

Discussion

We divided our subjects into surgical and medical patient groups based on the fact that patients who are rendered immobile, such as those undergoing surgery, may be at greater risk. There were 128 surgical patients (63.4%). Of the 128 surgical patients, 73 (57.0%) developed pressure ulcers in the operating room. Surgery is an important risk factor for HAPU development in many studies [18-21]. This is likely because the patients are immobile during their surgery, and anesthesia prevents them from feeling the pain caused by compression [18]. In addition, blood loss, lowered body temperature, skin moisture due to irrigation, and warming therapy during...
The time to pressure ulcer occurrence after admission averaged 15.2 days. About one third of the pressure ulcers (n = 70, 34.7%) occurred within 3 days of admission. This is much lower than the value reported in a previous study, which found that 59.1% of neurological patients in ICU developed pressure ulcers within 3 days of admission [14]. This could be due to the fact that our subjects were more diverse and from many different wards.

Of the 70 patients who developed pressure ulcers within 3 days, 58 were surgical patients, and 12 were medical patients. The surgical patients were more likely to develop pressure ulcers during the initial stage of hospitalization compared with the medical patients. In our hospital, most surgical patients undergo surgery on the first or second day of admission, so surgical patients develop pressure ulcers in the early stage of hospitalization. In a previous study, most of the patients who underwent surgery were found to have developed pressure ulcers on the day of or within 2 days after surgery [20].

Among the surgical patients, 28 (13.0%) and 11 (5.1%) developed pressure ulcers on the chest or cheeks, respectively, whereas no medical patients had pressure ulcers on the chest or cheeks. Patients with a pressure ulcer on the chest, clavicle, or rib were those who had surgery in the prone position. Patients with pressure ulcers on the face were those who wore a medical device, such as an oxygen mask, during anesthesia [22].

The multiple regression analysis showed that decreased consciousness and being on a ventilator were the most significant factors affecting the development of pressure ulcers in the initial stage of admission. Decreased consciousness and being on a ventilator are directly related to general anesthesia. In another study, all of the surgical patients with pressure ulcers had general anesthesia [23]. In addition, the use of cardiac stimulants, such as vasopressors, during surgery was a significant factor affecting the development of pressure ulcers during the initial stage of admission. Postoperative pain and fasting for various tests or surgery were also related to the occurrence of pressure ulcers in the early stage of hospitalization.

</tbody>
</table>

Sedative-hypnotics, steroids, and anticoagulants were factors affecting the development of pressure ulcers at a later stage of hospitalization. Sedative-hypnotics include sleeping pills prescribed for medical patients, and dexamethasone-like steroids and anticoagulants for heparin therapy were used to treat neurological diseases.

A nutrition consultation also was an important factor in the development of pressure ulcers at a later time during hospitalization. Nutrition consultations are rarely requested for patients in the early stage of hospitalization, and are mainly requested for patients with nutritional deficiencies admitted to a long-term ward. Impaired nutritional intake was an important factor in the development of pressure ulcers in a study of medical patients [24].

A tracheostomy tube was a risk factor for pressure ulcer development at a later stage of hospitalization. Tracheostomy tubes are mainly used in patients with long-term hospitalization, whereas patients with surgical procedures have endotracheal tubes for ventilator applications, which was a risk factor affecting pressure ulcer development at an early stage of hospitalization.

In summary, most of the patients who developed pressure ulcers early in their hospitalization were patients who had general anesthesia during surgery. Patients who are admitted for surgery have a high risk of developing pressure ulcers due to surgery, although they were assessed as low risk for pressure ulcers on admission.

In this study, we did not use the incident report as a data source to identify risk factors for pressure ulcers, but the incident reports can be connected with EHR to deepen the analysis of risk factors.

**Conclusions**

This study examined the factors affecting the time to HAPU occurrence during the hospital stay. These findings can be...
used to help nurses to develop nursing interventions to recognize and prevent HAPUs.

Abstract

Error-laden data can negatively affect clinical and operational decision making, research findings and funding allocation. This study examined the number and types of data errors in an electronic medical record (EMR) system in a Drug and Alcohol service. Specifically, errors in service data were examined. Three months after the implementation of the EMR system, 9,379 errors were identified from ten error reports generated between March 2015 and May 2016. The errors were grouped into four types: mismatched data fields (60.5%), duplicate medical record error (3.2%), date/time error (8.8%) and blank field error (27.4%). The errors can be prevented by adding functions, such as alert messages in the EMR system. How and why the errors occur need to be investigated in future studies.

Keywords: Electronic Health Records; Informatics; Medical Order Entry Systems

Introduction

The adoption and use of health information systems (HIS) has made large amounts of digital data available for use in clinical and operational decision making [1], research [2] and funding allocation [3]. However, data errors may jeopardize the realization of these purposes. For example, Ward et al. found that data errors in HIS time stamps can compromise the ability of an emergency department to accurately determine its operational performance [1].

Inherent data errors in clinical research databases may negatively impact the research findings [4, 5]. In a study comparing the estimation results of mortality rates using an error-free database and an error-seeded database, authors found that the overestimated mortality rates are typical results of using the latter database [6]. The estimates can be more than double the true value [6].

Error-laden data can also lead to misallocation of healthcare funding. In a study examining the consequences of miscoding in a hospital in Australia, authors found that about 16% of inpatient cases discharged from a specialized surgical unit during a six-month time period were miscoded. This led to an approximately $575,000 underpayment to the hospital [3].

Understanding the types and number of errors in an organization’s HIS is thus useful for managers to develop strategies to prevent errors. This will ensure that the HIS truly supports organizational performance measurements, decision making, research and funding allocation.

Data errors identified by previous studies include time stamp error [1], miscoding [3], missing data [7], data transfer error [8], spelling error [9], duplicate records [10, 11], drop-down menu selection error [10] and inconsistencies between data fields [12].

Causes of these errors are related to HIS design and how HIS are used [8]. For example, the drop-down menu selection error may be caused by too many items in the drop-down list or items being too close together [13]. Spelling errors may be attributed to healthcare providers documenting in a rush without proofreading [9].

Alcohol is one of the major risks for both physical and social health. Excessive consumption of alcohol can cause a wide range of harm including road accidents, domestic and public violence, family breakdown, crime, liver disease and brain damage [14]. Between 2014 and 2015, more than 115,000 Australians received over 170,000 treatment episodes from publicly-funded Drug and Alcohol (D&A) service [15].

In 2013, the public health in New South Wales (NSW), Australia moved from lump-sum funding of D&A services to funding based on treatment activities. The effectiveness of this new model of funding is substantially relied on the precision of data recorded in a HIS. Inaccurate recording may not only affect the amount of funding allocated to a D&A service, but also the managerial decisions made using this data, for example, in policy making, service planning, research and education [16]. To our knowledge, however, no study has investigated the precision of D&A service data under this model of funding.

Therefore, this study aimed to investigate the number and types of errors in service data in a D&A service in NSW, Australia.

Methods

Study setting

This study was conducted in a D&A service in NSW, Australia.

Data source

An electronic medical record (EMR) system was implemented in December 2014. Service activity data was extracted by performance unit staff from the EMR system and uploaded to Web Non-Admitted Patient (WebNAP), a system that reports outpatient activities to NSW Ministry of Health for use in state health policy decision making including funding.

The WebNAP system matched the uploaded activity data with its predefined activity classification. When the data did not match the classification, the WebNAP system identified an error and automatically recorded it in an error report. For example, the WebNAP activity classification showed that D&A was a community service, therefore D&A healthcare providers should always choose community as their setting type. If a provider chose hospital, an error occurred.

Datasets

Ten error reports generated between March 2015 and May 2016 were provided by the information manager in the D&A service, three to fourteen months after implementation of the system. This relates to approximately 150,000 records per year for 60,000 patients. On past experiences, errors would be expected in 7% of the records with more than one error in 2% of these records.

An error report contains the following data fields in an Excel spreadsheet: clinic name, healthcare worker’s name, client name, client medical record number, error description, appointment date/time, service date/time, referral date/time, referral receipt date/time, service type, provider type, setting type, modality of care, financial class, Department of Veterans’ Affairs (DVA) card type and DVA card number.

Names of healthcare workers and clients were deidentified to maintain confidentiality.

Data analysis

Data on error description was extracted for analysis by the researchers. The errors were labeled based on feedback from the WebNAP system and were further grouped to higher level categories. The number of each type of error was counted.

Ethics approval

Ethics approval to conduct this study was granted by the joint Health and Medical Human Research Ethics Committee of the University of Wollongong and the Illawarra & Shoalhaven Local Health District. Access to the error reports was granted by the service manager of the D&A service. Consent was obtained from healthcare providers for their error reports to be used in this study.

Results

Types of Errors in D&A Service Data

The identified errors were grouped into four types: ‘mismatched data fields’, ‘duplicate record’, ‘date/time error’ and ‘blank field’ (see Table 1).

There were two types of ‘mismatched data fields’. One was a ‘service option error’ and the other was a ‘DVA information error.’ ‘Service option error’ occurred when one of the three data entry fields, provider type, modality of care and setting type did not match what was set up in the WebNAP classification. Provider type described the job role of a healthcare provider e.g., a registered nurse, a psychologist or a counselor. Modality of care was the means for delivery of a service; e.g., telephone, email or face-to-face meeting between a healthcare provider or a group of healthcare providers and a client. Setting type was the location where the service was provided; e.g., hospital, community or home.

The ‘DVA information error’ occurred when the information provided in the two data entry fields, DVA card details and financial classification, did not match with each other. There were two situations. One was a ‘DVA card details supplied but financial classification is not DVA’ and the other was ‘financial classification is DVA but missing DVA card details’.

‘Duplicate medical record’ occurred when more than one encounter was created for a client in the EMR system. However, a client could only have one active encounter at a time.

The ‘date/time error’ was related to referral date/time, referral receipt date/time, service start date/time and service end date/time. These date/times include time information. The logical order of these date/times must be as follows: the referral date/time should be earlier than the referral receipt date/time which should be earlier than the start date/time and the service end date/time. When this order was turned around, an error occurred.

The last data error type was ‘blank field’ which occurred when a data entry field was blank. The identified blank fields were provider type, funding source, financial classification and address fields including post code, suburb and street.

Number of Errors in Each Error Type

Overall, 9,379 errors were identified from the error reports (see Table 1). A total of 60.5% of the errors were ‘mismatched data fields’, of which, the majority was a ‘service option error.’ The error that occurred most frequently accounted for 27.4% and were ‘blank field’ with ‘blank provider type.’ ‘Date/time error’ accounted for 8.8% of the total number of errors. ‘Service start date/time is after service end date/time’ was the major error which accounted for 6.3%. ‘Duplicate medical record’ was the least frequently occurring error which accounts for 3.2% of the total errors.
Discussion

As errors in operational data can be pervasive in the immediate period after the implementation of HIS [7], this study focused on analyzing error reports for an EMR system three to 14 months after its implementation. The large amount of errors found in this study may be due to the learning curve of healthcare providers. Further study will investigate trend in data errors over time.

We classified errors into four types. This is useful for investigating causes of error and developing different prevention and mitigation strategies required for different error types.

Causes of these errors might be related to the EMR system design issue, how the system was used, the environment in which it was used or a combination of them. For example, this study found that ‘service option error’ was the most common error in the D&A service data and wrong selection of ‘setting type’ was one immediate reason for it. In the WebNAP reporting system, the D&A service was mapped as a community setting. That means all healthcare providers working in the D&A service must select ‘community’ for setting type, regardless where the service was provided. This would ensure that funding was allocated to D&A service.

Some of the healthcare providers, although employed to work for the D&A service, were responsible for providing this specialist service in a hospital setting. A D&A healthcare provider might select ‘hospital’ for the setting type, because he or she provided the service there. This would result in a ‘service option error’ because the setting type of ‘hospital’ was not mapped in the WebNAP system for the D&A service. If this error was not corrected, funding would be misplaced to the hospital setting, instead of D&A service.

The term ‘setting type’ may confuse healthcare providers, especially new employees, on whether it means the location of service provided or the healthcare service by which the healthcare provider was employed. This could be one reason for the error to occur.

Another reason might be the design issue of the WebNAP system. The system used ‘setting type’ to determine which healthcare service would get funding. Actually, it could have used the information about the healthcare service by which the healthcare provider was employed to determine the correct ‘setting type’. This suggested that the system designer did not really understand how healthcare providers worked and how funding was allocated. Extraction of correct data elements would eliminate the error and ensure correct funding allocation.

A mix of system design issues and the environmental condition under which end users use the system may contribute to the occurrence of error. This study found that ‘date/time error’ accounted for almost 9% of the total number of errors. Date/time data were required from three forms that D&A healthcare providers used in the EMR system: intake form, assessment form and clinical note. The intake form was used when a client first contacted the D&A service. The assessment form was used to assess the person after intake. The clinical note was used in the subsequent visits of the client. The entire journey of the person with the D&A service from intake to discharge is an ‘encounter’. Each contact of the person with the D&A service may contain several ‘services’, e.g. counselling, rehabilitation or supervised medication administration. The three forms were used at different stages of the encounter. The intake form and the assessment form were used in the beginning of this encounter. The clinical note was used multiple times until the closure of the encounter.

Within each form, the service start date/time must be before the service end date/time. However, the way to record service start and end date/time is different among the three forms (see Table 2). The intake form automatically populated service start date/time from the computer, but required healthcare providers to manually enter end date/time. The assessment form required both start and end date/time to be manually entered. The clinical note required a manual entry of start date/time, but automatically filled in the end date/time. This mixed ways of recording date/time opens opportunities for error.

Another reason for the error to occur might be the environmental condition under which healthcare providers recorded data. Sitting with a client and recording data in a computer at the same time may increase the probability of making error. Automatic time recording may have better data accuracy than manual time recording [17]. A check of date/time by the EMR system at the data entry stage may also help to prevent the erroneous data from being recorded.

A lack of alert message function in the system may open opportunity for error. For example, although the percentage of ‘duplicate medical record’ is not high in this study, duplicate records can mislead healthcare providers in clinical decision making because they may miss important information that exists in a different record [11]. This error may also cause confusion in information retrieval [18]. Disruptive pop-up alert message [4] built into an EMR system may help to decrease this error.

The ‘blank provider type’ is the second common error found in this study. This error might be caused by system dysfunction. It may also be due to the inability of the system administrator to keep up with the workload of correctly mapping the providers in the WebNAP system because of the high turnover of D&A staff, or lack of information on changes in roles for staff members or new staff in the service. Further study is needed to investigate how and why this error occurred.

Since the service data was first extracted by the performance unit staff before submitting to WebNAP, it was possible that the errors reported in this study could also be injected during the process of data extraction.

With the increased use of EMR, research using EMR data has been prospering, for example in EMR phenotyping [19], clinical workflow modeling [20] and disease prediction [21]. The strength of evidence from the secondary analysis of EMR data can be hindered by errors contained in these data [4, 5]. In the case mentioned in the introduction section, the study comparing the estimation results of mortality rates using an error-free database and an error-seeded database, the analysis result using the error-laden data was more than double the true results using the error-free data [6]. This shows the negative impact of erroneous data in reducing accuracy of data.
analytics and lead to invalid findings. Therefore, data errors and their causes need to be identified, reduced or eliminated to ensure high data quality to provide accurate evidence for research and health decision making [22].

**Limitation**

We did not analyze all the error reports generated after the implementation of the EMR system since there was no health information manager at the D&A service for a period of three months. Consequently, no error reports were downloaded in this period. However, the errors made during that time period rolled over to the following months’ reports, so we think that we had all errors analyzed. Directly interviewing the healthcare providers who made the errors would give further insights about the reasons for the errors made, which would be beneficial for learning to prevent errors in the EMR system.

**Conclusion**

Error-laden data can jeopardize clinical and operational decision making [1], research findings [6] and funding allocation [3]. To manage errors, it is paramount for D&A service to understand the nature and extent of error and the environment that induce error [23].

This study investigated the number and types of errors in service data in a D&A service. The identified errors were grouped into four error types: ‘mismatched data fields’ (60.5%), ‘duplicate medical record’ (3.2%), ‘date/time error’ (8.8%) and ‘blank field’ (27.4%). The top three most frequent sub errors were ‘service option error,’ ‘blank provider type’ and ‘service start date/time is after service end date/time.’ The results from this study underscore the importance of understanding errors in EMR data. Further study will investigate the trend in data errors overtime and how and why errors occur in the EMR system.

**Acknowledgements**

We are grateful for the healthcare providers at the D&A service who provided consent for their error reports to be used in this study. We thank the director and service managers for their support and approval of this study. The health information manager Mr. Will Fernadez is acknowledged for supporting the data collection process.

Abstract

In times of steadily increasing numbers of administered drugs, the detection of adverse drug events (ADEs) is an important aspect of improving patient safety. At present only about 1–13% of detected ADEs are reported. Raising the number of reported ADEs will result in greater and more efficient support of pharmacovigilance. Potential ADE’s must be identified early. In the iMedication system, which is a rule-based application, triggers are used for computerized detection of possible ADEs. Creating a pilot system, we defined the relevant use cases: hyperkalemia, hyponatremia, renal failure, and over-anticoagulation; knowledge bases were implemented in Arden Syntax for each use case. The objective of these knowledge bases is to interpret patient-specific clinical data and generate notifications based on a calculated ADE risk score, which may indicate possible ADEs. This will permit appropriate monitoring of potential ADE situations over time in the interest of patient care, quality assurance, and pharmacovigilance.

Keywords:
Drug-Related Side Effects and Adverse Reactions; Drug Monitoring; Expert Systems.

Introduction

Medical errors or unintentional acts of omission or commission, or those that do not achieve their intended outcome [1] – such as inappropriate medication – do occur in hospitals. A recent study stated that medical errors are the third leading cause of death in the U.S. [2], making it more important than ever to prevent and mitigate medical errors, especially those causing damage to patients [3].

The fact that drugs are being administered in increasing numbers signifies a greater potential for drug-related harm, including adverse drug events (ADEs). Traditionally ADEs are tracked and reported on a voluntary basis. Hence the success of ambulatory error reporting systems has been limited; approximately 10–20% of medication errors and only 1–13% of detected ADEs are reported [4]. Additionally, the process of ADE detection consumes considerable resources in terms of time and money. Studies have shown that as many as 6% of all hospital admissions are due to ADEs, and this number is three-fold higher among elderly patients [5, 6]. Moreover, about 50% of these prescribing errors and ADEs are deemed avoidable [7].

Hospitals need a more efficient mode of quantifying the degree and severity of ADEs, such as automated or computerized detection. Identification of severe ADEs as well as measuring their frequency will enable pharmacists and physicians to take corrective measures.

iMedication supports the process of pharmacovigilance – the pharmacological science relating to the detection, assessment, understanding and prevention of adverse effects, especially the long-term and short-term side effects of medication [8] – by identifying potential ADEs. Using automated tools such as iMedication, it is possible to reduce the number and severity of ADEs over time, identifying potential ADEs as early as possible, supporting plausibility checks on suspected ADEs, and reporting verified ADEs in an appropriate and standardized manner. Furthermore, it can inspire physicians and pharmacists to report ADEs and – last but not least – save time and money during the reporting process.

Existing approaches for computerized ADE detection employ methods such as data mining [9] and decision trees [10] to automatically generate ADE detection rules. Another strategy is to utilize the rich semantics of ontologies such as SNOMED CT [11, 12], and apply it to the detection of ADEs via semantic querying and reasoning. Others approach the task by the automatic creation of rules with the aid of product label parsing [13]. In the iMedication project, we integrate the operative knowledge of local and remote experts by linking distributed knowledge repositories and manually derive specific rules from expert knowledge. This enables us to specify complex rules for the identification of ADEs. The system reports detected ADEs according to their severity. The reports additionally include an explanation as to how the knowledge base came to its conclusion to report an ADE. Furthermore, the report provides information that helps the physician or clinical pharmacist to take corrective therapeutic measures. If necessary, a report is forwarded to the Austrian Agency for Health and Food Safety (AGES), the agency responsible for pharmacovigilance in Austria. The workflow of ADE identification, verification, and reporting is shown in Figure 1.
In the present paper, we report the results of a pilot study on effectiveness performed in 2012. Using data on patients admitted to the University Hospital of Salzburg (UHS) in 2007 and 2011, we analyze the sensitivity and specificity of the system in detail.

Methods

Theoretical foundations

The iMedication system is founded on the principles of the “Institute for Healthcare Improvement (IHI) Global Trigger Tool” method [3] and Morimoto’s classification [14] for the detection of possible ADEs.

The IHI Global Trigger Tool for Measuring Adverse Events is a method of identifying adverse events – especially those causing harm – and measuring the rate of adverse events over time. The method employs triggers – clues on possible adverse events – to track adverse events, including ADEs. However, the tool is not meant to identify all adverse events, but rather performs a retrospective review of a random sample of inpatient data [3].

According to Morimoto et al. [14], irregular use of medication (referred to as incidents) can be classified in many ways: actual ADEs vs. potential; preventable vs. non-preventable; ameliorable vs. non-ameliorable; and errors vs. non-error. According to this method, an ADE is regarded as an injury due to medication.

In general, incidents are identified by collecting practice data, soliciting incident reports from patient caregivers, and surveying patients directly. These data are then independently reviewed by patient caregivers using various triggers, such as:

- Symptoms or actions that suggest a (potential) ADE or medication error, such as a new rash or new diarrhea.
- Diagnoses associated with (potential) ADEs or medication errors, such as poisoning by drugs.
- The use of specific drugs that suggest an ADE may have occurred.
- Drug combinations are known to cause ADEs or the use of duplicate drugs.

- Combinations of drugs and symptoms that might indicate a (harmful) reaction to the drug, such as diarrhea or eruption due to antibiotics.
- Combinations of drugs and patient diagnoses, such as bleeding and antiplatelet agents or warfarin.
- Combinations of drugs and other factors such as patient age or sex, or pregnancy.
- Laboratory triggers, such as microbiology results that show an improper use of antibiotics.

Study design, setting, and participants

We conducted a retrospective single-center cohort study on sample data that were collected prospectively and validated. The study was performed at UHS, a tertiary-care and teaching hospital. In this study, we focused on two key groups in ADE detection: women and the elderly. Data from the UHS were collected from patients admitted in 2007 or 2011 to any ward of the Department of Internal Medicine (I+II). All female adult patients (age ≥ 18 years) admitted for at least 24 hours were eligible for the study. An additional age constraint was imposed on patients admitted in 2007: all of them had to be older than 75 years.

Data management and sample size

Demographic patient information, as well as clinical and laboratory values, were obtained through systematic interrogation and sampling of the hospital information system (HIS). A total of 70 patient cases were selected for the study; 22 from 2007 and 48 from 2011.

Data sources

Patient data were collected from various sources, such as the UHS’s HIS, or manually entered data. The following six main categories were used:

- Demographic data including demographic information such as age, sex, weight, height, pregnancy, or epidemiological studies.
- Laboratory findings provided by the HIS, such as serum creatinine, potassium, sodium, etc. Different time frames exist for absolute and relative findings. Absolute values are only taken into account within a time frame of three days prior to the data of
calculation, whereas relative values permit a time frame of seven days.

- Symptoms that occurred during the preceding seven days are integrated into the analysis.
- Diagnoses are defined according to the 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-10). A single diagnosis is identified by a 3- to 7-digit code (such as E87.5 for hyperkalemia). When more than one diagnosis from a diagnostic group is detected in the patient’s chart, all of the diagnoses from this group are counted as a single trigger.
- Medications are specified by the Anatomical Therapeutic Chemical Classification System (ATC), according to which a single substance is defined by a 7-digit code.
- Hospital events denote any consultations of psychiatrists or trauma surgeons and internal accident reports during the hospital stay.

**Risk score calculation**

Risk score values and rules were determined by clinical and pharmacological experts and are assigned to ADE triggers which are processed by an algorithm to calculate an overall ADE risk score on a given scale (1–5). Based on the ADE risk score, appropriate reminders are sent to the physicians and pharmacists. Furthermore, reporting forms are prepopulated with the relevant patient data and the suspicion of an ADE.

The ADE risk score calculation consists of five main steps:

1. **Patient data filtering.** Only those data elements within a specified timeframe related to the calculation date and specified conditions are relevant for the calculation process. The time frames are based on clinical experience. Patient data shall be integrated when the medication that may cause an ADE has been administered during the preceding three days.

2. **The recognition of at least one medication which may cause an ADE is a prerequisite for the calculation of an ADE risk score and the specific rules.**

3. **Depending on the number of positive triggers from each category, a contribution to the ADE risk score is calculated. The maximum value of all categories is added to the ADE risk score (see Table 1).**

4. **The ADE risk score is adapted by a value that depends on the quantity of the patient’s medication (see Table 2).**

5. **Standardization of the last ADE risk score is the last calculation step. The maximum value for the ADE risk score is 5.**

**Table 2**– The adverse drug event score increases, depending on the number of administered medications

- The occurrence of 2–4 different medications from the medication lists causing the ADE for the use case results in an increase of the ADE risk score by 1.
- The occurrence of >4 different medications from the medication lists causing the ADE for the use case results in an increase of the ADE risk score by 2.

Note: ADE, adverse drug event.

**Knowledge base and data processing**

Four highly critical clinical situations, namely hyperkalemia, hyponatremia, renal failure, and over-anticoagulation, were defined as use cases for the iMedication project. These constitute significant ADEs in internal and geriatric medicine. The four knowledge bases in iMedication are based on these use cases, which are implemented in Arden Syntax, which is a knowledge representation and processing language supported by HL7 International [13]. Each knowledge base consists of several medical logic modules (MLMs) [16, 17], which are the basic knowledge representation and processing units in Arden Syntax and are executed by an Arden Syntax engine [18]. In all there are 33 MLMs, taking 51 ADE triggers into account.

Data are processed as follows: First, all relevant data are collected and aggregated into an information block – a patient object – and forwarded to the Arden Syntax server. The Arden Syntax engine processes the obtained information and returns one result object for each knowledge base and each day. The return objects contain complete patient data, thus permitting the explanation and tracing of decisions made by the iMedication system. Also, for each category, the fired triggers are stored and attached. The result object includes information on the severity of the detected ADE; this information determines the ADE risk score.

**Presentation of results**

We use patient demographic information (age, length of stay, number of verified ADEs) and treatment information (number of administered medications) to describe the patient population. We also discuss the number and risk score of ADE triggers during the study period. We define each ADE trigger with a risk score ≥ 4 as a “positive test”, and ADEs with lower risk scores as a “negative test”. Using this classification, we determine the effectiveness of the system as well as its sensitivity (SEN), specificity (SPE), positive predictive value (PPV) and negative predictive value (NPV) metrics.

**Results**

The mean age of the patients was 76.5 years (standard deviation 13.3 years, minimum 43 years, maximum 99 years). The mean duration of the hospital stay was 11.2 days (standard deviation 10 days, minimum 2 days, maximum 53 days). On average, a patient received 8.5 medications during his/her stay (standard deviation 4.7; minimum 1 medication, maximum 29 medications).
Of the 70 patients included in the study, 16 (22.8%) experienced one or several ADEs confirmed by patient caregivers. Twelve patients with ADEs were registered in the study population of 2007, and 4 patients with ADEs among those examined in 2011. In all 26 ADEs were confirmed for the four medical situations implemented in the knowledge base: 2 for hyperkalemia, 13 for hyponatremia, 8 for renal failure, and 3 for over-anticoagulation.

A total of 428 triggers were generated during the study period. An overview of these triggers and their scores are shown in Table 3.

Discussion

We present the iMedication system, a computerized system that supports pharmacovigilance by detecting and reporting potential ADEs. We outlined the underlying principles and mechanics of the system, and established the sensitivity and specificity of the current pilot system. However, it needs to be refined before it can qualify as a trustworthy alarming system (PPV 31%).

Computerized trigger tools for inpatient ADEs perform moderately well, are inexpensive to use, and already deployed in many hospitals [19]. The iMedication system was able to correctly identify 85% of all ADEs, which is many times higher than the numbers of commonly reported ADEs (1–13%) [4]. According to a recent study, only 4.5–5.5% of ADEs are reported in Austria [21].

The iMedication system is able to help clinicians in many ways. First, a retrospective evaluation of clinical data permits quality assurance through statistical analysis of detected potential ADEs. Second, physicians are given active feedback (notifications) during the treatment of their patients, thus enabling them to take corrective measures in a timely manner.

Finally, the iMedication system supports (semi-)automated ADE reporting by notifications to the pharmacist with prepopulated forms. As a result, ADEs can be avoided or corrected. When they do occur, their reporting consumes less resources.

The limitations of the study are worthy of mention. First, in the present evaluation phase, data input is accomplished semi-automatically because all relevant patient data are not available in electronic form. Furthermore, the four use cases currently implemented in the knowledge base need to be evaluated in a wider setting and improved in order to avoid alert fatigue. Finally, additional studies will be carried out to evaluate the iMedication phenomenon of much more frequent ADE reports to the AGES than is achieved by conventional reporting.

Conclusion

We showed that a comprehensive solution for the (semi-)automated detection and reporting of ADEs is not only feasible but also effective. Given the fact that the tracking and reporting of ADEs occur on a voluntary basis, the integration of an automated computerized method in clinical routine would provide more information about the scope of the ADE problem at a minimal expense of resources.

Usability Evaluation of an EHR’s Clinical Notes Interface from the Perspective of Attending and Resident Physicians: An Exploratory Study

Rubina F. Rizvi, Jenna L. Marquard, Marcus A. Seyward, Terrence J. Adam, Jed T. Elison, Gretchen M. Hultman, Kathleen A. Harden, Genevieve B. Melton

Abstract

Usability gaps between current and future improved Electronic Health Record (EHR) system designs exist due to insufficient incorporation of User-Centered Design (UCD) principles during System Development Life Cycle (SDLC). Usability of a commercial, inpatient EHR clinical notes documentation interface was analyzed from standpoints of two provider groups employing two standardized patient cases. Both objective and subjective data were collected from attending (n=6) and resident physicians (n=8) through usability testing employing a mixed method approach. The study results suggested that (i) EHR usability and desirability is influenced by user characteristics, (ii) workloads associated with H&P and progress notes writing are perceived differently between two groups, (iii) repeated task performance improves user efficiency and (iv) user performance is correlated to their subjective system assessments. Understanding usability of clinical documentation interface from perspectives of two different user groups, provides interface designers with an opportunity to develop an EHR system centered on UCD principles.

Keywords:
Electronic Health Record (EHR); User-Computer Interface; Documentation

Introduction

While Electronic Health Record (EHR) systems have been widely adopted with the ultimate goal of improved health care delivery [1], substantial gaps exist between the current state of EHRs and their potential usefulness [2]. Poor EHR usability appears to be a major factor for this discrepancy [2]. To facilitate optimal end product usability, it is critical to understand end users’ “usage behavior”, considered a core feature of a User-Centered Design (UCD) approach [3,4]. The UCD philosophy is that “the final product should suit the users, rather than making the users suit the product” [5]. According to the International Organization for Standardization (ISO)-framework used in this research study, usability is defined as the, “extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” [6]. Similarly, in EHR design, user involvement throughout the System Development Life Cycle (SDLC) can facilitate the development of systems that are easy to learn and remember, efficient, minimize errors and improve user satisfaction [7], which could improve EHR adoption and better patient outcomes [8].

Despite the critical role of the Human Computer Interaction (HCI) in the SDLC process [9], it is often neglected during EHR interface design. Usability studies on EHRs’ clinical decision support system and user interfaces for medical equipment have been done in the past [10,11], but there are not many studies focusing on clinical notes documentation within an EHR interface [12-15], with only few studies done on usability evaluation and prototyping of clinical notes user interfaces in the medical domain [12-17]. Similarly, usability of a system could vary with vendor types and user profiles (e.g. clinical experience, EHR training, age, gender, technology skills etc.) However, few research studies incorporate usability comparisons from diverse user perspectives (e.g., expert users vs. novice users; physician vs. patients; users vs. usability experts) [18-20].

Usability testing is accepted as the most effective usability methodology with greatest strategic impact [21]. It is an “activity that focuses on observing users working with a product and performing tasks that are real and meaningful to them” [9]. The purpose of this study is to quantify EHR usability around inpatient notes usage focusing on the clinical note documentation and clinical note viewing interface, an area that poses tremendous challenges to physicians and other clinicians working under time limitations [13]. Both objective and subjective data on users’ task performance were collected from two user groups (i.e., attendings and residents) and analyzed via usability metrics as defined by ISO (i.e., effectiveness, efficiency and satisfaction) [6]. Supplementary data were also analyzed for subjective workload using the NASA-TLX instrument [22] and system desirability with Product Reaction Cards (PRC) [23]. The insight gained through this research provides an opportunity to better understand EHR usability around clinical documentation from the standpoints of two provider groups and identify usability gaps to benchmark future EHR design.

Methods

This research study evaluated the usability of an enterprise EHR (Epic Systems Corporation) system at Fairview Health
Services, University of Minnesota Medical Center (UMMC). The study specifically focused on clinical documentation tasks (e.g., H&P and progress note writing). Scenario-based usability testing was conducted on two high-fidelity simulated test patient charts [24] in an Epic test environment replicating the real work environment, both in design and functionality. Testing was done at the usability laboratory.

**Study sample**

Physician participants (n=14) were from two user groups: attendings (n=6) and residents, excluding interns (n=8). Participants were in all cases either trained in Internal medicine or Family medicine with past and/or current inpatient experience with the Epic Fairview EHR. Detailed user characteristics categorized by user group, are summarized in Table 1.

A=Attendings; R=Residents; Clinical Exp.: Clinical Experience (Residency training and later); Epic Exp.: Total years of experience with using Epic

Participation was voluntary and participants received $50/hour. Each session was 2.5-3 hours long and each physician was at least 24 hours off night call on their day of data collection. The study protocol was approved by the Institutional Board Review.

**Data collection and analysis**

Two simulated, high-fidelity test patient charts with rich, realistic clinical data were created in an Epic test environment to provide scenario-based EHR usability testing [24]. Patients were built from representative cases after extensive discussion among five experts: the lead EHR physician trainer (MS) and four physician informaticists (RR, TA, GMM & EA). Patient cases with similar complexities were selected using a Charlson weighted comorbidity index and number of prior admissions, clinic visits, and clinical notes. In both clinical scenarios, patients with a history of Chronic Obstructive Pulmonary Disease and Congestive Heart Failure presented in the emergency department with sudden onset shortness of breath. Each participant was assigned two patient cases in a random order employing an online randomization tool [25]. A Randomized blocked design approach was used to create balanced distribution of test patients across two groups. Each participant performed the same tasks of entering a H&P and a day 1 progress note, on each test patient’s chart.

Raw data was extracted employing Tobii studio version 3.4.5 and was evaluated in three ways: (a) user satisfaction, via the System Usability Scale (SUS) questionnaire [26, 27] (b) efficiency, via time on tasks, key presses, & mouse clicks and (c) effectiveness, via note quality using the Physician Documentation Quality Instrument-9 (PDQI-9) [28] and overall Gestalt judgment [29]. Data from each user group was also analyzed for subjective workload index using the NASA-TLX questionnaire [22] and system desirability via Product Reaction Cards (PRC) listing 118 words [23]. All participants were asked to circle their top 5 choices, which were later compiled as a word cloud and Venn diagram to visualize total and unique word selection by each user group.

Note quality assessment was performed by two co-authors/physicians (RR and TA) using standardized metrics as previously reported with the Physician Documentation Quality Instrument-9 (PDQI-9) [28] and overall Gestalt judgment [29]. Pretesting of these instruments for note quality assessment was conducted on a set of unrelated notes to ensure that both reviewers shared a common understanding of item scoring. Once consensus was achieved, both evaluators reviewed and assessed approximately 14% of notes (8 of 56 notes). The consistency in quality assessment was checked by inter-coder agreement with final mean agreement for PDQI-9 of 81% (kappa=0.69) and Gestalt scoring of 87.5% (kappa=0.71). We report summative statistics using SAS enterprise guide 5.1 and StatPlus LE 6.0.3 (a statistical software plugin for Macintosh) with means and standard deviation (sd).

**Results**

While not statistically different, user satisfaction with respect to overall usability of clinical note entry was perceived worse by attendings (mean SUS = 60.8 ± 15.6 (i.e., marginal usability)) compared to residents (mean SUS = 73.4 ±13.5, (i.e., acceptable usability)), despite longer average Epic experience among attendings (≥ 5 years, n=5/6) compared to residents (< 5 years, n=8/8). The SUS and their interpretation [27] are illustrated in Fig 1.

![Figure 1-SUS based on users’ characteristics](image)

Efficiency was quantified based on time on task, key presses, and mouse clicks. H&P writing was more time-intensive than progress notes for both attendings (26.2 ± 9.7 vs. 14.0 ± 6.4 minutes) and residents (24.2 ± 7.7 vs. 12.3 ± 4.5 minutes). Residents took slightly less time than attendings writing both...
H&P (24.2 ± 7.7 vs. 26.2 ± 9.7 minutes) and progress notes (12.3 ± 4.5 vs. 14.0 ± 6.4 minutes). Time on task decreased from the 1st to 2nd patient, except for progress note writing among residents (Fig 2).

More key presses (KP) and mouse clicks (MC) were observed with H&P as compared to progress note writing for both attendings (KP=2,644 ± 1,535 vs. 1,433 ± 682, MC=201 ± 83 vs. 126 ± 60) and residents (KP=3,468 ± 1,199 vs. 1,758 ± 689 MC=214 ± 82 vs. 112 ± 46) with residents generally performing more key presses and mouse clicks compared to attendings with exception of progress notes where attendings had more mouse clicks. The number of key presses and mouse clicks decreased from the 1st to 2nd patient, except for residents’ number of mouse clicks during progress note writing (Fig 3, 4).

Effectiveness, as measured through PDQI-9 scores on note quality showed no quality differences between H&P and progress notes by attendings (34.9 ± 3.8 vs. 34.8 ± 4.8), though resident progress notes were slightly higher quality than H&P notes (35.5 ± 6.3 vs. 33.8 ± 4.0). Attendings’ H&P notes (34.9 ± 3.8 vs. 33.8 ± 4.0), and residents’ progress notes (35.5 ± 6.3 vs. 34.8 ± 4.8) showed only minimal quality differences. No noticeable differences in note quality between attending and residents were detected through Gestalt scoring both for H&P (3.7 ± 0.7 vs. 3.8 ± 0.8) and progress notes (3.9 ± 0.9 vs. 4.0 ± 1.0). PDQI-9 scores increased from the 1st to 2nd patient, except for residents’ progress notes (Fig 5).
This research study is an important initial step towards understanding the usability of EHR clinical notes documentation from attending and resident physician perspectives. EHR usability, as quantified through objective measures of user performance and their subjective perceptions, varied with each group, note type, and repeated tasks. Varying degrees of correlation were also discovered between variables, suggesting that user performance is related to their subjective system assessments. The insight gained through this research provides an opportunity to better understand EHR clinical documentation usability, identify and address existing usability gaps, and establish benchmarks for future EHRs.

Based on the SUS, residents perceived the system to have “acceptable usability” while attendings perceived the system to have “marginal usability”, despite attendings having more technical experience, leading to easier technology adoption. Thus, user characteristics appear to be a critical factor for EHR usability.

In terms of efficiency, as quantified by time on task, key presses and mouse clicks, attendings and residents both took significantly more effort with H&P compared to progress note writing. Residents perceived less subjective workload associated with progress notes suggesting that residents were more at ease in writing progress notes. A potential reason for this is the nature of progress note writing task itself, which is more repetitive and most likely to be influenced by a system’s usability (e.g., copying and pasting, auto population, multiple screen panel functionalities, etc.) In comparison, attendings showed less subjective workload with H&P writing suggesting that they are better skilled in writing H&P notes, a cognitively demanding task which involves providing a reason for admission and providing initial patient management direction. Thus, targeted note documentation training of physicians where there is a lack of proficiency (e.g., H&P among residents and progress note in attendings), would be a reasonable approach to consider. No noticeable difference in note quality between attending and residents was detected through Gestalt scoring.

Generally, efficiency improved as users performed the same note writing tasks on the 2nd patient with the exception of progress note writing among residents. The plausible explanation of the observed differences may be due to user familiarity with the system and faster cognitive processing as a result of repeated task performance, as well as specifics around the second patient case. No effect of patient order was observed on perceived workload while there was some indication of improvement in note quality, especially progress notes, among attendings and H&P writing among residents.

We discovered that increases in subjective workload (NASA) were associated with decreases in user satisfaction (SUS) and note quality (per Gestalt). Higher satisfaction was associated with better quality notes (per Gestalt). We found a strong positive correlation between PDQI-9 & Gestalt, but no correlation was detected between PDQI-9 & SUS or with time on task and note quality for both PDQI-9 & Gestalt.

There are some limitations associated with this study, including a small sample size lacking significant inferential statistical results. Generalizability is limited due to the inclusion of physicians (MDs) with training in either Internal medicine or Family medicine and testing of inpatient EHR interfaces only. Future studies are mandated with larger sample size, more diverse group of participants (e.g., medical students, nurses, ER physicians etc.) and on different EHR systems (e.g., EHRs used in ambulatory settings, emergency rooms and as well as specialty specific EHRs). Additionally, the impact of other user characteristics (e.g., age, gender, etc.) needs to be explored further. There are also some limitations associated with usability testing itself (e.g., relevance of scenarios/tasks being tested, system speed and connectivity etc.). In addition, understanding physicians’ EHR usage behaviors around clinical note documentation, the focus of our next study, is an essential area that needs to be further explored.

Conclusions

We discovered that EHR usability measures of satisfaction, efficiency, and effectiveness vary with users’ characteristics, specific note types, and from repeated performance of the same task on consecutive patients’ charts. This study provides preliminary, yet essential information on objective measures of user performance and their perceptions of EHR usability around clinical notes usage. These measures can serve as initial guidance to build EHR interfaces grounded on a “User-Centered Design” approach.

Strengthening Data Confidentiality and Integrity Protection in the Context of a Multi-Centric Information System Dedicated to Autism Spectrum Disorder

Mohamed Ben Saida, Laurence Robelb, Bernard Golseb, Jean Philippe Jaisa

aParis Descartes University, Faculty of Medicine, Department of Biostatistics and Medical Informatics, APHP - Necker Enfants Malades Hospital, Paris, France
bDepartment of Child Psychiatry, APHP - Necker Enfants Malades Hospital, Paris, France

Abstract

Autism spectrum disorders (ASD) are complex neuro-developmental disorders affecting children in early age. Diagnosis relies on multidisciplinary investigations, in psychiatry, neurology, genetics, electrophysiology, neuro-imageries, audiology, and ophthalmology. To support clinicians, researchers, and public health decision makers, we developed an information system dedicated to ASD, called TEDIS. It was designed to manage systematic, exhaustive and continuous multi-centric patient data collection via secured internet connections. TEDIS will be deployed in nine ASD expert assessment centers in Ile-de-France district. We present security policy and infrastructure developed in context of TEDIS to protect patient privacy and clinical information. TEDIS security policy was organized around governance, ethical and organizational chart-agreement, patients consents, controlled user access, patients’ privacy protection, constrained patients’ data access. Security infrastructure was enriched by further technical solutions to reinforce ASD patients’ privacy protection. Solutions were tested on local secured intranet environment and showed fluid functionality with consistent, transparent and safe encrypting-decrypting results.

Keywords:
Autism Spectrum Disorder; Data Encryption; Security Policy

Introduction

Electronic health record and patient personal information protection are critical for trust and reliability of an information system whether it is used within a locally accessible health care facility or over the Cloud and Internet network. A security policy and infrastructure was developed for both confidentiality and integrity of information managed in TEDIS [1,2], an information system, dedicated to patients with Autism Spectrum Disorder (ASD) [3].

TEDIS was developed in the Department of Child Psychiatry and the Department of Biostatistics and Medical Informatics (SBM) at Necker Hospital, in Paris, France. TEDIS is aimed at supporting medical community and public health decision makers to improve knowledge about psychopathological, physio-pathological, and etiological processes involved in ASD, to follow-up incident patient cohorts and to support decision making, patient care, and research. To reach these objectives, TEDIS was designed to manage systematic, exhaustive and continuous multi-centric ASD patients data collection via secured internet connections. Nine ASD patients’ assessment and multidisciplinary centers in Ile-de-France district collect a large amount of valuable clinical data. Eight centers evaluate children from 3 years to-up and one center provides ASD assessment information for teenagers and adults. ASD patient assessment lasts about three weeks in a specialized ASD assessment center. Patients undergo evaluation in a variety of domains: clinical assessment of psychological, motor and speech development, consultation in neurology and genetics, and specialized para-clinical exams including brain MRI with spectroscopy, contextual EEG, standard and high resolution caryotype, searches for chromosomes alterations by fluorescent in situ hybridization (FISH), Comparative Genomic Hybridization Array (CGH-Array) and for metabolic disorders. Additional investigations guided by clinical exam are prescribed as necessary. A written report is issued at the end of the assessment. It is transmitted to parents, care providers and/or institutions involved in the patient care. Formal demands are consequently addressed to specialized institutions to consider patient admission, to the Institution of Handicapped Persons (MDPH) to qualify the handicap and to the Social Security medical officer to qualify the long term character of the disease (ALD) in order to benefit from the medical care cost coverage. Treatment consists of life term care: series of early and individually adapted measures in domains of education, behaviour, and psychology. Treatment compliance, may significantly improve relational capabilities and social interaction with some degree of autonomy and possibility of language acquisition and non-verbal communication [1].

The national ethics and computing authority called Commission Nationale Informatique et Libertés (CNIL), authorized use of TEDIS within a conditional-framework based on patient’ consents, respect of privacy, and protecting personal information [2]. The main philosophy behind confidentiality and privacy protection was to limit without affecting the research objectives, risk of altering data integrity and risk of unauthorized access which may lead to data loss or to establish a link between patient personal information and clinical information. CNIL formally requested to restrict access to authorized professionals and to store information which may directly or indirectly lead to identifying patients’ (e.g. last name, first name, date of birth and sex), only in a strongly encrypted form on the database server.

On the other hand, TEDIS users particularly psychiatrists and clinicians, requested ability to visualize in plain text form patient identifying information – last name, first name, sex, and date of birth. Main point being to help directly

1 In french : Maison des Personnes Handicapée (MDPH)
2 In french : Affection de Longue Durée (ALD)
disambiguate patient’s identity, facilitate linking clinical data to appropriate patient and facilitate quality control. Therefore, patient phonetic search on the web page using a list of patients assessed within one clinical ASD assessment center is possible allowing access to ASD patient record for consulting and editing.

We obtained CNIL agreement in mid-2014. Medical experts, clinicians and interns in child psychiatry department at Necker hospital started testing TEDIS application, over a stand-alone computer-server managed by SBIM at Necker Hospital. The experimentation helped adapting and improving system performance and stabilizing conceptual data model. It allowed conducting proof of concept and demonstrated feasibility of proposed scenarios of use of TEDIS in the nine ASD expert assessment centers. TEDIS patient privacy protection became crucial in the perspective of opening internet access to professionals in the ASD assessment centers.

In the following, we will recap security policy adopted and describe in more details methods adopted in security infrastructure to reinforce patient privacy protection in TEDIS. We will then discuss strengths and limits of our approach and perspective of future improvements and optimization. To begin with, we look at literature feedback in relation with the raised questions.

Literature review

Several articles address electronic health record security and privacy protection in the context of electronic health care information systems. Two major axes, with related subtopics of interest to our study may be distinguished: Security policy and Security infrastructure. “The security policy should clearly define the guideline for creating, accessing and maintaining the integrity of patient e-health data and the scope of accountability for each responsible party. A security infrastructure covers the issues of login authentication, cryptography, access control,... audit,... and disaster recover” [4].

Securing connection between the client and the Server

A major part of the security policy relies on the hosting environment of the application and database servers. French legislation defined personal health data hosting criteria in decree n°2006-6 of Jan 4th 2006 [5]. All medical information systems in France, managing personal and health information via the internet must be hosted at an Accredited Internet Hosting Provider in conformity with the legislation.

In addition, securing the connections between client and server would be provided at the application and network levels. The application security infrastructure would support secure connections between a client and server through encryption and authentication. Additional authentication controls and verifications are performed to reduce opportunity for interception of messages and unauthorized access to the server. “At the network level, access to the Application server would be restricted by the client’s internet protocol (IP) address. Each site that wishes to use the service must submit the fully qualified domain name and static IP address of the machine that will run the client application. In addition, the server audits all access and requests and reports unusual activity to the system administrator” [6].

Access Control

R.R. Schell insisted on the “scientific and engineering rigor needed for a trustworthy system to defend the security of computers in three dimensions at the same time: mandatory access control (MAC) policy, protection against subversion, and verifiability.” [7], Jayabalan and O’Daniel emphasized ISO 22600-1:2014 principles and guidelines in a large systematic literature review of access control for electronic health record systems to protect patient’s privacy. ISO 22600-1:2014 defines principles and specifies services needed for managing privileges and access control for communication and use of health information distributed across policy domain boundaries. It highlights information sharing between diverse health care entities ... without compromising privacy and integrity of EHR [8]. In similar projects managed at SBIM-Necker for renal disease and for rare diseases domains, we developed experience with Discretionary Access Control (DAC) to organize users’ access to dedicated information systems [9,10]. DAC is “based on the decision of the owner, to limit access to patient data based on the identity of subjects and/or groups to which they belong” [4].

On another hand, Mandatory Access Control (MAC) [4] presents an interesting approach in that “it assigns security labels ... and allows access only to entities ... with distinct levels of authorization or clearance. MAC controls are enforced by the operating system or security kernel [5].

Confidentiality-Privacy protection

Cryptography is used for reinforcing patient privacy protection and data integrity. It is “the study of Secret (crypto-) writing (-graphy) that is concealing the content of message from all except the sender and the receiver and to authenticate the correctness of message to the recipient” [11]. Cryptography goals “include privacy or confidentiality, data integrity, authentication and non-repudiation”[4,11,12].

Chenglong addressing “internal staff member accessing and disclosing patient privacy information” suggested to “encrypt privacy data before” storing it on the server database “using traditional algorithms, so that the data even if being disclosed are also difficult to be decrypted and understood” [13].

In the present work we focused on the following technologies to reinforce privacy protection: symmetric cryptography [11,12,14], hash coding [15], Sealed Objects [16] and serialization [17,18].

- Symmetric cryptography: “In symmetric key cryptography the same key is used to encrypt and decrypt the data...The main problem with symmetric key algorithm is to exchange the secret key and cipher text between the sender and the receiver. It requires a secure channel” [11]. The authors compared symmetric keys (DES, 3DES, AES, Blowfish) performances. They concluded that “blowfish algorithm is superior to the other algorithms: DES, AES and Triple DES on the basis of key size and security. Blowfish algorithm runs faster than other symmetric key encryption algorithms and gives better performance in terms of encryption time, decryption time and throughput.” [11].

- Hash coding: “Whenever it is invoked on the same object more than once during an execution of a Java application, the hashCode method must consistently return the same integer...” [6,15].

- Sealed Objects: The SealedObject class in Java enables a programmer “to create an object and protect its confidentiality with a cryptographic algorithm” [16], while

- Serialization: “to serialize an object means to convert its state to a byte stream so that the byte stream can be reverted back into a copy of the object” e.g. “Object Serialization supports the encoding of objects and the objects reachable from them, into a stream of bytes”. Serialized objects may be stored in a file, directory or in a database [17,18].
We developed a solution which combines a sequence of cipher processes of patient private information starting from the user interface, to the middleware and to the server database. Whenever requested, backward decipher processes are executed from the server database to the middleware and to the end-user interface.

We organized the encryption/decryption sequence presented in the literature review section to provide a stable, performant and robust solution for preserving data integrity, hiding private data on the server side database.

Security policy

Hosting

In order to comply with the decree [5], we recently had a formal agreement with the informatics department of Assistance Publique des Hôpitaux de Paris (APH), as an Accredited Hosting Provider in Health Personal Data, certified by the Public Health Ministry to host TEDIS application and database servers and offers secured internet connections to the professionals in the ASD assessment centers.

Patients’ Consents

Given the complexity of ASD diagnoses and that only a subset of patients assessed in the specialized centers are diagnosed as ASD patients, child-psychiatrists at Necker hospital decided to solicit ASD patients’ consents when there is an agreement about ASD diagnosis among practitioners in charge of the patient. In this case, further multi-disciplinary investigations are prescribed and some like genetics require specific patient consent.

Patient data access:

TEDIS internet application is accessible only to authorized professionals within identified entities and identified IP address ranges.

A steering committee comprising psychiatric referents in each ASD expert assessment center, regional representative of health ministry, methodologists and physician responsible of TEDIS information system elaborated an ethical chart-agreement to commit all the participants to the TEDIS project.

The chart reminds patient ownership of the data produced in TEDIS as well as the mandatory patients’ consents prior to data collection. The chart reminds the contexts of accessing and processing nominative patients’ data and anonymized patient data: either for data production and quality control at the production entity site in the first or for aggregated patient data sets for statistical processing in the second case. Besides, the Chart also reminds the role of the scientific committee in selecting research projects and accrediting scientific publications as well as conducting and representing TEDIS project.

We define three contexts for users to access and use TEDIS patient private data:

- Nominative patient data and Data production context: Within an ASD assessment center where explicit nominative patient data, are needed for quality control. Authorized medical and clinical professionals directly participate in TEDIS ASD patients’ data production with support of a clinical research assistant (CRA) responsible for quality control and data consolidation. A psychiatric referent designates in each ASD assessment center, professionals authorized to use TEDIS information system and specifies their role. Each authorized professional, may access only patient information s/he is responsible for, within one ASD assessment center. S/He has to sign the chart agreement and is responsible for quality of information produced in TEDIS.

Centralized unique user name and password are issued and maintained by physician responsible of TEDIS at SBIM Necker.

Formal, postal correspondence to authorized professional, communicates access logging keys to use TEDIS, along with chart-agreement for signature and adhesion.

- Anonymized patient data and Data processing context: Only anonymized patient private data are used in this context, for presentations and/or local research projects, within one ASD assessment center or between multiple centers. In this context the CRA will organize periodically meetings with TEDIS steering committee to present the patient data production process, to comment the data quality control centers and to make suggestions for follow-up.

- Anonymized aggregated patient data may be extracted for broader research projects: Specific scientific and ethical authorizations might be required. TEDIS scientific committee has to decide on how to use TEDIS patient data and specifies conditions to accredit scientific work and publications.

Security infrastructure

Discretionary Access Control

Discretionary Access Control is implemented in TEDIS [4]. Users connect to the application with their user name and password on TEDIS web page [8]. Additional transparent authentication information is controlled when logging into TEDIS system. Number of connection failures is limited and network traffic surveillance permits detecting abnormal behavior and robot phishing [13,14].

We implemented TEDIS based on n-tier architecture and thin internet client. Most of the computing processes occur at the server side. We used Java JSP/Servlets technology and Apache Tomcat Web server to communicate between client and MySQL database server. The servers are deployed on Linux environment [1].

For maintenance and evolution purposes of the security technologies, we referred in our work to standard cryptography methods to reinforce patient privacy protection.

Personal data protection: Scenario of use:

Before submitting the web page form, patient private data are encrypted and sent over secured internet connection to the web server. We used a strong symmetric encoding algorithm (AES with 256 bits keys) in JavaScript, which integrates the time of user’s interaction with web-page to generate a single key and cipher text [15] (Figure 1). While building character String to encrypt, we used a standard field separator to distinguish each field (last name, first name, sex and date of birth), and augmented the String with additional information intrinsic to the patient record. The information is sent to the server via secured internet connection.

We decided to strengthen security at the server side, by encrypting again data submitted from the user-interface before storing it on the database server. We first encapsulated each of the cipher text and key respectively into a specific Java Objects called Sealed Object. We used SealedObject Class [9] which enables creating an object and protecting its
confidentiality with a cryptographic algorithm. We then serialized [10,11] the sealed objects and respectively saved them in distributed databases on the server side.

The link between patient private data and clinical data remains the patient ID, automatically generated by TEDIS information System. In case of stolen hard disc with the patients’ private data, and to make it more difficult for a non-authorized user to retrace relations between serialized objects and the patient ID, we decided to dynamically generate a one-way hash-coded patient-ID with augmented information and use it to appropriately map serialized objects in the databases [15]. The resulting hash-code-patient-id with the appropriate reference to the serialized objects is saved in separate correspondence database table. Logging access and actions to the correspondence table are particularly monitored within TEDIS application.

Patient data retrieval: scenario of use

To access one patient’s clinical record, TEDIS user either enters patient ID or selects patient ID from a list on the web-page. Patient private data retrieval has to go dynamically through the inverse process of encryption, sealed-object creation, and serialization in the database.

A first step is to rebuild the patient-ID-hash-code, then to step back through the distributed databases to select, de-sealize and unseal objects to original encrypted data and original cryptographic key. The latter are sent back to the user interface for decryption with the JavaScript program on the user web page [11]. The patient’s corresponding clinical information is directly selected from the database through separate queries and connections and displayed the dynamic web page for display along with the patient private data. The underlying retrieval and decryption processes are transparent. Newly created patient private data are directly encrypted in the database. Basic functionalities of creation, updating and retrieval work in transparent ways with fluidity.

In practice: Encrypting patient private data in TEDIS

Three hundred and sixty ASD patients’ records were entered using a prototype TEDIS application on a stand-alone computer server at SBIM Neckar. Patients’ private data were first saved in plain text form. We updated existing patients’ private data using encryption sequence processes described above. Plain text data were kept for verification. Manual control ensured data integrity and correctness.

We were interested in comparing TEDIS performance when saving and retrieving patients’ private data in plain text in one database table versus in encrypted serialized objects in distributed databases. We used local copies of the database and programs adapted to the plain text patients’ private data for comparisons.

Results

Security policy

Hosting TEDIS within the APHP infrastructure as an official Accredited Hosting Provider in Health Personal Data is a major issue for durability and reliability of our project in terms of security, maintenance, and institutional backing.

TEDIS Charter agreement was elaborated with the steering committee. It represents an ethical and organizational commitment support for all TEDIS users. It had large approval among medical and clinical communities involved in the project, regional health ministry representative and regional Association for ASD assessment centers where autistics patients’ families are represented.

TEDIS in the local stand-alone computer server environment showed correct, consistent, and fluid functioning of the ASD patient private data encrypting-decrypting process for creating a new patient, updating or retrieving patient private data. Comparison (Table 1) showed expected results but gives more precision, an important amplification when scaling (first line 5 seconds versus 81 milliseconds). Retrieving a complete patient record result is not expected, but we are in the time-range of milliseconds, while updating one patient record takes longer with encrypted data.

Table 1 – Performance comparison between one table saved plain text patient private data and distributed database tables saved encrypted patient’ private data

<table>

</tbody>
</table>

Figure 1 – The presentation layer (4), the style layer (3), the action layer (2) of the html web page layer (1). Information is unlocked in plain text at the presentation layer. The encryption algorithm dynamically integrates the interaction time. The resulting encrypted information is submitted to the server via secure Internet connection.

Discussion

While security policy fits with largely described approaches, we would like to discuss the private data encryption impact on the server database for TEDIS use in clinical setting environment.

In our model we processed multiple encryption processes to offer higher patient private data security, integrity and fluidity and efficiency of the solution.
A first consequence of encrypting patient private data on the server side, is to limit patient data phonetic searches only on the application user interface. To access patient record, users either have to enter known patient ID number or select it from a list of decrypted identities of patients assessed in one assessment entity.

While updating and retrieving one patient record remains in range of milliseconds, displaying a list of more than 300 patient private data after decryption processes, ranges between few seconds. It is still acceptable but borderline display waiting time. The main reason for slowness when scaling is multiple databases connections that have to be processed sequentially and properly.

The client desktop computer also needs to perform to permit fluent encryption-decryption. The JavaScript decryption process is still running sequentially on the web-page while clinical information for all patients is already there ready for appropriate display. Program and database optimisation are needed to improve performance when scaling.

Reducing number of encryption process might be another choice but it will weaken privacy security on the server side. We ended up with the encrypting solution presented in the article, as it showed consistency and stability compared to less elaborated solutions where we either had corrupted data on the server-side or unstable interface decryption.

Conclusion

The security policy, together with the security infrastructure provides a robust and reliable framework for a system like TEDIS to be used in clinical setting, and accessed via secured internet connection.

Acknowledgements

Medical experts and health professionals at the nine ASD assessment centres in Ile De France district and the Autism Resource Centre in Ile-de-France are warmly thanked for their support and feedback. This work is supported by the University of Paris Descartes, The Regional Health Agency of Ile-de-France and by the Necker Hospital and the Computing Department of Assistance Publique des Hopitaux de Paris.

Abstract

Electronic health records have often been criticized for poor interaction design. One major problem is the ‘display fragmentation problem’ i.e. the fact that conventional EHRs require the user to view many screens and retain information in memory or external tools rather than being able to view all relevant information together, increasing cognitive load and the possibility of errors and inefficiency. We describe a method for evaluating and depicting the extent of display fragmentation and discuss its potential uses in comparing systems, identifying navigation pathways and information juxtaposition, and improving EHR interaction design.

Keywords:
Electronic Health Records; User-Computer Interface; Computer Graphics.

Introduction

Healthcare information technology (‘health IT’) and electronic health records (EHRs) have great promise to improve care, reduce costs, and create a ‘learning healthcare system’ in which continuous improvement is possible by using data to analyze which treatments are most effective. However, optimal interaction design of such software has proven difficult, with the potential for health IT to introduce safety concerns.

The Institute of Medicine 2011 report \cite{1} identifies several concerns related to fragmented displays and the conventional interaction approach in which information location is fixed by the programmer and users navigate through menus. These concerns include the mismatch between programmer assumptions and actual work environment and the mismatch between developer and clinician backgrounds, resulting in unmet needs. Current displays may not reflect clinical associations, presenting related data separately. Activities are treated as belonging to individual clinicians, instead of to a sociotechnical system with many intercommunicating components and unpredictable ways \cite{1}. Inflexible order sequences may require providers to hold orders in mind while navigating, and time spent on cumbersome data retrieval and remodeling is time taken from other clinical demands \cite{1}.

Display fragmentation occurs in conventional systems when the end user must click through and view many different screens or parts of screens in order to view all the relevant clinical information. This necessitates sequential viewing and requires retaining information in memory while other parts of the information are sought. The end user must often then serve as the ‘de facto integrating agent’ \cite{1}, integrating information in mind rather than using external tools. This is a known cause of excessive cognitive load and may impair optimal clinical reasoning performance and other aspects of clinical cognition. Addressing the display fragmentation problem is therefore an important task in redesigning clinical information systems for better efficiency and cognitive support.

Prior work reveals conventional EHRs have an approximate six-fold greater number of clicks and screen transitions required to obtain complete information \cite{2} than systems in which the relevant information for a task can be included on one screen. Conversely, appropriate information juxtaposition can foster insight, creativity, sensemaking, and problem-solving \cite{3,4}.

Modular composable systems

Because the display fragmentation problem arises partly from the fact that information location is typically fixed by the programmer, one means of addressing it is to by making systems a) modular (i.e. pieces can be rearranged and reassembled flexibly according to different needs, like a Lego set), and b) composable by the end user clinician. Removing the requirement for a programmer to reconfigure displays and giving the clinician the ability to assemble any desired elements together on the same screen can allow patient-specific display of all relevant information on the same page, reducing cognitive load and respecting clinicians’ deep medical expertise in their choice of elements. Ease of use can mean that drag/drop assembly of ‘objects’ is a simple means of providing this functionality. Some other domains in which user expertise and security/reliability are important have also used this approach; NASA mission control tools are an example \cite{5}.

MedWISER system

Our experimental system, MedWISER, implements a modular composable architecture, in which elements are backed by a controlled vocabulary \cite{6}. Separation of the display elements and back-end data queries allows for a javascript framework which permits the end user to specify display of chosen elements (such as a lab value, note or note fragment, mashup of lab plots, RSS feed) in movable rectangular widgets. These can also be opened to large-screen size, collapsed with only a header showing, colored, retitled, and have other modifications which affect display. This gives the end user considerable power to select and arrange information elements \cite{7}. More advanced features are not discussed in this paper. By permitting choice and assembly of any elements by the clinician, these can be gathered on the same page before or during clinical review of the patient case. This then avoids the fragmentation problem, as repeated navigation to and viewing of other screens is no longer necessary (or minimally necessary). This should avoid the consequent cognitive load, forgetting, navigation inefficiencies and other problems inherent in our current conventional fixed systems. These typically...
present the user with a series of tabs, left-hand menus, drop-down lists or other affordances allowing the user to find and view different pieces of information configured as a hierarchical tree, with higher level menus providing access to more granular information as the tree is traversed.

One way to study and compare systems is to map the locations of the major information elements as they occur according to the navigation structure of the EHRs. This can help us understand the fragmentation problem, suggest design solutions, and compare systems. Here we describe a method of doing this, with a few examples.

**Methods**

**Modified Cognitive Walkthrough**

Cognitive walkthrough is an expert-based, usability evaluation method for identifying usability issues. The expert steps through a typical task, noting all navigation actions, system responses, and potential problems, according to well-established heuristics and expert knowledge. We make use of this basic technique to map information locations, creating the navigation tree by walking through each step from the top of the navigation tree (typically the selection of the specific patient from a patient list) [8]. An example of a map subsection appears below.

Sunburst Visualization

Many different visualizations of hierarchical structures exist with advantages and disadvantages. In this technique we have leveraged advantages of the sunburst visualization. This visualization displays tree structures in a circular fashion (as if the spine of the tree were wrapped around in a circle), facilitating display of entire trees in a single page, with drill down (in interactive versions) to details of leaves. This facilitates apprehension of the relationships between different regions, and makes it easier to show navigation pathways in relation to the overall navigation structures. It also addresses the problem that as the number of leaves expands more space is needed, since the deeper levels furthest from the trunk appear in the outer concentric circles, using the greater available space.

Microsoft Excel 2016 and other tools generate such displays from spreadsheets or hierarchical text documents. See Figure 1. Figure 1 (b) shows the sunburst visualization for the tree section shown in Figure 1 (a).

In the sunburst, sections at the same navigation level appear in the same concentric circle; with leaves below toward the outer rim. Items viewable together on the same screen are included in the same block (with the names all written together in the same sector). Items not viewable together on the same screen
but only sequentially as parts of separate screens accessed from the same menu level appear as separate sectors adjacent to each other, in the same colour as the higher menu level.

Figures 2 and 3 show the essential clinical elements coloured in black. Figure 3 shows the extent of display fragmentation; with each element in a separate sector if it must be navigated to separately, permitting analysis of the EHR structure and where elements are juxtaposed or not.

While figures shown here are relatively simple, visualization software is capable of rendering hierarchies with thousands of elements, with drill-down and expansion capabilities to facilitate examination of relationships between elements, pathway identification, and the study of subsections.

Quantification of Display Fragmentation

The fact that clinical elements appear in different subsections of the tree can be quantified, with respect to useful parameters such as the number of clicks or screen transitions required to access individual elements (starting from the top of the tree, or from intermediate points), as well as the likely numbers of clicks/screen transitions required for typical case review.

Derivation of an expression incorporating these parameters (including such things as requirements to scroll, or filtering functions) could allow comparison across commercial systems, and comparison of whether an interaction design improvement has successfully reduced the numbers of actions and fragmentation.
Results

Initial trials of this method revealed that a majority of end clinical elements (end leaves) of the navigation tree are located at least two levels below the top, and that consequently numbers of clicks and screens may reach dozens in order to view all relevant information. This echoes complaints by clinician organizations that 'too many clicks' are plaguing physicians in practice and delaying rather than hastening good use of the EHR and expected efficiencies [9,10].

Some systems attempt to reduce the problem by having pages for summaries, with varying degrees of success. Two problems identified in our preliminary work are the lack of inclusion of important clinical information in the summary, and the need for scrolling within elements in the summary, with uniform presentation of blocks of data regardless of whether the blocks are populated or not. This has the potential of wasting space and confusing the user, who may be unaware that the data exists elsewhere. The display fragmentation problem still exists where the user must take an action to view all the data on screen. Roman et al. describe the significance of within-page and between-page navigation as an important factor for EHR usability [11]. An example of the first problem is an outpatient system in which the clinical summary page includes demographic, billing, encounter and allergy data, but not other important clinical variables.

Discussion

Comparative studies across commercial and home-grown EHRs are under way, in order to identify the extent of fragmentation as a problem in general, and specific design
patterns which may contribute to it or conversely reduce fragmentation for specific tasks. The advent of mobile EHRs has also affected the fragmentation in both positive and negative ways. As mobile screens typically display less information, designers may have paid more attention to screen flow in order to ensure correct distribution of clinical values in a way meaningful and convenient to physicians. They are also able to make use of design patterns such as sequential tree menus to focus actions on immediate tasks without extraneous data. On the other hand, if poorly done, this can increase fragmentation, given the screen size limits and need to cater to finger- rather than mouse-driven interaction, which typically has smaller resolution.

The modified cognitive walkthrough method combined with sunburst display has several advantages for data collection. Cognitive walkthrough for the purpose of defining navigation structures is easy to teach, and easily grasped by non-researchers, allowing for others such as clinicians with access to systems to be data collectors. This can facilitate broader studies as specialized access need not be arranged. The use of Excel or similar spreadsheets is familiar to most people, and the branching structure, once explained, is also easy to understand. Automatic generation of sunburst as one of the now standard visualizations allows for easy experimentation. Formatting options allow manual coloring of subsectors. Some visualization tools generate the path from the top of the tree as a part of the legend, changing interactively as the user moves over different elements.

In preliminary studies, users are found to be mostly unfamiliar with the sunburst (unless their particular work requires it), but find it relatively simple to understand once its tree structure basis is explained. Prior empirical work on comparative visualization of hierarchical structures has shown sunburst visualizations to be more efficient for tasks involving perception of the hierarchy [12], with a shorter learning curve.

**Interaction Design Implications and Other Use Cases**

Mapping can support composable approaches’ reduction of fragmentation, and assist creation of safer design patterns, such as replacements for extensive dropdowns or other undesirable interaction features. Radial menus, for example, leverage humans’ good capacity to distinguish small angles. Mapping of redesigns can provide a measure of progress. Multiple workflow paths could be overlaid on the map, as a way of specifying efficient transitions.

EHR display fragmentation maps have other uses besides research. Interactive sunburst visualizations can be used to convey the navigation paths to particular elements, facilitating instruction. It is conceivable that use of maps for comparison of different EHRs might be used for purchasing processes, as part of evaluation of whether the system flow can be made to match workflow needs. In some systems, changes do not propagate to all areas automatically, and a map could facilitate any manual changes necessary. Development uses include to give initial overviews to developers or researchers seeking to improve workflow, and assessing the effect of software modifications on navigation structures, and thus likely effects on time, efficiency, and fit to task.

**Conclusions**

Display fragmentation is a critical problem for the usability of the electronic health record, and mapping EHR navigational structure with visualization presents useful ways to understand and address it. In addition such maps can be useful for related purposes such as instruction and software development. The method will allow comparison of fragmentation across EHRs, facilitating our understanding.

Strengthen Cancer Surveillance in Sri Lanka by Implementing Cancer Registry Informatics to Enhance Cancer Registry Data Accuracy, Completeness, and Timeliness

Kamal Seneviratne*a, Sudath Samaraweera*a, Eshani Fernando*a, Suraj Perera*a, Asanga Hemarathna*a

*a National Cancer Control Programme, Ministry of Health, Colombo, Sri Lanka

Abstract
Cancer surveillance is a process of systematic, continuous collection, storage, analysis, interpretation and dissemination of epidemiological information on cancer cases occurring in a particular geographic area. The process of cancer surveillance is also called 'cancer registration'. A system to conduct cancer registration is called 'cancer registry'. The purpose of the project is to implement cancer registry informatics to enhance electronic cancer registry reporting activities that take advantage of emerging health information technology. The expected function of the application is to strengthen the cancer registry data accuracy, completeness, and timeliness. The goals to be achieved are: determine the incidence of cancers with respect to geographic, demographic characteristics; monitor trends and patterns of cancer incidences over time; identify high-risk populations; provide data for epidemiological studies and prioritize health resource allocations.

Keywords:
Registries, Data Collection, Health Information Systems

Introduction
National Cancer Control Programme (NCCP) of Sri Lanka was established in 1980 based on the recommendations made by World Health Organization. NCCP is the national focal point for prevention and control of cancers in the country. The institution is responsible for policy, advocacy, monitoring and evaluation of prevention and control of cancers, conducting surveillance of cancers and facilitating research related to cancer.

Cancer Burden in Sri Lanka
A total of 13,635 new cancer cases had been diagnosed in 2007 [1]. Out of 13,635 new cases, 6,356 were males and 7,279 were females. In 2007 the overall crude cancer incidence rate (CR) was 68.0 per 100,000 population. There were 16,888 new cases diagnosed in 2009 with a CR of 82.6 [2]. In 1985 there were 5,012 new cases with a crude cancer incidence rate (CR) of 31.6 [1]. It is obvious that cancer prevalence is gradually increasing in Sri Lanka. This increase may be due to several reasons [3]. Since a considerable number of government and private health care institutions have started diagnosis and treatment of cancer patients, collection of data from these institutions and statistics related to cancer deaths from death registrars have become absolutely essential to include all these data to fulfill the four quality indicators recommended by the International Agency for Research on Cancer (IARC). They are comparability, completeness, validity and timeliness of information [4].

Importance of Cancer Surveillance
Cancer surveillance provides a quantitative portrait of cancer and its determinants in a defined population. It helps epidemiologists in descriptive studies and analytical studies on cancer [5]. Knowledge of trends in the incidence of cancer over geographical areas may be used for the projection of future incidence rates, case loads, and the need for treatment facilities. It contributes to the management of cancer care programmes to ensure that all patients with a given cancer are given the state-of-the-art diagnosis and treatment.

In cancer surveillance, cancer registries are definitive and unique resources for measuring the cancer burden in a community.

Cancer Registries and Cancer Registration
Cancer registry is a fundamental tool to controlling cancers in a given country. The cancer registry is the office or institution which attempts to collect, store, analyze and interpret data on persons with cancer and cancer registration is defined as the process of continuing systematic collection of data on the occurrences and characteristics of cancer with the purpose of helping assess and control malignancies in the community [6,7]. Cancer registries are an essential part of a complete cancer control program and help in finding etiological factors of cancers primary, secondary and tertiary prevention and monitoring [8,9].

There are three types of cancer registries available globally based on characteristics, purpose, and utility in cancer control. They are:

a) Hospital-based cancer registry (HBCR) [8,9]
b) Pathology-based Cancer Registry [8,9]
c) Population-based cancer registry (PBCR). Cancer information is collected systematically on all reportable neoplasms occurring in a geographically-defined population from multiple sources. These registries have a unique role in planning and evaluating cancer control programs [8,9].

Cancer Surveillance Informatics
The definition of public health informatics is given as the systematic application of information and computer science and technology to public health practice, research, and learning. It is a subdomain of the biomedical or health informatics [10]. Likewise, it is justifiable to use the same terminology in the cancer surveillance informatics domain. Therefore, it deals with the resources, devices, and methods to optimize the acquisition, storage, retrieval and use of information in cancer surveillance practices, research and learning [11].

The tools used in the domain include computers, information and communication systems, clinical guidelines, and formal medical terminologies [11]. Thus, using emerging technology to incorporate automated process and electronic data exchange
in cancer surveillance business is an efficient, fast and cost-effective way to obtain quality, accurate and complete cancer registry data as it increases data accuracy, completeness, timeliness, and comparability. It also minimizes manual handling of documents and manual processing of information.

The National Cancer Control Programme (NCCP) has been monitoring trends of cancer since 1985 and has been publishing the national cancer incidence data. Presently, the National Cancer Control Programme collects data (Figure 1) from case-finding sources including,

a) Nine provincial cancer treatment centers. These include Oncology units (9) and oncological surgery units (9). These provincial cancer treatment centers are located in 9 provinces.
b) Sixty-seven Histopathology and Hematology laboratories.
c) Twenty-five Oral and maxillofacial units.
d) Fifteen Government hospitals with specialist care, well woman clinics in Colombo district.
e) Five private sector hospitals and pathology laboratories located in Colombo district. Received data from 05 sources.
f) 42 death registrars’ offices located in Colombo district.

![Figure 1. Current cancer registry data flow](image)

Therefore, intended users of the database are the same institutions mentioned above. The current process of cancer registry data gathering from provincial cancer treatment centers as stated above is through an electronic application that was developed by NCCP and installed in a stand-alone desktop computer in each provincial cancer treatment center. The user export data as an excel spreadsheet, which is then sent to the NCCP quarterly. Data received from reminder case-finding sources are based on both paper-based and excel spreadsheets. Data received are then fed into another open source application called CanReg5 [12] for consistency check.

However, with the existing data collection method, the gap between diagnosis of cancer and the availability of data for analysis is significant. As a result, the publication of cancer registry data may reflect information about patients diagnosed more than a couple of years ago. In order to evaluate and react more effectively to trends, there is the need for availability of data on time. Data redundancy is also reported as the same data on time. Data redundancy is also reported as the same data on different dates using web 2.0 technology, open-source software, and mobile technology. Open-source license products were used to decrease the cost for the technical platform and also as a defining factor in terms of profitability. Although there is no clear-cut definition, the term web 2.0 suggests an upgraded and updated version of the web [14]. Web 2.0 is associated with web development and design. It facilitates interactive information sharing, user-centered design, and collaboration on the World Wide Web [13]. The web 2.0 is able to integrate different sources for a real-time cancer registry. The Java technology is used as the tool for the web development process. Java is an object-oriented sever-side programming language and is more suitable for both web and desktop application development and is enabled to write more secure programs [15]. The server is a Linux-based operating system with the Apache as the webserver. The database system for storing information is MySQL, which is multithreaded and multi-user database management system with more than 10 million installations [16]. It is distributed under a GNU General Public License (GPL) and hence has no running cost. The community involvement makes the software development progress to be steady [17]. MySQL can run over 20 operating systems including Linux-based and Windows. Its performance, scalability, and security system have made the system to be used by many large companies world-wide [17].

The software architecture of the Database Management System (DBMS) is client-server architecture. The client-server architecture is considered because this architecture has several advantages (Figure 2).

![Figure 2. Client-server architecture model](image)

a) Centralization: All the information is stored in a server. Clients can access the database over an authorized access. Every authorized client is given the opportunity to access information via the desktop or laptop interface and tools like spreadsheets. PowerPoint presentations can be used to deal with data with the help of database and application servers resident on the network to produce meaningful information.
b) Scalability: The server where the data are stored can be repaired, replaced, upgraded or relocated while the client or the end users remain unaware and unaffected by that change.
c) Availability: As the server is always turned on, data can be accessed at any time throughout the day and throughout the year.
d) Prevent from data losing: As data is stored on a server it is easy to make a backup. In case of data corruption or data loss, it can be recovered easily and efficiently from backup.
e) Security: Data can be better secured from unauthorized access by defining the permissions at the time of the setup of the server.
There are two models of client-server architecture namely, two-tier and three-tier architecture. From these two options, two-tier architecture is selected for the development of DBMS because it has several advantages over three-tier architecture.

1. Two-tier architecture is easy to maintain.
2. Modification of the database is relatively easy.
3. Communication between the end user and the database is faster.
4. Development cost is much less than the three-tier architecture.
5. Two-tier architecture is less complex than the three-tier architecture.

The mobile app is used to gather data from death registrars’ offices located in Colombo district, Government hospitals with specialist care, well woman clinics in Colombo district, private sector hospitals and pathology laboratories located in Colombo district. As the minimum dataset essential for the cancer registry is collected from these institutions, using of mobile technology is more convenient for them. This method of data collection is greatly supported by the fact that more than 23 million mobile connections exist in 2015 [18]. This figure exceeds the population of Sri Lanka [19].

The process of data collection procedure begins with abstracting data from case-finding sources to a summary sheet, which is designed following several rounds of discussions with stakeholders in order to satisfy their needs yet preserving standard coding and classification procedures and definitions for the population-based cancer registry [21]. It consists of two sections. Section I is related to personal identification and demographic data and is supposed to be completed by the nursing officer of the relevant oncology unit. Furthermore, she can further ascertain data when the patient attends oncology clinic. Section II is related to tumor details and is supposed to be completed by a clinician in relevant oncology unit except ICD-O3 coding. Section II is mostly composed of coded data fields. Just putting the code number in the relevant field is all that is needed. It is expected to improve efficacy on data reporting by releasing extra burden for busy oncology clinicians engaged in registry activities to some extent. Thus the abstracted data in the summary sheet are then transferred to the electronic system by a Data Entry Operator (DEO) through system’s web interface. Figure 3 shows the summary sheet to be used for feeding data to the system.

**Results**

The intended results to be expected by implementing cancer registry informatics is to enhance cancer registry data completeness, accuracy (or validity), and timeliness as well as comparability. A cancer registry of the modern era is a medical registry and fulfill the standards defined by Drolet and Johnson [22]. The standard explained five features. Data from multiple sources are combined to create an aggregate set of data called mergeable data (M). data such collected are standardized data set (D), in that the same set of characteristics is collected for each patient in the dataset according to the defined set of rules (R). Furthermore, patients in the registry have a unique identifier in order to follow up over time (O), and this helps to assess the occurrence of specific outcomes of interest (k) [22]. It is expected that the new system will fulfill all the criteria of a modern cancer registry.

As the value of any cancer registry relies on the underlying quality of its data and quality control procedures it has in place, the Cancer Incidence in Five Continents (C15) assesses three dimensions of quality to enable the comparison of cancer incidence rate across different population worldwide [23] They are completeness, comparability, and validity (or accuracy). Completeness is defined as the degree to which all diagnosed neoplasms within a registry’s catchment population are included in the registry database [23]. The indices of completeness are grouped into historical data, the proportion of cases microscopically verified (MV%), the mortality-to-incidence (M:I) ratio and death certificate method. Historical data are essential to find out the stability of incidence rates over time, to compare with incidence rates in different populations, to prepare age-specific incidence curves and childhood incidence rates [23]. Therefore the system is designed to include case-finding sources that are currently available with the facility for future expansion. The proportion of cases microscopically verified (MV%) is the percentage of cases that were diagnosed on the basis of microscopic verification of a tissue specimen [23]. This includes histologically, cytologically and haematologically confirmed specimens. As the system is able to integrate those data from relevant laboratories further strengthening the completeness. The cause for death due to cancer in death certificates plays a significant role in the completeness of the registry. It helps to track down the cases not captured by other registration procedures. On the other hand, it also helps to find out Mortality-to-Incidence (M:I) ratio. It is an important indicator of completeness [23] where it compares the number of death due to a specific type of cancer over a specific period of time with the number of new cases of that type of cancer registered during the same period [23]. The M:I ratio that is higher than expected raise the suspicion of completeness in that registry. As the data from death registrars’ offices are integrated into the system for PBCR not only enhance the completeness but helps in evaluating the quality of the registry.

Data quality is equal to the completeness of data and its accuracy (or validity)[21]. According to the International Standards Organization (ISO) data quality as “the totality of features and characteristics of an entity that bears on its ability to satisfy stated and imply needs” [23]. In the context of a cancer registry, it is defined as the proportion of cases in a dataset recorded as having a given characteristics that truly has that attribute [23]. Accurate or quality data is essential to compare data between registries within a single registry over time and within a single registry with respect to a specific subset of cases [23]. The proposed web-based system accomplishes data accuracy in several ways. The coding standards for neoplasms are maintained using the third edition of the International Classification for Oncology third edition (ICD-O-3) [24]. It provides standardized system for coding the anatomical site of primary tumor (Topography), and its histological type (Morphology) usually obtained from

![Figure 3. Summary sheets](image-url)
pathology report, its behavior (malignant, benign, in situ, or of uncertain behavior), grade (the extent of the differentiation of the tumor) and the basis of the diagnosis (the method of diagnosis used) [23]. Thus the NCCP act as the database administrator and registry staff review each record in the system carefully and verify ICD-O code against topography, morphology, and behavior and also against sex and age. Coding of neoplasms are done only by them and not the duty of the institution where data have been obtained. If data inconsistency found between demographic data and tumor data in a particular record, For example, retinoblastoma is a malignant disease of the retina, exclusively found in young children. If the record shows the morphology as retinoblastoma but the patient’s age as 45 years with the tumor behavior as benign or in another record topography has been recorded as prostate carcinoma for a female patient, then the DEO of the respective data center can be notified through the system by NCCP (registry staff). Then DEO of a particular data center is able to communicate with the clinician in order to rectify them accordingly. Figure 4 shows flagging system

![Flagging system with example synthetic patient data](image)

**Figure 4. Flagging system with example synthetic patient data.**

Thus, the system assists in maintaining data consistency as well as timeliness as the data can be viewed as soon as they are included in the system and ability to correct them as soon as possible. The stand-alone databases currently used to collect data in case-finding sources are unable to fulfill such advantages. Once confirmed by the NCCP a record as a completed record, it is shown as confirmed record in the system (Figure 5: image showing confirmed data).

Discussion

The intended results to be expected by implementing cancer registry informatics is to enhance cancer registry data completeness, accuracy (or validity), timeliness, and comparability. A cancer registry of the modern era is a medical registry and fulfill the standards defined by Drolet and Johnson [22]. The standard explained five features. Data from multiple sources are combined to create an aggregate set of data called mergeable data (M), data collected are standardized data set (D), in that the same set of characteristics is collected for each patient in the dataset according to the defined set of rules (R). Furthermore, patients in the registry have a unique identifier in order to follow up over time (O), and this helps to assess the occurrence of specific outcomes of interest (k) [22]. It is expected that the new system will fulfill the criteria of a modern cancer registry.

As the value of any cancer registry relies on the underlying quality of its data and quality control procedures, it has in place, the Cancer Incidence in Five Continents (C15), to assess three dimensions of quality to enable the comparison of cancer incidence rate across different population worldwide [23]. They are completeness, comparability, and validity (or accuracy). Completeness is defined as the degree to which all diagnosed neoplasms within a registry’s catchment population are included in the registry database [23]. The indices of completeness are grouped into historical data, the proportion of cases microscopically verified (MV%), the mortality-to-incidence (M:I) ratio and death certificate method. Historical data is essential to find out the stability of incidence rates over time, to compare with incidence rates in different populations, to prepare age-specific incidence curves and childhood incidence rates [23]. Therefore the system is designed to include case-finding sources that are currently available with the facility for future expansion. The proportion of cases microscopically verified (MV%) is the percentage of cases that were diagnosed on the basis of microscopic verification of a tissue specimen [23]. This includes histologically, cytologically and haematologically confirmed specimens. As the system is able to integrate those data from relevant laboratories further strengthening the completeness. The cause for death due to cancer in death certificates plays a significant role in the completeness of the registry. It helps to track down the cases not captured by other registration procedures. On the other hand, it also helps to find out Mortality-to-Incidence (M:I) ratio. It is an important indicator of completeness [23] where it compares the number of death due to a specific type of cancer over a specific period of time with the number of new cases of that type of cancer registered during the same period [23]. The M:I ratio that is higher than expected raise the suspicion of completeness in that registry. As the data from death registrars’ offices are integrated into the system for PBCR not only enhance the completeness but helps in evaluating the quality of the registry.

Data quality equals to the completeness of data and its accuracy (or validity) [21]. According to the International Standards Organization (ISO) data quality as “the totality of features and characteristics of an entity that bears on its ability to satisfy stated and imply needs” [23]. In the context of a cancer registry, it is defined as the proportion of cases in a dataset recorded as having a given characteristics that truly do have that attribute [23]. Accurate or quality data is essential to compare data between registries within a single registry over time and within a single registry with respect to a specific subset of cases [23]. The proposed web-based system accomplish data accuracy in several ways. The coding standards for neoplasms are maintained using the third edition of the International Classification for Oncology third edition (ICD-O-3) [24]. It provides standardized system for coding the anatomical site of primary tumor (Topography), and its histological type (Morphology) usually obtained from pathology report, its behavior (malignant, benign, in situ, or of uncertain behavior), grade (the extent of the differentiation of the tumor) and the basis of the diagnosis (the method of diagnosis used) [23]. Thus the NCCP act as the database administrator and registry staff.
review each record in the system carefully and verify ICD-O code against topography, morphology, and behavior and also against sex and age. Coding of neoplasms are done only by them and not the duty of the institution where data have been obtained. If data inconsistency found between demographic data and tumor data in a particular record, For example, retinoblastoma is a malignant disease of the retina, exclusively found in young children. If the record shows the morphology as retinoblastoma but the patient’s age as 45 years with the tumor behavior as benign or in another record topography has been recorded as prostate carcinoma for a female patient, then the DEO of the respective data center can be notified through the system by NCCP (registry staff). Then DEO of a particular data center is able to communicate with the clinician in order to rectify them accordingly. Figure 5 shows flagging system.

Thus, the system assists in maintaining data consistency as well as timeliness as the data can be viewed as soon as they are included in the system and ability to correct them as soon as possible. The stand-alone databases currently used to collect data in case-finding sources are unable to fulfill such advantages. Once confirmed by the NCCP a record as a completed record, it is shown as confirmed record in the system (Figure 5: image showing confirmed data).

Conclusion

The web-based application will ensure timely availability of information and it will provide accurate, complete and timely registry data to the stakeholders such as health policy makers, researchers, clinicians, and the general population.

Using Therapeutic Circles to Visualize Guideline-Based Therapeutic Recommendations for Patients with Multiple Chronic Conditions: A Case Study with GO-DSS on Hypertension, Type 2 Diabetes, and Dyslipidemia

Brigitte Séroussiab, Alexandre Galopinc, Mouhssin Gaouara, Suzanne Pereira, Jacques Bouaud

Abstract

Clinical decision support systems (CDSSs) have proven to potentially improve the compliance of physician decisions with clinical practice guidelines (CPGs). However, actual patients suffer from multiple conditions and CPGs that are usually single-disease-focused provide disease-specific recommendations with no support on how to manage adverse interactions between the recommended treatments. We have developed GO-DSS, a CDSS that implements an ontological reasoning process to perform CPG reconciliation. GO-DSS is applied to the concurrent management of hypertension, type 2 diabetes, and dyslipidemia. We proposed an innovative graphical interface to display medication recommendations as “therapeutic circles”. A qualitative evaluation of the system and of this graphical layout has been performed on simulated patient cases by a sample of 12 users with various backgrounds (think aloud method). The resulting usability of the system is highly appreciated with a mean rating of 90.7% according to the standardized System Usability Scale.

Keywords:

Introduction

Clinical practice guidelines (CPGs) are evidence-based recommendations to manage patients with specific conditions (e.g., 2014 Evidence-Based Guidelines for the Management of High Blood Pressure in Adults1, Standards of Medical Care in Diabetes – 20162, or 2016 ESC/EAS Guidelines for the Management of Dyslipidemia3). Based on the best available research evidence, CPGs are currently developed by health professional societies and national health agencies to improve the quality of clinical care and decrease health care costs. CPGs are usually elaborated as textual narrative documents. They may also include tables and graphs. More recently, the National Institute for Health and Care Excellence (NICE) has started to provide guidelines as structured dynamically interactive pathways4.

Despite the wide development and dissemination of CPGs, there are still unwarranted variations in clinical practice [1,2]. Indeed, simply providing CPGs in their original narrative format has proven to have a limited effect in changing physician behavior. Several reviews [3,4] suggest that clinical decision support systems (CDSSs) that provide patient-specific guideline-based recommendations may be efficient tools to promote the adoption of CPGs by physicians. However, although many studies have indeed showed positive effects, others have found only a limited impact of these systems upon physician practices [5]. Delivering patient-specific recommendations at the point of care appears to be “neither necessary nor sufficient” to ensure compliance [6]. Research is thus currently carried out to assess which factors are responsible of the success or the failure of CDSSs [7]. Beyond variations in clinical setting, culture, training, and organization, the aim is to analyze when CDSSs are used and how, in order to elicit the technical features, e.g., design, implementation, level of description, as well as usability and display that would predict their correct use and effectiveness to increase clinician compliance with CPGs. Some authors of this article already studied the patient effect on non-compliance with the ASTI system [8] concluding that for “complex” patient cases, general practitioners (GPs) accept help and on-demand guidance-based systems are more appropriate, whereas for “simple” patient cases, GPs do not think they need to be helped, and automatic alert-based CDSSs are both efficient and mandatory since GPs would not spontaneously seek for information.

However, although the implementation of CPGs in CDSSs may be useful to provide clinicians best patient-centered recommendations to manage a given pathology (e.g. hypertension, type 2 diabetes, or dyslipidemia), this does not solve the problem of improving care quality and overall public health which is the ultimate target of CPG development and dissemination. CPGs are focused on the management of a single disease, whereas multimorbidity is a common phenomenon [9]. This is known for elderly patients but also true for younger patients [10]. Thus providing CDSSs to improve adherence with monomorbidity-focused, mono-disciplinary CPGs for patients with multiple conditions may result in undesirable effects: each guideline provides a recommendation but there is a lack of support as to how to manage adverse interactions between recommended treatments and conflicting management strategies. For people with multimorbidity, current guidelines and recommendations rapidly cumulate to drive polypharmacy without providing guidance on how to compare relative beneficence of risks of treatments according to the severity of the different conditions to best prioritize recom-

recommendations or to select the recommendations that might be dropped.

To improve the management of patients with multiple conditions, some research is conducted on the *a priori* development of guidelines that account for multimorbidity. Epidemiological strategies based on the provision of a checklist of disease combinations that should be systematically considered during guideline development have been proposed to help guideline developers [11]. Other research teams have proposed to work on the *a posteriori* reconciliation of multiple single-disease CPGs. Wilk et al. [12] have proposed a framework employing first order logic to represent CPGs and to mitigate possible adverse interactions (drug-drug or drug-disease) when concurrently applying multiple CPGs to a multimorbid patient. This mitigation algorithm is used as an alerting tool to support the physician in the concurrent application of CPGs. More recently, this work has been refined to extend the mitigation algorithm and include patient’s preferences [13]. Other authors have proposed semantic web ontology-based approaches [14] for the integration of multiple single disease clinical pathways in a unified disease-specific clinical pathway. The execution of the ontological clinical pathway model is achieved through abstraction processes to assign functional behaviors to existing semantic properties and facilitate their execution [15].

Information visualization may be defined as the use of visual representations of data, information, and knowledge to help users gain a deeper understanding of the contents of a domain. Numerous research works are currently being carried out to develop health information visualization techniques expected to increase the benefits of health informatics databases and networks. The underlying principle is that the right display of health information should match the mental constructs and cognitive tasks of the user and thus should reduce the cognitive load of data interpretation. As a consequence, the capacity of patients, clinicians, and public health policy makers to make better decisions should be improved [16]. Indeed, literature shows that different types of graphical information can help or harm the accuracy on decision-making [17]. This has been shown at the population level [18], but also at the patient level with Computerized Physician Order Entry (CPOE). Poorly designed CPOE can lead to usability problems, users’ dissatisfaction, and may disrupt the normal flow of clinical activities. Wipfli et al. [19] proposed an alternative strategy to alert display and layout that reduces interruptions to physicians’ workflow. Payne et al. [20] recommended using visual cues, minimal text, formatting, content and reporting standards to improve drug-drug interaction alerts. The same conclusions apply to information retrieval of CPGs with an interactive graphical interface using an iconic language [21]. Understanding how to best visualize data, information, and knowledge, especially in CDSSs is a central challenge to improving healthcare.

We have developed GO-DSS, a guideline-based decision support system applied to the management of the cardiovascular risk [22]. GO-DSS uses an ontology-based approach to allow for the flexibility needed to deal with patients with multiple chronic disorders. A first implementation concurrently applying hypertension (HT) and type 2 diabetes (T2D) CPGs was previously developed [23]. The system was then successfully extended to integrate the management of patients with dyslipidemia (D). GO-DSS guideline-based recommendations have been extended to be displayed as “therapeutic circles”. This graphical layout of recommended drugs and drug combinations was evaluated by a sample of users with various backgrounds (clinicians, GPs, pharmacists, informaticians, engineers).

**Materials and Methods**

In this section, we describe the three CPGs we worked with, summarize the main functionalities of the guideline-based GO-DSS CDSS, introduce the therapeutic circles we used in GO-DSS to display recommendations, and present the protocol implemented to evaluate the global system.

**Hypertension, type 2 diabetes, and dyslipidemia CPGs**

We used CPGs synthesized by Vidal, a French company that markets a drug database and medical situations which have been evaluated for quality by medical professionals for decades. CPGs were manually translated into IF-THEN decision rules. THEN-parts contained “possible” actions, “recommended” actions, and “contra-indicated” actions according to CPGs. The 2016 dyslipidemia CPG was translated following the same method and format as the HT and T2D CPGs [22]. We therefore had generated three rule bases, for HT, T2D, and D CPGs.

**GO-DSS ontological reasoning**

The first step was to build an ontology of the cardiovascular domain. We reused an emergency care ontology (Ontolurgences®) where concepts relevant to cardiovascular risk management were extracted. This first ontology was then enriched to integrate the CPG-specific concepts used by the decision rules (IF- and THEN-parts) of the three rule bases. Concepts were structured by subsumption, equivalence, and disjunction relationships.

IF-parts of rules are logical expressions (mainly conjunctions) built with concepts from the ontology. The set of IF-parts of rules represent the set of theoretical patient profiles covered by CPGs. Each theoretical patient profile is equivalent to a new concept in the ontology, and as such can be classified by the ontological reasoner. Therefore, these profiles, and their corresponding rules, are organized in a subsumption graph, with the least specific profiles at the top and the most specific ones at the bottom.

At execution time, when an actual patient’s case is considered, patient data is encoded as a conjunction of concepts of the ontology to build the closest formalized patient profile. Processing the ontological reasoning consists of identifying all the CPG-based, rule-issued, patient profiles that subsume the formalized patient profile to collect the decision rules that apply to the patient. All the linkages between co-illnesses covered by CPGs are returned by the ontology. However, knowledge gaps in CPGs still produce missingness errors in the reasoning process. The subsumption graph of patient profiles/rules is also used to solve potential conflicts between inferred actions (within or across CPGs) by selecting the actions recommended by the most specific rules in the subsumption graph of profiles and by eliminating the actions of the more general rules, thus implementing a kind of non-monotonic reasoning [22].

As a result, we get all the actions (either “possible”, “recommended”, or “contra-indicated”) filtered by the conflict resolution process that apply, for the best management of the patient.

**Display of recommendations**

Therapeutic recommendations that are issued from CPGs for a given patient correspond to possible, recommended, or contra-indicated drug classes and drug combinations. In order to summarize all these drug-related recommendations for a given

---

5 https://www.vidal.fr/recommandations/
6 https://bioportal.bioontology.org/ontologies/ONTOLURGENCES
pathology/CPGs, we have introduced a graphical representation we called "therapeutic circles". A therapeutic circle corresponds to the circular disposal of discs where each disc represents one of the drug classes that can be prescribed for a given pathology (HT, T2D, and D) according to CPGs. When the drug class is just mentioned in CPGs, with no other inferred information, the disc is colored in grey. The disc is colored in yellow when the drug class has been mentioned as "possible" for the patient, in green when it is "recommended", and in red when it is "contra-indicated". When the disc has a bold outline, this indicates that the corresponding drug class is currently administered to the patient. Lines between therapeutic discs describe the combination of drug classes with the same color rules. Yellow lines indicate the combination is "possible", green lines indicate the combination is "recommended", and red lines indicate the combination is "contra-indicated". Figure 1 displays the therapeutic circle to represent guideline-based therapeutic propositions for a patient currently treated by ACE inhibitors (bold circle) for whom it is recommended to go for a bitherapy by adding a thiazide diuretic (green link). Adding calcium a channel blockers (CCB) or a beta-blocker is possible (yellow links), but adding an angiotensin II receptor antagonist (ARB) is contra-indicated (red link).

For a given patient, multiple pathologies/CPGs must be considered simultaneously. Following the principle of having patient problem lists in medical records as a way to "encourage doctors to think holistically about their patients" [24], we have structured the display of guideline-based decision support propositions per problem, with one column for HT, one for T2D and one for D. Within each column, we deliver six levels of information:

1. The description of the current treatment with the combination level and the list of drugs and their class,
2. The assessment of the current treatment in terms of compliance with guidelines and therapeutic efficacy,
3. The recommended level of drug combination (no drug, mono-, bi-, tri- and quadritherapy),
4. The therapeutic circle to represent guideline-based drug recommendations,
5. Indications about alerts, risks, and surveillance,

Figure 2 displays the six levels of information for a man of 84 years with asthma and uncontrolled HT despite a bitherapy of antihypertensive drugs, ACEi and a thiazide diuretic, a non-efficient metformin monotherapy for T2D, and a dyslipidemia non-currently treated. The current treatment globally complies with CPGs but is not efficient:

- For hypertension, a tritherapy is recommended, but a quadritherapy is contra-indicated. The recommended tritherapy is made of the combination of ACEi, thiazides diuretic, and calcium channel blocker (CCB). ARBs are recommended as a therapeutic drug class (green disc) but not in association with ACEi (red line). Beta-blockers are contra-indicated because of asthma (red disc) as well as any combination including them (red lines).
- For type 2 diabetes, a bitherapy made of a combination of metformin and a sulphonylurea is recommended.
- For dyslipidemia, a monotherapy is recommended, by either statins or ezetimibe.

**Evaluation protocol**

A pilot evaluation of the system has been made off-line for test cases. The evaluation protocol comprised four steps: (i) a tutorial to introduce GO-DSS, (ii) a training step, (iii) the unsupervised use of the system on simulated patient cases, and (iv) a qualitative user assessment through questionnaires. A whole evaluation session was expected to last about 45 minutes.

The first step presented the aim of the system, the context of its development, its main functionalities, and how to recognize and interpret the different types of information displayed in the user’s interface (UI). During the second step, the user utilized the system under the supervision of the evaluator on commented simulated patient cases. The aim was to make the user explore and discover GO-DSS functionalities. During this step, the user could ask any question about the system. The third step consisted in the autonomous use of the system by the user alone, without supervision. Two simulated patient cases were proposed. These cases corresponded to the longitudinal management of patients and included multiple consultations, the follow up of evolving chronic conditions, and multiple decision points with drug prescription and adaptation. Such cases were built to illustrate the different operating functionalities of the system. User prescriptions were collected, as well as any enunciated remarks (think aloud method). The user could exit the scenario planned for the simulated cases and he/she was permitted to try any arbitrary patient conditions to test the system response. At the fourth and last step, the user filled a questionnaire to indicate his/her professional profile, as well as his/her familiarity with CPGs and decision support tools. Questions about the medical relevance of recommendations, the consistency with the original CPGs, and the perceived utility were encoded using a 4-valued Likert scale. It was also possible to enter further comments about the system. Finally, a standardized SUS (System Usability Scale) [25] questionnaire was filled in by each participant.

**Results**

The assessment of GO-DSS was conducted according to the evaluation protocol by 12 testers with different professional backgrounds, and from different organizations. Five were general practitioners (GPs), two were medical specialists, all of whom were actual experimented practitioners (more than 20 years of practice). One was a pharmacist, two were non-clinician e-health informaticians, and two were engineers. Among them, 66% (n=8) already used a CDSS, and 75%
(n=9) were familiar with CPGs. Figure 3 reports the distribution of the participants’ answers to the qualitative questionnaire. Most of the responses, beyond 9/12, are positive (“yes” or “rather yes”). Free comments have been manually classified as positive or negative. Positive remarks were: clarity of the user interface, intuitive use, synthetic presentation of the patient case, possibility to get back to the original text of CPGs, the innovative presentation of recommendations as therapeutic circles (sometimes with some reservations). Negative remarks were: lack of connection with any EHR or CPOE, risk of an overloaded interface in case of many comorbidities, need for more classical textual expression of recommendations. The SUS score obtained from the 12 participants was measured as 90.7%. This result, according to the ratings of the standard with respect to usability, classifies the GO-DSS as an “excellent system” of “grade A”.

Discussion and Conclusion

GO-DSS is a CDSS to manage patients with multiple pathologies from single-disease guidelines. An ontological reasoning process allows for the management of intra and inter CPGs conflicts. Conflict resolution is completed before the display of therapeutic propositions, categorized as possible, recommended, or contra-indicated options. Therapeutic propositions are displayed per pathology in a new graphical representation called “therapeutic circles”. GO-DSS processing and interface have been evaluated by a sample of testers on simulated cases. The therapeutic options proposed by GO-DSS have been considered as medically sound by the clinicians, and in good coherence with CPG contents. The innovative presentation of recommendations as therapeutic circles was diversely appreciated: some testers were not comfortable with such a display considering it was not easy to understand, whereas others were enthusiastic asking for some refinements such as the possibility to link GO-DSS to a drug data base which allows to access the list of drugs when clicking on the disc of a given drug class, and select the appropriate drug. This could incrementally build the prescription in a way similar to the “Add to Cart” button used to build a shopping list. All testers considered that with some training, the display of CPGs as therapeutic circles was astoundingly modern and convenient. Another issue discussed concerned the increase in the number of pathologies and the possibility to have comorbidity-based columns used as tabs that could be dynamically opened/closed. The question of having a unique therapeutic patient-centered circle was set but considered as rapidly unreadable.

The design of GO-DSS’s interface and the display of medication recommendations as therapeutic circles were finally well accepted by the testers. However, due to the small size of the sample (although the analysis was qualitative), and the fact
that testers worked on simulated cases outside the actual clinical workflow, we cannot conclude that our results may be generalizable, and further work is needed to assess under real conditions the true value of such a display of guideline-based therapeutic recommendations. The first step will be to increase the size of the sample and organize an online evaluation of GO-DSS based on the same evaluation protocol and using GP social/professional networks for recruiting participants.

Development of a Service-Oriented Sharable Clinical Decision Support System Based on Ontology for Chronic Disease

Yong Shang, Yu Wang, Ling Gou, Chengkai Wu, Tianshu Zhou, Jing-song Li

Engineering Research Center of EMR and Intelligent Expert System, Ministry of Education, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, College of Biomedical Engineering and Instrument Science, Zhejiang University, Hangzhou Zhejiang Province, China

Abstract

Clinical decision support systems (CDSSs) have been proved as an efficient way to improve health care quality. However, the inflexibility in integrating multiple clinical practice guidelines (multi-CPGs), the mass input workload of patient data, and the difficulty in system sharing become barriers of CDSSs implementation. In this paper, we proposed a framework of CDSS for chronic disease based on ontology and service-oriented architecture (SOA) to improve these defects. We used ontology for knowledge base construction on multi-CPGs integration to overcome their differences as well as reduce the input procedure of patient data by ontology reasoning. Furthermore, we built the CDSS on an SOA structure to provide flexibility in system and data sharing, such that patients could get suggestions from the same system for self-management of chronic disease. A typical case was used to validate the CDSS functions and accuracy. Two clients were developed to illustrate the SOA superiority.

Clinical Decision Support Systems; Biological Ontologies

Introduction

A study of doctors’ workload in China indicates that on average clinicians work 54 hours a week and provide medical care for 22 outpatients every day [1]. Heavy workload affects health care efficiency and quality. Clinical decision support systems (CDSSs) could offer convenience for clinicians’ daily work, provide suggestions based on patient status, and further identify medical errors in clinical practice [2]. There have been studies suggesting that CDSSs can be an efficient instrument for the improvement of medical care [3]. The implementation of CDSSs could lower the workload of clinicians, leading to better health care quality and lower cost of medication. It could also be used for patients’ self-management by providing suggestions. Despite the advantages of CDSSs, their implementation still faces challenges. Some important considerations are: (1) proper methods for the representation of knowledge, (2) reductions on patient data input, and (3) function integration, reuse, and sharing between multiple medical systems [3][4].

CDSSs often derives knowledge from Clinical practice guidelines (CPGs). CPGs are systematically developed instruments to provide references at specific clinical situation [5]. However, patients may get through multiple disorders, which requires the combination of heterogeneous CPGs. The concepts between CPGs may have both common and specific disease medical knowledge. Also, since CPGs are mainly text-based, they may describe a concept in different syntax and even in different languages. To illustrate decision support properly according to multi-CPGs, the knowledge base must have a formalized structure to integrate concepts between CPGs and a standardized representation of concepts from different CPGs.

Ontology can be used as a suitable approach for multi-CPGs integration. Ontology can describe and structure knowledge in a formalized and standardized way. Heterogeneous CPGs can be extracted into one ontology model, and be represented as concepts and attributes in a standardized form. Knowledge between CPGs can be integrated properly using this ontology method.

Furthermore, many CDSSs are developed with specific computing requirements. Cross-platform adoption of CDSSs faces obstacles; data and suggestions from CDSSs are hard to share by different users such as in clinician-patient communication. This means a great waste to the knowledge base and functions in a CDSS. Also, with the development of medical knowledge, continuous improvement of knowledge and methods is a key to CDSSs [6]. Thus the quality of decision supports increases synchronously if the upgrade of a CDSS can instantly consider various users.

The service-oriented architecture has the potential to overcome the difficulty. A SOA is designed to allow different platforms to use services and create a new work process [7]. Applying SOA to a CDSS can modularize the system into various services that can be easily shared by different users. Developers can integrate required services and create personalized CDSS clients for different users, reducing the difficulty of integration through the interfaces of CDSS services. Clinicians and patients using the same CDSS service could get suggestions simultaneously in order to improve patients’ self-management and clinician-patient communication.

The main purpose of this study is to design a service-oriented CDSS base on ontology. The system shall provide the flexibility in the integration of multi-CPGs and the sharing of CDSS system.

Methods

Type 2 Diabetes Mellitus and Hypertension CPGs

We apply CPGs of Type 2 diabetes mellitus (T2DM) and hypertension (HT). The patient group of these disease is vast and these diseases are contribute to a large medication cost around the world. Also, T2DM and HT require patients’ self-management to improve prognosis. We collected T2DM CPGs from the Chinese Diabetes Society (CDS) and the American Association of Clinical Endocrinologists (AAE), and HT
CPGs from the Ministry of Health of the PRC and the Eight Joint National Committee (JNC8).

**Knowledge Base Construction**

The basic design of the knowledge base used in the system is consist of three parts: (1) CPG knowledge base class, (2) coding system class, and (3) patient class. The CPG knowledge base class is the core function, which stores all the knowledge extract from various CPGs. The coding system class is used to store codes that are used in hospital and medical institutes, like ICD-9-CM codes, for data mapping and auto input. The patient class is to create patient individuals with clinical data. The whole knowledge base was built by Protégé and encoded in OWL2.

The formalization representations of disease knowledge are manually extract and standardized from T2DM and HT CPGs. As mentioned, CPGs between T2DM and HT may contain intersection concepts and disease special concepts. Thus the main goal of the knowledge base modeling is to create infrastructure ontology and special ontology. The infrastructure ontology contains basic medical concepts for T2DM and HT CPGs, such as factors that cause the disease, treatment that may cure the disease, and examinations that should be done for the disease. Figure 1 shows the infrastructure of the knowledge base. The infrastructure also contains properties to give relations between individuals in these classes. For example, the property `hasContraindication` link individuals in `Medicine class` and `Disease class`, to express the relation when a drug is contraindicated to a certain disease. These properties will be used when filling the classes with detail individuals as special ontology. Figure 1 only shows part of the properties.

The special ontology contains more granular disease concepts that are mainly used by specific disease. These concepts will be treated as individuals to fill the infrastructure classes. For examples, in Factors class of the special ontology, we extracted disease causing factors from CPGs as individuals to fill under the class, and created a relationship using `hasFactor` property to link the factors to certain disease. By using OWL (explain this) Import property, the construction of special ontology for T2DM and HT can carry on simultaneously. In a new Protégé project, importing the infrastructure ontology and the T2DM disease knowledge base will have the same structure as the HT knowledge base. Since the structure and the properties are the same, it enables cross diseases decision support when the system needs to combine more diseases.

Concepts from different CPGs may be applicable to such ontology knowledge base. The classes of ontology knowledge base are listed in table 1. The treatment class consists of all basic treatment for diseases extract from CPGs. The recommendation, however, is the formalized treatment plan consisting of items in Treatment class to provide complete clinical suggestions from CPGs.

In addition to rule-based concepts extracted from CPGs, the rule system consists of rules for diagnosis, exams, medicines, surgeries, habits, data mapping, and evaluation. The rule system is encoded in Jena Rules and saved as separate files according to different functions. The rule system provides criteria to support a CDSS. Figure 2 shows an example.

The coding system class is used for integrating various systems. It is helpful when mapping patient data into a CDSS. In hospitals, the diagnosis and exam results have codes to indicates their categories. The code are automatically filled in the patient data to reduce manual work when using the ontology system. When inputting patient data with codes, the reasoner compares the code in the data to the code in the ontology, and maps the same data into patient individuals’ attributes.

The patient class is initially empty for users to create their own patients for decision support, which consist of exam results, diagnosis, daily behaviors, etc. These data are fundamental for CDSS to give personalized recommendation.

**System architecture**

To provide flexibility for the integration and reuse of the CDSS, the system was built in the form of a web service. As figure 3 illustrated, the system is separate into three parts: (1) knowledge base, (2) CDSS web services, and (3) clients. The CDSS services acquire input such as ontologies and rules from.
the knowledge base. They also get patient information and instructions from client programs. This would allow the system to provide personalized recommendation to the clients.

The knowledge base of the system was implemented using Protégé and Jena Rules. It contains all the medical concepts, properties and rules needed in the system. The knowledge base is maintained by medical experts. Client users communicate with the expert to give feedback so the experts can fine-tune the knowledge base. The client users however, can store their frequently used health care plans (e.g. prescription) into the knowledge base for easier reuse. Other types of users may also benefit from the plans stored by the client users, in order to reduce the workload of clinicians.

The main CDSS services of the system was built in Eclipse IDE using Java and Jena API, which is a library for ontology development and rule reasoning. This component was further rebuilt in Visual Studio as an ASP.NET Web API to provide RESTful CDSS web services. The CDSS reads in the ontology and rules from the knowledge base. Each user will have their own knowledge base ontology in the server. Since the ontology contains patient class for customized data input, this will keep the patient data secure and private. The cached ontology will be released once a client finished the use, so the patient data will never store in the CDSS system. The functions in the CDSS are encoded in different methods, and clients may select methods to fulfill their own purposes. Under the help of the coding system class, client can input patient data with their category code once for all, and the CDSS will automatically map these data into patient individuals. This could significantly reduce manual work for data input.

The client part was built for demonstration in this study. The structure of the system provides flexibility for client implementation and system integration. Either Ajax or ASP.NET Web API Client or other libraries may be used as a tool for services invoking and all the input and output data model are given as documents. The developers could integrate necessary services into their own program workflow to create a personalized CDSS. Data and suggestions from these CDSSs could share among clients.

Service methods

For the flexibility of invoking and integration, all functions of the CDSS are built as separate methods. Methods are relatively independent so the client may invoke only needed methods and create own CDSS workflow. Each method is encoded in Eclipse IDE in Java and then transfer into ASP.NET Web API with modelized input and output data models. The recommendation functions are mainly achieved by Jena Reasoner and SPARQL, collecting necessary patient data and medical knowledge to perform ontology reasoning and provide the recommendations.

To provide complete decision support for chronic diseases, the methods are classified into seven categories: 1) Data Input, 2) Knowledge Query, 3) Diagnosis, 4) Exam Suggest, 5) Treatment Suggest, 6) Lifestyle guidance, and 7) Evaluation. Data input methods focus on creating patient individuals for reasoning and providing functions for data mapping. Knowledge query methods mainly provide disease knowledge for referring. Diagnosis, Exam suggest, treatment suggest and lifestyle guidance methods are main functions to support clinical decision through inputted patient data. The Evaluation methods estimate the patients’ self-management on chronic diseases and the effectiveness of medicine plans.

System implementation

The CDSS services were hosted on Internet Information Server as a Web API. The sample demonstration clients were developed to invoke methods of CDSS services for decision support. To illustrate the system’s functions, we used a typical patient case with T2DM and HT combining with renal insufficiency to acquire clinical recommendation from the CDSS system.

Results

The knowledge base ontology consists of 47 classes and 182 individuals, together with 121 properties and 72 rules. The completeness as well as the correctness of concepts and their relationships were confirmed by clinical experts.

As for the CDSS system, a total of 32 methods were built in Eclipse IDE with Jena API for ontology query and reasoning. These methods were then packed and transferred into Visual Studio for ASP.NET Web API development. The methods were built as a RESTful Web API with formalized data input and output model. The data models were described using document for client development.

A WinForms program and an iOS app were built as demonstration clients to illustrate the invoking and integration of the CDSS services. The WinForms program client performs a complete workflow of decision support progress. It functions as a tool for clinicians to support outpatient service. Figure 4 shows one of the scenarios of the program for disease...
diagnosis. Patient data may be inputted into the program, and the program call diagnosis methods from CDSS and give diagnosis suggestions and reasons. Based on that, the user may ask for exam and drug recommendation, diet plan suggestions, and cure effect evaluation from the CDSS as a reference.

The iOS app was much simpler and aimed at diseases self-management for patients. Figure 5 shows an example of the demonstration client. According to the clinician’s decision from the WinForms program, the client provides relevant diet plan, exercise plan, daily habit instructions and control goal evaluation. The suggestions and data are shared in the CDSS service. Users may check recommended nutrition, smoke quitting suggestion, as well as weekly exercise time and goals.

The evaluation compares patient’s current clinical index to the controlled goal and use color coding to alert users on the goals they haven’t reached yet.

To illustrate the performance of multi-CPGs integration, we used a typical case of a 44 years old male patient who had T2DM and HT combined with renal insufficiency. The patient data showed FPG at 13.3 mmol/L, total cholesterol (TC) at 7.05 mmol/L, triacylglyceride (TG) at 3.36 mmol/L, HbA1c at 8.5% and a 160/90 blood pressure. The data was inputted into the CDSS by Web API, which returned the diagnosis, exam suggests, medicine suggests and lifestyle suggests. Table 2 shows the suggestions from the system compared to the decision made by a clinician.

The system provided suggestions according to the patient status. These suggestions included diagnosis of HT, T2DM and hyperlipemia based on patient data, and planned routine medical exams for T2DM and HT patient. The clinician made almost the same decision as the system. The system also provided medicine suggestions for T2DM, HT and hyperlipemia. Combining T2DM, HT, renal insufficiency and high TC and TG, the system provided medicines that are safe for patients with renal insufficiency, while maintaining the best choices for T2DM and HT treatment and avoided treatment of medicines for such patient with hyperlipemia like fluvastatin. The medicine chose by the clinician were all included in the suggestions.

Furthermore, contraindicated and cautious medicines were also listed by the system to warn the users, in order to reduce errors on decision making. The system also provided instructions on diet, exercise and habit, while the clinician only provided manuals without detail instructions. It is worth noting that the system suggested 80 mins of exercise per week rather than 150 mins considering the renal insufficiency of the patient.

All of the suggestions are acquired by the WinForms client to help a clinician’s work. Instructions on diet, exercise, and habit are also delivered to users through iOS app client for patient self-management since it used the same CDSS services.

**Discussion**

In this study, we adopt ontology methods to develop a multi-CPGs knowledge base to achieve a service-oriented architecture for CDSS services establishment. We built a fully functional CDSS web services as ASP.NET Web API, and developed two demonstration clients to illustrate the invoking of the CDSS services. We also demonstrated the functions of
the CDSS by a typical patient case, which received patient-specific suggestions for treatment decision.

Through the proper integration of CPGs using the ontology methods and the rule system for reasoning, the CDSS provided the best choices for treatment for this patient and gave warning about the contraindicated T2DM and HT medicines due to renal insufficiency of the patient. Since the CDSS functions as web services, the suggestions were able to deliver to both Winform client and iOS app client, leading to timely messages to both clinicians and patients and potential improvement of the communication between clinicians and patients.

Our ontology methods provided great flexibility for the integration between multi-CPGs. We used different editions of T2DM CPGs and HT CPGs to build the CDSS knowledge base. The infrastructure and the special ontology structure made it possible to overcome the difficulties of CPG integration. Those common concepts were captured and formed the infrastructure ontology, to provide OWL classes for both T2DM and HT to use. Disease specific concepts were treated as special ontology to provide knowledge that may be used in certain disease situations. Since ontology aims at formalizing and standardizing description of knowledge [8], the syntax and language differences between CPGs could be overcomed. Concepts, relationships, and rules were integrated well into one knowledge base for CDSS to provide suggestions. This may also be extended to other diseases by integrating their CPGs into our knowledge base.

Furthermore, the coding system in the knowledge base reduced the workload when using a CDSS system. Research had indicated that time to use the CDSS system should be minimized [9]. For ontology reasoning, the patient data from data bases can be automatically mapped to the patient individuals, since the data usually contain a code to indicate their category. With this function, the input procedure could be much more efficient. Users could load all the patient data and input into the CDSS once for all instead of classifying the data manually in advance.

By adopting the service-oriented structure, the functions of the CDSS are provided as web services, and can be easily utilized by various platforms. Building a CDSS as web services may reduce workload of client development and system integration. The knowledge and functions in the CDSS can then be shared to various users through service invoking. In this study, we had demonstrated two sample clients, a Winform program and an iOS app, and they functioned properly though different platforms and languages. By utilizing different methods, developers can create personalized clients. Dividing the functions into various sets methods provide flexibility for developers to integrate decision support into clinicians’ workflow, providing decision support at a right time and in a proper way.

It is possible to further improve the CDSS. Since not all the patient data are formalized when stored in data base, patients’ free text records still demands manual classification and input. Such manual work may negatively impact the implementation of CDSS and may cause human error. To overcome this issue, natural language processing may be a viable way to formalize free text records and extract useful information through ontology reasoning to map patient data [10][11]. Also, many EMR systems use international standard for data transfer such as HL7. Using HL7 may further lower the barrier in integration and data mapping of our system. Currently the system was only validated by one typical patient case. In the future, we will use larger group of patient data to validate and improve our system.

Conclusions

In this paper, we proposed an ontology and service-oriented architecture to provide flexibility in multi-CPGs integration and CDSS reuse and share, as well as procedure simplification in data input. A CDSS web service was built to provide clinical decision support through ontology reasoning based on a knowledge base derived from T2DM and HT CPGs. Demonstration clients were also developed to show the flexibility in CDSS services invoking, integration, and reuse. These clients achieved various functions by invoking different methods in the CDSS service. In future, we will incorporate natural language process and HL7 standard for data input, and perform cross-ontology reasoning by including more ontologies into the system.

Abstract

Risk stratification is essential to achieving the Triple Aim of better health, better care, and lower costs. Although risk tiers based on chronic disease diagnoses and recent healthcare utilization were predictive of healthcare utilization and charges in a managed population, their correlation with specific high-cost outcomes was unknown. More detailed analyses were performed to confirm that admissions for higher-risk patients were more expensive. However, these analyses found that charges for admissions of high-risk patients were actually not more expensive but 33\% less expensive. The billing categories of implants, surgery, and supplies accounted for 93\% of this difference. These findings may reflect that high-risk patients are less often appropriate candidates for elective surgery. An understanding of this difference, especially if validated by claims data and replicated in other populations, may lead to important insights into using risk stratification for predicting health services utilization in managed care populations.

Introduction

The Chronic Care Model and Risk Stratification

The Chronic Care Model [1] proposes improving the effectiveness of interactions between patients and providers as a way of promoting the “Triple Aim” of healthcare [2]: (a) better health, (b) better care, and (c) lower costs. Evidence has shown that patients with care coordinators have fewer emergency department and urgent care episodes [3], hospital admissions [4], and readmissions [5].

Unfortunately, healthcare often fails to provide effective coordination of care across a target population [6,7]. By bridging the implementation gaps in the Chronic Care Model, well-designed risk stratification supports the transition from the traditional “reactive” model of medical care [8] to proactively planning care in order to maintain health and avoid preventable conditions. Risk stratification is a potentially powerful tool for managing patient risk and improving outcomes, and stratifying risk by previous healthcare utilization has been shown to be a useful predictor of future healthcare needs[9].

LIGHT$^2$ and Risk-Stratification Tiers

LIGHT$^2$ (Leveraging Information Technology to Guide Hi-Tech and Hi-Touch Care) was a Health Care Innovation Award from the Centers for Medicare and Medicaid Services to examine the use of advanced health information technology and care coordination in a managed population [10]. With over 10,000 patient cases to be managed by fewer than 25 advanced practice nurses, the LIGHT$^2$ project needed clinical decision support to help focus preventive and longitudinal care on those patients who were at highest risk. The LIGHT$^2$ investigators defined four risk tiers as (1) Healthy, (2) Stable, (3) Unstable, and (4) Complex, on the basis of diagnoses that are included in the Chronic Conditions Data Warehouse (CCW) [11] and on healthcare utilization in the preceding year (see Figure 1).

These risk tiers supplied highly useful information about the prospective risk of patient healthcare utilization and charges [12]. However, their correlation with population-wide average healthcare charges was insufficient to demonstrate their correlation with specific high-cost outcomes such as inpatient admissions. Therefore, a detailed analysis of financial reporting data for the LIGHT$^2$ participants was needed to examine the assumption that admissions for high-risk patients were more expensive than for low-risk patients.

Objective

The primary objective was to test the hypothesis that admissions for higher-risk “unstable” and “complex” patients are more expensive than for lower-risk “healthy” and “stable” patients.

Methods

Data Sources

The LIGHT$^2$ program enrolled primary care patients at the University of Missouri Health System who were already enrolled in Medicare or Medicaid. The study cohort was comprised of 9,568 patients who were enrolled in LIGHT$^2$ on or before July 1, 2013. All data on patient diagnoses, prescriptions, and other clinical attributes were based on the electronic health records of the University of Missouri Health System as maintained by clinicians between 2011 and 2014. Charges per admission for thirteen billing categories were obtained from the IBM Cognos financial reporting system. The billing system is used by the hospital system for accounting and internal fiscal analyses. No missing data were detected.
Definitions

The four risk tiers were defined as shown in Figure 1. Patients who had none of the 27 chronic conditions identified in the Chronic Conditions Warehouse (CCW) [11] constituted the lowest-risk or “Healthy” category (Tier 1). Patients with one or more chronic conditions were placed in higher tiers depending on the number of their outpatient clinic visits and hospital episodes during the year prior to analysis. Patients with five to twelve related outpatient visits or one related hospital episode in a year were defined as “Unstable” (Tier 3), based on the investigators’ clinical judgement. Patients with chronic conditions but fewer visits and episodes than “Unstable” patients were defined as “Stable” (Tier 2), and those with more visits or more episodes than “Unstable” patients were defined as “Complex” (Tier 4).

In order to analyze the relationships between risk tiers and inpatient utilization charges, the hospital charges for inpatient admissions of patients in each tier were summed for each fiscal year. Only admissions for which the primary diagnosis was one of the 27 chronic conditions in the CCW were included in the sum of charges. All charges were measured in US dollars. For each risk tier in each fiscal year, the charges for all chronic-condition-related hospital admissions were averaged, in total and by billing category. Averages by risk tier and fiscal year were then compared, and the differences were subtotaled by billing category.

Results

The average charges by risk tier for chronic-condition-related inpatient admissions in fiscal year 2013 (FY13) and fiscal year 2014 (FY14) are shown in Table 1 and Figure 2. Additionally, Table 1 and Figure 3 subtotal these charges by thirteen billing categories.

In both fiscal years, average charges for chronic-condition-related inpatient admissions of “Complex” (Tier 4) patients were near the lowest for all risk tiers, at US $10,046 and $10,123 for the two years. The only lower average charges were for “Healthy” (Tier 1) patients at $8,162 and $7,164. The highest average charges were for “Stable” (Tier 2) patients at $11,954 and $14,835, and “Unstable” (Tier 3) patients at $13,633 and $12,423 (see Table 1 and Figure 2).

In all risk tiers for both fiscal years, nursing is the largest single billing category. However, the difference in average nursing charges for “Complex” patients ($4431) and Tiers 2 and 3 patients ($4605 combined average) is only 4% (see Table 1 and Figure 3). Charges in the implants, surgery, and supplies billing categories accounted for 93% of the difference between “Complex” patient charges and charges for “Stable” and “Unstable” patients (see Table 1 and Figure 3).

Discussion

The most remarkable finding of these analyses is that, in both fiscal years, charges for admissions of “Complex” patients were less expensive on average than those for “Stable” (33% higher overall) and “Unstable” (30% higher overall) patients (see Table 1 and Figure 2). Most of the difference seems to be explained by “Complex” patients getting less surgery and fewer implants than “Stable” and “Unstable” patients. This may be because complex-care patients are often less appropriate candidates for elective surgery such as joint replacement surgery.

Although joint replacements are known to be a significant driver of increasing healthcare costs [13-16], this study is the first to our knowledge on the interaction between patient risk stratification, surgical services, and the costs of hospital admissions at the level of population health management. Using risk stratification to help predict future healthcare utilization and charges is an important emerging technique in practice management. However, the “bottom line” numbers must be understood in some detail in order to discover the knowledge hidden in the data, as in this counterintuitive finding. Because this study was conducted within a US academic medical center, the findings may not be generalizable to every healthcare setting. However, if the cause of the higher charges incurred by relatively healthier patients is related to greater numbers of high-cost elective surgeries, such as those involving implants, this pattern might be expected in any healthcare system that routinely performs such surgical procedures.

Limitations

The use of charges as a proxy for costs limited precision of the financial analyses, particularly because nursing charges are the largest cost category and are calculated as fixed overhead cost. Since data was collected from a single healthcare system, some utilization of providers outside the system may be missing. This could affect both the risk stratification of patients and the number and cost of their admissions after stratification. These data gaps could be resolved by supplementing electronic medical records with insurance claims data for the same population over the same period.

Future Research

Although the billing categories provide some important insights into the lower charges for “Complex” patient admissions, more detailed billing data is needed to confirm that the type of surgeries and supplies reduced in “Complex” admissions are, indeed, related to implants and that these implants are for elective surgeries for which the complex-care patients were less appropriate candidates. More detailed billing data and chart reviews are also needed to answer what kinds of implants represent most of the difference in the charges, and whether the differences in charges are related to length of stay. Data for additional years should be analyzed to strengthen the association, and this analysis should be validated by replication in other populations.

Conclusion

The finding that “Complex” patients have markedly less expensive inpatient admissions, on average, than “Stable” and “Unstable” patients is contrary to the authors’ original hypothesis, and seems paradoxical. However, it may be explained by “Complex” or high-risk patients receiving less surgery and fewer implants than better surgical candidates in the “Stable” and “Unstable” risk tiers. An understanding of this difference, especially if validated by claims data and replicated in other populations, may lead to important insights into using risk stratification for predicting health services utilization in managed care populations.

A Design of a Surgical Site Verification System

Biyu Shen, Yan He, Haoyang Chen

Department of No.2 Affiliated Hospital of Nantong University, Nantong City, Jiangsu Province, China

Abstract

Patient security is a significant issue in medical research and clinical practice at present. The Surgical Verification System (Patent Number: ZL 201420079273.5) is designed to recognize and check surgical sites of patients so as to ensure operation security and decrease the risk for practitioners. Composition: (1) Operating Room Server, (2) Label Reader, (3) E-Label, (4) Surgical Site Display, (5) Ward Client, (6) Label Reader-Writer, and (7) Acousto-optic Alarm. If the Surgical identification, the surgical site, and so on are incorrect, a flashing label control will appear when the alarm rings. You can specify a sound to play for the alarm, a picture to draw, and a message to send. It is a user-friendly system.

Keywords:
Safety Management; Medical Errors

Methods

When a patient enters an operating room, the Label Reader will scan the E-Label of him/her for ID information and then check whether it is in accordance with that of the operating room information. If it’s correct, a body picture with the highlighted surgical site will be seen on the Surgical Site Display. Then the operation will begin when surgeons touch the screen to confirm the site information. In some applications, the Surgical Site Display is a touch screen, which makes a more convenient and clearer verification by touching the screen. The Surgical Site Verification System also includes an Acousto-optic Alarm, which is linked to the Operating Room Server. It will keep shining and making a sound for information confirmation.

The ID information of the patient is recorded in the E-label and will be recognized by the Label Reader connected with the Operating Room Server. The Surgical Site Display is connected with the Operating Room Server to illustrate the surgical site. The patient is equipped with the E-label and the Surgical Site Display is placed in the operating room. The E-label is a kind of electric chip to store information, which is put in a wristband of the patient in case of information losses or mistakes.

Discussion

 Guarantee of Accurate Patient Information: Surgical mistakes are one of the most serious incidents particularly in operating rooms. The American College of Surgeons reported that surgical site mistakes are the biggest medical incident in the country and set it as one of the most important goals in the operating room to ensure right patients, right surgical sites and right operating processes [6]. It is the prerequisite of safe medical care to correctly recognize the ID information of patients, which is also a guarantee for medical safety.

The ID wrist band contributes to a safe hospital management in the right direction, and offers an advanced and reliable auxiliary device in standard hospital management. The E-label could store accurate and reliable information of patients and help practitioners quickly identify the patient’s information. It contributes to a careful, definite and labeled information check. If
Identification of Surgical Sites: The Label Reader is linked with the Ward Client set in the ward area of the Inpatient Department and is also linked with the Operating Room Server to read the information of patients in the E-label. The Surgical Site Display, therefore, could point out the surgical site when connected with the Operating Room Server.

The Ward Client is connected with the Operating Room Server by the China Mobile GSM network. When the patient enters the operating room, the Label Reader will scan the E-Label of him/her for ID information and convey it to the Operating Room Server to check whether it’s in accordance with that stored there. If it is correct, a body picture with highlighted surgical site (A) will be seen on the Surgical Site Display and the Acousto-optic Alarm keeps making a warning tone until the surgeon and the other team members observe and touch the screen to confirm the site information (A). Then the operation will begin.

Conclusion

Identification of Patients: The ward nurses type in the identification information in the Ward Client, which includes ward section, ward bed number, name, gender, age, surgical site and remark, etc. Then the identification of patients will be transferred into the E-label by the Label reader-writer and sent to the operation room server so that the information will be stored for checking later.

There are any mistakes, the system will give a warning as an instant supervision. In contrast, a traditional wrist band is usually written by hand which has problems of unclear handwriting and possibly wrong information. The employment of the E-label involves double-checking by both human and machine, which increases the security of the operation. Especially for children, the elderly, and coma patients, it can greatly increase their security.

Reinforcement of Team Cohesion: The identification of patients and verification of surgical sites need to be implemented in various aspects and different times. People in clinical, technical and logistic departments are involved including patients, ward nurses, operating nurses, anesthetists and surgeons. Coordination and cooperation are necessary to make a successful treatment. Precaution is the most important point in safety management in the operating room. As a result, it’s necessary not only to introduce advanced technology but to lay emphasis on the team building. A surgical team consists of surgeons, anesthetists and operating nurses and have the main power to fulfill the surgery treatment. An excellent team is an efficient, optimized group of members who have complementary skills and skills so as to form an integral resultant force. Operating room workers should strictly obey the regulations, cultivate a rigorous attitude towards work and a high responsibility. Furthermore, effective precautions should be taken into account from the perspective of management and the Surgical Site Verification System is designed for this purpose.

It is estimated that there are 234,000,000 operations every year in the world [7]. According to a survey in 2009, the incidence of postoperative complications decreased from 11.0% to 7.0% with the application of the Surgical Safety Checklist [8], which proved most surgical mistakes could be avoided by safety checking. Nowadays [9], medical care in the world is becoming safer, more quality-oriented and much more economical [10,11], where surgical safety is key. The prerequisite of safety management is the implementation of safety checking regulations and procedures while the precaution of adverse events is the emphasis of operating room safety and risk management.

A mistake will cause results ranging from operation delay, treatment effect, waste of labor to serious incidents including disability and death of patients. The reliable and stable Surgical Verification System, as referred to in this paper, can help reduce the mistakes in operation. The double check by human and machine can avoid potential problems in operation, strengthen cooperation among team members, and increase work efficiency so as to contribute to better economic and social benefits.

The potential limitation is that this is just a design, there is no achievement of transformation. The relevant problems could be solved in a better way through data validation and after the transformation.

We have the 3D technology, and the computer will show the anatomy of the system, if the positioning of the scan is correct, then there will be flashing green light though, if not, then there will be a red light. It will ensure the correct operation site as to ensure a smooth operation.

Characterizing Restorative Dental Treatments of Sjögren’s Syndrome Patients Using Electronic Dental Records Data

Zasim Siddiqui, Yue Wang, Payal Makkad, Thankam Thyvalikakath

Abstract

Scant knowledge exists on the type of restorative treatments Sjögren’s syndrome patients (SSP) receive in spite of their high dental disease burden due to hyposalivation. Increased adoption of electronic dental records (EDR) could help in leveraging information from these records to assess dental treatment outcomes in SSP. In this study, we evaluated the feasibility of using EDR to characterize the dental treatments SSP received and assess the longevity of implants in these patients. We identified 180 SSP in ten years of patients’ data at the Indiana University School of Dentistry clinics. A total of 104 (57.77%) patients received restorative or endodontic treatments. Eleven patients received 23 implants with a survival rate of 87% at 40 months follow-up. We conclude that EDR data could be used for characterizing the treatments received by SSP and for assessing treatment outcomes.

Dental Records; Sjögren’s Syndrome; Dental Implants

Introduction

Sjögren’s syndrome (SS) is a chronic autoimmune disorder of exocrine glands, particularly salivary and lacrimal gland, characterized by lymphocyte infiltration of affected gland resulting in the dryness of the mouth and eyes [13]. It is the second most common autoimmune connective tissue disease affecting up to 3.1 million Americans, with approximately 1 in every 70 people affected by primary SS [17; 23; 40]. It is common among middle aged people, with a high prevalence in females (female: male 9:1) [6]. It can occur alone as primary SS or in conjunction with other connective tissue diseases as secondary SS, such as rheumatoid arthritis (RA), systemic lupus erythematosus, and systemic sclerosis [13; 16; 37]. Both primary and secondary SS have similar pathophysiology, signs, and symptoms [7]. The exact etiopathogenesis of SS is unclear and considered to be multifactorial. However, its etiology has been associated with endocrine, genetic and viral factors and alteration in the regulation of cell apoptosis [20; 24; 28]. At present, SS is an incurable disease with symptomatic management options. However recent evidence showed effectiveness of early immunomodulation in limiting disease progression among SS patients [33].

SS patients experience a high caries risk due to reduced salivary flow leading to premature tooth loss despite maintaining good oral health, visiting dentists more frequently, using fluoridated toothpaste, and having more awareness about their disease and oral health [3; 4; 10; 31; 38]. Hyposalivation and early loss of teeth significantly interfere with the individual’s normal oral functions such as speaking, chewing, and swallowing thereby compromising their physical, social and emotional quality of life [5; 15; 26; 29]. These patients often require costly, early life restorative treatments to maintain normal oral functions due to tooth loss [8; 38]. Despite their huge dental disease burden, limited studies exist characterizing SS patients’ oral health and dental treatments.

To date, most of the knowledge on SS treatments comes through surveys and interviews on patients’ experiences and challenges with maintaining good oral health and receiving dental treatments [2; 10]. Results from these studies report SS patients have difficulties with maintaining good oral health, high caries risk and incompatibility with tooth/tissue supported prosthesis due to mucosal dryness. These challenges with maintaining good oral health highlight the need for clinical research. Very few clinical studies have investigated SS patients’ oral health or outcomes from dental treatments received. Lately, implant retained prosthesis are heralded as the treatment of choice to replace lost teeth in patients with SS. However, implant success are inconclusive as they are either case reports or studies with small sample size [9; 19; 30].

The historic use of paper-based records in dental clinics makes retrospective studies of SS difficult. Also, challenges with identifying and confirming SS diagnosis and associated comorbidities were a major barrier in performing clinical studies. The increased adoption of EDR in dental practices offers an opportunity to study the outcomes of various dental treatments among SS patients using EDR data [34]. Studies have shown increased adoption of EDR in both private and academic dental settings in United States and this trend is expected to continue in the future [32; 34; 35]. This trend echoes with the EDR adoption and computer usage in dental practices in other countries including Canada, China, UK, and Brazil [1; 12; 18; 21]. Most countries showing high adoption of EDR used it not only for administrative purposes but also for patient care documentation at the point of care. However, few countries have also shown to be using EDR and computers in dental offices mainly for administrative purposes [1; 12]. In US academic settings, more than 90% of the dental schools document patient care using EDR [32]. Approximately 76% of US independent and group practices use EDR for patient care documentation in 2013 [34] compared to 48% of physician offices having a basic Electronic Health Record in 2014 [14]. Thus, EDRs are a potential data source for clinical research. In this study, we demonstrate the use of EDR data in evaluating dental treatment procedures and outcome for SS patients.

The objective of this study was to determine the feasibility of using EDR to characterize the restorative and endodontic dental treatments for SS and assess the longevity of dental implants placed in patients with SS at the Indiana University School of Dentistry clinics. The long-term objective of our
research is to advance our knowledge of SS and to develop best practice guidelines toward improved oral health and quality of life.

Methods

This study was approved by IRB 1611054551. We retrieved a limited data set of patients seen between January 1, 2005 and October 31, 2016 by performing keyword search for the term “Sjogren” in the EDR. We identified 270 records that contained the term “Sjogren” in the medical history forms, progress/clinical notes, specialty and medical consultation forms, carries risk assessment, and management forms. We used keyword search to identify patients diagnosed with SS as patient’s medical and medication histories are typically documented in free-text format or within progress notes.

Two trained dental researchers manually reviewed the clinical notes to identify patients who reported having SS. Unambiguous records stating patients diagnosed with SS were included whereas records only mentioning “Sjogren” as a suspected disease, differential diagnosis, or family history etc. were excluded. Disagreements between researchers were discussed and resolved through consensus.

Next, we retrieved the treatment history of these patients using Current Dental Terminology (CDT) [27; 36] codes that are routinely used to document dental procedures performed in dental practices. We identified the CDT codes related to restorative and endodontic treatment procedures and grouped them into five major treatment types (Table 1). Treatment types were further divided into treatment procedures based on the types of materials (resin-based composite, amalgam), location (maxillary, mandibular), and extent (partial, complete) (Table 2). Each treatment procedure included CDT codes representing that procedure type. For instance, Resin-based composite contains codes: D2330 - D2335 and D2390 - D2394. Amalgam restoration contains codes: D2140, D2150, D2160, and D2161.

We performed descriptive statistics on demographics and treatments. Life tables were constructed to assess survival rates of implant procedures. Two researchers also manually reviewed clinical notes of failed implant records to detect reasons for implant failure.

Results

A total of 180/270 patients were identified with SS. Among them, 165 (91.6%) were female, 11 (6.66%) male, and four patients (2.22%) did not report their gender. These patients had a mean age of 63.75 years (standard error: 1.06 years) with 160 (88.89%) of them being 45 years or older. Among the patients who reported ethnicity, 100 (55.56%) were Caucasian and 13 (7.2%) were African Americans. 61 (33.89%) patients did not report their ethnicity. Only 75 (41.66 %) patients had dental insurance. 120 patients (67%) had a follow-up visit of more than one year.  The average (41.66 %) patients had dental insurance. 120 patients (67%) had a follow-up visit of more than one year.  The average (41.66 %) patients had dental insurance. 120 patients (67%) had a follow-up visit of more than one year. The average follow-up was 5.23 years (SE: 0.32 years).

Tables 1 and 2 show the distribution of treatment types and treatment procedures, respectively. 104 (57.77%) patients received restorative and/or endodontics treatment. These patients received 1,085 different restorative and/or endodontics treatments while the remaining patients received oral examinations with diagnostic procedures, prophylaxis treatment, periodontal therapy, or surgical treatment including tooth extraction. Most common restorative procedures were resin-based composite and amalgam restorations followed by fixed partial denture procedures. 24 patients received 41 complete or partial dentures and 25 patients received 33 endodontic treatments. The mean patient age for patients receiving partial dentures, complete dentures, and endodontic treatments was 66.87, 62.14, and 58.78 years, respectively.

Eleven patients received 23 implant treatments, 12 (52.17%) in the maxilla and 11 (47.82%) in the mandible. As shown in Table 3, three implants failed (two in maxilla and one in mandible) making survival rate of approximately 87% during an average follow-up period of 40 months. These 3 implants failed in two patients in the second and fifth months after placement. One implant failed due to osseointegration and the
remaining two were removed due to mobility (lack of osseointegration), erythema of surrounding implant area, vertical bone loss and horizontal ridge deficiency after implant placement. All three implants were lost in the preloading phase. Survival rate of loaded implants was 100%. Table 3 demonstrates the survival rate of implants.

Table 3 - Life table analysis for implants showing the time interval in years, number of implants that existed during these time intervals (N), number of failures (NF), replaced implants (RI), failure rate (Failure%) and survival rate (% S) during this interval, and cumulative survival rate (Cum % S)

Discussion

In this study, we attempted to assess the feasibility of using EDR data to characterize the dental treatments for SS patients and determine the longevity of dental implants placed. Study results indicate that EDR data could be utilized to characterize the dental treatments in SS patients and assess the effectiveness of these treatments in restoring their oral functions. To the best of our knowledge, this is the first study of dental treatments among SS patients using EDR data. We identified 50% of SS patients received dental restorations using materials such as composite resin and amalgam. Approximately 14% of patients received endodontic treatments to treat infection/disease involving dental pulp. Implants are emerging as a popular alternative to restore lost teeth due to difficulty with tolerating removable denture prosthesis as a result of mucosal dryness. However, we identified only 11 (6.11%) patients who received implant treatment. The high cost and limited coverage of implant treatments under dental insurance in the United States could be reasons for this small number of implant placement. In addition, many of these patients already have high medical expenses due to associated comorbid conditions [38]. We found the average number of dental visits for patients with more than one year of follow-up to be 5.23 visits/year, which is higher than the 4 visits/year reported in a previous study on primary SS patients in the United States [38]. A high number of dental visits with only 41.66% of patients having dental insurance indicated that SS patients incur high dental expenses.

In this study, three implants failed in two patients. The failure rate of approximately 13% on 40 months of follow-up is higher than all the previous studies in SS patients except for the 1999 case review series by Isidor et al. in Denmark, which reported failure rate of 16.7% on 48 months of follow up [9; 11; 19; 22]. Implant failure rate in SS patients is high compared to the 98% success of implants in medically health patients on 10 years of follow-up [22; 25; 39]. Curiously, the three dental implants that had failed were all during the preloading phase, whether such a trend can be substantiated warrants further investigation. Furthermore, future research in this area is needed to evaluate the impact of different risk factors such as immunosuppressant therapy, associated comorbid conditions and smoking on the implants survival in SS patients.

Several limitations exist within our study. First, SS patients were identified by extracting information from the EDR using the term, “Sjögren”. Patients with Sjögren’s syndrome whose disease was documented using other lexical variations such as “SJIS” would not be identified using our extraction method. Second, Sjogren documentation was based upon patient self-reported data, the reliability of patient self-reported Sjögren’s syndrome have not been evaluated. Third, the survival rate of implants within our study was based on 23 implant treatments. The failure rate could be exaggerated due to the limited number of implants.

Future work would be to expand our terminology to include other terms for Sjögren’s syndrome. Additionally, we identified the Sjögren’s syndrome patient population using information within the EDR. To expand our cohort, we could also use other sources such as medical records for identifying dental patients with Sjögren’s syndrome. Furthermore, the accuracy of patient self-reported Sjögren’s syndrome needs to be validated with other sources such as medical records.

Conclusion

EDR data could be used for identifying treatments received by SS patients and assessing outcomes. However, further studies are required to evaluate the impact of confounding variables on the outcome of these treatments. Such studies will facilitate developing best practice guidelines to improve oral health among these patients.

Abstract

Clinical documentation using free text to describe a patient’s medical status is an essential component of electronic health records (EHRs), and the quality of information in documents plays a critical role in clinical practice and translational research. Physicians are the primary creators of EHRs, but their clinical practices vary substantially, resulting in variations in clinical documentation. These variations can represent a source for potential bias in clinical outcomes and downstream applications using EHRs. Asthma is one example, presenting an inconsistent ascertainment process and criteria. A recent study revealed that resident physicians’ knowledge of asthma diagnosis and management is relatively limited. In this study, we examined clinical documentation variations in asthma care between staff and resident physicians using individual words, topics, and asthma-related concepts in EHR clinical narratives. Additionally, we discuss potential biases in building an informatics model and further compare asthma diagnosis and outcomes between two physician groups.

Keywords: Asthma, Documentation, Electronic Health Records

Introduction

Asthma is one of the five most burdensome diseases [1] and the most common chronic childhood illness, affecting approximately 4%-17% of children in the United States [2; 3]. Structured data (e.g., ICD-9 codes) in electronic health records (EHRs) reveal a low sensitivity level to the accurate identification and management of children with asthma. The recent growth of unstructured clinical documents in EHRs and clinical text analytics using machine learning and natural language processing (NLP) have demonstrated great potential in the areas of clinical practice and translational research. These techniques have been successfully applied in asthma [4] and other various clinical applications [5-12].

The clinical documentation of a patient’s medical status using free text is an essential component in EHRs and the quality of information accumulated in clinical documents plays a critical role in patient care and clinical research. Physicians are the primary creators of EHRs, but their clinical practices vary substantially [13], which may significantly affect the quality of both structured (e.g., billing codes) and unstructured data (e.g., clinical notes) and cause potential bias in the secondary use of EHR data. Lack of a consistent approach to patient care may also result in higher costs and inevitably makes it necessary to reduce clinical variations at the point of care [14; 15]. For example, asthma has an inconsistent ascertainment process and criteria that cause delays in diagnosis, despite the availability of effective asthma therapies. Further, it has been reported that junior healthcare providers’ (e.g., residents) knowledge of asthma diagnosis and management is in development and needs to be improved through an interactive course [16]. Resident physician documentation often contains inaccurate information in progress notes [17] and as a result, the effect of a point-of-care personal digital assistant has been examined as a means of reducing resident documentation discrepancies [18]. Another study investigates the effect of an EHR template on family medicine resident documentation to improve asthma severity classification and treatment [19].

The quality of clinical documentation is crucial for downstream applications of EHRs to ensure the strong performance of informatics systems developed based on them. However, there are gaps between experienced (i.e., staff) and inexperienced (i.e., residents) healthcare providers in clinical documentation, and this can result in unintended consequences. To build accurate informatics systems, clinical variations between two provider groups need to be identified and addressed. Inappropriate or missing representations of a patient’s medical status as a result of inexperienced healthcare providers may diminish preventive opportunities and lead to inefficient healthcare delivery. This challenges physicians in their efforts to improve the value of healthcare delivery.

To address this problem, it is important to identify major variations in clinical documentation and understand the nature of those variations. Previously, researchers have investigated differences in laboratory tests in a physician’s practice to identify overlooked information regarding physician behavior [13]. The association between residency training and clinical practice [20; 21] was studied to identify variations in terms of clinical education. Regional variances among healthcare providers were also explored in diagnostic practices measured in Medicare claims [22]. Although it has been observed that the recent trend of novel efforts to promote rational use may cause variations in physician practice [23], the nature of such variations are not well understood. These previous studies utilized structured data and educational backgrounds to analyze physician behavior rather than the rich source of unstructured data in EHRs (i.e., clinical narratives).

In this study, we assessed variations in clinical documentation, especially clinical narratives, between staff and resident physicians in asthma care using individual words, topics, and asthma-related concepts. Further, we compared actual asthma diagnoses and outcomes between two physician groups and discussed the potential impacts of clinical document variations on quality of care and an informatics model.

Methods

We examined basic statistics and similarities in clinical documents between staff and resident physicians to identify clinical
documentation variations. Asthma diagnoses and outcomes statistics were then compared to analyze gaps in clinical practice. This study was approved by the Mayo Clinic Institutional Review Board. Detailed methods are described in the following subsections.

Patient Cohort

Our study subjects are children who received medical care from Mayo Clinic pediatric practice, Rochester, Minnesota. As of 2015 September, 19,064 children were cared for by Mayo Clinic pediatric practice. Of these, 9,277 children were included for this study who participated in an ongoing asthma intervention study.

To examine document statistics and similarities we used the all patient cohort (n=9,277) and associated clinical notes. For the comparison of asthma diagnoses and outcomes, we selected patients from 2013 to 2015 who had clinical visits with either staff or resident physicians in Community Pediatric & Adolescent Medicine (CPAM) based on the 2015 physician list (n=4,102).

Clinical Document Statistics and Similarities

Basic statistics on clinical documents (i.e., total number of clinical documents/tokens, frequency of asthma-related concepts, note types, and sections in clinical notes) were compared between staff and residents. Staff and resident clinical document similarities were also compared in terms of word-level, topic-level, and asthma-related concepts. We preprocessed the documents (i.e., tokenization, removing stop words, and stemming) and created a vector space model for each case to compare similarity. The similarity was measured by cosine similarity since it is useful for comparing how two documents or corpora are likely to be in terms of their subject matter [24].

The clinical documents were represented by tf-idf (term frequency-inverse document frequency) and latent topic-based vector for computing word-level and topic-level similarity, respectively. The tf-idf for the term \( t \) is defined by summation of \( tf(t)idf(t) \) for all documents in the corpus divided by total number of documents in the corpus, i.e., \( \sum tf(t)idf(t)/N \).

In order to compare clinical documents in the latent topic space, we employed a topic modeling method, Latent Dirichlet Allocation (LDA) [25; 26], to generate the document distributions in the latent topic space, i.e., \( p(z_k|d_i) \). In the latent topic-based vector representation, the topic \( z_k \) for the corpus \( C \) is defined as:

\[
p(z_k|C) = \sum_{d \in C} p(z_k|d_i,C)p(d_i|C) = \frac{\sum_{d \in C} p(z_k|d_i)}{N}
\]

To compute similarity of asthma-related concepts we extracted concepts used in the predetermined asthma criteria (PAC) (see Table 1) and represented them in a vector space model using the same notion of tf-idf representation.

Asthma-related Concept Extraction

We used the MedTaggerIE module [27] in MedTagger to extract asthma-related events and episodes. MedTagger is the open-source pipeline developed by Mayo Clinic that contains a suite of programs including three major components: indexing based on dictionaries, information extraction based on patterns, and machine learning-based named entity recognition [27; 28]. Asthma-related concepts (Table 1) were compiled from PAC [29] that were originally developed by Yunginger et al. [29] and have been used extensively in research for asthma epidemiology. Each concept consists of a set of keywords.

| Table 1. Asthma-related concepts used in predetermined asthma criteria. |
|------------------------|------------------|------------------|------------------|------------------|------------------|
| Cough, Asthma, Infantile Eczema, Wheeze, Night-time disturbance (nocturnal cough/wheezing), Hay fever, Dyspnea, Bronchiolitis, Pulmonary Test, Bronchodilator, Bronchospasm, Methacholine Test, Positive Skin Test, COPD, Nasal Polyps |

Asthma Diagnoses and Outcomes

We compared asthma diagnosis statistics based on both physician-diagnosis and PAC between staff and residents. Physician-diagnosed asthma was determined by examining the diagnosis section in clinical notes, and PAC-based asthma diagnosis was determined by applying our NLP-based PAC system [4]. Further we compared outcomes of asthma care, such as ER visits for asthma, hospitalization for asthma, and asthma exacerbation (i.e., oral steroid use for asthma).

Results

Clinical Document Statistics

The basic descriptive clinical document statistics of staff vs. resident physicians are shown in Table 2. The list of providers (i.e., staff or residents) was based on the year 2015. Staff have a higher number of patients and documents because they tend to stay longer than residents at the clinic. Interestingly, residents have a much higher median number of tokens (words) per document than staff. Both staff and residents have a similar proportion of documents that contain asthma-related concepts and median number of asthma-related concepts per document.

Figure 1 shows the distribution of asthma-related concepts between staff and residents. The concept ‘cough’ appears most dominant in both providers’ notes, but staff documented it more frequently than residents. The next most frequent concepts for staff were asthma, eczema, and wheezing, and for residents, asthma, dyspnea, eczema, and wheezing (asthma and dyspnea appear in very similar patterns). Residents’ documents have a much higher frequency for dyspnea than staff. It should especially be noted that asthma appeared less frequently in resident documentation, even though the other concepts appeared in similar proportion, including wheezing, which is the most important concept in determining a patient’s asthma status.

Figure 2 shows the distribution of note types that contain asthma-related concepts. Both staff and residents recorded asthma-related concepts dominantly in limited exam (LE) and multi-system evaluation (ME) notes. Residents also recorded these concepts in progress (PRG) notes and also used admission (ADM), observation (AOB), and consultant (CON) notes, while staff rarely used these note types.

The distribution of sections that contain asthma-related concepts between staff and residents is shown in Figure 3. Staff used history of present illness (HPI) most frequently, followed by impression/report/plan (IRP), but the order is reversed for residents. Residents also used the subjective section, which was rarely used by staff.
Clinical Document Similarities

Similarities between staff and resident clinical documents were examined in terms of word-level, topic-level, and asthma-related concepts (Table 3). Word-level similarity was not very high, but topics and asthma-related concepts between two provider groups were very similar.

Asthma Diagnosis and Outcome

Table 4 contains statistics pertaining to asthma diagnoses and outcomes for patients whose CPAM physicians have been either staff or residents for the past three years (2013 to 2015). Staff diagnosed asthma more than twice as often as residents in both physician-diagnosed (10.4% and 4.5%, respectively) and PAC-based asthma (10.5% and 4.6%, respectively) when compared based on the proportion of their patients. For each of three asthma outcomes (i.e., ER visit for asthma, hospitalization for asthma, and asthma exacerbation), staff demonstrated better quality of care (i.e., lower ratio of incidents) than residents and they were statistically significant (95% CI) when considering all three outcomes as a whole.

Discussion

Clinical documentation between staff and resident physicians in asthma care has been examined in terms of document contents, asthma diagnosis, and asthma outcomes. Basic document statistics (i.e., the number of documents, tokens, asthma-related concepts, and note types) differed in number, and the individual words used in documents were not so similar (word-level similarity = 0.718). However, concepts used in their documents were very similar (i.e., topic similarity = 0.991; asthma-related concept similarity = 0.964), which may reflect the fact that both staff and residents share common terms to describe asthma episodes and events.

For asthma-related concepts in clinical documents (Figure 1), staff and residents demonstrated similar distribution except for the concept of dyspnea (consists of keywords: dyspnea, shortness of breath, breathing difficulty, respiratory distress, etc.). Interestingly, residents recorded a much larger portion of dyspnea (17.3%) than staff (3.2%), which is close to the proportion of residents’ recorded asthma concepts (17.5%). Staff and residents showed different usage of note types that contained asthma-related concepts (Figure 2), although the top two frequently used note types were the same (limited exam, multi-system evaluation). Over 90% of asthma-related concepts were found in three note types for staff (limited exam, multi-system evaluation, subsequent visit), while residents used additional note types (progress, admission), up to 90% of asthma-related concepts. We also investigated overall note type distribution regardless of asthma-related concepts and observed that progress notes were the second most frequently used notes for residents (23%) after multi-system evaluation (23%). Staff rarely used admission and observation notes, which may be one reason for note type discrepancies that contained asthma-related concepts. The overall trend of using sections for asthma-related concepts (Figure 3) was similar between two physician groups, but interestingly, residents used impression/report/plan sections most frequently, as compared to history of present illness, which was most commonly used among staff. Additionally, residents did not use diagnosis sections as often as staff. This may reflect the fact that residents are less likely confirmative in their asthma-related observations with regard to patient medical status.
There were notable gaps in clinical documentation between staff and resident physicians in asthma care. Our study shows that residents were less likely to diagnose asthma than staff even though the distribution of other asthma-related concepts appeared to be similar. Subsequently, asthma outcomes (ER visits, hospitalization, and oral steroid use) among patients of residents were relatively poor when compared with those of staff.

The recent growth of EHRs provides potential for comprehensive tracking of patient history, which allows evidence-based medicine to address treatment uncertainty and reduce clinical variances. However, EHRs may contain hidden biases and noise factors unrelated to disease burden [30; 31]. Without careful analysis of such biases, an informatics model built on such EHRs may not perform as expected. Along this line, differences in clinical documentation between staff and residents observed in our study must also be considered in order to ensure the accuracy of informatics models.

The similarity measure of asthma-related concepts used in our study depends on the type of concepts in the entire documents of each physician group, not necessarily individual numbers of each concept per physician. The high similarity reflects that both staff and residents use similar concepts, and therefore residents may not be required to undergo additional education to ensure proper use of additional terms or definitions. However, it does not show the actual presence/absence of individual concepts representing a patient’s medical status per physician. Further assessment of detailed presence/absence concepts of residents’ documentation representing patient medical status and divergence analysis compared to staff could be a strong potential resource, not only in the education of residents, but also in an effort to improve clinical documentation so as to reduce clinical variations.

Limitations of this study include lack of analyzing effects of potential confounding factors (e.g., patient’s demographic, environment, risk factors, and healthcare utilization) and the use of a relatively short period of time (three years) to analyze and compare asthma diagnoses and outcomes. We plan to consider these factors in the future and expand divergence analysis in asthma care at the individual resident level.

**Conclusions**

Clinical documentation variations were observed in asthma care between staff and resident physicians when utilizing note types, sections, and ascertaining asthma-related concepts. Additionally, residents were less likely to diagnose asthma than staff and were responsible for relatively poor outcomes in asthma care because a delay in asthma diagnosis may prevent asthmatic children from access to therapeutic and preventive interventions. The variations identified by our analysis may represent a potential bias, not only for clinical outcomes, but also for downstream applications using EHRs, and this needs to be considered in order to better interpret clinical research outcomes and the performance of informatics models for clinical decision support.

Medical Effect of Venous Thromboembolism Prophylaxis Systems and Common Input Categories: Preliminary Findings from a Systematic Review

Julian Varghese, Maren Kleine, Sophia Isabella Gessner, Sarah Sandmann, Martin Dugas

Abstract

Computerized Clinical Decision Support Systems (CDSS) are implemented in hospitals to improve prevention of Venous Thromboembolisms (VTE). A physician-driven review was conducted to assess extent of patient outcome effects of recently published CDSS studies. To facilitate future re-implementations within existing hospital information systems, input variables of included systems were extracted, standardized and annotated with semantic codes. Item category coverages of the different systems were then compared. 73% of studies showed positive medical effect. Of these, 53% showed strong positive medical effect by reducing incidence of deep vein thromboses and pulmonary embolisms. Outcome-improving systems tend to cover more item categories. A broad set of clinically relevant input variables should be taken into account or reused from the electronic health record if considering CDSS implementation. Input data models are provided for download in different standardized formats. Site-specific organizational factors that determine how systems are introduced, implemented and tested are also crucial for success.

Keywords:
Clinical Decision Support Systems, Venous Thromboembolism, Common Data Elements

Introduction

Computerized Clinical Decision Support Systems (CDSS) are targeted to improve clinical decision making using individual patient characteristics to generate health-related recommendations with an aim to improve health care quality, clinical processes or cost-efficiency [1]. This work reports on preliminary findings of an ongoing systematic review on CDSS in inpatient settings but focuses on one disease entity where CDSS have been frequently applied: Venous thromboembolisms (VTE). VTE are responsible for a great number of complications in hospitalized patients. They are also one of the most common preventable causes of in-hospital deaths [2]. VTE represent a disease entity where CDSS could improve patient care at sites where guideline-adherent prophylaxis of VTE is under-utilized [3]. Comparing medical effectiveness of different CDSS studies leads to an analysis of different patient outcome measurements and effect sizes; and all of them weighing differently on the patient’s overall medical condition. For instance, patient outcome improvement in VTE prophylaxis is linked to many different patient outcome measurements such as number of events of deep vein thromboses or lung embolisms and adverse reactions to prophylaxis such as hemorrhages [4]. To our knowledge, there is no systematic review on CDSS that assigned full patient outcome summaries to different levels of clinical relevance. We deal with this issue using a new generic method, which intends to rate medical effect of CDSS interventions regardless of their targeted disease entity. The method is used by two physicians for medical evaluation and two biostatisticians for study quality assessment to analyze both clinical impact and risk of bias based on included CDSS studies.

There are regulatory and technical challenges when re-implementing CDSS from a study context into daily routine of hospital information systems. CDSS can also pose patient risk because of health provider’s dependency on its proper functioning. Regulatory frameworks approving CDSS software as a medical device need to be considered in the United States [5], the European Union [6] or elsewhere. Regarding technical challenges, necessary input data elements of the system might not be provided in an adequate way before a CDSS can even start to operate on any patient-related data. This leads to issues such as cumbersome manual data re-entry or tiresome mapping of available patient data to the input database of the CDSS [7]. The latter issue is also a result of lacking semantic interoperability in hospital information systems [8]. Data forwarding from primary data capturing systems to a desired database can result in data acquisition time delays or makes transfer of complex patient data challenging [9]. At the level of principal knowledge base of a CDSS the knowledge acquisition bottleneck describes the difficulty of acquiring domain-specific knowledge by experts [10]. CDSS solutions to improve guideline adherence might be hampered due to poor machine-readability of unstructured guideline text. Therefore, input variables and inference need to be clearly defined to facilitate CDSS implementations.

The main objectives of our review are summarized in the following:

1. Medical evaluation of CDSS impact on patient outcomes in inpatient settings and taking into account risk of bias assessment by using a standardized approach.
2. Identification and analysis of different item categories that were used by the systems. By doing this, we also approach to test whether outcome-improving CDSS studies implemented different or more item categories for input than outcome-neutral CDSS.
3. Generate a set of standardized electronic forms including metadata definitions that represent the input of all included CDSS studies.
Methods

The a priori design of the ongoing systematic review has been registered on PROSPERO register for systematic reviews [11]. This work focuses on VTE as a specific disease entity and elaborates on common input variables of CDSS that were applied as study interventions with patient outcome measurements. Two standardized tools have been used to provide high quality for systematic reviews: The 27-item checklist “Preferred Reporting Items for Systematic Reviews and Meta-Analyses” (PRISMA) [12] and the 11-item checklist of "Assessment of Multiple Systematic Reviews” (AMSTAR) [13]. Statement of checklist fulfillment is provided on our online supplement [14].

Search Strategy

Full text studies on CDSS in English were searched in MEDLINE, Cochrane Trials and Cochrane Reviews from January 2005 to April 2016; see table 1. Article references of all included articles and reviews were taken into consideration for further inclusion. A broad set of search terms was used based on recent systematic reviews [1, 15] on Health Information Systems and focusing on terms relevant for CDSS and outcome assessments. Two search phases were required for entire screening and analysis. The first started in July 2015 (articles screened from 01/2005 till 07/2015) and a second updated search started in April 2016 (articles screened from 07/2015-04/2016). Details of CDSS definition and exact search string are provided on the supplement [14]. CDSS studies suggested by expert opinions collected on MEDINFO Conference 2015 and Medical Informatics Europe Conference 2016 [16] were also taken into consideration.

Study Quality Evaluation of Included Studies

Study design characteristics such as outcome variables (primary and secondary), study period, principal study design, number of study arms, healthcare setting (e.g. single or multiple hospitals involved), study country, patient sample size, sample size calculation, statistical methods for baseline analysis and confounder adjusting were extracted by two independent reviewers wherever reported. Principal study designs were: 1) randomized controlled, 2) non-randomized interventional or pre/post design with at least one prospective study arm and 3) purely retrospective studies as retrospective cohorts or case-control studies. Randomization is distinguished by unit of randomization: 1) Patient level, 2) Health Care Professional, and 3) Site or ward. Randomization quality of CDSS studies improves in this order due to decreased probability of contamination [17]. Based on availability of reported characteristics, two biostatisticians used a standardized approach [18] to independently evaluate overall risk of bias (low, medium, high) for each study. Due to the heterogeneity of different principal study designs a meta-analysis for outcome analysis was not considered. Ratings of both reviewers were compared later, in case of differences, agreement was reached by consensus.

Coverage of Input Item Categories

For every included study, one health-IT expert was engaged to identify input data elements, which were required for the CDSS algorithm. A three point rating scale was used to assess reporting quality of such data elements (poor: Most or all input variables are not described, reproduction of the required input is not possible; questionable: Partially vague descriptions, reproduction of required input is uncertain; sufficient: Variables are reported sufficiently enough to reproduce the required input). Assessment was done by reviewer’s judgement on completeness and comprehension of reported data elements to reproduce the CDSS’ input that is necessary for the execution of the algorithm. To facilitate future re-implementations, for each study, reported input variables, associated data types and value-sets were identified and standardized within Operational Data Model (ODM) [19] and manually annotated with semantic codes from the Unified Medical Language System (UMLS) by a physician and uploaded to our medical data repository [20]. We compare item category coverage in outcome-improving vs. outcome-neutral CDSS studies.

After standardization of different input variables to ODM forms, CDEGenerator [21] was used to automatically identify common medical concepts. A medical concept was defined as common if it occurred at least in two of the included CDSS studies as an input variable. Based on clinical similarities, the common medical concepts were assigned to basic routine documentation categories. Thus, an overview of common input variable categories and their use in patient outcome-improving CDSS studies vs. outcome-neutral studies was established.

Medical Evaluation

Reported outcome measurements and results were rated independently by two physicians. For each study, they were instructed to assign all patient outcome effects to a level of clinical relevance. Clinical relevance represents impact on the patient’s overall medical condition using all reported outcome findings, taking into account both statistical significance and actual effect sizes. Similar to American Society of Anesthesiologists’ (ASA) classification [22] used to rate the patient’s preoperative health, the method both physicians used assessed relatedness to life-threatening conditions or mortality as a key indicator. By definition, studies significantly reducing mortality received the highest rating. The following point scale was used, which will be referred to as the medical effect score:

5: Mortality was reduced.
4: Strong positive effect: No effect on mortality was measured, but clinical events (e.g., adverse events or forms of morbidity) with immediate life threatening potential were reduced.
3: Medium positive effect: Clinical events with no immediate life threatening potential were reduced. Patients suffering from those events would require non-urgent treatment.
2: Light positive effect: Clinical events with no immediate life threatening potential were reduced. Patients suffering from those events do not necessarily require treatment.
1: No effect on medical condition was measured, or outcome findings were mixed (positive and negative outcome results).
A potential benefit for the patient’s medical condition is unclear or not expected. If a study had a negative outcome summary it was rated as “negative”. All ratings except for 1) required statistical significance. Weighted Kappa statistics were calculated to measure inter-rater reliability before consensus was reached. Details of calculation are provided in the supplement [14].

Results

Search Selection
Based on a set of 70 eligible CDSS studies from our ongoing systematic review [11], 15 studies focused on VTE prophylaxis; see figure 1. The full list of included articles and the rest of all excluded articles can be found in the supplement [14].

Study Characteristics
Non-randomized studies with a pre-post analysis or cohort studies with prospective data collection as a principal study design were most common (47%, n=7), followed by purely retrospective ones (33%, n=5) and then by randomly controlled studies (20%, n=3). 12 (80%) studies implemented CDSS in single hospitals while three managed to run CDSS in multiple hospitals. None of the studies reported on approval for medical device. Further details of study characteristics such as sample size, study duration, adjusting for confounders, study settings, study countries, and numerical outcome results are provided in the supplement [14].

Medical Evaluation
Figure 2 illustrates proportions of medical effect score values and risk of bias. Based on the two physicians review (weighted Kappa: 0.77, p<0.001), three out of 15 studies were evaluated to have a medium positive effect (score=3) due to a significant reduction of deep vein thromboses (DVT). Eight studies were evaluated to have a strong medical effect (score=4) as they additionally showed significant reduction of pulmonary embolisms. None of the studies were associated with high risk of bias or negative patient outcomes, e.g. due to an increased number of adverse events.

Technical Characteristics
Eleven studies out of 15 included studies (73%) provided sufficient information on input variables of the systems. Three studies provided questionable reporting quality and one study provided no information on input at all. Reasons for questionable reporting quality were vague descriptions on input variables, e.g., notations like “the algorithm is based on guideline XY” and XY lacks details for proper formalization.

Based on reported information, all systems were rule-based. Fourteen studies (93%) implemented CDSS as alerting tools and provided therapeutic recommendations specifically to the patient context. Only one system output alerts without further clinical advice and showed no impact on patient outcomes [23].

Fourteen out of 15 studies provided information on input data elements. Based on UMLS coding, CDEGenerator identified 34 common medical concepts. Based on clinical similarities of those concepts, routine documentation categories were assigned.

VTE as disease entity (n=15)

Figure 1– Search strategy of this work is based on our registered ongoing systematic review but with a focus on VTE as the disease entity

Figure 2– Evaluation of medical effect (a) and risk of bias (b). E.g., eight studies showed a strong positive medical effect of which approximately one third (3/8) were rated with low risk of bias.

Medical history was the most covered category dealing with different disease entities and was divided into further subgroups to represent the different disease areas; see table 2. Comparison of outcome-improving (medical effect score >1) vs. outcome-neutral (medical effect score=1) studies indicated that outcome-improving studies CDSS made use of more item categories overall. For each item category – except for Medical History of Vascular diseases – there are relatively more outcome-improving studies that covered the category than the outcome-neutral studies did. The biggest coverage
difference occurred in Demographics (90% vs. 50%) where age was required as input. Due to the low number of studies in both groups, statistical significance could not be detected (Fisher-Exact Test) within a single category. The full list of medical concepts within the categories is available in the supplement [14]. All input data elements for each study were standardized as ODM forms and annotated with UMLS codes. For technical reuse in diverse information systems, ODM input forms are available in different formats on our medical forms repository [24]. Figure 3 exemplifies an extract of a standardized form that represents input of the CDSS in the study by Mitchell [25], which covered most of all item categories.

**Figure 3– Extract of an electronic input form. Detailed information as variable definitions and semantic UMLS codes are available within various formats for reuse in different medical information systems.**

**Discussion**

Regarding study quality, majority of the studies were evaluated with medium risk of bias, which means study results are deemed to represent true treatment effect. The study is susceptible to some bias but the problems are not sufficient to invalidate the results [18]. The main reasons for not obtaining evaluation of low risk were failures to provide large patient sample sizes, sufficient adjustment for confounders and proper randomization. It has to be noted that randomization – other than drug studies – should not be applied on the patient level but on the level of health providers or hospital wards due to the mentioned contamination issues. Future CDSS studies should address those aspects to provide high study quality. Though all studies received study approval none of them reported on medical device approval. For dissemination of CDSS from a study context into daily routine practice, approval as a medical device is inevitable for systems that had shown to effect clinical processes or patient outcomes [5,6].

**Limitations**

Due to lack of existing standardized instruments for clinical CDSS evaluation we provided our own non-standardized evaluation method. It proved to be an easy-to-use protocol to link different outcome measurements even from different disease entities to a uniform level of clinical relevance based on physicians’ perception of mortality relatedness. In this work, weighted Kappa analysis indicated high inter-physician agreement before consensus was reached. Our criterion to identify CDSS effect solely based on patient outcome measurements is quite strict, since many studies do not manage to show significant changes due to limited patient sample sizes and observation time. Outcome factors such as quality of life or mental health may contribute substantially to patient’s overall health, but these were not reported within included CDSS studies. At the level of input variables, we could observe that outcome-improving systems covered more item categories, which probably is an informational advantage to predict individual patient risk with high sensitivity and specificity. But of course, as with all CDSS studies, site-specific clinical, contextual or organizational factors [26] might have been crucial for success as well as further technical characteristics regarding technical interoperability with the hospital information system.

As with all reviews, selective outcome reporting or publication bias is a given since positive outcome effects are more likely to be published than ones that were non-significant or negative [27].

**Conclusion**

The majority of CDSS studies indicate a clinically strong positive effect by managing to significantly reduce pulmonary embolisms. Greater coverage of VTE-related item categories could be observed in outcome-improving CDSS compared to outcome-neutral studies. Therefore, a comprehensive set of input variables should be considered for future re-implementation. Input data element forms were standardized and semantically enriched with UMLS codes and are available as download in different formats for reuse.

Abstract
Patients’ participation plays a crucial role in the management of chronic diseases. Educating patients about their diseases allows patients to self-regulate their daily health conditions more reasonably and effectively. This study focuses on an informative way to develop daily education and guidance among patients. We provide a systematic approach to establish, process, and present the knowledge map of chronic diseases. An ontology technique is used to model clinical knowledge and rules. Rule-based inference service is constructed based on the RETE reasoning algorithm. Several considerations in semantic visualization and interaction are listed as recommendations. A prototype of Chronic Disease Knowledge Education System (CD-KES) based on this approach has been built for diabetes mellitus. With the prototype, comparative evaluations for system performances in knowledge querying and browsing are taken. The results show the system can help patients to more easily understand medical knowledge and avoid potential negative consequences.

Keywords:
Chronic disease; Education of patients; Decision support systems

Introduction
Resulting from the large change in modern lifestyle, the global population with chronic diseases increases rapidly. Taking diabetes mellitus as an example, according to an estimation made by the International Diabetes Federation (IDF), 8.2% of adults aged 20-79 (387 million people in total) around the world were living with diabetes in 2014. In 2035, this number may rise beyond 592 million [1]. Diabetes, as well as many other chronic diseases, often lead to serious complications such as diabetic retinopathy and coronary diseases. Many of the complications may turn into long-term diseases if not treated in their early phases. Even so, an estimated ratio of global undiagnosed diabetes in adults is 46%, suggesting millions of people are unaware of their increased risk of diabetes-related complications [2].

Patients with chronic diseases and related complications require a comprehensive therapy, including daily treatments in medicine, exercise, and diet. To maintain a well-organized therapy, patients have to pay a lot for drugs, medical instruments, and advisors. In 2014, the estimated global average health expenditure of diabetic patients ranges from $1,583-2,842 USD [3]. Despite the financial burden, the time cost for both patients and doctors to arrange and monitor daily treatments is also very high. With the lack of medical care providers, it is hard for doctors to analyze all pieces of daily data coming from each patient.

A reasonable means to improve treatment efficiency and decrease time redundancy in healthcare is to educate patients with the knowledge of diseases. Enough knowledge storage allows patients to self-regulate diseases more positively and comprehensively. Traditional ways to pass medical knowledge include giving oral advice or delivering information booklets. Despite having been implemented for decades, these doctor-led educating procedures have several disadvantages [4]. In many cases, patients are often told only a small amount of caring knowledge, which doctors think to be most relevant to their symptoms. The effort to educate patients may also fail due to the lack of updated knowledge which suits newly occurred complications or body conditions.

Patients’ lack of an overall understanding of chronic diseases may cause serious consequences. When new symptoms show up, some patients may search online for treatment methods, which can be misleading such as drug advertisements or unproven therapies. Other patients may just ignore the newly grown complications, which leads to severe treatment delay that risks their lives. Therefore, it is important and meaningful to construct an accurate, explicit and flexible knowledge education system in which patients can conveniently learn, query and be notified about their most needed information.

The purpose of this paper is to introduce a system called Chronic Disease Knowledge Education System (CD-KES) and its systematic approach to establish, process, and present the knowledge map of chronic diseases. As a classic chronic disease, diabetes mellitus was selected to be the object of this study. An ontology model that contains diabetes-related knowledge resources was constructed. Rules based on standard clinical guidelines were settled to enrich semantic content and provide inference service. With the ontology based knowledge model and a flat designed user interface, patients would have flexible options to browse diabetes-related knowledge nodes and query treatment recommendations precisely.

Comparative evaluations of system performance on knowledge querying and browsing were also done. The query result was compared with the result gathered from search engines. The knowledge browsing ability was evaluated by comparing with an ontology visualization plugin OntoGraf. Evaluation results showed that CD-KES has a better performance on chronic disease knowledge educating.
Methods

The workflow contains procedures of disease modelization, inference rule mapping, semantic reasoning, model visualization, and personalized query service. These procedures can be separated into two phases based on the feedback loop shown in Figure 1. With this division, the procedures in phase 1 are processed beforehand and remain static during the interaction. Oppositely, procedures in phase 2 will circularly process user’s input personal data and refresh query results.

Modelization and Rule Mapping with Ontology Technique

In phase 1, the knowledge model and inference rules of diabetes mellitus are mapped from standardized clinical guidelines to ontology resources. Selected guidelines include classification, diagnosis standard, treatment recommendations of diabetes from WHO [5], ADA [6] and drug labels in FDA website. The mapped knowledge resources cover the main fields of personal details, general body findings, examinations, diseases, drugs, exercise, diet, units, usages, etc.

To support the inference service and maintain a flexible resource connection, we chose an ontology-based model structure. The ontology model of diabetes is stored in OWL (Web Ontology Language) files. OWL is a standard language recommended by W3C for ontology construction and storage. It is a higher-level language of RDF (Resource Description Framework) and expanded the framework with restraints such as disjoint and equivalent. These expansions made ontology more explicit and suitable for reasoning.

An ontology model contains resources of type Class, Property, and Individual. The constraints of a superclass will be inherited by its subclasses and individuals. A definitive resource of ‘diabetic_medicine’ is created with expressions in Figure 2.

![Figure 2 – Way to define ontology resource](image)

The expressions respectively announced this resource:

1. is a subclass of class ‘drug’
2. has a SNOMED-id of R-409C4
3. is a class resource

Despite ontology resources, triples of [object, property, subject] are stored to reflect relations in the real world. To fit the knowledge model with real medical conditions, we should control resources and triples to follow sets of constraints.

Though OWL provides inner axioms, several requirements are noted to be satisfied during modelization.

1. A class of ‘patient’ is placed outside knowledge base to simulate patients that have differed disease details.
2. Properties connected to ‘patient’ class cannot have other domains.
3. Properties not connected to ‘patient’ class cannot add new triples during rule reasoning.

With the above requirements and limitations, this knowledge model will remain static during reasoning and query processes. All properties are separated into patient properties and knowledge properties, so it is also constrained to reduce potential semantic conflicts, as what Figure 3 shows.

![Figure 3 – Restraints in knowledge modelization](image)

Rules express logical causality with format [name: conditions → inferred results]. When all conditions of a rule expression are satisfied, the inference engine will execute the inferred results. Rules are set to uncover indirect knowledge relations inside the ontology model. As an example, the following rules in Figure 4 are used to filter out forbidden drugs based on patients’ physiologic details.

![Figure 4 – Way to define inference rules](image)

Model Reasoning with RETE Algorithm

The inference engine in this study uses RETE algorithm to optimize reasoning efficiency. RETE was firstly developed by Charles Forgy. The core idea of the RETE algorithm is to decompose and interconnect elements in sets of rules to reduce redundant in data storage and calculation consumption [7]. Each rule can be separated into five types of nodes to share common components between rules, namely Root Node, Type
Node, Pattern Node, Join Node, and Terminal Node [8]. The optimized network is called a ‘genetic’ rule. To demonstrate the mechanism, we transferred the rules named ‘Drug02’ and ‘Drug03’ in Figure 4 into a genetic rule shown in Figure 5.

Figure 5 – Inference mechanism for RETE algorithm

A genetic rule network contains two sub-networks of α and β networks to support literal and inter-condition restrictions. In α network, ontology resources are sent to the Root Node when reasoning process begins. Type Nodes are applied to filter out resources that are not of required types. In this case, these required types are defined as domains and ranges of each property. Filtered resources are sent to Pattern Nodes to have constant value tests. All resources that satisfy restrictions in Type Nodes and Pattern Nodes will be listed in α memories. In β network, lists in α memories are joint by Join Nodes. Members from left and right lists are paired and Join Nodes will judge whether each pair fits the stored inter-condition restrictions. Each Join Node creates a new list of resource pairs and stores it in a β memory. The list will be connected to several following Join Nodes as left lists. After all lists in α memories being joint together, a final list will be sent to Terminal Node, which represents the exit of a rule. Terminal Node then executes the infered result in rule expressions such as changing status or appending additional triples.

An important feature of the RETE algorithm is the support for increment operation. Once an inference procedure finishes, inference results including final and partial results will still be stored in α and β memories for the possible repeating reasoning request. When any modification on resources or triples occurs, only the modified part needs to re-reason. Typically, if no change takes place in α memories, no further process or time delay happens in β network.

Since the diabetes ontology model is knowledge-based, which is much smaller than most databases, the memory redundancy in this case to support the RETE algorithm can be ignored for modern computers. It is also important to discuss whether the algorithm fits the system’s requirements. As discussed above, it is a limitation that only triples that have the specific domain as ‘patient’ class can be generated or edited. The knowledge model always remains static during query services, and so is the memory to store them. With a small amount of increment, the use of the RETE can shorten the time-consuming in query service and be a reasonable and ideal selection in this study.

Model Scanning and Visualization

Knowledge visualization is a young research area established on the foundation of data visualization and information visualization. Different from data or information, knowledge contains more abstract descriptions with full semantic structures. Therefore, Knowledge visualization focuses more on the direct and explicit presentation of concepts, experience, attitudes, expectations, opinions, advice, or predictions. It is also important in visualization to help acceptors better reconstruct and utilize knowledge.

Knowledge visualization based on semantic structure is called Semantic visualization. It is common to visualize a semantic model itself in semantic visualization processes, for the structure already contains huge semantic details. Typically, to visualize ontology models, the semantic elements of properties, triples, and rules should be emphasized.

With different user demand, semantic visualization can be implemented in three approaches [9].

1. Hierarchical semantics visualization
2. Relational semantics visualizations
3. Entity-based semantics visualization

The three approaches focus on knowledge structure, context, and isolated word respectively. In our study, the approaches are performed as a combination to offer query services in various scales. Though it is very flexible to build the visualization view, based on the features of patients such as the possible amateur background, we offer several recommendations that can help to maximum the knowledge display ability during semantic visualization.

1. The hierarchy of the knowledge model needs to be emphasized by visual elements such as size, color, shape, etc. Medical knowledge is more similar to a tree structure rather than graph. So that a display of hierarchy helps patients build an overall impression.
2. Every resource in ontology model needs to be presented and be focused as the central node. In this way, the context of each word or object can be fully expressed.
3. The description of each node and relation needs to be given in both structure context and natural language. This helps nodes to explain itself and patients can easier understand it.

The core consideration in visualization design is providing limitless scale for patients to browse the knowledge model. In our design, patients can go through the model from the very root to any arbitrary knowledge node. The context is shown in forms of relations. Once patients select an individual, all related knowledge nodes will be displayed as well.

Several guiding measures are designed to help understand and manage the knowledge map, such as navigations and tooltips. User interfaces to upload personal and examination details are provided. Drop-down menus and check boxes are used to simplify user operation in query service. The figure of UI is presented in Figure 6 in the result section.

Evaluation of System Performance

The purpose of this study was to offer daily education and advice services for patients. In this section, we designed two evaluation methods to determine system performance, including querying performance and browsing performance. The evaluation methods are applied to the prototype of CD-KES with a theme of diabetes mellitus.

To simulate patients’ possible daily action, we designed a scenario where a patient finds an abnormal test result from his blood glucose meter at home. To provide more specific settings for this scenario, we gave two sub-scenarios with body conditions of ‘mild renal insufficient’ and ‘pregnant’ respectively. We recruited six participants with no medical
background and randomly divided them into two groups. All of the participants are between age 20 to 24 and had experience using the internet for more than 5 years. Also, none of the participants had been renal insufficient or pregnant. Participants in each group role-played a patient with a FBG (fasting blood glucose) value of 11.0 mmol/L and one of the additional conditions above. Participants were told to freely, but independently search for online medical information for 20 minutes using search engines such as Google. Their searching results were compared with the query result from CD-KES to evaluate the efficiency and accuracy of our system.

<table>
<thead>
<tr>
<th>Scenario No</th>
<th>Symptom 1</th>
<th>Symptom 2</th>
<th>Replication Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FBG=11.0 mmol/L</td>
<td>Mild renal insufficiency</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>FBG=11.0 mmol/L</td>
<td>pregnant</td>
<td>3</td>
</tr>
</tbody>
</table>

Knowledge browsing performance is also a major indicator to evaluate the knowledge display ability of the system, especially the visualization part. In this part, the visualization view of the system was compared with views generated by OntoGraf plugin. We recruited 10 participants and divided them into two groups. We randomly selected five triples from the ontology model and provided them to all participants. Participants in one group needed to find the visualization elements representing the triples in OntoGraf view, while the other group used the view of CD-KES. Time costs and click times were measured to analyze system’s knowledge browsing performance. Since the evaluation focused on the browsing behavior, search bars in each view were banned.

### Results

#### Query Evaluation Result

To have a clear evaluation standard, though diet and exercise results are also offered from our system and online advice, only six types of diabetic drugs were compared in this section.

In both tables, single plus (+) symbol represents a drug that is recommended, single minus (-) symbol represents potentially forbidden drug, double minus (--) symbol represents clear forbidden drug. If two symbols are listed in the same cell, it suggests the advice differs with the specific drugs.

#### Browsing Evaluation Result

The visualization view for knowledge display and query is shown in Figure 6.

In both tables, single plus (+) symbol represents a drug that is recommended, single minus (-) symbol represents potentially forbidden drug, double minus (--) symbol represents clear forbidden drug. If two symbols are listed in the same cell, it suggests the advice differs with the specific drugs.

#### Discussion

In the case of diabetes patients with mild renal insufficiency, our system gave two kinds of recommended drugs and two kinds of forbidden drugs. However, participants were recommended to use additional; kinds of drugs such as the DPP4
inhibitor, Sulfonylurea or incretin mimetic products when they tried to get online advice.

A possible explanation is that participants didn’t notice whether one kind of drugs was useful for type-1 diabetes or type-2 diabetes. For example, DPP4 inhibitors and incretin mimetic are ineffective to type-1 diabetes. Since no personal detail was input about what kind of diabetes the patients had, our system gave out recommendations suitable for both kinds of diabetes. While a few of Sulfonylurea drugs like gliclizide, are harmless for patients with mild renal insufficiency, many of the drugs in this class are still forbidden base on drug labels. Some websites provided participants with misleading information which could have resulted in serious consequences.

In the case of diabetes, patients with the pregnant condition, two of the three participants refused to use any drugs. They were convinced that the safest way to treat diabetes during pregnancy is just to eat less fruit and sweets. However, it has been proven that most of the human insulin analogs are harmless for pregnant women. More importantly, the possible harm caused by using drugs such as biguanide or sulfonylurea will be much less than what could be caused by untreated diabetes. Blindly staying away from all drugs may cause treatment delay and hurt both the mother and the baby. Therefore, the results given by our system are more reasonable and comprehensive than the ones gathered from the internet. It also shows that CD-KES has the potential to educate patients with disease knowledge, help patients to better self-regulate their daily treatments, and reduce possible misleading information.

Discussion for Browsing Evaluation Result

It is hard to evaluate the performance of visualization views; and there is no golden standard for quantification. In this case, however, the time cost for participants to find triples in OntoGraf view was almost twice of that cost given by CD-KES. Though the time cost varied, the click numbers made by participants were close. The two measures suggested that participants with OntoGraf spent more time on going through knowledge nodes to find the correct ones. This result partly explained the differences in explicitness between two views that CD-KES performed better in knowledge exhibition. Since OntoGraf is still a wild-used plugin in the field of semantic visualization, it shows plenty of requirements for better visualization methods.

Conclusions

The aim of this study was to find an effective way to educate and guide patients with chronic diseases in their daily life. The article provides a knowledge education system called CD-KES and its systematic approach to establish, process, and present knowledge of chronic diseases. Evaluating the performance of this approach, a prototype system of CD-KES, with a scenario of diabetes mellitus is built. The evaluation results shows that this approach is reasonable and can largely reduce possible misleading information or treatment delays. It also has the potential to help patients self-regulating diseases and cut expenditures.

Abstract
Clinical decision support systems are information technology systems that assist clinical decision-making tasks, which have been shown to enhance clinical performance. Cluster analysis, which groups similar patients together, aims to separate patient cases into phenotypically heterogeneous groups and defining therapeutically homogeneous patient subclasses. Useful as it is, the application of cluster analysis in clinical decision support systems is less reported. Here, we describe the usage of cluster analysis in clinical decision support systems, by first dividing patient cases into similar groups and then providing diagnosis or treatment suggestions based on the group profiles. This integration provides data for clinical decisions and compiles a wide range of clinical practices to inform the performance of individual clinicians. We also include an example usage of the system under the scenario of blood lipid management in type 2 diabetes. These efforts represent a step toward promoting patient-centered care and enabling precision medicine.

Keywords:
Cluster Analysis, Expert Systems, Software

Introduction
Precision medicine has gained increasing attention as an innovative and revolutionizing approach of healthcare that takes individual traits into account in order to develop more effective ways to improve health and treat disease [1]. Unlike traditional medical treatments designed for the ‘average patient’ or ‘standard patient,’ precision medicine tailors medical decisions, practices, interventions, and products to individual patients based on their predicted response to treatment or risk of disease. While precision medicine aims at providing the best available care for each patient based on disease subclasses within a disease of common biological basis, the discovery of such subclasses, and the translation of this knowledge into clinical practice, depend critically on information technology [2]. One possible solution for subclass discovery is via cluster analysis, which fulfills the task of grouping a set of objects in a way that objects in the same group (or cluster) are more similar to each other than to those in other groups. Patient grouping via cluster analysis takes a solid step towards precision medicine by separating patients into phenotypically heterogeneous groups and defining therapeutically homogeneous patient subclasses. Patient clusters such as diagnosis-related groups and ambulatory patient groups were traditionally used for management purposes by identifying iso-resource groups (reviewed in [3]). Cluster analysis was also used for more accurate phenotyping of heart failure and related syndromes [4, 5]. A study of geriatric stroke patients using cluster analysis [6] represents an attempt to identify meaningful patient clusters for developing specific treatment programs.

Clinical Decision Support Systems (CDSS) are health information technology systems that assist clinical decision-making tasks. Studies in CDSS emphasize improvements in system quality, including enhancing clinical performance for drug dosing, preventive care, and other aspects of medical care. The effectiveness of CDSS in improving patient outcomes is mixed [7]. While traditional CDSS was based on domain knowledge, e.g., digitized clinical guidelines, real world evidence (RWE) has gained more importance in CDSS with advances in data accumulation and technology. RWE is the acquisition of evidence from data derived from medical practices among heterogeneous sets of patients in actual practice settings [8]. Cluster analysis of clinical data represents a class of methods to generate RWE. Though cluster analysis has demonstrated its usefulness towards personalized medicine, its potential has not been fully utilized in CDSS.

In order to take advantage of cluster analysis to further enhance clinical performance and improve patient outcomes using CDSS, we have implemented a system that uses cluster analysis for CDSS with the following steps. First, cluster analysis is conducted following the clustering pipeline. Statistical methods can then be applied to evaluate the clusters and discover group profiles. After deciding on the clusters, cluster representatives will be selected and used in assigning new patient visits into existing clusters. This assignment is automatically conducted in the background and is updated upon changes to the patient record. The assigned cluster’s profile will then be available for clinicians to provide evidence and support for clinical decision-making tasks upon new patient encounters. This work represents an integration of cluster analysis in clinical decision support systems, and has the potential to promote patient-centered care and enable precision medicine.

Methods
The method is organized into three parts:
1. Description of the working pipeline of the system, which includes the initial cluster analysis, statistical analysis after achieving clusters, cluster representative selection, and cluster assignment upon new patient visits
2. Description of the use of cluster analysis for CDSS
3. Description of a working example

Cluster analysis
A typical clustering workflow, as shown in Figure 1, includes three major steps:
1. Pre-clustering processing
2. Clustering
3. Post-clustering evaluation

Pre-clustering processing consists of feature engineering work including extracting features from raw data, imputing missing data, normalizing continuous features, selecting features relevant for the working task, and reducing dimensionality, all of which serve the purpose of increasing data quality and suitability for cluster analysis. Clustering methods such as hierarchical clustering, centroid-based clustering including K-means, model-based clustering, and density-based clustering like DBSCAN, have all been used in healthcare settings to separate patients into different clusters. The exact use of methods depends on the data characteristics, the requirements of the task, and user preference. Post-clustering evaluation includes internal evaluation and external evaluation with a different validation data source, data type, and evaluation objectives. Internal evaluation of sample separation is easy to conduct but is less effective at improving information retrieval and addressing clinical implications. External evaluation with known class labels or external benchmarks is ideal for assessing clustering quality, but these benchmarks are scarce in healthcare datasets. At times, statistical analysis described in the next step is used as a compromise.

### Statistical analysis

After cluster analysis, statistical analysis should be conducted to describe the profile of the clusters from three perspectives:

1. Summarize features with highest clinical relevance within each cluster; this generates the cluster profile
2. Extract distinct features of each cluster to provide justification and support for the clustering result
3. Summarize the representative action or response of each cluster with respect to the application

As an example, under a drug recommendation scenario, within each cluster, features with clinical relevance such as gender, age, disease stage or severity, and major disease history would be summarized as the cluster profile. Later, from each cluster, distinct features like ‘older than 60 years old’, ‘diabetes’ would be extracted as distinguishing features of this cluster to justify the underlying clustering rationale. Then, the drug usage would be summarized within each cluster to provide evidence for drug recommendation.

Apart from assisting in drug recommendation, statistical analysis can also provide insights into the common diagnosis of the cluster, the typical disease onset and progression of the cluster, the general disease prognosis or clinical outcomes of the cluster, the typical response to a clinical practice and drug effectiveness within the cluster. For example, patients within a cluster may have an especially high occurrence of a disease, poor survival rate, or a good response to a certain drug.

### Cluster representative selection

Cluster representatives are selected for two purposes:

1. To enable quick cluster assignment upon new patient encounter by comparing only against the selected representatives instead of exhaustively against all patient cases
2. To avoid comparisons against actual patient information, which can lead to a potential violation of privacy

Some clustering methods have nature cluster representatives, e.g., centroids in centroid-based clustering like K-means, mean values in Gaussian mixture model-based clustering. Representatives can also be defined in other clustering methods using mean values, or as the points with the highest kernel density. The determined cluster representatives can then be used by the system to provide decision support.

### Cluster assignment and background update

Because patient information and status changes over time, the patient information at a specific time is called a patient case in this work. The cluster analysis was conducted at a specific time, thus representing a clustering of patient cases. At the time of use, the patients may not have been used for cluster analysis or may have information changed. Before first use, the similarity between each patient and each cluster representative is calculated and stored at the time of initialization. Cluster assignment is then conducted based on the clustering algorithm and the selected representatives. The distance between the patient case and each cluster representative is calculated. The patient case is assigned to the cluster whose representative is most similar. This assignment is automatically conducted in the background and is updated upon patient record changes. The similarity between the patient case and all cluster representatives is updated incrementally based on the recorded changes made without complete recalculation.

### Cluster analysis for CDSS

After cluster assignment, the assigned cluster’s profile as achieved in the statistical analysis is available for the clinicians to provide evidence and support for clinical decision-making tasks upon new patient encounters. In the current scenario, given a patient record, treatment would be automatically recommended based on digitized clinical guidelines. The cluster profile is provided as real world evidence for decision support. The clinician can view the cluster profile, including summaries of clinically relevant features like gender, age, disease stage, or treatment history. The common diagnosis, typical disease onset and progression, general disease prognosis or clinical outcomes, typical response to clinical practice, drug effectiveness and usage within the cluster can also be viewed. The clinician can then leverage the information in his/her own prescription.

### Working example

An example dataset was used to demonstrate the usage of the system, which is a collection of type 2 diabetes patient records.
across multiple hospitals in a city of China. The working scenario of the system is for blood lipid management in type 2 diabetes patients. In this demonstration, the system was constructed following the workflow mentioned above, and used to provide evidence for guideline-based drug recommendation.

Results

A working example is shown in this section to demonstrate the use of the workflow and system in CDSS without special elaboration on and care for the construction and evaluation of the clustering pipeline or the scientific insights. The example is concerned with blood lipid management in type 2 diabetes patients where patients with high blood lipid level and satisfying certain conditions would be recommended to use statins to lower blood lipids per the clinical guideline. The usage of statins in the cluster that the new patient belongs to would thus be shown as real-world evidence for prescription. Since elevated blood lipid level is a well-established risk factor for cardiovascular disease, decrease in cardiovascular disease onset would be used to show the effectiveness of statin treatment.

Cluster analysis

The example cohort includes patients with type 2 diabetes. A patient case is generated each time a patient visits the hospital and obtains prescriptions. The patient’s clinical data from the preceding year is considered. A total of 187115 cases were defined. Features used for cluster analysis include demographics that were stratified and one-hot encoded, diagnosis history given by the International Classification of Diseases (ICD) code and counted, and treatment history as the number of times each medicine was prescribed. These altogether resulted in 1446 features. Mini Batch K-means was used with Euclidean distance to cluster the samples into 1000 clusters using sklearn [9]. The distribution of cluster size is shown in Figure 2 as a density plot (x-axis denoting the cluster size and y-axis denoting the corresponding density), where the majority of clusters have less than 100 patients and a few large clusters exist. Cluster representatives are defined as the centroids generated during Mini Batch K-Means clustering.

Statistical analysis was first conducted to summarize cluster features such as patient gender, age group, diabetes disease stage, hypertension, and hyperlipidemia in comparison with all patients. The usage of statins was also summarized at different levels: using statins or not, distribution of the statins’ generic names among patients using statins, and distribution of the statins’ brand name for each generic name.

Since elevated blood lipid levels are well-established risk factors for cardiovascular diseases, decrease in cardiovascular disease onset would thus be used to show the effectiveness of statin treatment. The response to statin usage within each cluster was calculated by stratifying the patients into two groups, those using statins and those not using statins, within which the number of patients later diagnosed with cardiovascular diseases were counted. Odds ratio is calculated to measure the association between the exposure (the usage of statins) and the outcome (cardiovascular disease onset) in each patient cluster. The odds ratios were plotted as dots in Figure 3, where the error bars show the 95% confidence intervals (x-axis representing the cluster index organized by increasing odds ratio and y-axis denoting the value of odds ratio or confidence interval). As shown, different patient clusters have different odds ratios compared to the odds ratio in the whole patient cohort (denoted by the red horizontal line). This provides evidence that the clusters have different responses to statin treatment and justification for the differential use of statins in different patient clusters.

Cluster assignment and background update

Euclidean distance was used as the distance measure in the previous clustering steps. As a result, patient cases were assigned to the cluster whose centroid is the shortest Euclidean distance away. The centroids from the cluster analysis would be stored with the system. During initialization, the similarity between each patient and each centroid would be calculated and stored, and each patient would be assigned a cluster following the above method. Afterwards, the cluster assignment would be updated in the background each time the patient record changes. A patient record change would require an update of the patient’s similarity to each centroid incrementally without completely recalculate the distances. Means of the background update of Euclidean distance are summarized in Table 1. In our working example, the features are either categorical or the number of times an event happens. The change in the squared distance can be easily calculated using Equations (1) to (3). Only features that have been changed were included in the calculation, where the contribution to squared distance change were calculated.
respectively. In Table 1, \( v_j \) denotes the value of a centroid at a specific feature, \( v_i \) denotes the previous value of the patient at this feature, while \( v_i' \) denotes the new feature value. After summing up all the squared value changes, the new distance \( (d'_{ij}) \) would be calculated from the original distance \( (d_{ij}) \) using Equation (8). Similarity value here is calculated as one minus the distance.

\[
\Delta d_{ij}^2 = (v_i - v_i')^2
\]

We also show in Table 1 the update of aggregate features. In Equation (4), \( m_i \) denotes the mean value before change, \( T_i \) denotes the number of records before change, and \( v_i' \) denotes the newly added value. The mean value after change (denoted by \( m_i' \)) can thus be calculated. The squared distance change can then be calculated using Equation (7), and the new distance can be calculated with Equation (8). Similar calculations can be done with (5) for maximum value, with (6) for minimum value, where \( m_i \) indicates the maximum value and minimum value respectively, each followed by calculation with (7) and (8).

The similarity values between the patient and each centroid can thus be updated. The patient cluster assignment changes if the most similar centroid changes. Centroids themselves do not change during system usage.

**Cluster analysis for CDSS**

The working example is about an application of cluster analysis for blood lipid management in type 2 diabetes patients. Statins are a group of cholesterol-lowering drugs. If elevated blood lipid levels are observed upon patient encounter, statins may be recommended for use based on clinical guidelines. At this time, a clinician may turn to the CDSS for evidence of statin usage among similar patients, i.e. patients in the same cluster. Screenshots of the system are shown in Figure 4.

The usage of statins in the patient’s assigned cluster would be used as evidence for prescription. In Figure 4, a page is shown with drug recommendations for blood lipid management, where statins and fibrates (medication that lowers blood triglyceride levels, always used in combination with statins, not elaborated on here) are listed in two independent tabs. In the screenshot, the total number of patients in this cluster is 2329. Of these, 1113 used statins (1031 used atorvastatin and 82 used rosuvastatin). After clicking the bar for atorvastatin or rosuvastatin, the distribution of brand names used are shown in the second and third plot. From Figure 4, we see that nearly half of similar patients used statins, where the majority of the statin users used atorvastatin, the major brand name being Atorvastatin Calcium Tablet (Lipitor). This thus provides the clinician with evidence from real-world data.

**Discussion**

We see the intuition of using cluster analysis in CDSS from two perspectives. First, both patient and disease heterogeneity are inherent, which divides patients into distinct clusters that have different clinical features such as disease onset, disease prognosis, or drug effectiveness. Second, doctors naturally make decisions based on experiences summarized from previous similar cases. In an effort to simulate human cognitive processes and provide more extensive and deeper insights, clustering is conducted to standardize the definition of ‘similar patients.’ Information on the previous treatment of a large population can be summarized and integrated for the doctor’s use. This system makes use of cluster analysis to provide real-world evidence for clinical decision support.

The system as a framework is useful, while the decision support aspect relies heavily on the data quality and cluster analysis pipeline adopted by the user. Many methods and approaches are available for use in all three steps of cluster analysis. However, as a class of unsupervised methods, cluster analysis cannot be easily assessed in terms of clustering quality and suitability for the application objective. This problem gets exacerbated in healthcare settings where data quality is not always satisfactory, and external benchmarks or data with known class labels are rarely available. Statistical analysis is thus included in the workflow after cluster analysis to provide some assistance for interpretation. Given this limitation of cluster analysis, we apply it to provide evidence for drug recommendations instead of directly providing recommendations in the demonstration. With improvements in data quality and clustering quality, this system has the potential to be used to directly provide drug recommendations.
Clinician trust in information technologies may be a main limiting factor in the application of the system in drug recommendation even when good data and algorithms exist for cluster analysis. Here, we advise readers not to take such a system as an independent thinking entity with unknown logic, but as a means to learn and present others’ experience to facilitate individual doctor practice.

**Conclusions**

Here, we formulated the application of cluster analysis as providing real-world evidence for clinical decision support. We described the workflow and provided a description with a demonstration of the system on an example dataset. The workflow, starting with cluster analysis and statistical analysis, generates cluster representatives, against which each new patient case would be assigned a cluster. The cluster assignment is updated in the background each time patient data gets updated. This system provides clinical decision support by presenting real-world evidence for guideline-based treatment. It has the potential to promote patient-centered care and enable precision medicine.

Context-Sensitive Clinical Alert Packages Written in Arden Syntax

Julia Zeckl, Katharina Adlassnig, Renate Fessler, Alexander Blacky, Jeroen S. de Bruin, Walter Koller, Andrea Rappelsberger, Klaus-Peter Adlassnig

Abstract
An increasing body of raw patient data is generated on each day of a patient's stay at a hospital. It is of paramount importance that critical patient information be extracted from these large data volumes and presented to the patient's clinical caregivers as early as possible. Contemporary clinical alert systems attempt to provide this service with moderate success. The efficacy of the systems is limited by the fact that they are too general to fit specific patient populations or healthcare institutions. In this study we present an extendable alerting framework implemented in Arden Syntax, which can be configured to the needs and preferences of healthcare institutions and individual patient caregivers. We illustrate the potential of this alerting framework via an alert package that analyzes hematological laboratory test results with data from intensive care units at the Vienna General Hospital, Austria. The results show the effectiveness of this alert package and its ability to generate key alerts while avoiding over-alerting.

Keywords:
Decision Support Systems, Clinical; Laboratory Critical Values; Infection Control

Introduction

Given the increasing body of raw clinical data being provided in electronic medical record (EMR) systems, a quality control mechanism is needed to ensure that potentially critical patient information is extracted from these large data volumes and offered to the appropriate patient caregivers in a timely manner. Clinical alerts are a part of such information; they make the patients' caregivers aware of immediate pathological, unusual, or occasionally life-threatening circumstances concerning the patient. Electronic storage of patient data creates opportunities for computerized monitoring of patients and subsequently computerized generation of clinical alerts. Over the years, a substantial number of monitoring systems have been developed for a variety of healthcare settings, especially in the fields of infection control and adverse event detection [1-5]. The benefits of such systems are manifold: they offer complete and timely information on patients who require the immediate attention of caregivers, errors can be prevented, patient safety is enhanced, and institutional quality standards for patient care are upheld or improved.

A drawback of these systems is that their embedded detection rules or classification methods are usually based on guidelines for “standard” cases. As such, the generated monitoring results and alerts may be valid only for patients without additional underlying conditions. For example, de Bruin et al. describe an automated surveillance system for monitoring healthcare-associated infections [6]. In their study, a false-positive infection episode was detected due to a large number of leukocytes. However, the underlying cause of the leukocyte abnormality was not an infection but the patient’s leukemia.

Modification of existing systems is not a viable option. There is usually little room for system or module customization; the systems are provided “as-is”. This limits their use in healthcare environments other than the one(s) they were developed for. Individual institutions or even departments within an institution may employ different guidelines or different interpretations of the same guideline. A configurable and extendable framework of alert systems was developed by the use of established standards for the creation and integration of clinical decision support systems (CDSSs). The framework can be used directly at the point of care, and is tailored to the needs and preferences of healthcare institutions, departments, or even individual caregivers.

In this paper we present a preliminary version of such a framework for clinical alerts. Using Arden Syntax [7], an HL7 International [8] standard for computerized representation and processing of medical knowledge, we created an alert framework that supports configuration according to departmental or institutional requirements, such as the configuration of critical value limits, optimization of alert frequency to prevent over-alerting, and adaptable alert timing. Using patient data obtained from the Vienna General Hospital (VGH), Austria, we describe the potentialities of this alerting framework through an implemented alert package for the analysis of hematological laboratory test results. By way of an example, time- and context-sensitive clinical alerts were constructed for two infection parameters: C-reactive protein (CRP) concentration and leukocyte count. The alert package provides alerts for “standard” situations, as well as a variety of nonstandard contexts, such as underlying leukemia or preexisting infection episodes. Furthermore, alerts can be configured to the preferred frequency, thus avoiding excessive alerting.

Figure 1 – The HTML5 web application frontend. On the left side, the patient’s laboratory values for C-reactive protein (CRP) and leukocytes are displayed for the present day and three preceding days; values in red are associated with a clinical alert. On the right side, clinical alerts are displayed together with a short description. On clicking the alert, a more detailed alert message is shown along with an overview of the laboratory values related to the alert over the past few days. Alerts shown in bold type are those for the present day.

Methods

Outcome and variables
The primary outcome measures were the frequency and nature of the alerts generated by the alert package for each of the aforementioned clinical variables.

We used patient demographics (age, sex, length of stay) to describe the patient population. Laboratory data for the clinical variables CRP concentration (mg/l), and leukocyte count (G/l) were used for the generation of alerts. We report on the number of generated alerts for each alert rule.

Study design, setting, and participants
A retrospective single-center cohort study was performed on prospectively collected and validated data at VGH, a 1,933-bed tertiary-care and teaching hospital, and was approved by the ethics committee of the Medical University of Vienna. All adult patients (i.e., age ≥ 18 years) admitted to a VGH intensive care unit (ICU) for at least 24 hours between 1 January and 31 December 2013 were eligible for the study. Patients for whom laboratory values for both clinical variables (CRP concentration and leukocyte count) were not available were excluded from the study.

Data management and sample size
Demographic patient data as well as laboratory test results were retrieved from the Philips IntelliSpace Critical Care and Anesthesia information system, which is in operation at almost every ICU of the VGH.

The interrogation of data sources using the previously mentioned selection criteria yielded a total of 266 patient stays comprising 2,830 patient days.

Knowledge base and data processing
The alert package discussed in this paper is part of a framework consisting of automated, context-sensitive and customizable alert packages targeting a variety of issues in clinical routine. They were created by repeated discussions with experienced clinical experts and by eliciting their feedback on a variety of use cases in which alerts were generated for different clinical situations. Based on these discussions and feedback, alert rules were implemented by clinical knowledge engineers that, based on laboratory test results for the aforementioned clinical parameters, generate one or multiple (different) alerts. We discuss ten alerts that were defined in the knowledge base: four for CRP levels and six for leukocyte count. These alerts, together with their context and corresponding rules, are shown in Table 1.

The alerts were implemented in a knowledge base with Arden Syntax. The latter is a programming language for the collection, description, and exchange of medical knowledge in a computer-executable format. For this project we used Arden Syntax version 2.10 [7]. An Arden Syntax knowledge base comprises a set of programming units known as medical logic modules (MLMs) [9]. In all 17 MLMs were constructed; 14 MLMs for data import and preprocessing, and three MLMs for alert generation for a variety of contexts.

Implementation, management, testing, and execution of the MLMs were done using the ARDENSUITE clinical decision support technology platform, which comprises an integrated development and test environment (IDE), as well as the ARDENSUITE server to execute MLMs [10]. The ARDENSUITE server can be accessed through web-service protocols, i.e., representational state transfer (REST) [11] or simple object access protocol (SOAP) [12].

Data presentation
For data presentation, an HTML5 web application was created using the Ionic framework [13] (Figure 1). Upon selecting a patient in the web application, the necessary MLMs are accessed using JavaScript Jquery [14] commands through REST calls. The ARDENSUITE server extracts parameter values from the POST REST call and executes the called MLM(s) with these parameters. The alerts generated by these MLMs are then transmitted back to the web application through a JavaScript Object Notation (JSON) [15] object and displayed in the web application.
Results

Of the 266 patients included in the study, 115 were female (43%). The patients’ mean age was 61 years, with an interquartile range (IQR) of 21 years. The mean duration of the hospital stay was 11 days, with an IQR of 11 days.

In all 5,492 data entries were registered for the two clinical variables: 2,697 entries (49%) for CRP levels and 2,795 for leukocyte counts. Values for both variables were available for 2,662 patient days (94%), only CRP levels were available for 35 patient days (1%), and only leukocyte counts for 135 patient days (5%).

During the study period a total of 2,382 alerts were generated for CRP levels and leukocyte count, amounting to an average of 0.89 alerts per patient day. The maximum number of alerts displayed on a single patient day was four; the most numerous alerts displayed for a single patient during his/her stay was 90, over a period of 81 days.

CRP levels were alerted on 459 occasions (19.3%), and leukocyte counts on 1,923 occasions. Table 2 shows the number of times each alert listed in Table 1 was generated.

Discussion

We present a configurable framework for automated alerting based on electronic patient data. We showed the feasibility and potentialities of the system with respect to its configuration for different contexts and the optimization of alert frequency.

We presented a configurable framework for clinical alerts implemented in Arden Syntax. Using the framework, healthcare institutions, departments, and patient caregivers can adapt alerts to make them more relevant and useful, and avoid over-alerting. Alert fatigue is a very serious problem in clinical routine. Various studies on alerting suggest that by far the large majority of alerts are ignored or overridden [16, 17]. Most patient caregivers (about 90%) do not respond to all alarms, but rather match their response rates to the expected probability of true alarms [18]. In view of these facts, it would be very important to use an alerting framework that can be configured to the preferences of a healthcare institution or caregiver. Last but not least, this would maximize the caregiver’s perception of the usefulness of alerts.

Through cooperation with clinical experts, it became evident that there is no real objective metric to establish when an alert is justified or not. Rather, there are some guidelines to when an alert is useful, namely, when it can be acted upon by some kind of intervention. Furthermore, there are some expectations as to the number of generated alerts; most physicians do not expect more than one alert per person per patient day. With a maximum of four alerts per day and an average of 0.89 alerts per patient day, the alert package discussed here proved to be quite conservative in its alerting frequency.

Of all the alerts, L2 was generated significantly more often (in all 1,032 times; see Table 2) than the others. This may be partly explained by the fact that the alert rule is very straightforward and therefore more likely to be generated. However, the L2 alert was only meant for patients with leukemia, which makes it less likely than many others. MLMs and data consultation disclosed that the leukemia diagnosis of a patient was not included in the data transfers from VGH. Therefore, the check as to whether the patient had leukemia was not conducted by the MLM; a leukocyte count of ≥ 12 G/l was used as the sole criterion. This resulted in the alert being generated for all patients with a leukocyte count ≥ 12 G/l and not adhering to the specific context of L2, which also explains the large number.

The limitations of this study are worthy of mention. First, as this was a pilot feasibility study, we conducted a retrospective cohort study on prospectively collected data. As such, prospective behavior in this framework still needs to be studied. Furthermore, as the pilot study was conducted on a single-center basis, the generalizability of these results needs to be reviewed as well. A third limitation is the lack of other relevant patient data. Although there are alerts especially for patients with leukemia, the (admission) diagnosis for leukemia by itself is regrettably not part of the data volume to distinguish between infection-triggered leukocytosis and leukemia. Finally, we need to assess the ease and practicality of adapting MLMs to caregivers’ preferences while adhering to institutional guidelines. Although the implemented alert package has been tested and adapted by clinical partners with diverse clinical backgrounds, a more extensive study with data outside the ICU setting and with multiple alert packages will be carried out for a better analysis of the framework.

Conclusion

We presented a configurable framework for automated alerting based on electronic patient data. We showed the feasibility and potentialities of the system with respect to its configuration for different contexts and the optimization of alert frequency.

Validation of the Chinese Version of the Functional Oral Intake Scale (FOIS)
Score in the Assessment of Acute Stroke Patients with Dysphagia

Hongzhen Zhoua, Yafang Zhub, Xiaomei Zhangb

Introduction

Approximately 22-65% of the patients with stroke have dysphagia [1], and it has been estimated that 40-50% of these patients encountered aspiration problems [2], dysphagia, and related complications, which will lead to prolonged hospital stay, and are associated with increased mortality, comorbidity, and health care costs [3-4]. According to the American Heart Association and American Stroke Association guidelines for early stroke management, the primary step is to screen aspiration before the administration of food, liquid or medication in stroke patients [5]. There are many bedside screening tools for aspiration in stroke patients, and the WST (water swallow test) may be the most convenient screening tool among stroke patients in nursing practice [6]. A recent systematic review has suggested that the WST have sensitivities between 64-79% and specificities between 61-81% [6]. However, the assessment of aspiration risk does not constitute the only objective in the evaluation of dysphagic stroke patients, in whom potential feeding problems should also be addressed [7]. Eating without knowledge of the dysphagia can lead not only to pneumonia, but also to life-threatening conditions, such as dehydration, malnutrition, and suffocation [8, 9]. Therefore, evaluation of oral feeding function is especially important. These concerns strongly require a reliable scale that is easy to use, to provide further swallowing function details in feeding and nutrient intake.

Concerning this problem, the Functional Oral Intake Scale (FOIS) for dysphagia in stroke patients, a novel oral feeding function rating system, was developed by the Florida Health Science Center in 2005 [10]. This is a 7-point ordinal scale that describes the typical functional oral intake of patients with stroke and dysphagia [11]. In the FOIS, all levels can calculate, such as what the patient consumes by mouth on a daily basis. Levels 1 through 3 are related to varying degrees of non-oral feeding, while levels 4 through 7 are varying degrees of oral feeding without non-oral supplementation, and it considers both diet modifications and patient compensations [10]. A score below 6, of a maximum of 7, indicates restrictions of oral intake of food and liquid [11]. A recent study shows that there is an association between the level of oral intake and the degree of oropharyngeal dysphagia in elderly post-stroke patients during chronic phase [12]. Another finding suggests a negative and moderate correlation between T-EAT-10 and FOIS [13]. However, this scale has been used in Japan [14] and Iran [15], but no Chinese version is available to date. The purpose of this investigation was to translate the English version of FOIS to Chinese, and to evaluate the interrater reliability, criterion validity, discriminant validity, cross-validation, and the sensitivity of the Chinese version of the FOIS in Chinese Han stroke patients with dysphagia.

Methods

This study was approved by the ethical committee of the Nanfang Hospital, Southern Medical University, Guangdong, China (No. NFEC-2016-145). Written and verbal informed consent was obtained from all patients or their caregivers, and all data were collected prospectively. A total of 128 patients with acute stroke, admitted to Department of Neurology (Nanfang Hospital, Southern Medical University) from April to October 2016 were included in this study. The inclusion criteria included willingness to participate in the study, being over the age of 18, normal cognitive function, admitted to Department of Neurology within three days of stroke onset, and having a clinical diagnosis of stroke confirmed by an attending stroke neurologist according to the World Health Organization’s definition of stroke [16]. Exclusion criteria were: 1) History of other diseases that affect swallowing function, such as head and neck cancer, esophageal cancer, brain injury, myasthenia gravis or Guillain Barre Syndrome; and 2) patients with nasal feeding on admission. Demographic data, vital signs, diagnosis, day of evaluation, NIHSS, MBI, and the extent of dysphagia according to the WST were recorded.

Translation of the Chinese version of the FOIS

The items of the FOIS were first translated to Chinese by two bilingual neurology specialist, who had more than ten years of clinical experience (forward translation). A meeting, in which four dysphagia experts participated, was held to confirm a
single scale with a consensus (synthesis). Necessary adjustments in the translation were made after the consensus. Then, a native English speaker outside of the medical profession and a dysphagia expert with experience of studying abroad translated the instrument into English (backward translation). Finally, comparison by two bilingual experts derived English text and converted into a scale. The backward translation was finally sent to the original creator of the FOIS to double verified. Every item of FOIS was identical to the original version (Table 1).

Interrater Reliability

Because of the characteristics of self-recovery of stroke dysphagia, this study did not assess the test-retest validity of the tool, but test interrater reliability to reflect the stability of FOIS. A one-page handout with written instructions describing the FOIS was provided to raters who were given opportunities to assess patients before study started. Through direct patient observation, or patient or caregiver statement, two stroke nurses, who were not involved with translation and have more than 5 years of clinical experience in neurology department, used FOIS to evaluate the amount, type and method of oral feeding or liquid to the newly admitted patients respectively. The WST was carried out according to the conventional method by 2 other stroke nurses at the time of admission. In addition, in order to minimize the possible changes in patient’s level of swallowing function, all the assessments were completed within 48 hours when no substantial change of the swallowing ability was expected to be taken place [13].

Criterion Validity

The criterion validity of the FOIS was determined by assessing the correlation between FOIS and WST, NIHSS or MBI. WST, a useful screening tool for aspiration, was used to evaluate swallowing function and reflects the severity of dysphagia. The WST has 5 levels in which level 1 means normal swallowing function, while level 5 represents severe dysphagia. In addition, studies showed that there was a significant correlation between the swallowing function and the severity of stroke [17, 18]. The National Institutes of Health Stroke Scale (NIHSS) is a validate instrument that evaluate the severity of stroke [19]. The Modified Barthe Index (MBI) was used to evaluate the patient’s performance in activities of daily living (ADLs). This scale is often regarded as a functional interpretation of disability or dependency in the ADLs. The potential associations between the FOIS ratings and the measures of stroke severity, ADLs, and swallowing ability were investigated by Chi-square, Cramer’s V (dichotomized data) or ϕ (multiple category data). Only when this measure was dichotomized, the obtained scores could be included in the analysis. Although no cut point on NIHSS scale is universally accepted, this value was chosen because a score of more than 8 was used in the National Institute of Neurological Disorders and Stroke recombinant tissue plasminogen activator study to define a severe post-stroke neurologic deficit [19]. Dichotomized cut-off scores were 15 for the MBI. Finally, FOIS ratings were compared with the established criteria. The above measurements were collected when the patient was admitted to a stroke unit.

Discrimination validity

Clinical comprehensive evaluation, as evaluation standard, was applied to this study [20]. On the basis of the patient's swallowing disorder and the severity of symptoms, the patients were divided into three groups: normal oral feeding group, oral feeding disorders without tube-feeding group, and tube-feeding group. The FOIS evaluation results of the three groups of patients were judged. The specific content of clinical comprehensive evaluation include the evaluation grade of WST, eating pattern and food form (exclude tooth or oral disorders), cough, whether nasal feeding, fiber optic bronchoscopy and so on. According to the actual situation of the patients and the analysis of the results of the patients' caregivers, clinical doctors and nurses, it is judged to be the existence of swallowing disorders when the patient's eating patterns and food patterns changed. In addition, cough during eating and drinking was also judged to be dysphagia.

Cross validation

Cross-validation was evaluated via comparing FOIS scores with the incidence of dysphagia and aspiration, and with the severity of dysphagia and aspiration according to video fluoroscopy swallowing study (VFSS), a golden standard for the diagnosis of dysphagia, impaired swallowing function, and aspiration [21]. All the above comparisons were completed within 72 hours of admission to the stroke unit.

Sensitivity to Change

In order to explore the sensitivity of the FOIS scale and to evaluate the changes of oral feeding function, the FOIS scale was used to evaluate the swallowing function in patients at 3 time points, at admission to the stroke unit, at 1 month post-onset, and at 3 months post-onset. Subsequently, the rating
distribution bar chart of FOIS was plotted to evaluate the changes of functional oral intake over time.

**Statistical Analysis**

Statistical analysis was carried out using Windows-based SPSS 20.0. Arithmetical means and standard deviations (mean ± SD) for quantitative variables were calculated, and categorical variables were presented as frequencies. All statistical tests were conducted at a 5% significance level.

For both the FOIS score and the WST, pairwise weighted K values were calculated. Interrater reliability was evaluated with the Cohen K statistic; A K statistic of 0.4 or less is considered poor, values between 0.4 and 0.6 are considered fair to moderate, those between 0.6 and 0.8 suggest good inter-observer agreement, and values higher than 0.8 suggest excellent agreement [22]. This approach is conservative for our reliability comparisons, in that the agreement among raters will be inflated by these automatically perfect agreements [23]. Chi-square and Cramer’s V correlation analyses were calculated to assess criterion validity and cross-validation. Discriminant validity was tested by non-parametric rank sum test. And the sensitivity of the FOIS scale for clinical assessment was investigated by plotting rating distribution bar chart.

**Results**

**Patient Characteristics**

From April 2016 to October, 128 patients were enrolled. Detailed patients’ characteristics are summarized in Table 2. The average age of patients was 59.16 years (median = 59 years, range = 22–80 years), and 70% were men. The diagnoses of the patients selected for the study were ischemic stroke (103 patients, 81%), hemorrhagic stroke (12 patients, 9%), unknown (13 patients, 10%). Twenty-nine patients (23%) were indwelled gastric tube.

**Criterion Validity**

The WST is a clinical screening instrument to assess the status of swallowing function in patients. As shown in the table, there is a strongest negative correlation between the FOIS and the WST (r = -.937, P < 0.001). The NIHSS and MBI were also significantly associated with the FOIS ratings on admission to a stroke unit (Table 4).

**Discrimination validity**

Clinical comprehensive evaluation was performed in all patients who met the inclusion criteria. According to the evaluation results of swallowing function, the patients were divided into three groups: normal oral feeding group, oral feeding disorders without tube-feeding group, and tube-feeding group. Non-parametric rank sum test was completed to evaluate the FOIS level among the three groups of patients. The evaluation results of the 3 groups were statistically significant difference (χ²=126.551, P<0.001) (Table 5), indicating the FOIS scale can be used to determine whether or not the patients had oral feeding disorder as well as the severity of the symptoms.

</tbody>
</table>
Sensitively reflect substantial changes of oral intake of food of a previous study [24]. Therefore, the FOIS scale can determine whether or not the patients had oral feeding disorder, as well as the severity of the symptoms. From the FOIS level distribution map, it seems sensitive to the changes in the oral feeding function of the patients. It is very important to accurately record the oral feeding function of the stroke patients throughout the whole time of their illness. We use the WST scale to evaluate the swallowing function of patients again, and combined use the FOIS scale to record the oral feeding status of the patients. In this way, doctors can have a better grasp of the patient's overall rehabilitation. Although there was a strong correlation between FOIS and WST scale, overall, there are some subtle differences that do exist. In the study, we found that the FOIS provides more details of swallowing function than WST, and therefore, it is superior to WST due to the availability of nutritional status, and has higher ability to recognize different stages of swallowing function. Thus, we suggest that the combination of WST and FOIS scale should be employed to evaluate the swallowing functions of patients with acute stroke.

**Cross-validation**

The cross-validation analysis data showed that the FOIS was significantly associated with presence of both dysphagia and aspiration derived from VFSS. Dysphagia severity was significantly correlated with FOIS ratings ($\chi^2=65.32; P<0.001$), but the aspiration severity was not (Table 6).

**Sensitivity to Change**

Data of oral feeding function of stroke patients at admission to a stroke unit, at 1 month and 3 months post-stroke were shown by FOIS level distribution map (Figure 1). The oral feeding function of the patients showed a gradual improvement within three months after stroke, which is consistent with the results of a previous study [24]. Therefore, the FOIS scale can sensitively reflect substantial changes of oral intake of food and liquid for stroke patients.

**Discussion**

As an oral feeding function evaluation tool, the FOIS scale is easily mastered and used in a diverse range of patients. It is a clinically useful instrument to record the severity of symptoms, and to monitor the progression of the disease and the effect of treatment. It has been shown to be strongly associated with swallowing dysfunction [13, 14, 25]. What is more, it has important clinical significance to accurately record the symptoms of dysphagia and the changes of oral feeding function in patients during the whole treatment period. Therefore, it is necessary to use the FOIS scale in clinical practice.

**Conclusion**

The Chinese version of the FOIS scale can be used to reliably assess oral feeding function in adult Chinese patients with acute stroke and is worthy of recommendation and application in clinical practice.

Abstract

We explored how drug switching impacts adherence measures for common chronic oral medications. Switching between ingredients with the same indication was detected within a 30-day grace period. The proportion of days covered (PDC) and adherent status (cutoff 0.8) for each ingredient was calculated and compared between different censoring approaches: censoring drug switching (PDCswitch), censoring the end of dispensing (PDCend), and fixed 365-day period (PDC365). Overall, 854,380 (15.9%) patients in the Optum ClinFormatics (Optum) and 150,785 (22.0%) patients in the MarketScan Multi-state Medicaid (MDCD) had at least one switch within one year. Compared with PDC365 in Optum, PDCswitch means were higher: 0.85 vs. 0.41 for antihypertensive, 0.82 vs. 0.46 for antihyperglycemics, and 0.84 vs. 0.33 for antihyperlipidemia. Further, the percentages of adherent patients were higher: 95.8% vs. 17.9% for antihypertensive, 85.5% vs. 18.9% for antihyperglycemics, and 72.1% vs. 5.3% for antihyperlipidemia. Significant and modest changes were observed between PDCswitch and PDCend.

Introduction

Medication adherence can be objectively assessed using prescription dispensing records from electronic databases, such as medical record systems, insurance claims, or pharmacy dispensing databases. Various medication adherence measures have been established to estimate the proportion of the number of days supply during a specified time period or during refill intervals following a drug or a set of drugs [1-3]. Several studies also identified medication discontinuation when patients failed to refill their prescription within certain number of days after exhausting a previously dispensed supply [1-2]. However, these existing measures usually do not specifically address the issue of drug switching. Drug switching or switching between drugs, ingredients, and classes is not uncommon in patients with chronic conditions because of the side effects, perceived efficacy, cost, or patient preference [6-8]. Some studies proposed to combine the number of days of supply for all drugs or to the average adherences of all drugs when patients have been dispensed multiple drugs in a certain observation period [3-5]. However, adherence may vary between drugs that were prescribed even when they treat same disease. While there is a large literature evaluating medication adherence of specific medical products, there is little standardization among the approaches taken to estimate adherence with an array of different assumptions being applied to administrative claims data. For example, 12 recent publications assessed the adherence of metformin or atorvastatin using either medication possession ratio (MPR) or proportion of days supplied (PDC) as the primary metric. Within these papers, researchers varied in their assumptions around the time window of interest, with some using six months and others following 12 months from initiation of therapy. Perhaps most striking was the disparity across the community in handling censoring in the adherence metric; the predominant approach was to follow patients for the full fixed time window from the index day [6-9], but four papers modified this approach to terminate the time window to the when the index drug was stopped [10-13], and two papers considered switching to alternative treatments for the same indication when censoring a patient’s time [14-15]. Other papers simply excluded patients with switches in therapy from consideration [16-17]. The impact of these varied assumptions has not been fully evaluated.

In this study, we develop an approach that incorporates drug switching into medication adherence measures. We then explore the difference between this approach and existing common adherence measures using dispensing records of chronic oral medications.

Methods

Data Sources and Settings

We extracted pharmacy dispensing records from Optum ClinFormatics (Optum) and MarketScan Multi-state Medicaid (MDCD), both formatted in the Observational Medical Outcome Partnership Common Data Model (OMOP CDM) [18]. The Optum and MDCD databases capture person-specific information centered on administrative information, such as age, gender, pharmacy claims data, physician and facility claims data, and lab test results data. The Optum database represents over 34 million distinct individuals from September 1, 2005 to March 31, 2012 with an average of 27 months of longitudinal observation. The MDCD database represents data on 9.6 million distinct patients from January 1, 2006 to December 31, 2009, with an average of 11 months of longitudinal observation. Source pharmacy dispensing records of Optum and MDCD were translated to the OMOP CDM drug exposure tables, which capture inferred utilization of dispensed drugs, such as drug concept, the number of days of supply, quantity, the start date and end date of the current...
dispensing. The local drug codes in the source data were mapped to the RxNorm drug concepts. All records in the drug exposure tables were available for this study. Analyses were conducted independently for the Optum and the MDCD database.

Eligibility Criteria

The study cohort was selected from patients who were dispensed any common, single ingredient, chronic oral medications used to treat hyperglycemia, hyperlipidemia, and hypertension. These medications include sulfonylurea, biguanides, statin, beta-blocker (BB), angiotensin-converting-enzyme (ACE) inhibitor, angiotensin II-receptor antagonist (ARB), calcium-channel blocker, and Thiazolinedione (TZD). Drug attributes (ingredient, therapeutic class, and primary indication) were identified from the OMOP vocabulary. Patients who took combination drugs were excluded. Eligible patients’ prescription-filling behaviors were followed up for 365 days from the initial dispensing event of each ingredient.

Measurements

Definition of Drug Switching

Drug switching was identified when a different medication with the same indication (drug B) was initiated within 30 days of an existing medication (drug A) being terminated. At the same time, the existing medication had to be terminated within 30 days after the replacement therapy started. Switching was distinguished from the drug augmentation, which is a situation that the existing medication was not stopped within 30 days of the new drug initiation. In this study, we only probed ingredient switching within a 365-day follow-up period from the existing medication index event. Multiple switches might be identified between ingredients but only the first one was counted for this study. In the OMOP CDM, multiple dispensing records with same ingredient can be used to construct a drug era with a specified length of gap. In this study, we allowed a 0-day gap for aggregating dispensing events into a drug era, and we detected drug switching during gaps less than 30 days between drug eras. We classified the switching index into four categories according to the time when switching occurred relative to the last drug era of drug A; A) during the last era of drug A; B) at the end of the last era of drug A; C) after the last era of drug A; and D) before the last era of drug A.

Comparison of Interest

Patient medication adherence for each ingredient was measured by the proportion of days covered (PDC) following up 365 days. PDC was defined as the total number of medication-covered days divided by the number of days of the observation time period. PDC can be calculated even if a subject has only one fill and has been using increased to measure patient medication adherence for quality assurance [19]. Within a 365-day follow-up time period, three observation windows were applied to each ingredient: a fixed 365 days with no censoring included (PDC365), censoring based on the last dispensing date (PDCend), or censoring based on the date when a drug switches to another ingredient treating the same disease (PDCswitch). These three censoring strategies reflect the most common situations when patients change medications. Using a conventional cut-off (0.8), PDC was further classified into two levels: adherent (≥0.8) and non-adherent (<0.8). Patient PDC and adherence rates were compared between different censoring approaches: censoring switching versus censoring last dispensing date, and censoring switching versus a fixed 365 days.

Statistical Analysis

For each category of therapeutic medication, a descriptive summary of medication dispensing events, patient characteristics, and proportion of drug switching were reported. Medication adherence and adherence classification for each patient with drug switching were calculated independently for PDC365, PDCswitch, or PDCend. Paired t-tests were conducted to assess differences of patient PDC for all subjects and subgroups stratified by indication. Chi-square tests were performed to detect the difference of adherence classification between comparison groups. In addition, across all three therapeutic areas, the proportion of changes in PDC (decreased, increased, or unchanged) within each switching index category were reported. A p-value less than 0.05 were considered significant. All analyses were implemented using SAS 9.2 (SAS Institute, Cary, North Carolina).

Results

Patient Measure Summary

A total of 1,261 distinct oral single ingredient drugs for 60 ingredients (41 for hypertension, 11 for hyperglycemia, and 8 for hyperlipidemia) were identified from the OMOP vocabulary. There were 5,365,644 patients in Optum and 684,102 patients in MDCD who were dispensed at least one studied ingredient. Following up 365 days for each ingredient for each patient, 854,380 (15.9%) patients in Optum and 150,785 (22.0%) patients in MDCD had at least one switching event between ingredients. Patient demographic and switching frequencies in each therapeutic area were reported in Table 1. Compared with PDCend, the average PDCswitch was slightly higher in antihypertensive, antihyperglycemics, and slightly lower in cholesterol lowering medications in both the Optum and MDCD databases. Consequently, adherence status (PDC=0.8) were 5-15% higher in antihypertensive and antihyperglycemics, and about 10% lower in cholesterol lowering drugs. In Optum, antihyperglycemics had the highest percentage of patients changing adherence status (35.1%) followed by antihypertensive (30.5%), and cholesterol lowering drugs (19.2%). Similar percentages of patients who changed adherence status were observed in MDCD: 35.9% for antihyperglycemics, 37.1% for cholesterol lowering, and 26.5% for antihypertensive drugs (Table 1).

Compared with PDC365, the average PDCswitch was higher in all three drug therapeutic classes: 0.85 vs. 0.41 for antihypertensive, 0.82 vs. 0.46 for antihyperglycemics, and 0.84 vs. 0.33 for cholesterol lowering drugs in the Optum. Further, the percentages of adherent patients were much Higher: 95.8% vs. 17.9% for antihypertensive, 85.5% vs. 18.9% for antihyperglycemics, and 72.1% vs. 5.3% for cholesterol lowering drugs. Sixty-seven to 80% of patients changed adherence status; among those patients, more than 98% of patients changed from non-adherent to adherent. Similar increases were in observed in the MDCD (Table 1).

PDC Differences

Paired t-tests were conducted to compare the PDCs measured by applying different censoring approaches. In Optum, there was a significant difference between PDCswitch (M=0.85,SD=0.17) and PDC365 (M=0.41,SD=0.28); t(1209534)=1503.2, p<0.0001. Similarly, in the MDCD, there

Note. AH (antihypertensive); AG (antihyperglycemics); AL (antihyperlipidemia); EOD (end of dispensing event)

was a significant difference between PDCswitch (M=0.83,SD=0.18) and PDCend (M=0.80, SD=0.22); t(236038)=60.8, p<0.0001, and there was a significant difference between PDCswitch (M=0.83,SD=0.18) and PDC365 (M=0.38,SD=0.27); t(236035)=664.3, p<0.0001. When stratified by indications, the PDCswitch values were higher in antihypertensive and antihyperglycemics, and the PDCswitch was lower in cholesterol lowering drug when comparing with PDCend (Figure 1A). Compared with PDC365, the PDCswitch values were higher (0.3-0.5) in all three subgroups (Figure 1B). We also observed approximately 10% PDCswitch values increased 0.9 compared with PDC365 in each subgroup.

Switch Index Affects Medication Adherence

In Optum, the majority of switching occurred during the last era of drug A (43.7%), followed by before the last era of drug A (30.7%), after the last era of drug A (24.3%), and at the end of the last era of drug A (1.3%). Compared with PDCend, PDC switch might decrease, increase, or remain unchanged with different proportions (more or less) when switching occurred during or before the last era of drug A. However, PDC switch decreased when switching occurred after the last era of drug A, and remained unchanged when switching occurred at the end of last era of drug A. Compared with PDC365, PDCswitch values were largely increased in all four switching index categories (Figure 2). Similar results were observed in the MDCD (data not shown).

![Figure 1 - Distribution of PDC changes stratified by indications](image1)

![Figure 2 - PDC change patterns across three indications by switch index category](image2)
Discussion

There are two main findings from this study; 1) drug switching was frequently observed in antihypertensive, antihyperglycemics, and cholesterol lowering drugs in both a commercial claims database and a Medicaid supplement database; 2) censoring drug switching significantly impacts medication adherence measures and classifications in commonly used chronic oral medications. Our study results showed that a fair number of patients switched to another ingredient within one year: near 20% for antihypertensive, 20% for antihyperglycemics, and 6-7% for cholesterol lowering drugs. These numbers were consistent with previous findings in the literature. Bernard observed that 6-9% of patients switched to new therapeutic class of antihypertensive medication within 12 months [20]. Dailey, et al. found that near 30-40% of patients with antihyperglycemics monotherapy, modified treatment within 1-year follow up period [21-22]. Simpson et al. reported that 18% of patients with statins monotherapy and uncontrolled lipoprotein cholesterol experienced medication switches or titration within 12 months in a managed care setting [23].

Incorporating censoring of drug switching into the adherence estimation significantly affected medication adherence measures. When PDCswitch and PDCend were compared, a modest, but significant PDC difference in the population mean was observed. Further investigation by paired t-test of PDC at patient level, showed that censoring switching might either increase or decrease PDC with a balanced distribution. As a result, the PDC difference at the patient level might average out in the population mean. However, 30% of patients changed their adherence status, either from adherent to non-adherent or from non-adherent to adherent, which suggested that failing to censor PDC based on drug switching may either over-estimate or underestimate patient adherence status. One possible explanation for why 30% of patients changed their adherence status is that the PDCend values for these patients might be near 0.8, thus a minor change in PDC may cause patient adherence status change. However, we investigated that PDCend values of these patients were broadly, rather than narrowly distributed around the 0.8 cutoff. For example, in Optum, the PDCend median was 0.9 (Q1 0.7, Q3 1.0). In contrast, when comparing PDCswitch with PDC365, mean PDC was markedly increased (more than 0.3) in antihypertensive, antihyperglycemics, and cholesterol lowering drugs. The paired t-test at patient level also suggested that PDC increased more than 0.4 when censoring drug switching, and 60-80% of patients changed adherence status, mainly (95-99%) from non-adherent to adherent.

Medication adherence is an important factor linking treatment effectiveness, patient outcomes, and healthcare economic consequences [24]. Non-adherence to prescribed medication regimens relates to poor disease control, causes higher rates of mortality and morbidity, and increases health care costs [25-28].

Over a decade ago, the WHO stated that an effective adherence intervention might have a greater effect on population health than any other medical treatment improvements [29]. Recently, both the Pharmacy Quality Alliance and the National Quality Forum endorsed the PDC-based adherence measures. Accurately assessing patient medication adherence is essential to optimizing drug therapy, as well as to identify non-adherence patients for targeted interventions. Our study showed drug switching is frequently observed among patients with chronic conditions, and censoring drug switching significantly changed PDC values: less than 20% of patients remained the same PDC value as the PDCend, and less than 0.5% of patients remained the same PDC value as the PDC365 (Figure 2). Failing to censor drug switching may miscalculate the patient adherence measure and consequently misclassify adherence status. An appropriate approach to measure adherence should take drug switching into account when patients switched to a new drug, their medication taking behaviors for previous drugs should be censored, including both the number of days supply and the observation period. At the same time, adherence for the new drug should be measured, starting at the time point when the patient modified their therapy.

Limitations

This study explored how censoring drug switching affected medication adherence measures in patients with single ingredient chronic oral medications. Certain limitations should be acknowledged. First, we only focused on switching between ingredients. We did not investigate dosage change or changes from monotherapy to combination treatment; therefore the switching rate might be under-estimated. Second, patient dispensing patterns (including drug switching and medication adherence) were only followed up for one year and findings may not represent long-term patterns [30]. Third, we use a 30-day grace period as a general observation window to detect drug switching for all 60 ingredients. In clinical practice, a more specific grace period might be applied for certain drug switching due to side effects or perceived efficacy [31]. Fourth, we assumed that patient dispensing data were complete and we have may missed patient dispensing information if a patient changed their insurance plan. However, the MDCD is a Medicaid supplement database which represented a relative stable population, yet demonstrated similar findings with Optum. Finally, we did not study specific drugs and diseases, results from this study only provided general knowledge on how censoring drug switching impacts medication adherence measures. One interesting finding is that censoring switching mainly increases the PDC in antihypertensive and antihyperglycemics, while decreases PDC in cholesterol lowering drugs. A more disease-specified study should be conducted to understand more about the different effects of censoring drug switching on medication adherence measures.

Conclusion

To our knowledge, this is the first study to explore how censoring drug switching affects adherence measures and classifications in common chronically used oral medications. We found that drug switching frequently occurred in real-world practices and significantly affected PDC values in various ways. More importantly, censoring drug switching largely impacted patient adherence status. It is critical to account for drug switching in medication adherence measures in order to accurately assess patient medication taking behavior.

Abstract

The acceptance and feasibility for using mobile health technologies for diabetes management in Saudi Arabia remains to be explored. We created the Mobile Health Effectiveness and Readiness Questionnaire (MEHRQ) to measure its validity and reliability in assessing the readiness of Saudi diabetic patients use of mobile health technologies for diabetes self-management. The study was able to measure the validity and reliability of MEHRQ and found that MEHRQ provides promising results for Saudi diabetic patients’ use of mobile health technologies.

Keywords:
Mobile health; Diabetes; Saudi Arabia

Introduction

Saudi Arabia has the second highest diabetes prevalence rate in the Middle East and seventh in the world [1]. The use of mobile technologies in health care, and especially, for chronic disease management, such as Diabetes, has been shown to have positive impacts on health [2]. The purpose of this study was to validate a questionnaire for helping assess the attitude and acceptance of mobile health technologies by diabetics for self-management in Saudi Arabia.

Methods

We created the Mobile Health Effect and Readiness Questionnaire (MEHRQ) that was adapted from the Telemonitoring Readiness and Effectiveness Questionnaire (THREQ) [3]. The questionnaire was translated into Arabic following the process of translation recommended by the World Health Organization (WHO) and consisted of three main sections: demographic, clinical data and thirteen questions scored on a five-point Likert scale that related to the readiness in using mobile technologies for diabetes self-management. In March 2017, to validate the questionnaire, a pre-test was conducted on a target population consisting of ten patients visiting the primary care clinic at King Khalid University Hospital (KKUH), in Riyadh, Saudi Arabia. Data were analyzed and the items that did not show acceptable reliability were modified. For the pilot test, a sample size of 30 diabetic patients from KKUH were collected by face-to-face interviews.

Results

Overall, the MEHRQ showed excellent internal consistency (\(z=9\)). Results also showed that 19 (63\%) participants kept their blood glucose values on paper. None of the participants recorded their blood glucose values on a mobile health device or their personal computer.

Participants’ response to the thirteen MEHRQ items are summarized as follows: 77\% of the participants agreed that sending their diabetic data using technology helps them cope better with their diabetes and makes them feel healthier. Also, 80\% of the participants agreed that knowing a healthcare professional and having them review their diabetic data gives them a more secure feeling that their condition is being managed.

Results also showed that 63\% of the participants were willing to use mobile health from home to transfer blood glucose values to their diabetes professional. 80\% of the participants reported that they were willing to ask their healthcare professional questions using mobile technologies.

Other results showed that 60\% of the participants were willing to use mobile technologies during holidays to transfer blood glucose values to their diabetes healthcare professional and 70\% reported their willingness to ask their healthcare professional questions using mobile technologies while on vacation. 63\% of the participants were willing to ask other diabetic patients questions using mobile health technologies, however, 43\% of the participants were not willing to use mobile health technologies to transfer blood glucose values to another diabetic patient.

Conclusions

Preliminary results show that MEHRQ to be satisfactory for assessing Saudi patient acceptance for using mobile health technologies for diabetes self-management.

Saudi Diabetic Patients’ Attitudes Towards Patient Portal Use and Their Perceived E-Health Literacy

Rawan AlOthman, Nasriah Zakaria, Ahmed AlBarrak

Medical Informatics and E-learning Unit, Medical Education Department, College of Medicine, King Saud University, Riyadh, Saudi Arabia

Abstract

A cross-sectional study (n=130) was conducted to identify diabetic patient’s attitudes, patient portal feature preferences, and e-health literacy at two tertiary hospitals in Riyadh, Saudi Arabia. 51% of patients had positive attitude towards the patient portal, 82% think a portal could help with self-care management. 53% of patients had low e-health literacy levels and 9% had high e-health literacy levels. The majority of the study sample have a positive attitude with low e-health literacy levels.

Keywords:
Diabetes Mellitus, Health Literacy

Introduction

The patient portal is a secure platform that allows users to gain access to personal health information regardless of their location. Evidently, such a platform can provide the patient with an expanded potential to improve their process of managing chronic diseases such as diabetes mellitus. 

Objective: To assess diabetic patients attitude towards patient portal use for self-care management, preferences towards patient portal features and their general e-health literacy level using a cross-sectional study and convenience-sampling technique.

Methods

Data was collected via self-administered structured questionnaires [1,2] from diabetic patients who visited outpatient clinics at King Khalid University Hospital (KKUH) and King Faisal Specialist Hospital and Research Center (KFSH&RC) in Riyadh, Saudi Arabia, from February to April 2017.

Results

A total of 130 diabetic patients type 1 and 2, male were 47% and female were 53%. The highest age group was 55-64 years 32%. Only 14.7% had used the patient portal, yet the majority of participants had never used a portal 85%. However, 51% of patients had positive attitude towards the patient portal and 82% think the portal could help with the self-care management. It is found that, 53% of diabetic patients had low e-health literacy level. Whereas, 36% of participant had moderate level along with only 9% who had high e-health literacy level. Over 50% of patients expressed that they prefer to get health information from the Internet. The reminder function, scheduling clinic visit and more information on the medication were the most preferred features in a portal.

Conclusion

The majority of diabetic patients had positive attitude along with low e-health literacy levels. The reminder function and scheduling clinic visit were the most preferred features.

Acknowledgements

Great thanks to Abdullah Alqarni for his kind help with the data collection.

Development and Deployment of an e-Health System in UNRWA Healthcare Centers (HCs): The Experience and Evidence

Ghada Ballout¹, Najeeb Al-Shorbaji², Amin Shishtawi¹, Fathia Abuzabaida¹, Yousef Shahin¹, Ali Khader¹, Wafa’a Zeidan¹, Yassir Turki¹, Ahmad Al-Natour¹, Rawan Saadeh¹, Majed Hababeh¹, Akihiro Seita¹

¹Department of Health, UNRWA, HQ; ²Director, Knowledge, Ethics and Research (Retired), World Health Organization, Geneva

Abstract

UNRWA recognized the need to develop and introduce eHealth programme based on needs assessment. The web-based e-Health application was developed and deployed in 116 out of 143 HCs in the five fields of operation. Evaluation of the application revealed positive outcomes in terms of reporting requirements, statistics, time saving, efficiency, drug compliance and workflow in general.

Keywords: Efficiency, Internet, Telemedicine

Introduction

United Nations Relief and Works Agency for Palestine Refugees in the Near East (UNRWA) is the main provider of health services to more than 5.8 million Palestinian refugees in its 5 fields of operation: (Jordan, Syria, Lebanon, West Bank and Gaza). In 2009 UNRWA started developing an Electronic Medical Record system. The primary aim of developing the system has been to improve the quality of services, and facilitate patient’s flow within the UNRWA HCs.

The UNRWA eHealth system

The UNRWA e-health system is a locally developed web-based, patient-centered system that caters for all types of illnesses. By December 2016, 116 out of 143 HCs, covering almost 90% of the refugee populations, had the e-health system fully functional, and managing 8 million patient visits a year making 90 HCs paperless.

Evaluation of the UNRWA eHealth system

The system was formally evaluated by a group of experts and staff to identify the benefits gained and lessons learned since its deployment in 2011 to end of 2015. The following key findings were identified:

- The daily medical consultations per doctor were reduced on average from 104 to 86 a day;
- The time needed to collect prescribed medication was reduced to 3 minutes;
- The antibiotics prescription rate was decrease from an average of 27.0% to 24.7%;
- The dashboard enabled managers and supervisors to remotely monitor all HCs daily operations and health care provided to patients;
- Comprehensive reporting and statistics on a daily basis;
- 89% of the physicians who were surveyed expressed satisfaction on e-Health, particularly on the fact of time-saving that allowed them to provide better and more attention to patients;
- Managing the crowds in a timely manner and with fairness.

Conclusions

The e-health system is efficient in managing time and service quality, and supports cost containment and client satisfaction.

Abstract

A major hurdle in eHealth implementation is that it is difficult to put into practice. In this study, the primary aim was to identify the main barrier associated with implementing eHealth. This study surveyed IMIA members from May to November 2015. From the results, it is clear that medical professionals were recording most of their data by hand. This paper culture is a paradigm that is difficult to break. Cultural factors are the primary barrier in eHealth implementation.

Keywords: Computer systems; Telemedicine; Medical Informatics

Introduction

Working without paper is not an easy goal because barriers are not solely technological and technology is more accessible. Rather, workflow processes require rethinking and breaking also with aspects of the culture of using paper. [1] eHealth refers to the application of information and communication technologies (ICT) across the whole range of functions that affect health. [2]

Methods

In order to collect data about cultural problems associated with the implementation of eHealth, we conducted a survey. Inclusion criteria for participants included medical informatics experts who are members of IMIA working group forums. The survey was distributed by e-mail using Survey Monkey. The survey included questions that asked about the topics below.

Do you think that it is important:

A. To break the culture of paper first?
B. To keep in mind local languages and terms used in each region or country?
C. To study first the idiosyncrasies of each place and to adapt technology?

Results

A total of 111 responses were received (response rate 92%), where, 27 came from South America, 24 from North America, 27 from Europe, 3 from Africa and 30 from Asia. Responses were excluded if the participant did not answer >2 questions.

Conclusions

Cultural barriers are one of the most important barriers in implementing eHealth, [1-2] a finding supported by this study.

Management of In-field Patient Tracking and Triage by Using Near-Field Communication in Mass Casualty Incidents

Po-Liang Chengab, Yung-Cheng Su a, Chung-hung Hou a, Po-Lun Chang b

 a Emergency Department, Dalin Tzu Chi Hospital, Chiayi County, Taiwan, China
 b Biomedical Institute, National Yang-Ming University, Taipei City, Taiwan, China

Abstract
Near field communications (NFC) is an emerging technology that may potentially assist with disaster management. A smartphone-based app was designed to help track patient flow in real time. A table-drill was held as a brief evaluation and it showed significant improvement in both efficacy and accuracy of patient management. It is feasible to use NFC-embedded smartphones to clarify the ambiguous and chaotic patient flow in a mass casualty incident.

Keywords:
Disasters; Smartphone; Triage.

Introduction
Due to the limited information in the early phase of rescue operation in the mass casualty incident (MCI), the government, emergency medicine service (EMS) systems and the population in Taiwan usually get the ambiguous information of damage. Utilization of the medical electronics with well-established infrastructure of information communication technology to manage affected population in such scenario is thought to be practical and useful. Near field communications (NFC) is an emerging technology that may be potential to develop novel disaster management systems [1]. Recently, an NFC based medication system may be used to effectively reduce medication errors in a simulated environment [2]. The aim of the project is managing the dataflow of the patients with the NFC-embedded smartphones.

Methods
The information platform as an independent smartphone app was programmed by Dr. Cheng under the developed environment of Android Studio 2.0. An unique NFC tag would be placed on the patient in the incident scene by the emergency medical technician (EMT). The EMT would operate the smartphone-based app and the patient information would be transmitted into the encrypted NFC tag. Subsequently, the NFC tag would be transferred along with the patient so that the location and condition would be updated every time after the NFC induction. Instant and editable information will be provided to the clients including the EMTs in the incident scene, the staffs in the hospitals and the commanders. All data in transit will be encrypted because of the security concerns. Afterward, a table-drill was held to evaluate the efficacy and efficiency. There were 50 EMT trainees recruited and then divided into 2 similar groups. A 30-minutes mini-lecture about simple triage and rapid treatment (START) was instructed by Dr. Hou in advance. Fifty scenario cards were given to the two different groups. In the first group, they were asked to complete triage by using the NFC-embedded smartphone. In the second group, they would complete other triage by using traditional paperwork alone. Finally, they must calculate and report the total injuries and their dispositions. The time and accuracy was recorded by comparison.

Results
There was significant difference in the total triage time between the NFC group (32.38 minutes) and the paperwork group. (49.58 minutes) \((p<0.001)\). Besides, it was significant difference in sorting the information between the NFC group (29 seconds) and the paperwork group. (8.08 minutes) \((p<0.001)\). It mean that it is time-consuming to find out which destination and the transfer time. The accuracy was also significant difference between the NFC group (49/50, 100%) and the paperwork group (31/50, 96%).

Conclusion
It is feasible to use a NFC-embedded smartphone to triage and tracking the patient dispositions in the early phase of a mass casualty incident. The limitation in this brief study are the small convenient samples and scenarios.

Development of Day Care Management Systems for Elderly

Ming-Chu Chiang\textsuperscript{a}, Yu-Ting Yeh\textsuperscript{a,b}, Chien-Tsai Liu\textsuperscript{a}

\textsuperscript{a} Graduate Institute of Biomedical Informatics, Taipei Medical University, Taipei, Taiwan, China,
\textsuperscript{b} Taipei Medical University Shuang-Ho Hospital, Taipei, Taiwan, China

Abstract

The purpose of this study is to build a practical, highly efficient management information system (MIS) for elderly day care (EDC) centers to improve elders’ lives. Based on system requirements and the management operation guidelines for EDC, we have developed an MIS. The introduction of the system will help EDC management to be more accurate, comprehensive, and efficient.

Keywords: Management Information Systems; Adult Day Care Centers; Long-Term Care.

Introduction

Aging population is a serious challenge that many developed countries have to face together in the twentieth-first century, and so is the case in Taiwan. The elders (of age 65 and over) accounted for 7% of Taiwan’s population in 1993, entering an aging society. According to a projection by Taiwan’s National Development Council of the Executive Yuan, Taiwan will become an aged society in 2018 (increasing to 14%), and further to a super-aged society in 2026 (up to 20%)\textsuperscript{[1,2]}. Taiwan started to promote the ‘‘Ten-Year LTC Plan’’ (2008-2017). The plan is to expand and popularize the capacity of the resources of the service system, strengthening the popularization and the localization of the long-term care services, in order to raising the quality of the long-term caring.

Methods

This study is in the cloud platform to build EDC center system, improve the EDC center of the manual management process, and develop a series of mobile integration system in future. Microsoft cloud development tools are leveraged to integrate automated physiological measurement equipment, formulate form design standards to deal with different management forms, this set of EDC center intelligent management functions, including authorization management, case filing, case management etc. [Figure 1]. Therefore, this study provides the development of science and technology management of community care services, which is conducive to the country to continue to promote long-term care services to enhance the quality and achieve good results in community service.

Results

The following is the result of building a day care center management system. The system is developed on Microsoft ASP.NET MVC 5 Framework and built on the MS Azure cloud platform. Moreover, the software design is based on the Model-View-Controller structure and use the database of MS SQL server. The system develops many functions to improve the daily operations. It will prompt the staff to do the regular evaluation, for example ADL (activities of daily living), iADL (Instrumental activities of daily living). Those evaluation records will be kept in the system for future inquiry. The evaluation sheet includes the profile information, the disabilities and the score of the case. The system also provides foolproof mechanism and avoids the data repetition to confirm the data accuracy. Each month will produce list, lead to the Government subsidy. The system win lots of praise from the user and the care staff during the trial phase. The system is able to shorten the procedure of operation.

Conclusion

The system won lots of praise from the caring staff during the test runs, e.g., when the vital signs measurement is completed, the system simultaneously marks the elders’ presence records and simplifies the operation procedures. The prompting of the daily pending tasks such as conducting the periodic evaluation, doctor consultation, medication, and etc., has promoted the caring quality.

Use of Person-Generated Health Data in Kinect-Based Stroke Rehabilitation Systems: A Systematic Review

Gerardo Luis Dimaguila, Kathleen Gray, Mark Merolli
Health and Biomedical Informatics Centre, University of Melbourne, Melbourne, Victoria, Australia

Abstract
It is important for patients to have access to the health information they generate, for them to be actively engaged in their own healthcare. This is relevant to Kinect-based post-stroke rehabilitation systems, as such there is a need to review the literature based on person-generated management and utilisation. Previous systematic reviews on Kinect for stroke rehabilitation have not used this as part of their criteria. This systematic review fills that gap.

Keywords:
Review, Systematic; Stroke; Health Technology

Introduction
Person-generated health data (PGHD) are health, wellness and clinical data that people generate, record and analyse for themselves [1]. While PGHD’s importance for individuals or patients has yet to be conceptually defined, it is well known that when patients understand their illness, they become active problem solvers and improve their health behaviour, e.g., people will stop smoking when they personally see the connection between that and an illness they are experiencing [2]. It is therefore important for patients to have access to the health information they generate. This is relevant to post-stroke rehabilitation systems using body-tracking technology, Kinect, which have been developed as a response to the need for the effective home-based rehabilitation that requires less professional and financial resources [3-5] because such systems generate patient-relevant data. There is therefore a need to review the literature on Kinect-based stroke rehabilitation to understand if and how person-generated data are managed and utilised. Previous systematic reviews [3-5] have focused on describing the intervention, methodologies and results, and have not given attention to person-generated data management.

Methods
The terms “Kinect”, “stroke”, “cerebrovascular accident”, “CVA” and “rehabilitat* (% for ACM)” were used to search for peer-reviewed English articles in PubMed, BioMed Central, IEEE Xplore, and ACM. There was no date restriction. Papers included are those that used Kinect as a body-tracking device for a technology-based stroke rehabilitation system. The search was last updated on December 7, 2016.

Results
A total of 35 papers were included in the review, out of 88 search results. It was discovered that patient data access came in the form of feedbacks. 15 of the studies provided visual or auditory feedbacks for patients to follow correct gestures or positions; 3 studies provided task counts, e.g., completed/to be completed; 5 studies simply provided game scores, not clearly related to performance; and 13 studies did not discuss provision of feedback or data utilisation. The numbers include 1 paper that provided both performance feedback and task counts. For the complete list of papers, please contact the corresponding author.

Conclusions
The results show that there is insufficient attention given to person-generated data from Kinect-based stroke rehabilitation systems. While most studies provide some form of feedback, they do not allow the patients to actively engage in their own rehabilitation, nor do the studies try to understand the health behaviour impact of providing data access to patients. This is indicative of the need for future researchers of technology-based rehabilitation to consider PGHD and patient access to information in their systems’ design and implementation.

A Serious Game for Anterior Cruciate Ligament Rehabilitation: Software Development Aspects and Game Engagement Assessment

Marcos Cordeiro d’Ornellasa, Alison Santos Machadoa, Jefferson Potiguara de Moraesb, Ana Lúcia Cervi Pradob

Abstract
This work presents the steps for developing a serious game that allows the interaction through natural gestures, whose main purpose is to contribute to the treatment of individuals who have suffered an injury to the anterior cruciate ligament (ACL). In addition to the serious game development process, the users’ gaming experience were performed. Through the evaluation assessment, positive results were obtained in relation to various aspects of the game engagement, proving the playful factor of this activity.

Keywords:
Anterior Cruciate Ligament, Rehabilitation, User-Computer Interface

Introduction
The knee is one of the joints that have a higher incidence of injuries resulting from sports activities. Among the most frequent injuries in the knee joint are the injuries to the anterior cruciate ligament (ACL). Most ACL injuries in soccer players happen when a player lands unadroitly in the wake of bouncing. Since ACL tears do not mend, those wishing to come back from a soccer injury are urged to have the ACL reconstructed [1].

This paper presents a serious game for ACL rehabilitation using natural user interfaces. The game helps the therapist in assessing the quality and efficiency of the treatment and encourages patients using a serious game that uses quantitative measures to assess game engagement while using existing interfaces for user-computer interaction.

Methods
The game (see Fig. 1) has several settings that can be changed by the physical therapist. The simplicity of the controls offers an amount of variation when players are shooting. They can take a few shots to get the direction and spin aspects just right to score.

In order to measure engagement, players were asked to complete the Game Engagement Questionnaire. The questionnaire is a nineteen-item scale that assesses several aspects related to gameplay engagement. These include presence, flow, immersion, and absorption. Rasch analysis of (GEQ) responses and relationships with other questionnaires and with participant behavioral responses provided indications that the game engagement questionnaire is a reliable and valid measure of engagement in playing video games [2].

Results
To compare each of the engagement scales between conditions, a statistical analysis was performed using two-way analysis of variance (ANOVA). Based on the results achieved during the in-game engagement assessment, the prototype performed to specification quite well.

Conclusion
Through tests conducted by the GEQ, it was possible to verify that the developed game reached the goals being evaluated positively. Future studies suggest the evaluation of GEQ with individuals who participate in the treatment of recovery after ACL injuries in order to evaluate the engagement of people who have limited dexterity.

Comparing the Human Papillomavirus Vaccination Opinions Trends from Different Twitter User Groups with a Machine Learning Based System and Semiparametric Nonlinear Regression

Jingcheng Du*, Jing Huang*, Rui Duan#, Yong Chen#, Cui Tao*

*School of Biomedical Informatics, University of Texas Health, Houston, TX, USA.
#Department of Biostatistics and Epidemiology, University of Pennsylvania, Philadelphia, PA, USA

Abstract

HPV vaccination refusal is a serious public health issue. Opinions on Twitter have been influential to potential consumers on vaccination behaviors. Public opinions toward HPV vaccination were extracted from Twitter by leveraging machine learning models. We used semiparametric nonlinear regression models to study the association between people’s public opinions on HPV vaccination at Twitter and the number of followers. Trend patterns of opinions from Twitter users groups with different number of followers were identified and compared.

Keywords:
Vaccination; Machine learning, Social media.

Introduction

Vaccination refusal of human papillomavirus (HPV) vaccines is a serious health problem, attracting attention from informatics researchers [1]. Social media information could affect consumer health behavior [2]; analysis of public HPV opinions from social media is very important. Twitter provides a rich data source to access public opinions on HPV vaccines. Before quantifying the influence of Twitter users on others’ vaccination behavior change, it is interesting to study the association between the users’ own opinions with the number of followers. Successful quantification of such association may help design more effective interventions to mitigate the vaccination refusal.

Methods

Tweets were collected from November 2, 2015 to March 28, 2016 using HPV vaccine related keywords through the Twitter Application programming Interface. We leveraged Support Vector Machine (SVM) models [3] to categorize the tweets into three opinion groups including “Positive”, “Negative”, and “Neutral”. Other tweets were grouped as “Unrelated”.

Tweets were grouped into four subgroups by the posters’ followers numbers using quartile function. We then fit polytomous logistic regression models of the categorized opinions on each subgroup for number of followers and calendar time, using polynomial splines.

Results

Among the 184,214 tweets collected, 73,436 tweets were grouped as “Unrelated”, 39,704 as “Positive”, 35,428 as “Negative”, and 35,591 as “Neutral”. The number of tweet followers were grouped into four groups: 0-121, 121-441, 441-1,460, and 1,460 or more. The number of followers was significantly associated with vaccination opinions (p ≤ 0.01).

During the study period, among all users groups except 121-441, we observed similar trends in our polytomous logistic regression models with splines. More specifically, we found that the probability of “Negative” opinions decreased until 02/2016 and increased afterwards; the probability of “Positive” opinions increased and then decreased starting 02/2016. User group trends with 121-441 followers differed from other groups with decreased “Negative” opinions until 02/2016 and increased “Positive” opinions afterwards.

Conclusions

Based on our previous work, we leveraged a machine learning based approach to extract public opinions toward HPV vaccination from Twitter. By grouping users based on the number of followers and fitting logistic regression models, we accessed and compared opinions trends. Except for Twitter users groups with 121-441 followers, the trend patterns were similar. Analysis of the similarity and difference in opinions patterns can be provided to health professionals to more efficiently and precisely lead the the public opinions on Twitter. A larger Tweets corpus is being collected and more robust conclusions will be made based on the larger dataset.

Social Media as a Communication Support for Persons with Mild Acquired Cognitive Impairment: A Social Network Analysis Study

Aboozar Eghdam*, Ulrika Hamidia, Aniko Bartfai, Sabine Koch

*Health Informatics Centre (HIC), Department of Learning, Informatics, Management and Ethics (LIME), Karolinska Institutet, Stockholm, Sweden,
*Division of Rehabilitation Medicine, Department of Clinical Sciences Danderyd Hospital, Karolinska Institutet, Stockholm, Sweden

Abstract
This study was conducted as a social network analysis of a Facebook group for Swedish speaking persons (1310 members) with perceived brain fatigue after an illness or injury to the brain to address the lack of research examining social media and the potential value of on-line support for persons with mild acquired cognitive impairment.

Keywords:
Social Support, Cognitive Dysfunction, Social Media

Introduction
One of the leading causes of disability in many developed countries is brain injury. Mild Acquired Cognitive Impairment (MACI) is a term used to describe persons with non-progressive Mild Cognitive Impairment (MCI) acquired from a brain injury. They can have multiple cognitive (e.g., memory impairment) and/or somatic (e.g., headaches, fatigue) symptoms in addition to mild physical disabilities and their access to rehabilitation services to improve their affected skills is limited [1]. Social media has the potential to increase social participation and support for the well-being of individuals with chronic medical conditions [2]. To date, Facebook is the most popular social medium for different types of communication. However, there is a lack of knowledge about the potential use of Facebook as a mean of communication for persons with potential MACI.

Objective
The aim of this study was to explore how persons with MACI, specifically persons with perceived brain fatigue after brain injury, communicate through Facebook, to classify the content of the communication and to visualize the frequency and types of interactions.

Methods
A social network analysis (quantitatively and qualitatively for a period of a whole year) of the interactions between members of a public Facebook group for Swedish speaking persons (1310 members) with perceived brain fatigue after an illness or injury to the brain was performed.

Results
The results showed how members use social media technology and Facebook as a means for communication and support for their condition. Individual group members showed very different patterns of communication and interaction. However, for the group as a whole, the most frequent topics in their communication were related to informational support and banter in posts, and socialization in comments. The findings also showed that the majority of members only communicated with few other members and had few direct communications. The most used communication feature of Facebook was likes in form of “thumbs-up”.

Conclusion
This study indicated that social media and in this case Facebook is used for communication and social support by persons with MACI and revealed that their communication behavior is similar to the healthy population. Further studies relating specific cognitive problems of the participants to the use of social media would provide more reliable results for this specific group.

Acknowledgements
This study was financed by the Health Informatics Centre, Karolinska Institutet and it has been part of in the PhD thesis of the main author [3].

Rapid Development and Distribution of Mobile Media-Rich Clinical Practice Guidelines Nationwide in Colombia

José F Flórez-Arangoa,b, M Sriram Iyengarc, Indira T Caicedod, German Escobarc

*College of Medicine, Biomedical Informatics Group, Texas A&M University, College Station, TX, USA
bEscuela de Ciencias de la Salud, Universidad Pontificia Bolivariana, Medellín, Antioquia, Colombia
cOficina de Calidad, Ministerio de Salud y de la Protección Social, Colombia

Abstract

Development and electronic distribution of Clinical Practice Guidelines production is costly and challenging. This poster presents a rapid method to represent existing guidelines in an auditable, computer executable multimedia format. We used a technology that enables a small number of clinicians to, in a short period of time, develop a substantial amount of computer executable guidelines without programming.

Keywords:
Practice Guideline, Multimedia, Telemedicine.

Introduction

Compliance with evidence-based Clinical Practice Guidelines (CPGs) by health workers, and consumers and caregivers) can result in improved patient outcomes [1]. The Ministry of Health in Colombia (MinSalud) has developed almost 60 CPGs across multiple specialties including pediatrics, infectious- and chronic diseases, and cancer. These are published as PDFs. Factors preventing widespread CPG use include guideline complexity, presentation as linear, non-interactive text, lack of multi-media. These make it very difficult for many to understand and comply with CPGs. Another issue is that it is impossible to track the usage of CPGs.

Methods

MinSalud sponsored a project that takes advantage of the widespread adoption of smart-phones (typically Android OS) in Colombia and a technology, originally developed at NASA, called GuideVue®(GV), for developing media-rich interactive guidelines (MRIGs) without programming. These MRIGs are executed on the web (http://gpcdigital.minsalud.gov.co) and also on Android smartphones. MRIGs, based on Persuasive Technology [2] and Felder-Silverman Learning [3] theories, have been shown to increase compliance, decrease errors and perceived workload among health workers [4]. After downloading on the smartphone, connectivity is not needed to execute these MRIGs. Usage tracking is one of the features of GV technology. Twelve healthcare professionals and an editorial coordinator converted PDF-based CPGs into MRIGs using GV Author, Windows software that enables MRIG creation, by using a visual, no-coding, point-and-click, drag-and-drop graphical user interface. Although none of these individuals had any training in programming they rapidly became proficient in GV Author. These MRIGs were carefully reviewed by MinSalud prior to release. Although the CPGs varied widely in scope, topic certain heuristics were designed to apply to all of them. These include: i) Each step expressing a single action, concept or decision, ii) No more than 5 decision choices in each step, iii) Color-coded decision buttons, iv) Still images and videos to assist in the understanding of the step’s content; videos only when an action is to be illustrated (e.g., performing exercises).

Results

In early 2016, a total of 116 MRIGs were created by 12 individuals in 8 weeks, covering 53 topics. Of these, 53 MRIGs were targeted to healthcare workers and 63 to consumers. The system was officially launched on 14/oct/16. Guideline changes can easily be propagated by editing the MRIG in the Author visual editor software. The project is sustained by MinSalud to enhance health literacy among both healthcare consumers and professionals.

Discussion

The GV Author software enabled a small number of non-programmers to create 100+ MRIGs in 8 weeks. These individuals were able to rapidly become productive, typically with only 4 hours of training. For almost all 53 topics two versions were created: one for healthcare professionals, the other for consumers. The consumer version explained the same topic in layman’s terms.

Conclusion

The technology described has great potential to support rapid development of media-rich clinical practice guidelines on web and smartphone platforms.

The Diffusion of mHealth Applications

Parisis Gallos, John Mantas

Health Informatics Laboratory, School of Health Sciences, National and Kapodistrian University of Athens, Athens, Attica, Greece

Abstract
The aim of this preliminary study is to present the usage behaviour of mHealth applications. A survey was conducted among 352 Smartphone users; 109 of them had used mHealth applications as well. The usage of these applications seemed to be quite low. Young people had used mHealth applications more than the elders. Also, there was not found a statistically significant relationship between the gender and the usage of mHealth applications.

Keywords:
Telemedicine, Mobile Applications; Surveys and Questionnaires

Introduction
A lot of attempts have been made lately on the development of mHealth applications [1-4] in Greece. Additionally, several studies have been made related to mHealth technologies [5,6]. According to relative surveys, mHealth applications usage has been doubled in the last two years [7]. The aim of this preliminary study is to present the diffusion of mHealth applications’ usage among Smartphone users.

Methods
A simple anonymous questionnaire was distributed on-line, over the social media, in order to record the stakeholders’ frequency of usage of mHealth applications. The questionnaire was in Greek language and included questions related to the usage of the mHealth applications. The size of the sample was 352 persons who were using Smartphones. The data analysis was conducted using the SPSS.

Results
Only 109 persons had used a mobile health application (31.1% of the total). The 33.9% of those were males and 66.1% were females. The average of the age was 26.54 years old, with Std. Deviation of 6.78 years. The minimum age was 18 and the maximum 58 years old. The median of the age was 25.50 years old. In the statistical hypothesis testing, age found to be related with the mHealth applications usage ($p = 0.03$). On the other hand, there was not a statistically significant relationship between the gender and the usage of mHealth applications ($p = 0.87$).

Based on the study findings, it can be assumed that the majority of the responders do not use any mHealth applications yet. This can be explained by the fact that there are not a lot of mHealth applications available in their language or maybe there are having thoughts about the validity of the applications’ content. Also, young people are using mHealth applications more than the elders as they might be more familiar with the mobile technology. In addition, males seems to use the mHealth applications as much as the females.

Conclusions
According to the results, it can be assumed that mHealth applications’ usage has a low diffusion on Smartphone users in Greece. Also, mHealth technology seems to be more popular among the youths. Current research actions include a further investigation of the mHealth technology diffusion, and the effect of this technology in people’s health status.

Warfarin Guide: Co-Design of a Mobile Computer-Assisted Anticoagulant Therapy

Martin Gerdes\textsuperscript{a}, Santiago Martínez\textsuperscript{b}, Berglind Smaradottir\textsuperscript{c}, Rune Fensli\textsuperscript{a}, Jarle Jortveit\textsuperscript{c}

\textsuperscript{a} Department of Information and Communication Technology, University of Agder, Grimstad, Norway
\textsuperscript{b} Department of Health and Nursing Sciences, University of Agder, Grimstad, Norway
\textsuperscript{c} Sørlandet Hospital HF, Arendal, Norway

Abstract

Patients with some types of cardiovascular disease are prescribed anticoagulation therapy with Warfarin in order to control the ability of blood clotting. This work presents a co-designed mobile application, called Warfarin Guide, for a computer-assisted anticoagulant therapy. The application addresses the challenges that unexperienced patients may find when having to remember to regularly check their INR values and make temporary adjustments for INR value fluctuations that are not easy to interpret without direct medical advice.

Keywords:
International Normalized Ratio, Computer–Assisted Drug Therapy, Medical Informatics

Introduction

Patients with some cardiovascular disease types, e.g., mechanical heart valves, are prescribed lifelong anticoagulation therapy with Warfarin to prevent thromboembolic complications. The intensity of the anticoagulation therapy is based on the International Normalized Ratio (INR) value. A low INR value indicates a risk of increased blood clotting which can cause life-threatening conditions, while a high value of INR indicates a high risk of bleeding. Food intake (especially vitamin K-rich vegetables), alcohol consumption, physical exercise, illness and stress may also influence the INR values. Patients treated with Warfarin are recommended to self-monitor their INR values with a portable coagulometer device that samples whole blood obtained by fingerprick, and self-management of the Warfarin therapy. It might be difficult, in particular for unexperienced patients, to regularly check their INR values and make necessary changes in warfarin dosing based on the measured values, in light of previous studies which have reported low time within therapeutic INR range.

The aim of this project is to develop an easy-to-use mobile application for computer assisted anticoagulation therapy. The project is divided in two phases: 1) a co-design, 2) a usability test of the application and 3) a randomised control trial. This work presents the results of the first phase.

Methods

The co-design process was carried out with 8 students of the Master of Health and Social Informatics’ at the University of Agder (UiA), Norway and iteratively tested in the Usability laboratory at UiA with patients who were prescribed an anticoagulant therapy.

The Master students co-designed a non-functional prototype of the Warfarin Guide application (WGA), and the explanation of their prototype was recorded on camera. The application developers watched the recordings and implemented a working prototype. The prototype was iterated through 2 usability tests with 5 anticoagulant therapy patients. The first test included a cognitive walkthrough process with an individual interview after using the application. The second test targeted specific tasks of the refined user interface.

Results

The co-design process allowed the Master students to create a non-functional prototype of the application, including different features based on their experience of working with patients prescribed with an anticoagulant therapy. The co-design provided developers with a useful insight about what was important for end-users, prioritising meaningfulness of messages and user friendliness of the user interface (UI). The cognitive walkthrough was useful to understand, step by step, how patients interacted with the application in order to obtain the exact dose, keep track of their INR values and set up a reminder for next dosage intake. The usability tests helped to iteratively improve the UI. The individual interviews allowed the research team to understand the way that the WGA could address users’ needs.

Conclusions

Self-management medication for anticoagulation therapy presents two challenges to unexperienced patients: remember and maintain a regular monitoring of their INR values; and calculate an exact dosage intake adjusted to the nonuniform fluctuations of INR values. The co-designed WGA tested in the laboratory provided an up-to-date monitoring of INR values and an individualised calculation of dosage adjustment, including a valuable reminder function for medication intake and upcoming measurements. The adherence, effectiveness and benefits of the computer-assisted anticoagulant therapy will be clinically verified in a clinical randomised control trial.

Acknowledgments

The authors would like to thank all the anticoagulant therapy patients who participated without bias in the project.

Patient-Clinician Co-Design Co-Participation in Design of an App for Rheumatoid Arthritis Management via Telehealth Yields an App with High Usability and Acceptance

Rebecca Graingera, Hermaleigh Townsleya, Tobias Langlotzc, William Taylora,b

a Department of Medicine, University of Otago Wellington, Wellington, New Zealand,
b Hutt Hospital, Hutt Valley District Health Board, Lower Hutt, New Zealand

c Department of Information Science, University of Otago, Dunedin, New Zealand

Abstract
People with chronic conditions like rheumatoid arthritis (RA) self-manage on a day to day basis. They may be able to assess disease activity and communicate this via an app to their healthcare team to enable clinical review for medical management at the most appropriate times. This work describes the successful co-design of a patient-held app for monitoring and communication of RA disease activity.

Keywords: Telehealth, Patient participation, Arthritis, rheumatoid.

Introduction
Traditional management of rheumatoid arthritis (RA) is by rheumatologist review 3 to 6 monthly. This is not sustainable in many healthcare systems as demand exceeds rheumatologist capacity, with these demands projected to increase. Mobile software (an application or app) could enable patients to provide remote monitoring of health status via patient reported outcomes (PROs), patient-performed joint counts, and electronic messages to health care professionals (HCP). This work aimed to 1. Assess opinions of people with RA and health care professionals (HCPs) regarding design and functionality of an app and acceptability and usefulness of an app assisted telehealth approach for RA, 2. Develop an app, and 3. Assess usability of the app.

Methods

Interviews
Semi-structured interviews were undertaken with people with RA (American College of Rheumatology 2010 criteria) and HCPs, recruited from a hospital rheumatology service. Interviews explored technology use, app functionality, barriers and facilitators to app use, and potential impacts of app implementation on service provision and experience. Thematic analysis was performed and recruitment concluded when saturation was achieved.

App Development
An app (RAConnect) was developed in iOS and Android in co-operation with professional software developers. App design and function was informed by interview data, along with design principles informing high user-experience.

App Usability
People with RA recruited from the hospital clinic trialed RAConnect on their mobile devices for one month. App usability was assessed using a “think aloud” interview post app download, an online survey which included the System Usability Scale (SUS) and free text feedback.

Results

Interviews
Nine people with RA (27-79yrs, 7 females, 1-26yrs of RA, low-moderate disease activity) and 11 HCPs were interviewed. Four themes were identified:

1. Variable app readiness.
2. Reduced barriers with high app usability and text message communication.
3. Pros and cons of PROs, with some ambivalence
4. Resource allocation and engagement - PROs reporting via an App is acceptable to guide HCPs in allocation of limited resource while also increasing patient engagement.

App Usability
Usability testing with 16 people with RA confirmed RAConnect had high usability (SUS 80/100, 90th centile). Both the app and a telehealth approach had high acceptability. “I think a wraparound thing like RAConnect would allow better spacing between appointments and for me it would make them less stressful.” 48 year-old Male. “I think that it has the potential to be very useful in managing my RA. It is easy to use and may mean less visits to the rheumatologist.” 49 year-old Male. “It’ll be a great tool for both the Doctors, their clinical staff and their patients.” 70 year-old Female.

Conclusions
A patient-held app for RA monitoring and communication with rheumatology care provider will be acceptable and desirable for many patients. Further research is required to develop multi-media material to train people with RA to perform joint counts and to validate patient-performed joint counts. During implementation assessment of the patient experience of using this telehealth system, disease outcomes, costs, and impact on workflow of HCPs will be required.

Rebecca Grainger: rebecca.grainger@otago.ac.nz
Competencies for Effective Use of Online Depression Information Among College Students

Yulong Gu*, Zornitsa Kalibatseva†, Xu Song*

*School of Health Sciences, †School of Social and Behavioral Sciences, ‡School of Arts and Humanities, Stockton University, Galloway, New Jersey, USA

Abstract

Mental health issues such as depression are rising among young people, who may benefit from online depression related information. However, the competencies required to search for and evaluate health information on the Internet were reported as poor among this population. We designed a web-based questionnaire survey including four case scenarios to understand how college students use online depression information, and what competencies or factors may facilitate effective use of the online resources.

Keywords:
- Depression; Internet; information literacy.

Introduction

Depressive disorders are common among college students in the United States (US), with 14.9% students reporting a diagnosis of depression in their lifetime [1]. Depression is a disabling condition, and is sometimes accompanied by self-harming behaviors. Among college-age Americans, suicide has remained a leading cause of death in recent years (ranked No. 2 since 2013) [2]. Evidence-based treatments for depression exist, but are not accessed by majority of the college students with symptoms. Depression information services and programs on the Internet have been developed partly in response to this challenge. These online resources hold promise to reach college students, to support them in self-help, and to encourage them to seek professional help. But little is known about the effectiveness of online resources outside of the laboratory setting. Although young people regularly use and are generally satisfied with online mental health resources, more research is needed to determine if these resources effectively facilitate help-seeking behavior [3]. Moreover, college students may feel comfortable searching health information online, but their information literacy, in terms of searching for information and evaluating the information quality may be poor [4]. To understand how well college students can search the Internet for depression information and what relevant competencies they have, we designed a web-based questionnaire survey.

Methods

The questionnaire includes four realistic case scenarios to assess a participant’s performance in finding and using online depression resources. In each case, the participant is asked to use the Internet to find answers to depression-related questions. We also ask participants to rate (in Likert scale) their health and information literacies. This questionnaire was piloted with two faculty and two students who confirmed its face validity. In November 2016, 168 students enrolled in six undergraduate classes at a US university were invited via class group emails to complete the web-based questionnaire survey. Additionally, 50 students were recruited through the university Psychology Research Pool. Data analysis aims to understand how well participants can use the Internet to answer questions, and what competencies / factors may facilitate effective use of online resources. The study protocol was approved by Stockton University Institutional Review Board.

Preliminary Results and Discussion

Among the initial survey respondents who completed the survey in the first week of the study period (N=149, median age=20; 79% female), 49% performed well in answering depression related questions in the case scenarios (>90% accuracy), and 29% had good depression knowledge (>90% accuracy). Less than half (44%) reported their health literacy level as moderate or higher (by familiarity with medical terms). More participants reported moderate or higher level of critical health literacy (73%) and information literacies (86%). The linear multiple regression model on all of the above knowledge and literacy factors indicates that the participants’ performance in cases is associated with their depression knowledge (p<.01) and self-reported information literacy level (p=.01).

Mental health issues such as depression are rising, with depression being the second contributor to global burden of disease. Information on the Internet may support people dealing with depression. Preliminary results detected suboptimal health literacy and depression knowledge levels, and the students’ depression knowledge and information literacy are significant predictors for effective use of the Internet. Thus, systematic training to develop these competencies may be necessary.

Flexible Detection of Fall Events Using Bidirectional EMG Sensor

Hao Han\textsuperscript{a}, Xiaojun Ma\textsuperscript{b}, Keizo Oyama\textsuperscript{c}

\textsuperscript{a} The University of Tokyo Hospital, Tokyo, Japan,  
\textsuperscript{b} The University of Tokyo, Tokyo, Japan,  
\textsuperscript{c} National Institute of Informatics, Tokyo, Japan

Abstract

Falling is one of the most serious life-threatening events for the elders, and the growing population of elderly people motivates the development of ICT-based healthcare-oriented solutions for fall detection prevalently. In this poster, a bidirectional EMG (electromyographic) sensor network model is proposed for a more efficient and flexible detection of fall events based on simple communication between users and nursing care staff.

Keywords: Fall Detection, Healthcare, Electromyographic Sensor

Introduction

As a nation running ahead of the curve in coping with the problems of an aging population, Japan has to face up the problem of a serious shortage of nursing care staffs in small and rural hospitals and healthcare facilities for the elderly. In this poster, we propose a wearable bidirectional EMG sensor network for flexible communication between users and nursing care staffs, and explain that this solution performs more realistically and rationally.

Wearable Bidirectional Sensor Network

For fall prediction, the analysis of health and medication data extracted from EHR (Electronic Health Record) is conducted [1]. However, it cannot realize a real-time prediction. Single-direction communication, such as surveillance camera and nurse call, is inefficient, and a simple "call/reply" interactivity is more effective in falls prevention [2] and can reduce workload of nursing staffs. We aim to detect falls with high positive predictive value and sensitivity, which means most real falls are correctly detected and less false falls are wrongly recognized. An interactive communication is provided between nursing care staffs, users, and the sensor network for releasing nursing workloads. When the fall prediction works, the users are soon warned, and when the fall detection fails, nursing staffs are called for helps through a light and easy-to-use interface.

An armband-type EMG sensor is imported to evaluate and record the electrical activity generated by skeletal muscles since arms give a sudden movement naturally and instinctively to stop falls. The sensor is also equipped with Wireless LAN, gravitational acceleration and gyroscope sensor. Through wearable sensor, the live logs are collected and stored in real-time. Live logs contain the continuous information of location (estimated by trilateration), status of movement and arm electromyogram data of users. The nursing staffs can learn the status of target users through the monitoring anytime. The collected live log is analyzed in real-time, and the fall alarm (location and user profile) is sent to nursing staffs if a fall event is detected (one of fall patterns is matched). Moreover, a vibration "call" (trigger built-in vibration motor) is remotely sent to the sensor as a confirmation for a possible "reply" from the detected target user. The nursing staffs run to the fall location to help fallen users, or stop the help if they receive a cancellation "reply" from the user. Here, by repeating a predefined special hand gesture (e.g., hold fist and rotate) which is seldom occurred in general life and easily learnt by the elderly, users can send a "call/reply" message to the system as a simple and quick communication between users and nursing staffs when a wrong or missed detection happens. Moreover, based on the analysis of personal activity patterns, fall history records, profile information and various statistics (e.g., dangerous areas like stairs), a user-oriented customizable prediction mechanism is constructed. If a possible coming fall is predicted, a notification "call" is sent to the sensor as a warning message.

Results

Thirteen (13) panel users assisted our experimental data collection by wearing the armband sensor on their right forearms in activities of walking/sitting/falling/leaning (arms against wall to stop a fall). Through the raw data, we can find that the acceleration and gyroscope sensor data are not adequate enough to clearly recognize the falling since there were many slow-falling instead of sudden and fast falling. Therefore, the analysis of EMG data would contribute to a more precise fall detection as an important detection factor since there were violent fluctuations in the signals of sensors at muscle near ulna and radius when the users fell or almost fell (leaning). Here, positive predictive value = 81.8% and sensitivity = 69.2%, which performs better than sensors without EMG data.

Conclusion

A model of bidirectional EMG sensor network is designed to detect/prevent elder-oriented fall events, and EMG data was proved to be contributing factors of a more precise detection and prediction result. As future research, we plan to explore further the problems of fall pattern learning and recognition based on gathering more real data.

Design of Rehabilitation Treatment Coach Robot

Seung-Ho Han, Han-Gyu Kim, Chan-Yong Park, Ho-Jin Choi

School of Computing, KAIST, Daejeon, Korea

Abstract

In the rehabilitation treatment for at-home patients, it is not only costly for a patient to hire a professional therapist or personal trainer, but also time consuming for a therapist or trainer to visit all the patients. To improve the situation, we propose the rehabilitation treatment coach robot which helps the patient to do rehabilitation exercises alone. Designed economically with cheap parts, our robot provides multiple functions: rehabilitation program suggestion, rehabilitation posture correction, and emergency detection. A brief plan is presented for data collection and performance evaluation.

Keywords: Exercise Therapy, Robotics, Neural Networks (Computer)

Introduction

Rehabilitation treatment helps patients with various physical or neurological diseases to restore physical or mental capabilities. It is important for the patient to practice consistently the given treatment until it is cured. In case of at-home patients, however, it is costly to hire professional therapists or personal trainers. Moreover, doing exercise alone can exacerbate the patient's condition if an improper posture or program is adopted. In order to help this situation, we propose a rehabilitation treatment coach robot. The robot not only helps the at-home patient to exercise alone, but also is designed to be cheap enough.

Methods

In order to design the robot as cheaply as possible, we use the most basic hardware, such as Microsoft Kinect, a display with touch sensors, a processor, a battery, and wheels with electric motors. Such rehabilitation coach robot has three functions: rehabilitation exercise suggestion, rehabilitation posture correction, and emergency detection.

The rehabilitation program suggestion module will recommend proper exercises to the patients for quick rehabilitation. The suggestions of rehabilitation program is mainly decided by communications with doctors.

In case of the posture correction module, the robot should be able to recognize the posture of the patient first. To do this, we use the Microsoft Kinect and its SDK that facilitates an extraction of the human skeleton data using built-in sensors. And then, since deep neural network (DNN) based posture recognition [1] is already shown good performance, we will train the model using deep learning algorithm to determine whether the posture is correct or not by using the skeleton data as an input to the model. Lastly, we will correct the posture of the patient using the output of the model.

In order for the robot to detect the emergency situation, we use the voice from the microphones and video input from cameras as an input to the DNN model [2]. Using this model, our coach robot automatically recognizes the emergency situation and calls the doctor.

Experiment Plan

We plan to collect datasets for each module in the following ways. For the speech recognizer, the speech data is collected from at least 50 persons, and for posture correction module, the correct and incorrect postures are collected from professional trainers and ordinary persons. For emergency detection module, some emergency scenarios are designed and the datasets are collected from those scenarios.

We plan to use two evaluation criteria: automatic evaluation and human evaluation. For automatic evaluation, the criteria of evaluation is predefined for each module individually. For human evaluation, overall performance of the robot is evaluated by a group of therapists, trainers and patients.

Conclusions

In this paper, we have proposed a coach robot that helps and assists at-home patients during rehabilitation exercise alone. Designed with cheap parts, the robot has several main functions: exercise suggestion, posture correction, and emergency detection. We have presented our experiment plan for data collection and evaluation.

A Patient Centric Nursing Mobile App Redesign

Navas Hernán\(^a\), Dozo Mariano\(^b\), Dourado Ezequiel\(^b\), Canteros Fernando\(^b\), Rung Ingrid\(^a\)

\(^a\) Sanatorio Finochietto, Buenos Aires, Argentina, 
\(^b\) Gizmedic, Buenos Aires Argentina.

Abstract

Sanatorio Finochietto has a nursing mobile app that allows safely preparing and administering medications. Hospitalized patients care experience is influenced by the system, the care process and nurse response, in this context, technology acts as a facilitator for care and humanized treatment. A "Patient-Centered Management System" would assist caregivers and patients to make individualized decisions about optimal care. This paper describe a paradigm shift to a mobile patient centered nursing application.

Keywords:
Electronic Health Record, Mobile Applications, Patient-Centered Care.

Introduction

Sanatorio Finochietto has a mobile solution for nurses that allow safe and fast administration of medicines and mobilize nursing processes [1]. A "Patient-Centered Management System" would assist caregivers and patients to make individualized decisions regarding optimal care for common clinical situations. It should also explicitly incorporate patient preferences, and would reinforce such decisions through patient focused performance measures.

This paper aims to describe a paradigm shift on a mobile app for nurses, initially developed to simplify nursing processes and redesigned to serve a patient centered model.

Methods

A multidisciplinary team was gathered to address this issue, including nursing leaders, user experience designer and developers experts, IT department members, and process specialists. The team analyzed nursing processes and tasks in different services of the institution, including interviews with users to know their opinions on the existing mobile app and their requirements, and observing users on their daily routines. The team also analyzed usage data from the existing mobile application (for drug administration) to identify heavy users and value their comments on the app [2].

After three years utilizing and improving the initial mobile app, the team focused on shifting from the nursing processes centric app to a patient centric version. To be able to achieve this objective, the patient will be the starting point of all nursing activities. Instead of being able to access all potential tasks, nurses will have a redesigned app which will display the list of assigned patients once the user logs in.

The beginning of the care process will be given by a portal that will provide information for each patient. This change will allow the nurse to have more information about the patient before beginning the care process. With this, the personal context of each patient will be present in every interaction.

Results

The multidisciplinary team decided gradual deployment of the app. This allowed all stakeholders to participate on the process and be prepared for the changes the app brought. The gradual deployment started with functionalities related to information visualization. Later on simple records of information were incorporated, until completing all the services developed until today. The user's feedback and constant monitoring of the process led to issues related to daily use of this sort of app and to identify users’ needs. The earned knowledge are the base of all the changes planned for the app redesign.

Conclusion

The formation of the multidisciplinary work team together with user's involvement throughout the process generated a positive feedback with the nursing area. This led to motivating the nursing team to participate actively on the deployment of new phases of the solution, facilitating the implementations.

The nursing mobile app new format should simplify how to adapt tasks and processes to different type of patients (adult in general admission, obstetric patient, adult intensive care unit, or neonate intensive care unit), guiding the user in the specific context of each patient and allowing for a more assisted process for the nurse while doing their tasks.

Connecting PHRs and EHRs for a Sustainable National Health System

Evelyn Hovenga RN PhD FACHI FACS FACN, Heather Grain A Dip HIM G Dip IS MHI FACHI

eHealth Education Pty Ltd, East Melbourne, Victoria, Australia

Abstract
An EHR for integrated care (IEHR) is defined by the International Organization for Standardization (ISO) [1]: “…a repository of information regarding the health status of a subject of care, in computer processable form, stored and transmitted securely, and accessible by multiple authorised users, having a standardized or commonly agreed logical information model that is independent of EHR systems and whose primary purpose is the support of continuing, efficient and quality integrated health care. It contains information which is retrospective, concurrent and prospective.” We need to differentiate between EMR/EHR and the lifelong PHR in terms of type of data storage, sharing and use [2-3].

Keywords: Medical Records, Integrated Health Care Systems, Personal Health Records

Introduction
EMR/EHR: episodic medical/health record documenting all events managed by one healthcare service provider in real time and in sufficient detail enabling decision making.

- Data sharing and secondary data use purposes:
  - National policy evaluation and development
  - Personal health observations incl. fitness, wellness monitoring.

![Figure 1: PHR-EMR continuum](https://en.wikipedia.org/wiki/OpenEHR)

<table>
<thead>
<tr>
<th>PHR</th>
<th>EMR/EHR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Individual controlled health record</td>
<td>Information exchange or shared use, under mixed governance models</td>
</tr>
<tr>
<td>Healthcare provider controlled health record</td>
<td></td>
</tr>
</tbody>
</table>

There need to be stringent data management requirements for all data managed by healthcare providers to ensure data integrity, completeness, meet medico-legal requirements and to protect confidentiality. Connectivity and interoperability continue to be huge challenges to be addressed globally.

Methods, Results, and Conclusions

Connectivity and Semantic Interoperability

- Agreed platform & national reference architecture [4]
- Agreed set of datatypes
- Well managed unique identifiers
- A standard ‘language’ & terminologies
- Data sharing agreements between custodians
- Governed agreed minimum data sets.
- Governance of clinical knowledge stored in computable formats.
- Global equipment/supplies catalogue standard
- Legislation and regulation supporting these interoperability principles.

Intelligent Digital Environment for Wellbeing and Health

Inga Hunter\textsuperscript{a}, Caroline Lockhart\textsuperscript{a}, Phoebe Elers\textsuperscript{a}, Dick Whiddett\textsuperscript{a}, Hans Guesgen\textsuperscript{b}

\textsuperscript{a}School of Management, Manawatu Campus, Massey University, Palmerston North, New Zealand
\textsuperscript{b}School of Engineering and Advanced Technology, Manawatu Campus, Massey University, Palmerston North, New Zealand

Abstract

This three-phase project seeks to identify the user-requirements and develop a novel and unobtrusive technology platform interpreting and integrating diverse sources of information from a variety of digital devices monitoring the health and wellbeing of an older person with social media networking. This technology platform will communicate that information within an individualised support network thus supporting the older person to "age in place". This poster presents the process and preliminary results of phase one.

Keywords:
Technology; Delivery of Health Care; Social Networking.

Introduction

Developed countries are experiencing an ageing population, often with complex health problems, placing unsustainable demand on health care services [1]. Staying at home in age-friendly communities supported by primary health care and family (age-in-place) is a preferred option of older people, can provide better quality of life and be a more sustainable model of care enhanced by information technology [1, 2].

Smart home information technologies (sensors, recording devices, etc.) create intelligent environments that monitor and control the environment, track activities of daily living, and recognise significant departures from normal behaviour [3]. Social media networks offer many-to-many (M:N) relationships between the older person, family/friends, aged care workers and health providers, widening and individualising the care/support network of the older person.

Despite the relative maturity of smart home and social media technologies, they have not been integrated within the ‘ageing in place’ model of care and there is a lack of research into the socio-technical aspects of information sharing using social media that this project seeks to fill [4, 5].

Methods

A literature review identified key questions for an expert group workshop. The workshop was conducted with 24 attendees of the annual conference of Health Informatics New Zealand, a member society of IMIA. A many:many (M:N) collaborative information flow model was developed to facilitate discussion (Figure 1).

The outer ring represents health providers, the middle ring the older person’s support network and the inner ring the older person. Information can flow within and between each ring in any direction. Responses were analysed by thematic analysis.

Results

Key themes for user requirements were identified:

1. Data and Information – methods of data retrieval, processing and interpretation;
2. Connection and Collaboration – impact of digital connection on education, wellness and user roles;
3. Autonomy and Control – technologies’ impact on user autonomy and control.

The respondents identified that sharing information on health and wellbeing to identify early deterioration in health status was more important than sharing specific illness information.

Conclusions

Existing literature primarily focuses on the problems with smart home/social media technology adoption. The workshop themes suggest user requirements to resolve these problems which will be further investigated in phase two with semi-structured interviews/focus groups with older people, members of their support network and health providers. Phase three will use a co-design with end-user development process.

Abstract
This paper describes development of mHealth application ‘mWellcare’ for the integrated management of hypertension and diabetes in public primary health care settings. mWellcare application was developed in four phases: identifying gaps in usual care; identifying components of intervention; developing intervention; evaluating acceptability and feasibility through pilot testing. Final version of mWellcare application is capable of computing personalized evidence-based management plan for hypertension, diabetes and co-morbid conditions (depression and alcohol use disorder).

Decision Support Systems, Clinical; Primary Health Care; Chronic Disease.

Introduction
Cardiovascular diseases (CVD) and diabetes are among the leading causes of premature adult deaths in India [1]. Systematic reviews have shown that mHealth based Decision Support System (DSS) improves preventive care and physician’s clinical decision quality in hypertension and diabetes management[2]. The aim of this paper is to describe the steps and processes in the development of mWellcare, a complex intervention based on mHealth technology.

Methods
We used the framework for the development of ‘complex’ interventions proposed by the Medical Research Council (MRC), United Kingdom[3]. Based on this framework, we followed these steps: 1) Identifying the gaps in usual care; 2) Identifying the components of intervention; 3) Development of intervention components; and 4) Evaluating acceptability and feasibility through pilot testing.

Results
The mWellcare system platform is built with Python using django web framework, mobile application is driven by an XML application configuration layer with JavaRosa at the core and database is Couch DB. Standards used for its development are ICD 10 for diagnosis, LOINC for lab results, UIDAI (Unique Identity Authority of India) Aadhaar for patient identification, HL7 for messaging, CCD for clinical document exchange. It is used by primary care nurses and doctors and has the ability to: store and integrate longitudinal health records electronically; provide automated guideline-recommended treatment plan and life style advices tailored to patient clinical profiles; enables longitudinal patient monitoring and alerts to the need for changes in management; send out automatic short-messaging services (SMS)reminders and alerts to patients ; serves as data collection tool for remote quality assurance of NCD programs; and exports standards compliant healthcare data to relevant receiving healthcare systems. mWellcare system is currently in use in 40 community health centers in two states of India, Haryana in the north and Karnataka in the south.

Conclusions
We have described the process of development of a mHealth intervention seeking to improve the integrated management of hypertension and diabetes in primary care level. The effectiveness and cost-effectiveness of the intervention is currently being evaluated in a cluster randomized controlled trial in India (trial registration number NCT02480062).

How Are Doctors Using Mobile Electronic Medical Records? 
An In-Depth Analysis of the Usage Pattern

Juntae Kim\textsuperscript{a}, Yura Lee\textsuperscript{b}, Sanghee Lim\textsuperscript{c}, Jae-Ho Lee\textsuperscript{b,d}

\textsuperscript{a} KAIST 85 Hoegiro, Dongdaemun-gu, Seoul Korea, 
\textsuperscript{b} Department of Biomedical Informatics, Asan Medical Center 88 Olympic-ro 43-gil, Songpa-gu, Seoul Korea 
\textsuperscript{c} The Johns Hopkins Carey Business School 100 International Drive, Baltimore, MD 21202, USA 
\textsuperscript{d} Department of Emergency Medicine Asan Medical Center 88 Olympic-ro 43-gil, Songpa-gu, Seoul Korea

Abstract

In recent years, major hospitals have started using mobile electronic medical records (m-EMR). However, usage patterns based on actual log data have rarely been discussed. In this study, we investigated usage patterns of a m-EMR in several dimensions to understand the m-EMR in depth.

Keywords:
Telemedicine, Electronic health records, Hospitals, Clinical laboratory information systems

Introduction

Recently, major hospitals have started using mobile electronic medical records (m-EMR) in practice; evidence suggests that they are underutilized [1]. Prior studies primarily focused on the design of m-EMRs and the behavioral factors that influence their adoption. Few studies have investigated use patterns using an actual m-EMR record. An in-depth understanding of these patterns based on real logs is important for illustrating the value of using an m-EMR. We aimed to scrutinize the usage patterns of m-EMR by investigating usage patterns of an m-EMR designed to access hospital information systems (e.g., Picture archiving and communication system and laboratory information system).

Methods

We examined an m-EMR with 13 menus used by the biggest hospitals in South Korea. We collected 524,345 records from 653 doctors (272 residents, 174 fellows, and 246 professors) March 2015- December 2015. We excluded 625 logs for two non-physician menus. We performed descriptive analysis in five perspectives: hourly units, daily units, user positions (rank), departments, and menus.

Results

The frequency of use differed between time units and days (Figures 1-2); 2) The frequency of use depends on doctor rank and department type; and 3) usage distributions of each function by department and time unit were found.

Discussion

Doctors used the m-EMR early in the morning (6-9 am) and most often on Sundays. An m-EMR was used when the doctor could not access EMR through PC. The usage by resident surgeons was very low. Investigating factors related to the low use of m-EMR by resident surgeons is needed. Since menus can be interrelated, we expect that clustering analysis will provide useful insights.

Conclusion

The use of m-EMR in clinical practice was early and there was little evidence of successful assimilation of m-EMR in major hospitals. Thus we believe that much research is needed to improve the use and functions of m-EMR.

A Content Analysis of Mobile Apps for Chronic Kidney Disease Patient Care: Searching in English and Chinese

Ying-Li Lee*a, Yan-Yan Cui*b, Polun Chang*b

*aDepartment of Nursing, Chi Mei Medical Center, Tainan, Taiwan, China
bInstitute of Biomedical Informatics, National Yang Ming University, Taipei, Taiwan, China

Abstract

Chronic kidney disease (CKD) is a global public health issue. Mobile technology is pervasive and widely used in chronic disease care. More and more, CKD mobile applications (apps) can be found on popular mobile application platforms, especially in Chinese. We aim to explore current mobile apps for CKD patient care (searching in English and Chinese) through content analysis to identify the app functions that health professionals can use in CKD patient care and to help CKD patients with self-management.

Keywords:
Mobile Applications; Renal Insufficiency, Chronic; Self Care

Introduction

The prevalence of CKD worldwide is on average around 13.4% (11.7-15.1%) [1]. According to Diamantidis and Becker, patients with CKD would ideally have confidential and convenient mobile access to their therapy plans and medical records [2]. Various CKD-related mobile apps in different languages can be found on several popular mobile application platforms. We aimed to explore currently available mobile apps for CKD patient care (searching in English and Chinese) through content analysis, a common method for exploring the content and functions of mobile apps, to identify functions that health professionals can use in CKD patient care and to help CKD patients with self-management.

Methods

Two researchers with prior training in coding principles searched the Apple store, Google Play, and 360 mobile assistant using the keywords "Kidney", "Renal", "Nephro", "Chronic Kidney Disease", and "CKD". We included apps that were related to CKD care and that could be used on smartphones or tablets, but excluded journals, medical conference manuals, hemodialysis-related or inoperable apps. The content and functions of the programs were coded separately by two people. The target users (health professionals, patients or both) were determined according to the actual function content. Two coders compared and discussed the coding results to achieve consensus. If no consensus was reached, a third researcher reviewed, there are 64 that target health professionals as users. Following exclusion based on default criteria, 166 CKD-related apps were left for the analysis. In all, 27.11% of the reviewed apps had a final release in a recent year. The main app language was English (51.81%), followed by Simplified Chinese (18.67%), and 11 apps that were multilingual. Also, 69.28% apps were free, 19% had privacy claims, and 39.76% required registration.

Results

As of June 5, 2016, we identified 105 apps available from the Apple store, 130 apps on Google play, and 69 apps on the 360 mobile assistant. After deduplicating, 189 apps were remaining.

Conclusions

The study shows that the functions of current CKD mobile apps are to support various types of numerical calculation and provide information about disease and nutrition care. The Simplified Chinese language APPs were developed to support patient and physician interaction. We suggest that CKD mobile apps be designed to protect the confidentiality of data, to assist patients in self-management, and to aid health professionals with individual patient management.

Developing Mobile Health Management System for Patients with Musculoskeletal Tumor

Nai-Wen Liang a, Hung-Yi Liu a, Chun-En Chien a, Qi-Guang Chen a, Po-Lun Chang a, Wei-Ming Chen b, Bo-Gui Wu b

a Institute of Biomedical Informatics, National Yang-Ming University, Taipei, Taiwan, China
b Division of Joint Reconstruction, Department of Orthopedics, Taipei Veterans General Hospital, Taipei, Taiwan, China

Abstract
This research provided a postoperative system for osteosarcoma which is separated into two parts, Bone Patient and Bone Care. We focus on using smartphone features and proper interface design to facilitate self-monitoring, health analysis, and to make appointments. It achieves the effects of shared decision making (SDM). During the two weeks of research, we achieved satisfied with 4.03 ± 0.67 TAM score.

Keywords: Telemedicine; Osteosarcoma; Decision Making.

Introduction
Osteosarcoma patients are more likely to be cured if they are cancer-free five years after diagnosis or if they have completed chemotherapy, including regular physical examinations and/or medical tests [1]. In the past, inefficient phone interviews were used to track patients’ situations.

Methods
In this study, we developed two functions: Bone Patient, for osteosarcoma patients and Bone Care, for case managers (Figure 1).

We used Android “navigation drawer” and “card collection”. As a server receives the record, it is saved into a MySQL database. Bone Patient includes file uploading, follow-up visit, inspections, self-evaluation, questionnaires, health education, and related links. Bone Care includes to-do-lists and completed tasks. We applied primary data collection with the use of judgment sampling, like basic personal information about patients, the test of TAM and integrated advice.

Results
The system made it easier for patients to make appointments. Also, the camera and voice recorder helped to describe symptoms and pain. It made it simpler for case managers to arrange and sort appointments by date or urgency (Figure 2).
Setting the Agenda for Personal Health Records in Low- and Middle-Income Countries

Thomas Mwogi* and Martin C. Were

* Institute of Biomedical Informatics, Moi University, Eldoret, Kenya, 
Department of Biomedical Informatics & Medicine, Vanderbilt University, Nashville, TN, USA, 
† Vanderbilt Institute of Global Health, Vanderbilt University, Nashville, TN, USA

Abstract
In the developed world, Personal Health Records (PHRs) have been demonstrated to improve patient adherence, reduce medical errors, improve patient-provider communication, improve chronic disease management, and promote behavior change. PHRs have not been widely adopted in low- and middle-income countries. There is rising use of smartphones, adoption of national-level electronic health systems, and change in historical perceptions on acceptance of technology. It is thus an opportune time to critically examine the potential role and approaches to PHRs in LMICs.

Keywords:
Health Records, Personal; Telemedicine; Smartphone

Introduction
In developed countries, PHRs have been demonstrated several benefits[1, 2]. The literature describes three predominant models of PHRs implementations, namely: Stand-alone, Web-based, and Integrated PHRs.

In general, Integrated PHRs show greater benefits when compared to the other types of PHRs [2]. In developed countries, PHRs are in wide use, but these systems are yet to be widely adopted in Low- and Middle-Income Countries. Several factors make this an opportune time to reconsider the role and feasibility of PHRs in LMICs. In particular, the exponentially increasing ownership of powerful smartphones and tablet devices, and the widespread and national-level adoption of Electronic Health Record systems (EHRs) make it highly feasible to adopt integrated PHRs that can be availed to individuals within LMICs.

An Approach to Implementing PHRs in LMICs

PHRs implementations in LMICs need to be supported with rigorous evidence. This is particularly important given that implementation can introduce new challenges around data privacy, security, literacy, and patient-provider relationships[1].

Given that integrated PHRs provide the most benefit, it is highly recommended that emerging PHRs for use within LMICs are integrated with nationally-endorsed EHRs. Figure 1 provides a schematic of such an integration with the OpenMRS EHRs that is being widely deployed in LMICs. Core to the PHRs agenda is to define perceptions on PHRs and desired core features (Table 1). There also needs to be a multi-dimensional and comprehensive approach to the agenda for implementing PHRs (Table 2).

Empathy Bot: Conversational Service for Psychiatric Counseling with Chat Assistant

Kyo-Joong Oh, DongKun Lee, ByungSoo Ko, Jonghwan Hyeon, Ho-Jin Choi

School of Computing, KAIST, Daejeon, Korea

Abstract

There are earlier studies for psychiatric counseling using chat bots. These studies have not considered the user’s emotional status and ethical judgment to provide interventions. This paper proposes an intelligent assistant for psychiatric counseling that understands dialogues using high-level features of natural language understanding, and multi-modal emotion recognition. A response generation model using machine learning provides suitable responses for clinical psychiatric counseling.

Keywords:
Psychiatric Nursing; Emotional Intelligence; Natural Language Processing

Introduction

Chat bot is intelligent assistant software that responds to the users as conversational interaction. In an early study, Roberts et al. have developed a chat bot providing interventions to change subsequent behaviors for young adults who have alcohol risk [1]. Elmasri and Maeder provide emotional responses for mental health care according to user’s behaviors and dialogues with a online chat bot [2].

In this paper, we propose a chat assistant called “Empathy Bot” which provide interventions and emotional responses for mental health care in a chat bot platform. We develop a deep interaction model that understands emotions and dialogues based on emotion recognition and natural language processing.

Methods

Empathy Bot consists of two parts; multi-modal emotion recognition, and natural language processing.

Multi-modal Emotion Recognition

To provide psychiatric counseling, we have to recognize user’s emotional status in communication through text, voice, and visual expression. To recognize user’s emotion, the service applies multi-modal emotion recognition methods from dialogues, intonation, and facial expression. The methodologies enable continuous observation of emotional changes sensitively.

Natural Language Processing

The empathy bot, which provides conversational service for psychiatric counseling collects and summarizes the dialogues of text. For the intelligent response we apply case-based reasoning, continuous long-term monitoring, and ethics judgment, etc. As to response generation for psychiatric counseling, we apply a hybrid of template-based and machine learning-based approaches.

Conclusion

We have presented a chat bot called “Empathy Bot”. More accurate emotion recognition based on multi-modal approach and appropriate responses based on clinical psychology with ethical judgment showed better satisfaction to users who need psychiatric counseling for mental health care.

Factors Influencing Progress of Health Information Exchange Organizations in the United States

Lauren M. Overhage\textsuperscript{a,e}, Jennifer Covich-Bordenick\textsuperscript{b}, Xiouchun Li\textsuperscript{c,e}, J Marc Overhage\textsuperscript{d,e}

\textsuperscript{a} Adler University, Chicago, IL, US, \textsuperscript{b} eHealth Initiative, Washington, DC, USA
\textsuperscript{c} Indiana University School of Medicine, Indianapolis, IN, US, \textsuperscript{d} Cerner Corporation, Kansas City, MO, USA
\textsuperscript{e} Regenstrief Institute, Indianapolis, IN, USA

Abstract

Progress is being made toward improved healthcare interoperability in the United States, but exchange between electronic health records alone is insufficient. Using data from the eHealth Initiative’s Annual Survey of Health Information Exchange, we developed models of HIE financial and operational progress. Our analysis suggests that organizations that focus on enabling exchange thorough education and policy need to be considered separately from those focused on the actual exchange. The associations between characteristics and progress in data exchanging HIEs suggest that diversity of participants as both originators and receivers of data and breadth of data are important underlying success factors.

Keywords:
Health information exchange; Program evaluation; United States

Introduction

Health Information Exchange organizations (HIEs) have emerged as one component of a multifaceted approach to enabling interoperability in the US. Some, however, have questioned the viability of HIEs [1, 2]. In order to understand the factors that may be important in sustainability of HIEs, we undertook an analysis of data from the eHealth Initiative’s annual survey of organizations and initiatives working in the area of health information exchange in order to validate other’s findings and to model the progression of HIEs using longitudinal, contemporaneously collected data.

Methods

We used data from the eHealth Initiative’s (eHI) annual survey on Health Information Exchange. We used responses to the questions which were the same or, that we judged to be sufficiently similar, from the surveys in 2006, 2007 and 2008—a total of 334 in all. In order to establish useful and meaningful taxonomy of HIEs, we reviewed previous publications describing HIEs, created multidimensional visualizations and then used a modified Delphi process to define taxa.

We grouped initiatives reporting their progress stage as 1 through 3 as not yet operational; those reporting stage 4 as pilot and HIEs that characterized themselves as stage 5 through 7 as operational. Because HIEs might be optimistic in their self-classification, we adopted a data driven definition as well. We calculated Spearman correlations using SAS\textsuperscript{8} to find correlation coefficients for the predicted stages of HIEs.

Results

Based on our definitions we found that only 117 (76%) of the 154 HIEs responding to the survey we focused on exchanging data and of those only 42 (27%) were operational in 2008. Progress is, however, not linear. Only a minority (16%) of HIEs regressed year to year with approximately 40% progressing. A large majority of the HIEs were able to correctly predict their own developmental stage on eHI’s maturity model for the upcoming year with Spearman correlation coefficients of 0.89, 0.88 and 0.93 for 2006, 2007 and 2008 respectively. The variables with the highest odds ratios in association with financial progression from highest to lowest were hospital as a receiver of data, one time or recurring fees from participants, receiving grants, laboratory or radiology as a data provider and ambulatory physician as a receiver (all p<0.01). The variables associated with operational progression were hospital as receiver, ambulatory physicians as receivers, laboratory or radiology as a data provider, one time or recurring fees, having received grants and sum of the unique types of participants (all p<0.01).

In the multivariate analysis, using all the independent variables of interest to predict the two outcomes, none of the independent variables had significant impact. When we examined pairwise correlations among the independent variables most of them are significant, which indicates strong multi-collinearity (highly correlated predictor variables) making simple interpretation of the regression coefficients as measuring marginal effects from the multivariate model unwarranted.

3D Documentation of Chronic Wounds Using Low-Cost Mobile Devices

Ekaterina Sirazitdinova\textsuperscript{a} and Thomas M. Deserno\textsuperscript{b}

\textsuperscript{a} Department of Medical Informatics, Uniklinik RWTH Aachen, Aachen, Germany
\textsuperscript{b} Peter L. Reichertz Institute for Medical Informatics, University of Braunschweig, Braunschweig, Germany

Abstract

The state-of-the-art wound assessment is manually performed by clinicians. This is ineffective and imprecise. Special devices have been developed for automation, but they are expensive and often lack portability. We present a concept of a low-cost system for wound documentation and analysis. Using computer vision techniques, 3D reconstructions of wounds can be created from images taken with a simple camera, such as those embedded in mobile phones.

Keywords:
Wound Healing, Documentation, Imaging, Three-Dimensional

Introduction

We aim to provide a new standard for documentation of chronic wounds by introducing an automatic 3D method for wound reconstruction followed by automatic analysis of the lesion. Our goal is to make the technology inexpensive, connective, and available for broader use.

Method

Images and inertial measurement unit (IMU) data are recorded using the interactive mobile app (Figure 1).

\textbf{Figure 1 – System architecture}

For 3D reconstruction, we adapt a method, where dense tracking is performed in each recorded frame [1]: camera positions are estimated using a dense feature-free monocular camera tracking and corrected using the information from the IMU. Based on the overlap between images, selected key-frames are rectified according to the camera position of incoming frame and dense stereo matching is performed using stereo block matching. The acquired depth maps are integrated into a volumetric model using the KinectFusion algorithm [2].

\textbf{Result}

Our system design is composed of two loops (Figure 2).

\textbf{Figure 2 – Processing chain}

Conclusions

A concept of a system using inexpensive consumer-level hardware for 3D wound reconstruction is presented. A novel approach to 3D reconstruction using mobile devices equipped with a single RGB camera is adopted into the medical domain. Accompanied with color correction, tissue segmentation, and tracking over time, the proposed system design is capable of providing objective and quantitative measurements of wounds.

A Document-Based EHR System That Controls the Disclosure of Clinical Documents Using an Access Control List File Based on the HL7 CDA Header

Toshihiro Takeda a, Kanayo Ueda b, Akito Nakagawa a, Shirou Manabe a, Katsuki Okada a, Naoki Mihara a, Yasushi Matsumura a

a Department of Medical Informatics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan
b Division of Medical Informatics, Osaka University Hospital, Suita, Osaka, Japan

Abstract

Electronic health record (EHR) systems are necessary for the sharing of medical information between care delivery organizations (CDOs). We developed a document-based EHR system in which all of the PDF documents that are stored in our electronic medical record system can be disclosed to selected target CDOs. An access control list (ACL) file was designed based on the HL7 CDA header to manage the information that is disclosed.

Keywords: Electronic Health Record, Information Management, Medical Records Systems.

Introduction

To facilitate the smooth continuation of medical treatment, it is necessary to share medical information between care delivery organizations (CDOs). Because electronic medical record (EMR) systems have been widely implemented in Japan, the data entered into the EMR database must be transferred to the electronic health record (EHR) database. Various standardized data can be shared via the Japanese standard repository, SS-MIX [1]. However, the existing EHR systems have two major problems: 1) it is still difficult to share non-standardized data, and 2) the EHR system does not offer detailed control of the documents that are to be disclosed. Our hospital implemented a document-based EMR system called DACS [2]. In this system, print images of all medical records generated by the EMR systems were stored in the DACS database in the PDF format. In this study, we demonstrate the document-based EHR system.

Methods

The existing EHR system was used for network security (OD-VPN), user management and patient management. The standardized data are opened using the existing EHR function. The non-standardized data can be opened from the DACS database as PDF documents. The doctor can disclose all clinical documents with the selection of the target CDOs and the documents to be disclosed. We designed an access control list (ACL) file based on the HL7 CDA header to manage the settings for document sharing. The ACL file includes document information (document ID, version, document class code, document title and event date), patient information (patient ID, patient name, sex, and birthday), and information about the original user and generator (facility ID, facility name, original user ID, original username, generator ID and generator name) and the facility that is permitted to view the document (facility ID and facility name).

Results

The doctors in the service CDO select the target CDOs and the documents that they intended to disclose on the DACS viewer (Fig. 1). With this information, the DACS generates an ACL file and transfers selected PDF documents and their ACL file into the SS-MIX repository. The report viewer at the target CDO makes a list of the disclosed documents according to the information contained in the ACL file. The user in the target CDO can select the PDF images that they wish to browse.

Conclusion

With the document-based EHR system, the documents are disclosed through the Japanese standard repository, SS-MIX and the document disclosure information is controlled by the ACL file, which is created based on the HL7 CDA header.

School-Based Telemedicine: Perceptions About a Telemedicine Model of Care

May Lin Tyea, Michelle Honeyb, Karen Day*

*a Health Systems, School of Population Health, University of Auckland, Auckland, New Zealand, b School of Nursing, University of Auckland, Auckland, New Zealand

Abstract
A school-based store-and-forward telemedicine program, which is delivered to school children by school staff is an acceptable model of care for treating skin infections. This indicates that non-clinicians have potential to play a key role in telemedicine. Benefits include empowerment and role redefinition of staff, and potential improvements in health awareness of children, with no major issues perceived in the current program.

Keywords:
Telemedicine, school health services, staphylococcal skin infections

Introduction
Telemedicine is the delivery of medical care, involving an element of distance, and involves the use of information and communications technology (ICT). [1] Store-and-forward (SAF) telemedicine involves a collection of information which is sent to a physician who can respond in their own time. [2] In New Zealand (NZ), an SAF telemedicine program has been implemented in 21 schools in the Far North and in South Auckland as a potential solution and facilitator of access to care for children with skin infections. In NZ, the incidence of serious skin infections in children aged zero to 14 is high, with increasing hospitalizations which almost doubled between 1990 and 2007. [3] This program is delivered by school staff including teachers, principals, and administration staff. Within this telemedicine program, health information of children is collected and entered into an application (app) on a tablet or smartphone. This is sent to a clinical team who can remotely assess it and develop a management plan, which is authorized by a doctor. The research question is: How is a telemedicine model of care for skin infections in school children perceived by the school staff delivering the program? Sub-questions are: 1) How acceptable is telemedicine for school children to non-clinically trained people administering it? 2) What are some perceived benefits and issues with the current program?

Methods
This exploratory, descriptive study has been approached with qualitative methods, specifically an interpretivist approach. Sampling first involved sampling the schools, and secondly sampling staff within the schools. Schools were selected through convenience sampling. 13 schools were approached, with five agreeing to participate, and eight school staff being interviewed. A sociotechnical theory developed by Lamb and Kling reconceptualizes the user of ICT as a social actor. [4] The four constructs of this model: identities, affiliations, interactions, and environments, guided interviews, and analysis. A semi-structured interview, using an interview schedule was adopted in order to elicit narratives. Interviews were one-on-one, lasting up to one hour.

Results
Telemedicine aligned with identities of staff, fulfilling a duty to care for students, and fulfilling school values. Affiliations and close relationships with children, support from the community, and the telemedicine team enabled the program. Delivering telemedicine is an opportunity for staff to have interactions with children, and interactions between children reflected empowerment and awareness of health. Environments, in terms of embedded practices of the school, were influenced by the initial challenge for staff fitting telemedicine into workflows, and some concern of overuse of program by children. Physical environments were flexible, and staff recognized the importance of balancing the need for privacy while protecting a child’s vulnerability.

Conclusion
School-based telemedicine delivered by school staff who are not clinicians is perceived as an acceptable model of care for skin infections in school children. Benefits include empowerment, potential improvement in health awareness, and literacy. No major issues perceived, except initial challenges to day-to-day practices, and balancing privacy and vulnerability. Non-clinicians can play a key role in telemedicine delivery.

Acknowledgements
This research was completed for a Bachelor of Health Sciences (Honors) dissertation at the University of Auckland. No conflict of interest exists.

CLARUS as a Cloud Security Framework: e-Health Use Case

David Vidal, Santiago Iriso, Rafael Mulero

Information System Department, Fundació Clinic per a la Recerca Biomèdica (Hospital Clinic i Provincial de Barcelona), Barcelona, Spain

Abstract

Maintaining Passive Medical Health Records (PMHR) is an increasing cost and resource consumption problem. Moving to the cloud is the clearest solution to solve the problem as it offers a high amount of space and computation power. But the cloud is not safe enough when dealing with this kind of information because it can be easily accessed by attackers. The European Commission funded research project CLARUS contributes to protect healthcare-sensitive information in a secure way.

Keywords:
Telemedicine, Medical Health Records

Introduction

The PMHR is the information from patients who have no more contact with the hospital in a time period of 5 or more years for any reason (moving to another country, death). In some cases, such as patient healthcare, research or legal requirements, this information has to be accessible to professionals from the hospital as well as external healthcare professionals if needed.

Nowadays, this data is being stored on premises where space is limited and the resources for computing this amount of data are not enough as they are being used to manage the non-passive medical health records. Thus, moving to a cloud solution looks like the clearest solution to store and process this information providing more space to local servers and decreasing the resource consumption.

The main problem is that the e-health data privacy and security laws [1] are very strong. In this context, it’s therefore necessary to apply a solution ensuring the security and confidentiality of the information in order to use a cloud solution not only to store but also to compute the data. Cloud solutions nowadays don’t offer this level of security for this kind of information which is one of the main reasons that they are not being extensively used in the healthcare sector. CLARUS [2] is a Horizon 2020 European Commission funded project where the main objective is to design a framework to protect sensitive information in the cloud.

Methods

The Information System Department (ISD) of the Hospital Clinic of Barcelona has collaborated in the CLARUS project as a use case where a framework is applied to healthcare data. First, the ISD elaborated a synthetic dataset based on real distribution of the data, in order to have a fake dataset to work with. The ISD also created a demonstrator application showing the process of retrieval and computation of this data using the CLARUS solution. Encryption (searchable-encryption) or anonymization (k-anonymity and t-closeness) was applied to add more security to the dataset before moving it to the cloud. With searchable-encryption, the data is encrypted on cloud, making it unreadable, and it’s possible to make queries directly over the encrypted dataset without prior decryption. With k-anonymity and t-closeness the data is masked or changed in some parts in order to preserve the privacy and usability of the data.

Results

In the case of data retrieval using the CLARUS solution:
- The information accessed directly in the cloud is completely useless for unauthorized users.
- Using CLARUS, the encrypted information is returned in clear for allowed users.

In the case of the data cloud computation:
- The information in the cloud doesn’t show any identifier or data that could identify a patient.
- When comparing the computations over the original and anonymized dataset, a non-significant deviation appears depending on the filters applied for the computation queries.

Conclusion

Using CLARUS as a framework for cloud security allows the storage, retrieval and in cloud computing of e-health sensitive information with a high level of protection. To ensure the usability of this solution more tests are needed, not only to improve the cloud computation, but also to avoid any access attempts by unauthorized users.

An Interdisciplinary Approach Between Medical Informatics and Social Sciences to Transdisciplinary Requirements Engineering for an Integrated Care Setting

Jan Vielhauer*, Britta Böckmann*a,b

*Department of Medical Informatics, University of Applied Sciences, Dortmund, NRW, Germany
*bIMIBE, University Hospital Essen, Germany

Abstract

Requirements engineering of software products for elderly people faces some special challenges to ensure a maximum of user acceptance. Within the scope of a research project, a web-based platform and a mobile app are approached to enable people to live in their own home as long as possible. This paper is about a developed method of interdisciplinary requirements engineering by a team of social scientists in cooperation with computer scientists.

Keywords:
Mobile Applications, Health Services Needs and Demand, Home Care Services

Introduction

Due to the demographic change in society, a growing number of people will live to an older age and thus the demand for nursing and care will increase [1,2]. In this project, we will help to reveal and capitalize resources supporting the patient’s daily activities and delay the need for inpatient care for as long as possible by means of a digital networking platform. This work is about a new method to gather and control the requirements of very specific and heterogeneous actors by combining methods from social science with scrum.

Methods

Considering the heterogeneity of the actors in this process, a team of software engineers, medical information scientists, and social scientists has been formed who will conduct the requirements engineering and reveal the special needs and potential resources. To get to a point where medical computer scientists and social scientists working together on the derivation of requirements the working methods of the domains need to be merged. In a setting where software engineers are using scrum as an agile and iterative development method, the requirements may be changed at any time. The results of the feedback from the scrum product owner are to be reevaluated and then stored as new items in the domain backlog [4]. Requirements engineering from the social scientist teams point of view is done by open interviews with a snowball sampling technique [3]. The interviewed persons will be asked to provide more persons that could be relevant as a requirement source for the project and thus build and extend a focus group. Members of this group will be interviewed in the next iteration step with the improved interview guideline of the last iteration step. In order to get to a point where the software engineers can use the gathered information to build a software, Scrum User Stories became apparent as a suitable method of extracting concrete requirements out of ideas and impressions by non-computer-scientists [4].

Results

As a result, a three-step iterative way of gathering and detecting requirements has been developed. It will put out and reevaluate user stories to the software engineers building the software. In the first step, a nursing service is accompanied in their daily work by a social and a medical computer scientist. Ideas for improvement will be gathered passively. The second step is a comparison of information by the engineers which aims to reveal missing information and review ideas by both experts so that unusable ideas can be rejected out of hand. The final step is to interview the focus group members and generate improved user stories with every iteration step.

Conclusion

First results of the developed method have shown it to be very effective in view of the aim of the project, to reevaluate both the social and the technical requirements iteratively. The resulting requirements from a both points of view are wide-ranging, yet goal-driven, as the developed method creates needed transparency for all actors in the development process. Future research will show how effective the developed software from our requirements will be according user acceptance and prolonged time in the living environment of the patient.

Use Contexts and Usage Patterns of Interactive Case Simulation Tools by HIV Healthcare Providers in a Statewide Online Clinical Education Program

Dongwen Wang, PhD

Arizona State University, Scottsdale, AZ, USA

Abstract

We analyzed four interactive case simulation tools (ICSTs) from a statewide online clinical education program. Results have shown that ICSTs are increasingly used by HIV healthcare providers. Smartphone has become the primary usage platform for specific ICSTs. Usage patterns depend on particular ICST modules, usage stages, and use contexts. Future design of ICSTs should consider these usage patterns for more effective dissemination of clinical evidence to healthcare providers.

Keywords: Computer Simulation, Information Dissemination, HIV

Introduction

In recent years HIV research has made rapid progress. Timely dissemination of the latest findings to healthcare providers is a key step for improvement of HIV patient care. We previously reported the development of interactive case simulation tools (ICSTs) for dissemination of HIV clinical evidence and the initial usage data of an ICST for Insomnia Screening and Treatment [1]. In this study, we further analyze ICST usage by including the use contexts, extending the study to additional ICST modules, and conducting assessment in both the initial and stable usage stages. These analyses will identify ICST usage patterns and assist the design of effective approaches for dissemination of clinical evidence through ICSTs.

Methods

The ICSTs in this study were developed for New York State (NYS) HIV-HCV-STD Clinical Education Initiative (CEI). We selected four ICSTs for analyses: (1) Insomnia Screening and Treatment; (2) Mental Health Screening; (3) Post-Exposure Prophylaxis Following Occupational Exposure (oPEP); and (4) PEP Following Sexual Assault (nPEP). Development of these ICSTs was based on the related clinical guidelines. The initial usage stage was 195 days for the Insomnia ICST and 97 days for the other three ICSTs. The stable usage stage for the Insomnia and Mental Health Screening ICSTs was 111 days. For data analyses, we characterized ICST use context by: (1) new vs. returning user; (2) access from large-screen equipment vs. small-screen hand-held device; and (3) use through web browser vs. native app. These use contexts were extracted from the system logs of the CEI web servers. To analyze ICST usage patterns, we profiled the frequency of visits to specific ICST sections, i.e., recommendation, sample case, user-defined case, and cross-box, by each dimension of the use contexts described above. For each of these usage profiles, we used chi-square test to examine the statistical significance.

Results

In the initial usage stage, we recorded a total of 512 visits to the Insomnia ICST, 422 visits to the Mental Health Screening ICST, 82 visits to the oPEP ICST, and 80 visits to the nPEP ICST. Analyses of use contexts and ICST sections found 82-98% visits from new users, 48-78% visits from native apps, and 34-70% visits from large-screen equipment. Usage pattern analyses found that: (1) new users were more likely from small-screen devices; (2) visits to user-defined cases were more likely from small-screen devices; and (3) small-screen users were more likely to access ICSTs through native apps.

In the stable usage stage, we recorded a total of 898 visits to the Insomnia ICST and 1560 visits to the Mental Health Screening ICST. Analyses of use contexts found 79-92% visits from new users, 81-90% visits from native apps, and 26-31% visits from large-screen equipment. Usage pattern analyses found that new users were more likely to use large-screen equipment.

Conclusion

We have characterized the use contexts of four ICSTs in both the initial and stable usage stages, and identified specific usage patterns and their changes in the two usage stages. Results from these analyses have shown that: (1) ICSTs are increasingly used by HIV healthcare providers; (2) smartphone has become the primary usage platform for ICSTs; and (3) various other usage patterns are related to particular ICST modules, usage stages, and use contexts. Future design of ICSTs should consider these use contexts and usage patterns for more effective dissemination of clinical evidence to healthcare providers.

\textsuperscript{c} Institute of BioMedical Informatics, National Yang-Ming University, Taipei, Taiwan, China

Abstract

An informatics system was developed based-on Excel Visual Basic for Applications (Excel VBA). It allows patients waiting for appointment complete their admission or satisfaction forms on a Window-based mobile device in stead of paper. Their data will be stored in the tool and analytical charts will automatically be presented in the interfaces.

Keywords:
Information systems; Students, Nursing; Appointments and schedules

Introduction

Patients usually were required to complete some forms for gathering information during the first clinic visit. Paper questionnaires as a traditional way were most frequently used if necessary. However, using questionnaires not only has a potential problem for long-term storage, but forces nurses to allocate time to enter the information into a database. Research shows nurses enabled with information technology would reduce indirect care time and improve patients' satisfaction [1]. We designed an information system based on Excel VBA to make it easy to collect data, automate data analysis and present our results.

Methods

The system was designed at the end of the Excel VBA Courses for masters in nursing informatics [2]. The core technical components of the system was composed of module design, creation of survey data pivot tables and animated charts from a database or list enable nurses to summarize data. The questionnaire was designed based on Marshall's patient satisfaction questionnaire [3], which consisted patient's information and their satisfaction about nursing service.

Results

Our system started with a friendly splash screen and the login interface. The option to validate the data in an automated way was available. Data could automatically be summarized, analyzed, and presented by flexible pivot tables, charts, and graphs (Fig.1). It is transparent to demonstrate which nursing service needed to be improved. All data were stored in electronic form and can be exported to another statistical software.

Discussion

Using paperless and electronic scales on mobile platforms for patient check-in or information collection in hospital would drive trend in the future. The system is a practical and user friendly tool that allows users to select by touching the screen with their fingertips. As a functional platform, it also allows for data pooling and automatically analyses.

Informatics competency is an essential skill for all nurses and nursing students. A VBA training program appeared to be a practical strategy to promote nursing informatics by allows nurses to design susystem on their own.

Acknowledgements

Funding was provided by the New Xiangya Talent Project of the Third Xiangya Hospital of Central South University (Zhishanlingpao Program:20170305).

Personal Health Self-Management in a Data Perspective

Yiqin Yua, Xiang Lia, Gang Hua, Haifeng LIUA, Jing MEIA, 
Yuan Ni, Guoyu Tang, Guotong XIEA, Weiming XUB

aIBM Research – China, Beijing, China, bIBM Global Business Services, Wuhan, China

Abstract
Along with the growth of numbers of patients with chronic diseases, personal health self-management becomes critical. The heterogeneity of self-management requirements makes the detail design and implementation of self-management program a non-trivial work. In this paper we address the problem with the Personal Health Advisor (PHA) application by introducing a personal health data flow mechanism, as well as modules including personal health risk assessment, similar patients profiling, and health question answering.

Keywords:
Self Care, Risk Assessment, Health Education

Introduction
While evidence suggests that chronic disease self-management programs can improve health status and outcomes while reducing hospital visits [1], the heterogeneity of self-management requirements makes the implementation of self-management tools a non-trivial task. In this paper, we try to address the personalized health self-management problem in a mobile-based, data-driven and patient centric mode. We design the modules following a “cognitive” process for the self-management of chronic diseases, that is: awareness of the current health status and potential health risks, comparison with similar patients, and learn from questioning and answering.

Methods

The Personal Health Advisor (PHA) is implemented as a mobile app. All the components work with the personal health data flow mechanism illustrated in Figure 1. The Printed Medical Records Extractor module is used to collect and extract structured clinical data from uploaded medical record photographs, whose precision reaches 0.945 and recall 0.880 [2]. Each input will generate a new instance of the Personal Health Data Profile. Then, the data profile instance will be passed to the Risk Assessment and Alert module. Once the hitting criteria of a certain model in this module is triggered, the corresponding model is applied to the current data profile and generating health risk scores, risk factor impacts, and risk alerts. The Similar Patients Profiling module calculates the distance among the current profile and profile of other users, and generates health summaries using the most similar users. With the current profile, the user can also ask oral questions about his/her health conditions and get answers from the Health Question and Answering module, which are retrieved from online public Q&A service websites in China.

Case Study
Two case studies were performed. In the first one, the PHA was used for the personal health self-management of Chinese elder patients with chronic conditions. By initializing the specified disease suit for elder patients, PHA adapts itself to the generic progression of elder users’ health conditions and provides up-to-date risk assessment results for 10-years stroke onset and 4-years congestive heart failure onset, summarizing 2000 similar patient’s profiles who might also have diabetes and hypertension, and personalized educational health information. In another case, in cooperation with the obstetrical department of a private hospital in China, we integrated PHA with their register appointment app to enhance self-management. The disease suit is specified for common pregnancy diseases in China including gestational diabetes mellitus and preeclampsia. Once an agreement is signed, the registered pregnant women can visit their health record from this hospital directly from the app, or can upload medical record photograph from other hospitals. Personal risks for the two diseases are calculated. Answers for pregnancy knowledge and diet and exercise-related questions during pregnancy are also provided.

Conclusion
PHA is a practical tool for personal health self-management. It facilitates user centric health self-management by applying health data collection, risk assessment, patient similarity analysis, and question answering in a “cognitive” way.

Nurses’ Interest, Readiness and Absorptive Capacity to Information Technology: A Survey in China

Boning Zhang*, Ping Liu*, Qian Xiao*

*Beijing Children’s Hospital, Capital Medical University, Beijing, China
* Xuanwu Hospital, Capital Medical University, Beijing, China
* School of Nursing, Capital Medical University, Beijing, China

Abstract

To investigate nurses’ interest, readiness and absorptive capacity to information technology, 261 nurses were investigated using anonymous questionnaires. This study showed: 1) the top 3 information technologies were personal digital assistant (PDA), Hospital Information System (HIS) and wireless mobile nursing trolley; and 2) the mean scores of interest, readiness and absorptive capacity to information technology were 16.3, 56.7 and 46.8, respectively. Further educational programs should be provided for nurses.

Keywords:
Capacity Building; Nursing Informatics; Education

Introduction

Information technology (IT) has been increasingly available for health care and nursing work, which has not only changed the traditional mode of nursing, but also promoted disease management and the efficiency and quality of nursing. Technology readiness refers to individuals’ overall state to embrace and adopt new technology. [1,2] Absorptive capacity represents individuals’ external technology acquisition activity and innovation performance. Given the increasing use of information technologies in nursing, this study aimed to explore the technology interest, readiness and absorptive capacity of nurses in China.

Methods

In hospitals in China, 261 nurses with more than 6 months working experience were surveyed using a questionnaire to perform a cross-sectional survey. The questionnaire mainly includes four aspects: (1) general information, including age, education, working period, and position, (2) interest in information technology, (3) readiness to use information technology, assessed based on the Parasuraman technology readiness index [4], and (4) absorptive capacity towards information technology, assessed based on an IT absorption capacity scale. [3]

Results

The top 3 information technologies used by nurses were PDA, HIS and wireless mobile nursing trolleys. The score of nurses’ interest in using information technology ranged from 4 to 20, with a mean score of 16.3 (SD 2.8). Different education level and position at work are associated with interest score, with statistical significance (P<0.05). The average technology readiness score was 56.7 (out of 90) and positively correlated with the interest score (P<0.01).

Discussion

Higher interest and higher readiness appear to be associated with higher overall information technology absorptive capacity. Interest in IT and readiness to use IT are both important to enhance the technology absorptive capacity of nurses.

Conclusion

Continuous educational programs should be provided for nurses to enhance their interest, readiness and absorptive capacity to information technology.

A Deep Learning Approach to Neuroanatomical Characterisation of Alzheimer’s Disease

Abhinit Kumar Ambasthaa, Tze-Yun Leonga, b, The Alzheimer’s Disease Neuroimaging Initiative

* Medical Computing Laboratory, School of Computing, National University of Singapore, Singapore
b School of Information Systems, Singapore Management University, Singapore

Abstract

Alzheimer’s disease (AD) is a neurological degenerative disorder that leads to progressive mental deterioration. This work introduces a computational approach to improve our understanding of the progression of AD. We use ensemble learning methods and deep neural networks to identify salient structural correlations among brain regions that degenerate together in AD; this provides an understanding of how AD progresses in the brain. The proposed technique has a classification accuracy of 81.79% for AD against healthy subjects using a single modality imaging dataset.

Keywords:
Alzheimer Disease; Machine Learning; Artificial Intelligence

Introduction

Alzheimer’s disease (AD) is a chronic degenerative disease that occurs in middle or old age, due to neuronal loss in the brain. It is a prevalent cause of premature senility and leads to a steady decline in a person’s capability to carry out activities of daily living. Early detection of AD enables preventive measures and lifestyle changes to be employed to slow down the progression of the disease. Current evidence supporting AD management are mainly based on epidemiological studies. Existing studies that involve computational methods usually provide effective classification but minimal explainability. For example, Heung-II Suk et al. [1] conducted multimodal fusion with deep learning for AD/Mild Cognitive Impairment classification; Adrien Payan and Giovanni Montana [2] used deep convolutional neural networks to analyse and classify AD patients from healthy subjects. Neuroanatomical characterisation of AD uses a computational method is a novel approach. From an anatomical perspective, atrophy and connectivity changes in AD are well studied topics, and it is established that these changes can be used to explain behavioural changes in AD subjects. In this work, we focus on atrophy-based neuroanatomical characterisation of AD.

Methods

We propose a method to quantify the correlated regional atrophy that occurs in the brain during the course of AD progression. We examine a set of cross-sectional structural magnetic resonance images (MRI) from The Alzheimer’s disease Neuroimaging Initiative (ADNI) data repository in this study. We use MRI data from 100 patients in the screening stage of the ADNI-I study (50 AD, 50 Healthy Controls), between the ages of 59 and 88. These images were preprocessed, normalised and registered to a template. We extract and select voxel features from the brain regions using deep neural networks and identify their contributions towards AD using an ensemble learning algorithm. We use convolutional neural networks with dual region inputs to detect correlated degeneration between the input regions and apply the AdaBoost algorithm to identify the saliency of the region pairs towards AD. We construct brain region networks by detecting the edges among brain regions that degenerate together in AD.

Results

The output of our method is an auto-associative model which identifies cliques of brain region networks that degenerate together in AD. We compared our work with classification using Bayesian structure learning algorithms. The classification accuracy of our model is 81.79% compared to 74.01% for score-based structure learning algorithms and 74.42% for constraint-based structure learning algorithms.

Conclusion

The identified regional pairs can potentially explain several behavioural changes that commonly occur in AD patients, e.g., the cerebellar vermis region was found to atrophy in a correlated manner with the left hippocampus region. The cerebellar vermis region is the region responsible for locomotion and gait, which is observed to be disturbed in AD patients. These correlations are aligned with other statistical and computational study findings which motivated this work [1,2]. Our future plans include automatically selecting regions of interest (ROI) based on a region proposal network (RPN). Using an RPN will remove the dependency on the atlas selected for sampling the brain regions. The next stage is to identify the neuronal tracts in the brain which degenerate together. Neuronal tracts enable inter-region signaling in the brain. Examining the damage progression of these tracts will help predict the behavioural changes in AD patients.

Three Dimensional Virtual Planning Through Cone Beam Computed Tomography for Surgical Guidance Production

Kaline Thumé Antunes, Marcos Cordeiro d’Ornellas, Daniani Deliberalli Noedela, Gustavo Nogara Dotto, Renésio Armindo Ghres

Grupo de Computação Aplicada em Saúde (CA+SA), Universidade Federal de Santa Maria, Santa-Maria-RS, Brasil
Hospital Universitário de Santa Maria (HUSM), Universidade Federal de Santa Maria, Santa Maria-RS, Brasil

Abstract
This paper describes a methodology through digital planning and computed tomography for the purpose of making surgical guides for insertion of skeletal anchorage devices in dentistry. Mini-orthodontic screws for anchorage are inserted virtually in the region of interest located between the teeth of the second premolar and first molar bilaterally. DICOM images were converted to STL format and overlaid by scanning the upper plaster model in order to plan the surgical guide virtually.

Keywords:
Radiography, Panoramic; Cone-Beam Computed-Tomography; Radiation Dosage

Introduction
Biomodels, replicas of an anatomical structure, are produced through a chain of processes that begins with the acquisition of computed tomography (CT) and magnetic resonance imaging (MRI). DICOM files are preprocessed using specific applications, which allow to generate a 3D representation of the surface of the object. The resulting file has an STL extension (stereolithography) that is used to manufacture the biomodel.

Considering the increasing applicability of Computerized Tomography in Dentistry, it is very important to determine which image acquisition protocol is capable of providing a three-dimensional visualization with resolution and sharpness appropriate for measuring the structures.

Methods
Computed tomography were obtained with voxel of 0.25mm, time of acquisition of 20s. Plaster models were also digitized in the same way with DICOM 3.0 format archiving for 3D STL reconstruction in appropriate software. The anchoring is decisive for the success of the orthodontic treatment, existing several intra and extraoral resources to be used. After this preparation of the images and virtual planning, the mini-implant is created in the program and its properties such as diameter and thickness are determined. The digital model is used to select the region on which the guide will be drawn (Fig. 1).

The software calculates the characteristics of the design so that the guide can be milled with the use of biocompatible and transparent material (Acrylic Resin - VIPI). Mini-implants can contribute to a stable intraoral bone anchorage, without risk of reciprocal movement of the active unit as a reaction to the action of orthodontic forces generated in the anchorage unit, and may be installed in several areas of the alveolar bone.

Results
The results have shown countless advantages. The degree of stability, better exploration of the available locations for the devices to be inserted, and the integrity of adjacent structures are directly influenced when a technique is performed. However, the proximity of the dental roots may compromise the stability of the mini-implant and thus narrower regions require very well-planned and accurate techniques. The images generated by a Tomograph have been improved, seeking not only the gain in image quality and the reduction of artifacts, but also the reduction of the radiation absorbed by the patient during the examination.

Conclusion
A new approach for making surgical guides to insert mini-implants has been presented. Through computerized tomography and digital models, the guide made using dental milling has the potential to reduce clinical intercurrences, such as root damage or perforation of other anatomical structures.

“Big Clinical Data” Analysis of Intravenous to Oral Conversions of Non-Antimicrobials

Patrick E. Beeler, David W. Bates, Jürg Blaser

Abstract

Advantages of early intravenous (IV) to oral (PO) switches of antimicrobials are well known. Yet, little data have been published on reasonable IV-to-PO switches of other drug classes, although interventions to promote early IV-to-PO conversions may further increase patient safety and decrease costs. We therefore analyzed IV-to-PO switches of non-antimicrobials.

Keywords:
Administration, Intravenous; Pharmacoepidemiology

Introduction

Early intravenous (IV) to oral (PO) conversions may increase patient safety and decrease costs. Studies successfully promoted earlier IV-to-PO conversions of antimicrobials [1]. Yet, little data have been published on IV-to-PO conversions of other drug classes. This analysis aims to generate more knowledge on IV-to-PO conversions beyond antimicrobials.

Methods

In this retrospective study at a Swiss teaching hospital (850 beds) all orders for inpatients between 8/2009-4/2014 were processed. When an IV drug was discontinued, the time frame -0.5 to 3.0 hours (interquartile range, IQR) was used to find starting PO therapies. The approach how we calculated the IQR is explained in figure 1. However, not only IV therapies that were switched to PO in the process were analyzed but also IV therapies without switch, i.e. therapies either discontinued or the patient was discharged. Only throughout the hospital stay were durations of IV and PO administrations considered.

Results

A total of 547,153 IV orders were analyzed. Of them 69,981 (12.8%) were switched to PO. Among frequently ordered IV drugs (table 1) metamizole was switched to PO in 37.4% of cases, whereas potassium was switched in only 6.0%. For table 2, only drugs were considered that were switched to PO ≥30 times and had mean IV administration durations of ≥3 days: those compared to IV drugs not switched in the process, the latter had up to 3 days shorter IV administration durations which may suggest potential for earlier switches as well.

Conclusion

“Big clinical data” analyses are an important pharmacoepidemiological tool to identify targets for interventions in order to improve patient safety and cost efficiency of drug therapies.

MetaMap Lite in Excel: Biomedical Named-Entity Recognition for Non-Technical Users

Ravi Teja Bhupatiraju, Kin Wah Fung, Olivier Bodenreider

National Library of Medicine, Bethesda, MD, USA

Abstract

We developed an easy-to-use tool for non-technical biomedical researchers to conduct Named-Entity Recognition (NER) on biomedical text, in a familiar spreadsheet environment. The system is a simple, offline, easy to install, end-user front-end to the new MetaMap Lite. Early adopters found it to be a quick starting-point to incorporate NER in their investigations.

Keywords:
Natural language processing; Unified medical language system.

Introduction

The application of Named Entity Recognition (NER) has become pervasive. Biomedical researchers, who may not have strong computer skills, often wish to apply NER methods and tools to extract information from text.

MetaMap (https://metamap.nlm.nih.gov/) is one of the most popular tools for biomedical Named Entity Recognition (NER), more specifically for identifying terms from the Unified Medical Language System (UMLS) Metathesaurus in biomedical text. MetaMap Lite is a recent Java reimplementation of the original MetaMap. Running these tools on biomedical text and parsing their output generally requires some programming skills, which places them out of reach for non-technical users. Our objective is to make biomedical NER tools easier to use by non-technical users.

Methods

We developed an easy-to-use tool for non-technical biomedical researchers to use MetaMap Lite on biomedical text, in a familiar spreadsheet environment, supporting interactive and batch processing operations.

Our system does not depend on network or external resources. Instead, a zero-configuration backend server provides an HTTP service that a spreadsheet function consumes to perform named entity recognition. The function supports output field selection (e.g., “pref.stype” returns the preferred name and semantic type, along with the UMLS concept unique identifier, or CUI). Matched text and source vocabulary may also be requested. By default, the system only returns the UMLS CUI and the preferred name). Semantic type restriction may also be specified (e.g., “phsu.antb” returns only those terms that have been categorized as pharmaceutical substances or antibiotics).

The backend server serves a self-documenting spreadsheet template for users to get started. It supports automatic update of NER results as users edit entries, and batch processing by dragging fill handles to apply the function to rows of natural text inputs. The function may be combined with other functions for further automation.

Results

Figure 1 illustrates a typical use case for our tool. Users copy biomedical text in one column (A) and use the mmlite function in another column (B) to identify UMLS concepts from the text in column (A).

From a technical perspective, the backend can run anywhere a Java Virtual Machine (JVM) is available. The Windows installer for the software package contains all the necessary software components for running the mmlite function in Excel.

On informal inquiry, users found the software easy to install and use. Response times were quick, at about 30ms per request on a Xeon ES-1620 v3 3.5 GHz with 16 GB RAM.

An Exploratory Analysis of Questions Submitted to a Brazilian Telemedicine System

Jacqueline Brixey\textsuperscript{a}, Juliana J. Brixey\textsuperscript{b}

\textsuperscript{a}Department of Computer Science, University of Southern California, Los Angeles, CA, USA, \textsuperscript{b}School of Biomedical Informatics and School of Nursing, The University of Texas Health Science Center at Houston, Houston, TX, USA

Abstract

The Rede NUTES telemedicine question submission system provides second opinions to remote healthcare professionals in the northeastern state of Pernambuco, Brazil. Submitted questions to the telemedicine system by general practitioners and nurses were analyzed using big data exploration techniques to summarize topic, trends and lexical features.

Keywords: Telemedicine; Brazil, Mining

Introduction

The Brazilian constitution guarantees free public healthcare to every citizen, however, many specialists are concentrated in the large coastal cities of the country, resulting in an underserved rural population [1]. The Health Ministry of Brazil implemented the Programa Telessaúde Brasil Redes to combat this issue by providing health support, advice from specialists, and permanent health education via telemedicine. Telemedicine can connect any member of the health care team across the continuum of care to enhance outcomes. For example, the Rede offers second opinions to submitted questions via their online submission system to be reviewed by other health care professionals [2]. The opportunity to seek second opinions allows for non-specialists to provide specialized service in remote areas, thus saving patients from undertaking a costly trip for care. Data from the Rede NUTES submitted questions were analyzed and explored using big data methods to gain insights into how and for what Brazilian nurses and general practitioners (GPs) utilized the system.

Methods

The data set analyzed comes from text questions submitted from the years 2010-2012. In total, 5580 questions were submitted and answered. In the pre-processing phase, all identifying information was removed by hand to comply with HIPPA standards. The data exploration phase followed a four step process.

Step 1 was to identify and isolate questions submitted by nurses and GPs to compare how these groups used the Rede system in comparison to their peers. In step 2, the questions were reviewed by calendar months. This visualized usage trends over the course of a year. Step 3 was to determine question themes by month. By visualizing question topics and clustering those topics in a timeline, it was possible to understand topic trends in the data. In the final step, the data were reviewed for lexical relationships using Linguistic Inquiry and Word Count (LIWC) program in Portuguese [3]. LIWC returns values on dimensions, for example the number of self-references and level of positivity, that insights about the state of mind of the writer.

Results

Nurses and nurse technicians submitted the most questions to NUTES for two out of the three years reviewed (38% in 2010 and 32% in 2011), and in all three years combined (36%). This group submitted 92% of all questions in December 2012. The top question topics submitted by nurses concerned cardiology, gynecology, obstetrics, pediatrics, and dentistry. GPs did not use the question system as prolifically, and submitted only 6% of the total number of questions during the three years. Questions submitted by GPs largely focused on cardiology, such as queries about hypertension management.

Conclusions

Exploratory data analysis is the first step in using big data for future experiments. It also allows researchers to detect mistakes in the data that could potentially skew machine learning results, and check intuitions about the data. It is an essential step in telemedicine systems to evaluate and analyze trends for a topic and usage in order to better serve future users of these systems.

Integrating x4T-EDC into an Image-Portal to Establish an Ophthalmic Reading Center

Philipp Bruland\textsuperscript{a}, Ulrich Kathöfer\textsuperscript{b}, Maximilian Treder\textsuperscript{c}, Nicole Eter\textsuperscript{c}, Martin Dugas\textsuperscript{a}

\textsuperscript{a}Institute of Medical Informatics, University Hospital Münster, Münster, Germany, \textsuperscript{b}ITZ FuL, University of Münster, Münster, Germany, \textsuperscript{c}Department of Ophthalmology, University Hospital Münster, Münster, Germany

Abstract

Reading centers provide centralized high-quality diagnostics in ophthalmic clinical trials. Since ophthalmic images are captured in electronic format at peripheral clinics, an integrated workflow for image transfer and creation of structured reports is needed, including quality assurance. The image portal and the study database are separate components. We assessed whether this integration is feasible with trial-related IT standards and built a prototype system as a proof-of-concept. CDISC ODM and OAuth authentication were used to integrate the image portal with x4T-EDC, facilitating automatic data transfer and single sign-on.

Keywords:
Electronic Data Capture, Reading Center, System Integration

Introduction

Assessment of ophthalmic images requires a standardized procedure, especially in clinical trials. Therefore, so-called reading centers are established to receive images from participating study sites, assess those by medical experts in a standardized manner and document results in the study database [1]. Reading centers usually consist of an image portal into which images of study subjects are uploaded. Separate from the portal, a database is used for study documentation. In this regard, validated electronic data capture (EDC) systems are applicable that fulfill certain regulatory requirements for use in clinical trials. Nevertheless, such systems are usually separated IT components resulting in error-prone and time-consuming disruptions of the reading workflow.

Hence, the aim of this research is to investigate, whether it is feasible to connect an image portal with an EDC system using trial related IT standards.

Methods

System requirements were identified through meetings with clinical partners from the clinic of Ophthalmology. For this proof-of-concept the capabilities of an image portal and the x4T-EDC system [2] were analyzed. x4T-EDC is an in-house developed EDC system supporting mainly investigator initiated trials and diverse register projects. Different formats for data transfer between the portal and the study database (x4T-EDC) were reviewed such as CSV files or the XML-based format ODM (Operational Data Model) of the CDISC (Clinical Data Interchange Standards Consortium) [3]. To prevent users entering their credentials into both systems, single sign-on mechanisms such as OAuth were examined.

Results

ODMs “ClinicalData” part was used to transfer basic information of the uploaded image via web services, like visit number, date, eye location, image type and recording device from the portal to the x4T-EDC system. Single sign-on was established using OAuth-similar authentication mechanisms. The x4T-EDC system was enhanced towards a more specific right-management for preventing readers to access the reports of other readers. x4T-EDC compares the reports of both readers to support quality assurance performed by a senior reader. Possible deviations are presented by x4T-EDC to the senior reader and again examined. Information regarding image status is communicated between the portal and x4T-EDC to support the reading workflow.

Discussion

Defined interfaces allow the integration between the reading portal and the study database. Based on the well-established and widespread format CDISC ODM, which is used by most EDC solutions, the exchange of data is realized. Single sign-on mechanisms allow a slim and clear process from the examination to the assessment of images. The separation of both systems (image-portal accessible via internet, study-database only via intranet) is an advantage regarding security. At present, the implementation of the reading-center is a successful proof-of-concept. We also intend to perform an usability evaluation with the system usability scale.

Conclusion

Integrating x4T-EDC into an image-portal with trial-related IT standards and technologies is feasible.

Abstract
Clinical use of pharmacogenomic (PGx) knowledge at the bedside is new and complex. Our program has implemented multiple PGx-CDS interventions in different clinical settings and in multiple commercial EHRs. Herein, we discuss lessons learned and propose general technical guidelines related to PGx implementation.

Keywords: pharmacogenetics, clinical decision support systems, electronic health records

Introduction
Precision medicine will revolutionize the current model of healthcare to allow the delivery of personalized care based on multiple predictors including individual genetic information. Pharmacogenomics (PGx), the study of the role of genetics in drug response, is one aspect of precision medicine that promises a significant impact to the general population. In fact, the vast majority of the population has at least one variant in genes associated to the metabolism or mechanism of action of drugs (pharmacokinetic and pharmacodynamics) or immune-related genes that increase risk of hypersensitivity reactions. Although many challenges have hindered the implementation of PGx into clinical practice, it is now increasingly evident that the time has come for widespread adoption [1].

PGx-CDS Implementation
The Mayo Clinic Center for Individualized Medicine has implemented a Pharmacogenomic Program to translate genomic knowledge into clinical practice. Using institutional resources and a comprehensive operational model [2, 3], a multidisciplinary group of experts developed and implemented multiple CDS interventions integrated in two EHRs to alert for 19 drug-gene interactions.

Lessons Learned
During the PGx-CDS implementation, many challenges and opportunities were identified. We have grouped these in several main themes.
1. Integrated multidisciplinary team approach: PGx-CDS implementation should not be a standalone project.
2. Structured format of PGx test results: Translation of the PGx test reports into structured format (discrete results or constrain text) in the EHR is critical for implementation.
3. Complementing EHR functionalities: Current EHR functionality is sufficient, though not perfect to implement PGx-CDS. Pop-up alerts should not be the only intervention.
4. Clinical champions and education: Clinical champions from different specialty areas should be invited to participate in the development of PGx-CDS to help decrease clinical resistance.
5. Establish a process for ongoing maintenance: Long-term maintenance cannot be underestimated. PGx-CDS needs very frequent updates due to changes in laboratory methodologies, discovery of novel variants, new medications, and emerging research evidence resulting in changes to the interpretations of existing variants and PGx guidelines.

Conclusion
PGx-CDS implementation is feasible by using current commercially available EHR systems. However, PGx is an evolving science and the PGx-CDS interventions require constant review and updates. PGx-CDS implementation benefits from a multidisciplinary infrastructure supporting not only the implementation team but also the clinicians receiving the CDS alerts.

Abstract

High fidelity simulation-based teaching has played an important role in medical education, especially in anesthesiology and emergency. But there is not any currently validated scoring system or prediction model for high fidelity simulation. We will develop a validated prediction model to enhance the efficiency and validation of clinical training with high fidelity simulation.

Keywords:

Anesthesia; Education, Medical

Introduction

High fidelity simulation-based teaching currently has played an important role in medical education, especially in anesthesiology and emergency. After several years of pilot exercise, Taiwan Society of Anesthesiologist have formal put high fidelity simulation into part of board examination. After literature review, there is not any currently validated scoring system or prediction model for high fidelity simulation. Therefore, development of a validated scoring or model is an important task for us to keep teaching with high fidelity simulation.

Methods

We had collected the data of anesthesiologist board examination in 2013. De-identification was also done at the same time for data privacy. The typical simulation scenario to build relational database is perioperative myocardial infarction (MI). It’s a rare but fatal complication during operation. Early vigilance and appropriate treatment is the key to save patient’s life.

50 chief residents of anesthesiology had took this examination. Their performance were rated with a check list of 41 technique-related items and 8 non-technique items by 2 independent rater. Final outcome of each examinee is a global rating score from 1 to 10.

Eighty percent of the dataset were used as training data, and remaining were used for model testing. We utilized various machine learning algorithms, such as decision tree (DT) with the implement of Categorical and Regression Tree (CART), random forest (RF), support vector machine (SVM) with different kernel and linear regression. The model’s performance was evaluated with root mean square error and Pearson correlation coefficient. Feature selection was also done with random forest.

Results

All machine learning algorithms that we used have good performance in prediction, but SVM with linear kernel and random forest are slight better than others with correlation coefficient 0.99 and 0.98, respectively. Top 7 important features ranked by random forest include 3 technique features and 4 non-technique features as table 2.

Conclusions

In this preliminary study, we find both SVM with linear kernal and RF could build accurate prediction model in this simulation test. Otherwise, according to the result of feature selection by RF, evaluation of non-technique factors may play a more important role than before. Due to limited case number, larger study maybe conducted to confirm the prediction accuracy in the future.

How to Use TCM Informatics to Study Traditional Chinese Medicine in Big Data Age

Shi Cheng, Gong Qing-yue, Zhou Jinhai

College of Information Technology, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China

Abstract
This paper introduces the characteristics and complexity of traditional Chinese medicine (TCM) data, considers that modern big data processing technology has brought new opportunities for the research of TCM, and gives some ideas and methods to apply big data technology in TCM.

Keywords
Electronic Health Record; Research; Medicine Chinese, Traditional.

Introduction
Chinese medicine believes that disease is the result of the struggle between “righteousness” and “evil”. All that are conducive to the body against disease are considered “righteousness”, things not conducive to human health survival are “evil”. Classification of disease contains human information and insight into people’s understanding of disease in the macro environment. In the course of thousands of years, Chinese medicine has accumulated rich experience and knowledge in the application of acupuncture, massage, and other methods of diagnosis and treatment. These big data are an extremely valuable asset worth exploring. Thousands of traditional Chinese medicine hospitals in China have adopted an Electronic Medical Record system to record clinical data. Accumulating over a long period, Chinese medicine data is amazing, containing conditions worth further exploring in the era of big data technology.

Methods
Chinese medicine is considered as “unscientific” due to the lack of objective data and standardized scientific language. These shortcomings make traditional Chinese medicine information processing difficultly. Traditional Chinese medicine uses the doctor’s sensory organs to collect patient data (subjective data of doctors) and most of the data recorded by inquiry describes the patient’s subjective sensory. This data is recorded in natural language. Traditional computer data is objective. Modern big data technology (e.g., Google Flu) provides a new opportunity to use computer technology to study subjective traditional Chinese medicine data.

Results
We believe that in a pilot implementation, we can choose several Chinese medicine hospitals and suitable clinical research projects for early exploration. Traditional Chinese Medicine clinical data can be standardized in accordance with the requirements of the State Administration of Traditional Chinese Medicine. This pilot will allow us to accumulate experience and methods about modernization of Chinese medicine.

Conclusion
The big data age provides new insight that could not be acquired with smaller data sets. Modern large-scale data processing technology has brought new opportunities for traditional Chinese medicine research. In this paper, the characteristics and problems of traditional Chinese medicine data were analyzed and new ideas and methods were proposed.

Identifying Use Cases for Electronic Nursing Record Systems Using Clinical Workflow Observations and a Delphi Survey

Insook Cho\textsuperscript{a} and Joohyun Chung\textsuperscript{b}

\textsuperscript{a} Department of Nursing, Inha University, Incheon, Republic of Korea, 
\textsuperscript{b} College of Nursing, University of Massachusetts, Dartmouth, USA

Abstract

This study describes the process of identifying use cases for next generation electronic nursing records in a high-level view. Literature review, clinical observation, and a Delphi survey were employed. Eight use cases were identified with importance and convergence scores.

Keywords: Nursing records; Medical records systems, computerized.

Introduction

Electronic nursing record (ENR) systems have been adopted world-wide as an essential part of clinical practice. Due to the lack of a knowledgeable nursing executive and clinician workforce regarding standardized processes and data, most ENR systems are not based on explicit and implicit models for information and content standards. Instead, they are based on paper-view models. This has hidden many of the benefits of an ENR, such as supporting efficient, complete, and accurate information in paractice, support of quality improvement, analytics, and research [1]. In addition, nurses’ dissatisfaction with ENRs has been frequently reported as those are not aligned with workflow; it is critical that clinical work process be supported. We aimed to understand and delineate a clinical work process from the end users’ point of view.

Methods

A Literature review of nursing documentation standards and guidelines, EHR usability, and ISO S/W quality specifications was performed. Clinical observations took place at 24 medical and surgical units from six tertiary hospitals located in a metropolitan area of South Korea. A time-motion method was used and 72 nurses from 24 units at each hospital, plus an additional 32 non-participating nurse observers were included. Out of 108 sessions, we randomly selected 21 (20%) samples for qualitative analysis. The patterns were described and abstracted to several use cases. Each use case was structured by definition and requirements on functional, data and information, and design. In a Delphi survey, two panels were recruited: (1) six nurse managers from the participated hospitals, plus two nursing directors; (2) three academic nursing informaticians (NI).

Results

Figure 1 shows the eight high-level use cases identified from clinical observation pattern analysis. In Delphi survey, the Daily car plan & set goals and the Evaluation use cases showed lower importance and convergence scores.

Discussion

The Plan of care & set goals and Evaluation use cases were less important. There were many different perspectives for defining the intervention use case specifications, even when considering importance scores. We also found gaps between nurse managers, NI experts, and nurse managers.

Conclusion

We identified eight important use cases for clinical practice.

Acknowledgements

Delivering Digital Drugs: An Exploratory Study of the Digitalisation of Supply and Use of Medicines

Tony Cornford\textsuperscript{a}, Valentina Lichtner\textsuperscript{b}, Jane Dickson\textsuperscript{a}, Ralph Hibberd\textsuperscript{a}, Ela Klecun\textsuperscript{a}, Will Venters\textsuperscript{a}, Bryony Dean Franklin\textsuperscript{c}

\textsuperscript{a} Department of Management, London School of Economics, London, UK
\textsuperscript{b} University of Leeds Business School, University of Leeds, Leeds, UK
\textsuperscript{c} UCL School of Pharmacy, University College London, London, UK

Abstract

Medicines' supply and use is increasingly reliant on digital means and information. This poster presents exploratory research over five episodes of digitalisation of medicines across the supply network. We 'follow the drug' through this emerging field, providing an initial map of this new territory.

Keywords:
Drug utilization; Information systems; Precision medicine.

Introduction

\textit{It was all very well to say 'Drink me,' but the wise little Alice was not going to do that in a hurry. 'No, I'll look first,' she said, 'and see whether it's marked "poison" or not' (Alice in Wonderland, Chapter 1)}

The Delivering Digital Drugs (D3) project is concerned with the accelerating digitisation of the chain of production and consumption of therapeutic drugs (medicines) and the emergence of what we term 'digital drugs' [2].

Health care is increasingly reliant on medicines as a primary means of therapy and medicines are increasingly developed and delivered by reliance on associated and accompanying data and information technologies within a rich and rapidly changing data ecosystem. Today a medicine can be seen as a hybrid artefact, part chemical, part data, part supply chain and logistics, part knowledgeable practice that is itself part embodied and part algorithmic. This raises many complex intersecting issues including: what drives this process of digitalisation; what constitute appropriate functional uses of data - e.g. in prescribing, in research, in audit, in monitoring individual or population wide effectiveness or value for money, in monitoring side effects etc. There are also substantial new issues of data stewardship, openness and ethical data governance practices. At the core are the questions of what is or may become deemed appropriate professional practice, taking into account issues of safety and avoidance of errors, as well as the status and role of patients as active participants in medicines use.

Methods

Our methodology is cross-disciplinary and exploratory. It includes five case studies of the processes of digitalisation sampled along the chain of supply and use of medicines:

1. Anti-counterfeiting in the medicines supply networks,
2. Hospital prescribing and supply of drugs and related data infrastructures,
3. Pharmacovigilance and the monitoring for adverse effects of therapeutic drug use,
4. Research data services, principally the aggregation of patient data for secondary use,
5. Patient views’ of use of medicines and of technology to support patients in their role as active participants in their therapy.

A mix of qualitative data collection methods were applied: interviews, observations and documentary analysis. The cases are explored both as single episodes and in their interconnections. In order to facilitate the latter, we apply a tracer approach [1] and ‘follow the drug’ through and between the cases. Drugs are taken as ‘tracers’ that can reveal digitalisation paths and flows within and across cases. Thus the ‘digitalization of medicines’ is studied ‘following the drugs’ from the moment they enter the market for clinical use, through their transit through pharmaceutical supply networks [case 1] to the process of prescribing and dispensing [case 2], to patient’s decision making [case 5], to the capture of aggregated data around the use of therapeutic drugs [case 4] and the outcomes of this use [case 3-4].

Concept Embedding for Relevance Detection of Search Queries Regarding CHOP

Yihan Deng\textsuperscript{a}, Lukas Faulstich\textsuperscript{b}, Kerstin Denecke\textsuperscript{a}

\textsuperscript{a} Bern University of Applied Science, Bern, Switzerland, \textsuperscript{b} ID Information and Documentation GmbH, Berlin, Germany

Abstract
Automatic encoding of diagnoses and procedures can increase the interoperability and efficacy of the clinical cooperation. The concept, rule-based and machine learning classification methods for automatic code generation can easily reach their limit due to the handcrafted rules and a limited coverage of the vocabulary in a concept library. As the first step to apply deep learning methods in automatic encoding in the clinical domain, a suitable semantic representation should be generated. In this work, we will focus on the embedding mechanism and dimensional reduction method for text representation, which mitigate the sparseness of the data input in the clinical domain. Different methods such as word embedding and random projection will be evaluated based on logs of query-document matching.

Keywords:
Automatic Encoding, Classification, Machine Learning

Introduction
In order to claim costs to the health insurance and for clinical documentation purposes, it is necessary and even legally required to encode diagnoses and procedures by classification codes from relevant classification systems. In Switzerland, these are ICD-10-GM for diagnoses and Schweizerische Operationsklassifikation (CHOP) for medical procedures. In order to facilitate the subsequent query matching process based on deep learning, we investigate the possibilities of direct embedding of concept through word2vec principle (Skip-gram, continuous bag of words, negative sampling) as well as the dimension reduction with the input of sparse concept vector. We would like to figure out whether the embedding method can be applied on the concept vector directly and which type of embedding (Skip-gram and CBOW) is more suitable for the concept embedding from domain specific data.

Methods
For test and development, we are using semantic representations in vector form generated from search entries and, on the other hand, target catalog texts that have been generated from the CHOP classification texts. As is illustrated in Figure 1, for each query – classification code text pair it has been assigned whether the classification text matched the user query or not. For generating the vectors, search entries and classification texts have been mapped to concepts of a medical terminology by the terminology server ID MACS®. As pre-processing for the query matching system, the input layer is in charge of the representation generation and dimension reduction. This layer is trying to represent the word in a corpus by a special instantiation of a set of hidden variables. The embedding process learns the representation of each word by maximizing the log likelihood of each word given its context (context window). Our evaluation platform will test the embedding result based on CBOW, Skip-gram, and random projection. The embedding is implemented with Tensorflow [1].

Results
20067 logs are used to do the embedding and evaluation. Based on the annotated relevance metrics [1], the average match rate of Skip-gram embedding based on concept only vector representation has achieved the best relevance match (0.63), while the CBOW has achieved clearly less match rate (0.43). The random project has only reached the least match rate around 10%.

Discussion and Conclusion
Concept embedding can largely reduce the sparseness to make a suitable input for the deep neural network. The skip-gram is most suitable method for encoding short text queries referring to clinical or surgical procedure, since keywords are short and relatively independent. The portability and scalability of the method will be tested in other medical natural language text.

Classifying Clinical Notes with Pain Assessment

Samah J. Fodeh\textsuperscript{a}, Dezon Finch\textsuperscript{b}, Lina Bouayad\textsuperscript{b}, Stephen Luther\textsuperscript{b}, Robert D. Kerns\textsuperscript{a}, Cynthia Brandt\textsuperscript{a}

\textsuperscript{a}Yale Center for Medical Informatics, Yale University School of Medicine, New Haven, CT, USA
\textsuperscript{b}HSR&D Center of Innovation on Disability and Rehabilitation Research, James A. Haley Veterans Hospital, Tampa, FL, USA

Abstract

Pain is a significant public health problem, affecting an estimated 100 million Americans. Evidence has highlighted that patients with chronic pain often suffer from deficits in pain care quality (PCQ). Efforts to improve PCQ hinge on the identification of reliable PCQ indicators such as pain assessment. In this study, we developed a classifier that leverages narratives in clinical notes to derive indicators of pain assessment for patients with chronic pain.

Keywords:

Pain, classification.

Introduction

Currently, there is no intelligent and reliable approach to identify patients with clinically significant pain in the EHR [1]. Capturing data elements related to pain in most EHRs is not standardized. While a growing number of pain-related studies have utilized structured and easily retrievable coded fields in the EHR, none have explored the utility of provider narratives in clinical notes. We employed machine learning (ML) algorithms to analyze unstructured narrative text data in the EHR to develop a reliable classifier that identifies clinical notes with pain assessment.

Methods

Using data from the Veterans Health Administration (VHA) system, we abstracted a random sample of 1058 primary care notes from the medical records of patients with initial Musculoskeletal Diagnoses (MSD) in 2011. The views expressed in this poster are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs. We manually annotated the data and generated a reference standard for the purposes of building a classifier that labels clinical notes with indicators of pain assessment as positive and other notes as negative. Pain assessment information that was annotated in the notes include terms related to intensity, quality, persistence, diurnal variation, aggravating factors, alleviating factors and functional assessment. Inter annotator agreement was 72%. A note that included any of the relevant terms was deemed positive. We experimented with multiple classifiers including decision tree (DT), support vector machine (SVM), k-nearest neighbor (KNN), and random forest (RF). We used two-thirds of the data for training and one-third for testing. We performed 10-fold cross validation to train the classifiers and measured performance via accuracy, positive predictive value, sensitivity, F1-score and area under the curve (AUC).

Results

Table summarizes the average performance of the different classifiers on the training and test sets in all measures. On the training data, the RF classifier did best in most measures; the highest F1-score and area under the curve were achieved .94 and .94, respectively. Similar performance was observed on the test set, nonetheless, the K-nearest neighbor classifier outperformed RF in terms of sensitivity. We used 6 neighbors to estimate the label of a given clinical note (i.e. k=6); adding beyond that did not seem to change the results. KNN, however, still did worse than all classifiers in terms of the other remaining measures for both training and test data sets as shown in the table. The best performance of RF is explained by the combined predictions of several base classifiers which likely improved generalizability and robustness over a single classifier. In our experiments we combined 100 learners for prediction.

Conclusion

The developed pain assessment classifier is potentially useful for improving quality of pain care. We vision it as an agent that can automatically sift through the EHR to pull clinical notes with pain assessment for further pain quality research. The RF classifier outperformed other single classifiers. In future work, we will build a more granular classifier that determines what type of assessment has been done on patients in clinical notes.

Modeling an IT Support for Handling Serious Adverse Events in Clinical Trials

Simon Fonek, Thomas Deserno

Department of Medical Informatics, Uniklinik RWTH Aachen, Aachen, Germany

Abstract
Serious adverse events (AE) or reactions (AR) may occur in clinical trials and require particularly regulated reporting. Manual management is inefficient and ineffective. Based on a description of regulations, we have developed a data model with class-, state-, use-case- and activity diagrams, which can be used for automatic code generation of an assisting software tool for AE / AR data management.

Keywords:
Clinical Trial, Adverse Event, Software Engineering

Introduction
Several IT systems are used to support clinical trial conduction but they are usually disconnected from the hospital information systems (HIS). Therefore, the principle investigator of a controlled clinical trial might not be informed when a serious adverse event (SAE) or a suspected unexpected serious adverse reaction (SUSAR) occur. To ensure information exchange between the HIS and the clinical trial management system (CTMS), we model an appropriate IT infrastructure supporting SAE / SUSAR identification. Furthermore, the tool is designed to support and assist the trial team in timely and accurate reporting of such events.

Methods
There are several software engineering tools, such as the unified modeling language (UML) [1] used to describe the functional requirements for the SAE tool and the occurring processes within models provided by the UML. Based on a comprehensive description of regulatory requirements and a desired workflow [2], we created

- Use-case diagrams to describe functionalities from the user’s view;
- Activity diagrams to represent the data- and controlflow;
- Class diagrams to define the structure of the system;
- State diagrams to compose a finite number of system states.

These models serve as basis for the automated code generation [3] of an web-based SAE management tool, its documentation, and the verification of the implemented source code.

Results
The SAE management is divided into two processes: automatic SAE identification and manual monitoring of SAEs including parallel automatic support. In a relational data model, only eleven tables are required.

Discussion
Comprehensive modeling supports the developer during the implementation process. The software will simplify the management of SAEs in clinical trials. Automatically generated messages guide research nurses to keep track of SAEs, lower the risk of missing a case, and increase security and quality of clinical trials in general.

A Study on Data-Driven Novel Cancer Staging Methods

Yuan Gao, Yu Tian, Shengqiang Chi, Yao Lu, Xinhang Li, Tianshu Zhou, Jing-song Li

Engineering Research Center of EMR and Intelligent Expert System, Ministry of Education, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, College of Biomedical Engineering and Instrument Science, Zhejiang University, Hangzhou Zhejiang Province, China

Abstract

This paper presents a data-driven method to study the relationship of survival and clinical information of patients. The machine learning models were established to study the survival situation at the time of interest based on survival analysis. The way to determine the time of interest is an innovation of this paper. The distribution of survival time is considered, namely the three quartiles, as well as the traditional analysis experience is taken into consideration.

Keywords:
Colorectal Neoplasms, Machine Learning, Survival Analysis

Introduction

According to the recent studies, the widely used 7th AJCC TNM staging system cannot make a linear prediction on survival, which means the survival rate is not getting smaller as the staging gets higher, but there is a fluctuation[1]. This paper attempted to implement data-driven machine learning algorithms, built several different models, and finally, the resulting models were assessed and compared. This paper concluded three quartiles of the survival rate of the patients from data above using survival analysis[2], which are 3, 5, and 7 years after diagnosis. The idea of research of this paper is not from experience but from the data itself, which provides a new way of thinking of research on cancer staging method.

Methods

The data used in this paper is the follow-up data from the 2080 patients admitted in 1985-2011 by the Department of Surgical Oncology, Second Affiliated Hospital, Zhejiang University College of Medicine. Multivariate Imputation by Chained Equations based on random forest model is introduced[3] to process the missing values. Logarithmic transformation is used to remove the effect of outliers and Min-Max Normalization is used to balance the contribution of different features. Through the survival analysis of the original data, the overall distribution of the data is obtained: three quartiles of the survival time, which are the time of interest points we need. In this paper, three machine learning models suitable for binary classification are selected: logistic regression model, support vector machine model and random forest model.

Results

According to the result of survival analysis, 3 quartiles of survival time was obtained. They are 40 month, 59 month, and 85 month. This paper identified the time points of interest are 3 year (36 month), 5 year (60 month) and 7 year (84 month) in order to take into account the general experience of the time points of study. According to the accuracy, the prediction of the models of 3-year survival performs the best overall, followed by that of 7-year and 5-year. It is the SVM model of the radial kernel function (3-year), and the logistic regression model (5-year and 7-year) that used to show the relatively good performance at each time point. However, if we take into account the specific circumstances of the prediction, the accuracy of negative samples at 3 years is much higher than that of positive samples. Meanwhile, the time of 7 years is the opposite, and the time of 5 years is more balanced.

Conclusions

Although the final result is not ideal, this paper has guidance for the future work, because it provides a complete data analysis process relatively. In the future work, with the acquisition of more clinical information and genomic information, it is believed that the result of this method could be improved.

Methods for Faster and Efficient Data Entry in Electronic Medical Records

Shashi B. Gogia\textsuperscript{a}, Anand N. Malaviya\textsuperscript{b}

\textsuperscript{a} Software Developer and Surgeon In-charge, Sanwari Bai Surgical Centre, New Delhi, India
\textsuperscript{b} Consultant Rheumatologist, Indian Spinal Injuries Centre, New Delhi, India

Abstract

Data entry remains the slowest link in the value chain inhibiting growth of Electronic Medical Records and attendant benefits towards Meaningful use. We designed templates for user forms customized by specialty. Here, we demonstrate the functionality of our software and provide instructions on how these can be adopted by other developers.

Keywords:

Meaningful Use; Electronic Health Records; Software.

Introduction

While Moore’s law assisted by creating memory that allows faster speeds for Information Systems, manual data entry methods remain relatively static. This is the slowest link in the value chain and is inhibiting growth of Electronic Medical Records (EMRs). Short cuts like Copy Paste are frowned upon. Issues important for IT personnel may not be viewed the same by clinicians (e.g., security protocols may not be essential and bog down the user).

The authors are clinicians developing software for more than 20 years. We have templates for user forms which can be customized quickly as per speciality. The software has list selects customized by the user. (e.g., Rheumatoid Arthritis (M05/6.x) ICD code specification triggers the DAS 28 (Disease Activity Scoring for 28 joints) screen with a homunculus image directing the user to the joint of interest). See Figure 1.

Blocks of expected repeated information become one-time entries by the clinician which can be edited. The software intelligently pastes text using keywords and permits editing at multiple layers depending on privileges. Some learning and assistance by the vendor or local IT team, is however required. Linkages to standardised codes can be done.

Methods

We demonstrate the above and provide instruction for adoption by developers. We have also analyzed user outcomes from Rheumatology. There are recordings of total patients and time spent in clinic before and after the software was adopted. Additionally, a survey was administered to patients comparing their overall experience during different stages of software development [1,2].

Results

With use of such techniques, total time spent by the patient in Rheumatology OPD decreased from 120 minutes to 45 minutes for the first visit and from 45 minutes to 25 minutes for revisits. The number of patients given appointment as well as seen, increased. Similar but less dramatic outcomes have been found with other specialties.

Conclusion

Adoption of EMRs and EHRs remains slow despite incentivization [3]. Our example results in better clinician engagement. Helpful features include:

- User created lists which allow auto completion and filtered selects via list boxes.
- Nicknames and codes which translate to bulk text.
- Multi-select list boxes with user created choices (e.g., nicknames).
- Bulk entry across linked columns (e.g., autofilled address information).
- Block standardized text entries (e.g., Operation notes).
- Labels and attributes are organized upon selection.

The system displays information understandable to the user. Besides ICD, physicians did not prefer other codes, even though available. Analysis can be performed with simple SQL. The scope can be configured for other specialities and diseases.

Users are the best developers. EMR adoption can be eased through deeper user engagement and decreased data entry time.

Comparative Analysis of Geriatric and Adult Drug Clinical Trials on ClinicalTrials.gov

Zhe He, Aisha Langford

*School of Information, Florida State University, Tallahassee, FL, USA

Department of Population Health, New York University, New York, NY, USA

Abstract

Clinical trials generate gold standard medical evidence, but are often criticized for the lack of population representativeness. We performed a comparative meta-analysis of drug trials that focus on older adults (≥ 65 years old) and adults (18 – 64 years old). The major finding is that a higher percentage of geriatric drug trials were terminated or withdrawn than that of adult drug trials.

Keywords:
Clinical Trials; Health Disparities; Geriatric Research

Introduction

Clinical trials, especially randomized controlled trials, are widely regarded as gold standard medical evidence. However, they are often criticized for the lack of population representativeness and poor generalizability. Older adults are often underrepresented in clinical trials on various disease domains due to their multiple chronic conditions. In this study, we performed a comparative analysis of drug trials that focus on geriatric and adult populations based on the trial summaries collected from ClinicalTrials.gov.

Methods

We have previously built a relational database of clinical study summaries on ClinicalTrials.gov called COMPACT [1], which includes both trial metadata (e.g., intervention type, intervention name, study phase, study design) and structured eligibility criteria. We downloaded the MeSH-based medical conditions annotation file of the AACT (Aggregate Analysis of ClinicalTrials.gov) database (version: March 27, 2015) [2], developed by US Food and Drug Administration and Duke University. From the COMPACT database [1], we found 654 drug trials that recruited patients ≥ 65 years old only with a start date between January 2005 and September 2016. We analyzed their medical conditions, primary purpose, endpoint classifications and overall status. For the trials that were withdrawn or suspended, we further analyzed the reasons for their withdrawals. We compared the results with adult drug trials that only recruited patients between 18 and 65 years old (minimum age ≥ 18, maximum age ≤ 65).

Results and Discussion

Top 10 medical conditions of drug trials that focus on older adults included Alzheimer’s disease (n=22), hypertension (n=19), delirium (n=18), breast cancer (n=16), multiple myeloma (n=14), acute myeloid leukemia (n=13), non-small cell lung cancer (n=12), osteoporosis (n=10), depression (n=10), and dementia (n=10).

Table 1 shows the comparison of drug trials that recruited older adults and younger adults. A higher percentage of geriatric drug trials were withdrawn or suspended than adult drug trials. The major reasons of termination for the 59 geriatric drug trials were slow accrual (45.8%).

Generation of openEHR Test Datasets for Benchmarking

Samar El Helou¹, Tuukka Karvonen², Goshiro Yamamoto³, Naoto Kume⁴, Shinji Kobayashi⁵, Eiji Kondo⁶, Shusuke Hiragi⁶, Kazuya Okamoto⁶, Hiroshi Tamura⁶, Tomohiro Kuroda⁶

⁴ Department of Gynecology and Obstetrics, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Abstract

openEHR is a widely used EHR specification. Given its technology-independent nature, different approaches for implementing openEHR data repositories exist. Public openEHR datasets are needed to conduct benchmark analyses over different implementations. To address their current unavailability, we propose a method for generating openEHR test datasets that can be publicly shared and used.

Keywords:
Electronic Health Record; Benchmarking

Introduction

OpenEHR is a technology-independent, open-source specification for Electronic Health Records’ (EHR) architecture adopting a two-level modeling approach [1]. The choices of database technologies and approaches for repository implementations are left for the developers. Benchmarking performance of different repository implementations in different use-case scenarios is needed [2]. Usually, benchmark analyses include the comparison of query response times and thus require access to shared openEHR datasets, often unavailable due to strict medical privacy laws.

The effectiveness of a benchmarking dataset is affected by its level of accessibility, realism and evaluation capabilities. In the case of openEHR benchmarking datasets, the structure of the data is constrained by the reference model and archetypes’ definitions, thus the evaluation capabilities can be defined and artificially simulated. As for realism, some could be potentially sacrificed in favor of accessibility in cases where real data is difficult to come by.

This work provides a method to generate open application-specific openEHR test datasets. The resultant datasets should comply with openEHR’s information and archetype models and allow queries applicable in real world scenarios.

Methods

First, we identified the clinical concepts involved in a pregnancy home-monitoring application and determined a list of realistic data entries. Next, we mapped the clinical concepts to openEHR archetypes available in the openEHR Clinical Knowledge Manager (CKM) and created data value sets corresponding to the possible data entries. We applied an Object Relational Mapping (ORM) approach to design a relational schema allowing the persistence of the required archetypes over classes from the openEHR Reference Model.

We created data generation plans using the archetypes’ structure and data value sets, as shown in Figure 1. The plans were executed using Microsoft Visual Studio 2010 to populate an SQL Server database. Finally, we identified application-specific search scenarios for which we formulated and executed SQL queries solely using the archetypes’ definitions.

![Figure 1 - openEHR dataset generation process](image)

Results

The method was applied to generate datasets simulating a pregnancy home-monitoring repository. A set of seven queries were executed and generated non-empty result sets. Datasets of 10k and 100k records in CSV and JSON formats can be accessed via github.com/samarhelou/data. Cypher queries are also provided to allow dataset import, visualization, and testing in Neo4j, a labeled property graph database.

Conclusions

We proposed and tested a method for generating test openEHR datasets. Future work requires the inclusion of data generation rules to reflect the real distributions of medical cases in the population. The generated datasets will be used to benchmark an openEHR repository implementation using Neo4j.

Mining Associations Between Genes and Clinical Conditions of Breast Cancer by Using Gene Expression Data

Yuefang Hou, Hao Zhang, Han Zhang, Lei Cui

School of Medical Informatics, China Medical University, Shenyang, Liaoning, China

Abstract

Recent studies have identified some genes related to cancer phenotypes, but lack of comprehensive clinical information. Here we present an integrated data mining method to find associations between genes and multiple clinical conditions of breast cancer by using gene expression data from Gene Expression Omnibus. The associated modules of genes and clinical conditions were built and some potential related genes were suggested.

Keywords:
Data Mining; Gene Expression Profiling; Breast Neoplasms

Introduction

High-throughput data are used for establishing expression patterns to recognize specific phenotype, predict the outcome of disease, and promote the development of precision medicine. Recent studies have explored the association between genes and clinical conditions, but lack of comprehensive clinical information. We present an integrated data mining method with gene expression data and clinical annotation of breast cancer. The associated modules of genes and conditions are built for management of cancer.

Methods

Gene expression data of breast cancer in Gene Expression Omnibus GSE2109 were downloaded and organized into gene-sample expression matrix. The data were normalized by logarithmic transformation, mean value centerization for each gene. We selected differentially expressed genes among samples and got 616×358 gene-sample expression matrix. On the other hand, 72 clinical conditions, including personal attribute, behavior, medical history, pathological stage, grade, ER, PR, HER2 and histology, et al, were extracted from the sample descriptions and then standardized to build a 358×72 sample-condition matrix. The above two matrices were multiplied to get a 616×72 gene-condition matrix. Then the association modules between genes and conditions were extracted with biclustering analysis. Both GO and KEGG pathway enrichment analyses were applied to each cluster of genes. We analyzed the biological mechanism of genes to predict potential relations between genes and conditions of breast cancer.

Results

Twenty gene clusters were built with biclustering. The module map shows that 7 gene clusters are correlated to the stage, grade, ER, PR, HER2 and histology of cancer. Another 7 gene clusters are associated with different personal attribute, behavior and medical history. Some associations, such as LCN2, CDH1, GATA3 and different clinical conditions, are consistent with the prior knowledge in OMIM database. Moreover, we found several potential associations. For example, the expression level of 16 genes in cluster1 (including CDH1) may coordinately affect grade, histology and ER expression of breast cancer. The genes expression of cluster19 are associated with tobacco, alcohol and oophorectomy.

Conclusion

Through the data mining method we developed, the possible associations between genes and clinical conditions of breast cancer are summarized. Our analysis presents multiple research directions for diagnostic, prognostic and therapeutic studies.

Comparing Different Adverse Effects Among Multiple Drugs Using FAERS Data

Jing Huang*, Xinyuan Zhangb*, Jingcheng Dub, Rui Duan*, Liu Yangc, Jason H. Moorea, Yong Chena#, Cui Tao#

a University of Pennsylvania, Philadelphia, PA, USA
b University of Texas Health Science Center at Houston, Houston, TX, USA
c Mayo Clinic, Jacksonville, FL, USA

Abstract

US Food and Drug Administration (FDA) Adverse Event (AE) Reporting System (FAERS) is a major source of data for monitoring drug safety. However, there is not a general procedure to systematically compare drugs group. We present a statistical method, which can effectively identify significant differences in AE rates among drugs and estimates the differences in age and gender distributions.

Keywords:
Adverse Drug Reaction Reporting Systems; Data Mining.

Introduction

Post-marketing surveillance is critical to ensure long-term safety, study rare adverse events (AE), and adverse reactions [1]. The US Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) is a post-marketing surveillance program seeking voluntary inputs on AEs to monitor drug safety [2]. We propose a statistical pipeline that provides interpretable results and is convenient to implement. It systematically compares the differences between groups of drugs for specific AEs and can be used to select candidate AEs that are potentially important for future investigation. The method can also be used for other types of reporting systems. We use FAERS data to compare three Hepatitis C therapies.

Methods

The procedure was carried out in three steps.

Step I: Descriptive Analysis and Visualization

Compare the total number of adverse events distribution between the three therapies using side-by-side histogram plots.

Step II: Difference in AE Rates Among Groups

For each type AE type, compare the reporting rates among the different treatment groups using the chi-squared test and select AEs with significantly different reporting rates by therapy group.

Step III: Quantify and Visualize Risk Factor Effect Size

For each selected AE from step II, investigate whether the difference in reporting rates can be explained by differences in demographics by comparing the effect sizes before and after adjusting for these variables.

Results

The FAERS data contains the top 30 most frequently self-reported AEs of the three Hepatitis C therapies: 28,192 patients were in Therapy A, 5,035 in Therapy B, and 7,820 in Therapy C (Therapy A and B drugs). In step I, we observed that Hepatitis C therapy C caused more AEs than B and C. In step II, the chi-squared test significantly different rates of AEs among the three therapy groups, after Bonferroni correction, except for “arthralgia”. In step III, we found that for the 30 most frequently reported AEs, the adjusted odds ratio was less than the unadjusted odds ratio for 15 AEs and was greater than the unadjusted odds ratio for 15 AEs. The difference between the adjusted and unadjusted odds ratio attributable to age and gender ranged from 0.2% to 14.8%.

Conclusion

In this paper, we provided a statistical procedure to compare the difference between AEs among multiple drugs using FAERS data. We are currently developing an R package, “AEtools”, to semi-automate the proposed pipeline for statistical analysis and visualization. Such a procedure, including the R codes, is useful for pharmacoepidemiological studies and will be made publicly available.

Abstract

NLP-PIER (Natural Language Processing – Patient Information Extraction for Research) is a self-service platform with a search engine for clinical researchers to perform natural language processing (NLP) queries using clinical notes. We conducted user-centered testing of NLP-PIER’s usability to inform future design decisions. Quantitative and qualitative data were analyzed. Our findings will be used to improve the usability of NLP-PIER.

Keywords: Information Storage and Retrieval; Natural Language Processing; Evaluation Studies.

Introduction

NLP-PIER was created to provide an accessible solution through a search interface to clinical researchers interested in or requiring access to clinical NLP capabilities of clinical documents [1]. The system has two interfaces: a full text search interface and a custom interface for searching Unified Medical Language System (UMLS) concepts [2]. We were interested in understanding potential design opportunities and user acceptance of NLP-PIER and to more broadly understand the needs of clinical researchers when using a self-service NLP tool.

Methods

This study was conducted at University of Minnesota (UMN) as part of its broader clinical and translational science research platform. We designed standard tasks to use NLP-PIER and asked clinical researcher participants (n=11) to complete these tasks, usability instruments (system usability scale (SUS) [3] and NASA-Task Load Index (NASA-TLX) survey [4]), a brief interview, and exit questionnaire. Time on task, task completion percentage, and survey results were assessed. Interviews were transcribed and coded for themes.

Results

For the full text search interface, questionnaire scores were 69.4 (19.8) (SUS) and 18.8 (5.7) (NASA TLX) and for the Concept search interface scores were 66.1 (32.4) and 21.8 (7.7). Average time on task and task completion varied widely. In interviews, all participants expressed that NLP-PIER was easy to use and would be useful in their work.

Conclusion

End user testing of NLP-PIER identified a number of usability challenges and several solutions. Our study also demonstrated that substantial variation exists between different users. Overall, our findings illustrate the importance of incorporating user testing and feedback in the design process.

Explore Care Pathways of Colorectal Cancer Patients with Social Network Analysis

Tianyao Huoa, Thomas J George Jrb, Yi Guoa, Zhe He, Mattia Prosperid, François Modavea, Jiang Bianb

Abstract

Patients with colorectal cancer (CRC) often face treatment delays and the exact reasons have not been well studied. This study is to explore clinical workflow patterns for CRC patients using electronic health records (EHR). In particular, we modeled the clinical workflow (provider-provider interactions) of a CRC patient’s workup period as a social network, and identified clusters of workflow patterns based on network characteristics. Understanding of these patterns will help guide healthcare policy-making and practice.

Keywords:
Colorectal Neoplasms, Workflow, Electronic Health Records

Introduction

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths in the United States. The quicker the patients get diagnosed and treated, the higher the survival rate. Understanding variations of care pathways (i.e., the sequence of clinical encounters) can help improve the workflow efficiency and ultimately quality of care [1]. Many factors may influence these care pathways. This study is thus to explore the characteristics of patients, providers, and the healthcare system that potentially influence the care pathways of CRC patients’ workup period using social network analysis (SNA).

Methods

The study cohort is patients diagnosed with CRC identified with ICD-9/10 diagnostic codes. We obtained 1,924 patient records from the University of Florida (UF) Health Integrated Data Repository. The resulting dataset contains demographics, encounters, diagnoses, procedures, and labs of eligible patients between June 2011 and February 2015. The workup period is defined based on procedure codes (i.e., ICD and CPT codes). The starting point of the workup period is the date of the diagnostic procedure (e.g., colonoscopy); and the end point is the date of surgery/chemotherapy. Out of the 1,924 patients, 327 patients’ workup periods can be defined (since some patients were not diagnosed or treated at UF Health).

SNA studies the relationships (edges) between a set of actors (nodes). In our study, the nodes are patients’ encounter events such as office visits, lab tests, and procedures. The edges depict the relationships between the encounters, such as referrals, orders, and reports, where the edge weight is the time delay between two encounter events. Figure 1 illustrates a care pathway network. We can quantitatively measure network patterns using metrics such as path length.

We then infer clusters of patients that share care pathways (network patterns). We first used random forest (RF) regression to explore the associations between the network metrics and the length of the workup period; and from which, we derived a similarity score for each pair of patients. We used hierarchy agglomerative clustering (HAC) algorithm to infer clusters of patients based on these similarity measures. We followed best practice in tuning the RF model (e.g., parameter tuning and holdout validation) and conducted the Silhouette analysis to choose the appropriate number of clusters.

Results

The mean workup periods is 98 days with large variations (±212). On average, patients have 30 (±43) encounters with 10 (±9) providers. Using the network metrics as predictors, the trained RF regression model performed well $r^2 = 0.81$. Through Silhouette analysis, we identified 3 clusters of patients using HAC based on the similarity measures.

Table 1 - Descriptive Statistics of the Clusters.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Cluster 0 (n=110)</th>
<th>Cluster 1 (n=119)</th>
</tr>
</thead>
<tbody>
<tr>

<td>248.5 (±315.1)</td>
<td>15.2 (±10.7)</td>
</tr>
<tr>
<td># of Nodes</td>
<td>16.7 (±11.6)</td>
<td>7.7 (±4.7)</td>
</tr>
<tr>
<td>Path Length (weighted)</td>
<td>15.7 (±27.6)</td>
<td>2.1 (±1.8)</td>
</tr>
<tr>
<td>Never Smoker</td>
<td>41.82 %</td>
<td>47.90 %</td>
</tr>
</tbody>
</table>

Table 1 shows some of the characteristics of two clusters. It is clear that these two clusters show distinctive patterns.

Conclusions

Guidelines of CRC, such as those published in the National Comprehensive Cancer Network (NCCN) Clinical Practice Guidelines in Oncology, do exist. However, demonstrated by our study, real world practices are vastly different. Understanding these derivations is critical for reducing time needed for patients to receive appropriate care. SNA is a promising approach in exploring patterns of care pathways.

Constructing an Open-Access Bio-Signal Repository from Intensive Care Units

Doyeop Kim, Sukhoon Lee, Tae Young Kim, Sanghyung Jin, Jae Yeon Park, Jeong Gil Ko, Rae Woong Park, Dukyong Yoon

* Department of Biomedical Informatics, Ajou University School of Medicine, Suwon, South Korea
b Department of Software Convergence Engineering, Kunsan National University, Kunsan, South Korea
c Department of Software and Computer Engineering, College of Information Technology, Ajou University, Suwon, South Korea
d Department of Biomedical Sciences, Ajou University Graduate School of Medicine, Suwon, South Korea

Abstract

Bio-signals can be crucial evidence in detecting urgent clinical events. However, until now, access to this data was limited. We aim to construct and provide a new open bio-signal repository with data gathered from more than 40 intensive care unit (ICU) beds. For doing so, we completed the interfacing system with the patient monitors at the target beds and plan to expand this data set to more than 100 ICU beds. Once completed, we plan to publicly open the data to catalyze interesting clinical-event detection research.

Keywords:
Biomimetics, Intensive Care Unit, MIMIC

Introduction

Bio-signals such as electrocardiogram, continuous blood pressure and oxygen saturation can act as evidence in detecting clinical events. The Multiparameter Intelligent Monitoring in Intensive Care II (MIMIC II) database provides a diverse set of clinical and bio-signal waveform data from real clinical practice [1]. The database has contributed to many research work from clinical research to biomedical engineering. However, since MIMIC is the only qualified bio-signal database, the researchers using the MIMIC database have suffered from the lack of cross validation data. To address this issue, we plan to construct a new publicly-open bio-signal repository with data collected from ICUs. Our repository is designed to overcome limitations of the MIMIC database, such as the linking issues between clinical and waveform database, data source diversity.

Methods

The subject hospital for data collection is a tertiary teaching hospital in South Korea, with 158 beds spread over eight ICUs equipped with patient monitors from three different vendors, General Electronics, Phillips and Nihon Kohden. Currently, our bio-signal repository interfaces with the Nihon Kohden and Phillips patient monitors. For Nihon Kohden devices, we collect bio-signal data via the Health Level 7 (HL7) protocol using a designated gateway, while Philips devices utilize RS232 connection.

Results

At the current state, we are done interfacing 30 Nihon Kohden devices for beds covering two ICUs. Quantitatively, we collected data from 605 patients from Aug 31 2016 to Apr 6 2017, corresponding to 139,392,966 vital signs samples and 2,910,025 waveform files (10-minute signal data per file).

We plan to finalize the interface process with the Philips devices within the second quarter of 2017. At the end of this phase, we expect a total of 108 connected patient monitors.

<table>
<thead>
<tr>
<th>Collected waveforms</th>

<td>30.91%</td>
</tr>
<tr>
<td>End-tidal CO2</td>
<td>45</td>
<td>7.44%</td>
</tr>
</tbody>
</table>

Proportion indicates proportion of patients measuring the waveform among entire patients

Discussion

We are constructing the qualified bio-signal repository. It will be linked with clinical database like diagnosis, procedure, or prescription. Furthermore, we aim to open the whole database to the public after anonymization. Different ICU monitoring systems (Nihon Kohden and Philips) generate different format of data. However, since we use a standard data model, the users do not have to consider data sources.

Conclusion

This abstract introduces our efforts for developing and deploying a publicly open bio-signal repository. We envision that our repository can interact with MIMIC as a database for enabling new research in bio-medical informatics.

Depression, Impulse Control Disorder, and Life Style According to Smartphone Addiction

E. Y. Kim\textsuperscript{a}, S. W. Joo\textsuperscript{b}, S. J. Han\textsuperscript{a}, M. J. Kim\textsuperscript{a}, S. Y Choia

\textsuperscript{a}Department of Health Care Administration, Seoyoung University, Paju-si, Gyeonggi-do, Republic of Korea, \textsuperscript{b}ACE Hospital, Ansan-si, Gyeonggi-do, Republic of Korea

Abstract

We examined depression, impulse control disorder, and lifestyle by degree of smartphone addiction. Chi-square tests and ANOVA were used to identify significant variables. CART was used to generate a decision making diagram of variables affecting smartphone addiction. The severe smartphone addiction group had rates of depression and impulse control disorder than the initial smartphone group.

Keywords:
Smartphone; Behavior, Addictive; Depressive Disorder

Introduction

Smartphones are convenient, many people are using them resulting in tolerance, addiction or difficulties in daily life, depression, learning disability, and impulse control disorders. Smartphone addiction is a serious problem \cite{1,2}, especially in the field of information technology \cite{3}. We aimed to predict factors affecting smartphone addiction.

Methods

University students (n=132) answered questions about: smartphone addiction, depression, impulse control disorder, and lifestyle. Participants were classified into smartphone addiction groups (normal/suspected/serious), and depression and impulse control disorder groups (normal/poor/serious). Chi-square and ANOVA were used to identify significant variables. CART was used to generate a decision making diagram of variables affecting smartphone addiction.

Results

Men were more addicted to smartphones than women (p=0.029). Those in the more severe smartphone addiction groups slept less than 6 hours a night (p<0.001) and exercised less (p=0.011) than those in the less severe addiction groups (Figures 1 and 2). Severe smartphone addiction groups had more depression (p=0.005) and impulse control (p<0.001) than the initial addiction group (p=0.005). The initial smartphone addiction group had higher impulse control than the normal addiction group (p=0.002). Those in the more severe smartphone addiction groups were more likely to objectively indicate having smartphone addiction (p=0.007).

Conclusion

Problematic smartphone use increases depression and anxiety. Effectively use requires education to change user preceptions.

Abstract

This study objectives to investigate a range of Partin table and several machine learning methods for pathological stage prediction and assess them with respect to their predictive model performance based on Koreans data. The data was used SPcdb and gathered records from 944 patients treated with tertiary hospital. Partin table has low accuracy (65.68\%) when applied on SPcdb dataset for comparison on patients with OCD and NOCD conditions. SVM (75\%) represents a promising alternative to Partin table from which pathology staging can benefit.

Keywords: Prostate Cancer, Machine Learning, Pathology staging

Introduction

Machine learning based on prediction of prostate cancer pathological stage is an essential step in a patient treatment [1]. Prediction model determines the treatment that will be applied further. Generally, medical experts use the pathological stage predictions provided in Partin tables to support their decisions. However, Partin tables are based on simple statistical method and built from US data [2]. This study objectives to investigate a range of Partin table and serval machine learning methods for pathological stage prediction and assess them with respect to their predictive model performance based on Koreans data.

Methods

The data was collected by the Smart Prostate Cancer Data Base (SPcdb) and gathered records from 944 patients treated with prostatectomy in tertiary hospital [3]. Our study aims at classify the OCD (Organ-Confined Disease; 621 patients) and NOCD (Non Organ-Confined Disease; 323 patients). In addition, a selection of machine learning classifiers including Back Propagation Network (BPN), Support Vector Machine (SVM), Naïve Bayes (NB), Bayesian Networks (BNs), Classification and Regression Tree (CART) and Random Forest (RF) was applied to the same data and using Weka 3.8 software. The classifiers input following variables: PSA, Gleason score (Sum), clinical T stage and positive core count.

Results

We use the 10-cross folds to evaluate performance. Partin tables have low accuracy (65.68\%) when applied on SPcdb dataset for comparison on patients with OCD and NOCD conditions. Comparing a range of machine learning classifiers shows that SVM generally outperform other methods. The results of BPN (73.41\%), BN (74.36\%), NB (74.79\%), CART (70.66\%), RF (68.75\%) and SVM methods (75\%) are overall improved. SVM show higher accuracy than the other methods.

Conclusions

The performance of Partin tables can be described as low to moderate on Korean data. This means that following the predictions generated by Partin tables, Korean patients would received an inappropriate treatment. In addition to demographic differences between Korea and the original US population, the machine learning methodology and in particular Partin table present limitations. Also, SVM represents a promising alternative to Partin table from which pathology staging can benefit.

Avoiding Overfitting in Deep Neural Networks for Clinical Opinions Generation from General Blood Test Results

Youjin Kim, Han-Gyu Kim, Zhun Li, Ho-Jin Choi

School of Computing, KAIST, Daejeon, Korea

Abstract

We have used deep neural networks (DNNs) to generate clinical opinions from general blood test results. DNNs have overfitting problem in general. We believe the complex structure of DNN and insufficient data to be the major reasons of overfitting in our case. In this paper, we apply dropout and batch normalization to avoid overfitting. Experimental results show the improvement in the performance of the DNNs.

Keywords:
Hematologic Tests, Neural Networks (Computer), Clinical Decision-Making

Introduction

Blood tests have been used to detect diseases in the body. One of the previous works analyzed a certain type of blood test results and made a prognosis for one disease using the Deep Neural Network (DNN) [2]. In [1], we created a DNN model that analyzes general blood test results and provided clinical opinions for various diseases. However, the DNN in the previous work suffers from overfitting problem. 1.7 million parameters of the complex DNN and insufficient data cause overfitting. To avoid overfitting, we apply dropout and batch normalization. We find optimal hyperparameter values and get the best performance.

Methods

Overfitting, which occurs with the complex structure of DNN and small size of training data, dramatically decreases the generalization performance of DNNs. The overfitting is highly probable to happen in the clinical domain, as clinical data is generally insufficient. Dropout temporally cuts connections of hidden layers to avoid overfitting. Cutting connections instantaneously reduces DNN complexity. By applying dropout in various manners, we have found out that it works best when dropout is applied to the first layer of the DNN with dropout rate \( p=0.32 \).

Batch normalization prevents overfitting by normalizing the activations of the hidden layers which help to regularize DNN. By implementing various experiment on batch normalization, we have discovered that the batch normalization should be applied to all hidden layers in order to obtain the best performance.

Results

We conducted clinical opinions generation experiments on the collected dataset of Koreans containing 14,479 instances.

Table 1 implies that applying dropout and batch normalization improves the opinion generation performance with larger F1-measure values by achieving larger precisions and recalls simultaneously compared to the existing DNN. F1-measure of dropout is slightly larger than that of batch normalization, but the difference is not significant, implying that both of them work similarly.

<table>
<thead>
<tr>
<th></th>
<th>Precision</th>
<th>Recall</th>
<th>F1-measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNN</td>
<td>0.904</td>
<td>0.879</td>

<td>0.898</td>
</tr>
<tr>
<td>DNN-BatchNorm</td>
<td>0.907</td>
<td>0.883</td>
<td>0.894</td>
</tr>
</tbody>
</table>

Conclusions

We apply dropout and batch normalization to avoid overfitting in the DNN that generates clinical opinions from general blood test results. Experimental results show that dropout and batch normalization improve the performance of the DNN. In clinical opinion generation, it is more important to detect the abnormal status of the patients than to find out the normality of healthy persons. We will conduct further researches by focusing on such abnormal cases.

Li2b2-Façade: Simulation of i2b2 Data Warehouse Server and Client for Interaction with Other Systems

Raphael W. Majeed⁹, Tingyan Xu⁹, Mark R. Stöhr⁹, Rainer Röhrig⁹

⁹ Department of Medical Informatics, Carl von Ossietzky University, Oldenburg, Germany, UGMLC, German Center for Lung Research (DZL), Justus Liebig University, Giessen, Germany

Abstract
Since its release in 2004, the i2b2 data warehouse software has become a valuable tool for clinical researchers. Physicians can use its browser-based query frontend intuitively without additional training or reading through documentation. While the i2b2 software describes its API as “REST”, it is neither stateless nor does it follow the common guidelines for RESTful APIs. Thus, interfacing other software with i2b2’s custom RPC-style XML-API is a very cumbersome process. To overcome these issues, we developed a lightweight software abstraction layer “lightweight i2b2 façade” (li2b2-façade).

Keywords: Systems Integration; Databases, Factual; Information Storage and Retrieval

Introduction
For the German national registry of emergency care (AKTIN)[1], we installed i2b2 data warehouse servers at several emergency departments all over Germany. Interaction with other software requires certain functionality of the i2b2 server to be accessed from other applications. While the i2b2 software describes its API as “REST”, it is neither stateless nor does it follow the common guidelines for RESTful APIs[2]. Thus, interfacing other software with i2b2’s custom RPC-style XML-API is a very cumbersome process.

To overcome these issues, we identified four requirements in our scenario in order to develop a lightweight software abstraction layer “lightweight i2b2 façade” (li2b2-façade):

1. Authentication: The i2b2 user management needs to be accessible from other software.
2. The i2b2 query history must be manageable from other applications.
3. Other applications need to run queries in i2b2 and retrieve the results.
4. The i2b2 ontology needs to be accessible from other applications.

Methods
The communications between the i2b2 server and the webservice was analyzed in order to identify the HTTP calls needed to run the i2b2 webservice without a server as well as HTTP calls needed to access the i2b2 server without the webservice.

The library and source code is developed in Java 8, using current security standards and technologies.

Results
Communication analysis of i2b2’s “REST” XML-RPC messages yielded a minimum of 15 calls in four i2b2 components “PM”, “ONT”, “CRC” and “WORK”, which we implemented to satisfy the i2b2 webservice’s functionality. An additional 16 calls were implemented in order to allow complete control over user management and query management.

The developed library “li2b2-façade” was able to satisfy our requirements. All source code is open source and available online at GitHub: https://github.com/li2b2/li2b2-facade

Discussion
Usual interaction between the frontend user and the i2b2 data warehouse requires a synchronous connection, which may be difficult for some hospital environments. In this case, the li2b2-façade could be used to allow disconnected clients to run queries asynchronously by establishing a transparent middle layer between client and server. This decoupled client/server architecture allows arbitrary additional processing in-between, like e.g. query manipulation, term mapping or even distributing the query to multiple servers.

Conclusion
We were able to develop a lightweight software abstraction layer “lightweight i2b2 façade”: li2b2-façade, which can be used for (a) simplified access of i2b2 content/functionality from external applications, (b) simulation of an i2b2 server or client, as well as (c) separation and injection of additional functionality between i2b2 server and client. In addition to the AKTIN project [1] which motivated our work, the software is also used by two additional Health IT projects.

Asynchronous Query Distribution Between Multiple i2b2 Research Data Warehouses: Li2b2-SHRINE

Raphael W. Majeed a, b, Mark R. Stöhr a, Volker S. Thiemann b, Rainer Röhrig b and Andreas Günther a

a UGMLC, German Center for Lung Research (DZL), Justus Liebig University, Giessen, Germany
b Department of Medical Informatics, Carl von Ossietzky University, Oldenburg, Germany

Abstract
Clinical Data Warehouses are established sources for research and quality management. The open source data warehouse software i2b2 enjoys good reputation and wide-spread use in the international medical informatics community. We developed a novel infrastructure to allow queries to be distributed asynchronously between i2b2 data warehouses.

Keywords:
Biomedical Research; Information Storage and Retrieval

Introduction
Clinical Data Warehouses are established sources for research and quality management. The open source data warehouse software i2b2 enjoys good reputation and wide-spread use in the international medical informatics community. Federated searches across different hospitals are possible with the “Shared Health Research Information Network” (SHRINE) [1] software which unfortunately has some limitations for hospitals with rigid IT security policies and counties with strict data protection – most notably requiring direct network access to participating hospitals as well as not allowing per query approvals by hospitals due to the synchronous query connections.

Aim of this project is the development of a software prototype which overcomes the above shortcomings and allows distribution of queries to federated data warehouses asynchronously without the need for direct network connections to the hospitals.

Methods
The development of an asynchronous network of i2b2 data warehouses can be broken down into three parts: (a) distribution infrastructure, (b) central query frontend and (c) integration software for all participating data warehouses.

For the decentralised query distribution infrastructure, we used software from the German emergency care registry [2]. The infrastructure is content-agnostic and supports any format or language for queries as well as query responses.

Central frontend and data warehouse integration is realized with i2b2-façade [3] with focus on minimal integration effort.

Results
We developed a standalone central server application which employs the original i2b2 webclient to formulate queries. Queries are stored and can be retrieved by data warehouse nodes at any time. Results are transferred back to the server and displayed in the web frontend.

Terminology and logic of the central queries can be adapted to local characteristics via customizable XML transformations.

Each additional SHRINE-node requires an API-Key in the central server configuration file. The distributed query network was successfully tested with 20 virtual data warehouse servers.

All source code is open source and available online at GitHub: https://github.com/li2b2/li2b2-shrine.

Discussion
In contrast to the original i2b2 SHRINE project [1], our solution does not require a full data warehouse installation for the central query interface. The server as well as the data warehouse connector run on any system without installation.

The presented software can be easily adapted to allow other data warehouse software to join a network of i2b2 data warehouse servers: Quick evaluation showed that a commercial data warehouse software with a RESTful query interface could be integrated with 200-300 lines of code (source link above).

Conclusion
Our software “li2b2-shrine” allows data warehouse queries to be distributed to multiple i2b2 data warehouses asynchronously without the need for firewall adjustments. Existing i2b2 data warehouses can be interconnected with minimal effort.

Deep Diabetologist: Learning to Prescribe Hypoglycemic Medications with Recurrent Neural Networks

Jing Mei\textsuperscript{a}, Shiwian Zhao\textsuperscript{a}, Feng Jin\textsuperscript{a}, Lingxiao Zhang\textsuperscript{b}, Haifeng Liu\textsuperscript{a}, Xiang Li\textsuperscript{a}, Guotong Xie\textsuperscript{a}, Xuejun Li\textsuperscript{c}, Meilin Xu\textsuperscript{d}

\textsuperscript{a}IBM Research China, Beijing, China,  
\textsuperscript{b}Department of Computer Science, Peking University, Beijing, China,  
\textsuperscript{c}Department of Endocrinology and Diabetes, the First Affiliated Hospital, Xiamen University, Xiamen, China,  
\textsuperscript{d}Pfizer Investment Co. Ltd., Beijing, China

Abstract

In healthcare, applying deep learning models to electronic health records (EHRs) has drawn considerable attention. This sequential nature of EHR data make them wellmatched for the power of Recurrent Neural Network (RNN). In this poster, we propose “Deep Diabetologist” – using RNNs for EHR sequential data modeling to provide personalized hypoglycemic medication prediction for diabetic patients. Our results demonstrate improved performance compared with a baseline classifier using logistic regression.

Keywords: Decision Support Systems, Clinical; Neural Networks (Computer); Electronic Health Records

Introduction

In China, over 100 million adults suffer from diabetes, and most Chinese diabetic patients go to hospitals regularly to receive medications. With large numbers of patients and limited number of diabetologists in China, is there any way to learn to prescribe hypoglycemic medications by deep learning from data (so as to provide clinical decision support for general practitioners in community hospitals)?

Methods

We propose to leverage advanced deep learning algorithms for medication learning from Electronic Health Records (EHR). Technically, we first do EHR data preprocessing (cleansing and imputation). As a result, we extract 481 clinical variables, including 350 3-digit ICD-10 codes, 124 lab tests, and 7 previously used drug classes. Then we apply LSTM for RNN implementation, on a machine configured with GPU using Theano backend. We train each LSTM for 20 epochs and to avoid overfitting, we stack a dropout (of 0.5) layer before the last Dense layer of the output vector. Besides, to address the variable-length inputs to RNN, we set a maximal length of 20 for input (if an instance has length less than 20, then we will mask the rest as 0), and a masking layer with mask value of 0. Hidden layers are set up with 64 cells, and the batch size is 32.

Results

For experiments, we use a cohort of 21,796 patients from a regional EHR repository of a tier II city in China (population of about 3.9 million). The cases to be studied are outpatient hypoglycemic prescriptions after the first observed type 2 diabetes diagnosis in adults. A case is counted per day per patient, and the total number of cases is 620,633. All models are trained on (randomly selected) 80% of the cases and validated on 10%, remaining 10% for testing.

As shown below, we have 3 predictors: Prev., Logistic Regression (LR) and RNN. The Prev. uses the previous medication for the current prediction. LR is the best candidate for a baseline classifier, while our RNN inputs features at every time step and outputs the 7 drug classes. The evaluation measure is AUC (i.e., the area under the curve), and we report the AUC scores for 7 drug classes, respectively. Results of Prev. are quite high, and the performance of LR is slightly improved, while our RNN outperforms Prev. and LR.

<table>
<thead>
<tr>
<th>Drug Class</th>
<th>AUC Prev.</th>
<th>AUC LR</th>
<th>AUC RNN</th>
</tr>
</thead>

<td>0.9422</td>
</tr>
</tbody>
</table>

Besides, we report the results of accuracy = #Hit/#Sample, where #Hit is the number of cases in which the predicted label equals to the targeted label, and #Sample is the number of samples. Moreover, we separately report results for those head cases, tail cases, and all cases – the head case means the first medication of a patient’s sequence, and the tail case means the last medication of a patient’s sequence, while the average is calculated for all cases of a patient’s sequence. The head accuracy of Prev. is not available, since there is no previously prescribed medication to count in for the head case.

\textsuperscript{d}Division of Genetics, National Cancer Center Research Institute, Tokyo, Japan

Abstract

In the collaborative research to support genomic medicine, we aim to improve the efficiency of operation such as prevention of hereditary cancer syndromes. In the present work, we built a prototype system to record a pedigree chart, clinical and genetic information on individuals during a genetic counseling session. In a mock examination, we were able to draw the pedigree chart of four generations in about four minutes and to record necessary information without disrupting conversation with counselees.

Keywords:
Hereditary Cancer Syndrome; Genetic Counseling; Pedigree

Introduction

FUJITSU Ltd. and the National Cancer Center (NCC) have carried out collaborative research for the development of ICT to provide the support required for introducing genomic medicine in a cancer clinic. As one of the approaches to this, we commenced prototyping and verification of the system that is required for supporting genetic counseling for consultation, diagnosis, and prevention of hereditary cancer syndromes.

Methods

We are compiling information such as transmission of genetic traits and medical history to a pedigree chart for the prognosis of the development of hereditary tumors during a genetic counseling session. So, the major requirements are as follows: 1) A pedigree chart can be created easily and quickly during a conversation with the counselee, 2) attribute information and the contents of consultation can be recorded easily at the same time as that in the pedigree chart, 3) information can be managed, retrieved, and accessed in pedigree units.

Of these requirements, we built a prototype system—Pedigree Chart Editor and Pedigree Viewer. The entry format of the pedigree chart complies with that of the National Society of Genetic Counselors (NGSG) \cite{1}.

The system was tested by four members such as doctors in charge of outpatients of genetic counseling to mainly evaluate the operability of Pedigree Chart Editor. By conducting mock genetic counseling with a model pedigree chart, the time required for creating a pedigree chart was measured.

Results

All four members evaluated the system with regard to its operability and suitability for the support of genetic counseling and efficiency improvement. The members were able to draw a pedigree chart of four generations only within the kinship in about four minutes. On the other hand, recording of attribute information required about fifteen minutes in total. In the mock genetic counseling, the members could input information without interrupting the conversation.

Discussion

In the development of the system, particular attention was given to “concise operability without interrupting a conversation”. A new data input interface, “Float Menu”, delivered the required result. This function realized the idea of displaying mental options on the input section with minimum pointer movements from the current input section. This was particularly useful for having concise operability and improving the input performance.

Recording of attribute information that involves input of characters and numeric digits requires a longer time than inputting kinships. To enhance the objectives of the system, it is necessary to introduce a menu for the frequently input patterns and to review the operation structure.

Conclusions

In this research, we built a prototype system that can support genetic counseling. The result of testing showed that the system allows for the 1) recording of information without disruption of conversation with counselees and 2) efficient digitization of pedigree charts.

Estimating Sample Size for a Feasibility Study of Computer-Assisted Input Support to EDC

Naoki Nishimotoa, Naomi Tamurab, Jun Kunikataa, Sumiko Akahoric, Tomoaki Sogoc, Yuma Taniö, Hideto Yokoia,c

a Clinical Research Support Center, Kagawa University Hospital, Kita-gun, Japan
b Graduate School of Health Sciences, Hokkaido University, Sapporo, Japan
c Department of Medical Informatics, Kagawa University Hospital, Kita-gun, Japan
d Graduate School of Medicine, Kagawa University, Kita-gun, Japan

Abstract
The aim of this study was to estimate the sample size for the assumed feasibility study of the computer-assisted input support on a clinical trial. More than 1,500 observations were required for the feasibility study with assumed settings. Further study was required for more efficient research design.

Keywords:
Sample size, electric data capturing, hospital information systems

Introduction
In clinical trials, clinical research coordinator (CRC) inputs clinical information to an electronic data capturing (EDC) on their daily work. Direct data transfer was required for precision and reducing the labor intensive work, however, electronic health record (EHR) has been disconnected from the internet for the security reason. EHR data was standardized by HL7 format in almost all the university hospital of Japan. Computer assisted input support on clinical trials was not studied well so far, we are developing the tool for the work. We are planning the feasibility study to evaluate the performance of the tool. In the software validation, sample size estimation was less implemented. Binary outcome, such as success or fail, was well interpretable however, it was difficult to scoring the software performance. Zhang et al. proposed the sample size estimation method for the paired binary outcome for this problem. In our research, the aim of this study was to estimate sample size for the assumed feasibility study of the computer-assisted input support for the clinical trial.

Methods
We assumed the following scenario:
1. CRC or other clinical staffs, such as nurses, pharmacists, laboratory technologist
2. Computer assisted input vs manual input
3. Cross-over design with paired binary outcomes
4. Some missing was assumed from EHR
At first, we calculated the sample size based on the exact McNemar test using SAS 9.4 (SAS Institute Inc., Cary NC) with significance level 5% and power 80%. Then, we used Zhang’s method for the sample size calculation and simulation with missing data[1].

Results
When the difference of paired proportion was 0.05 (P1-P0) and the correlation was increased from 0.0 to 0.5 by 0.1, then we obtained the sample size from 1537 to 770. Then, we set the correlation was 0 in Zhang’s method with missing proportion increased from 0.01 to 0.1 by 0.01 in pre- and post treatment. The estimated sample size was shown in the table.

<table>
<thead>
<tr>
<th>Correlation</th>
<th>Exact McNemar test</th>
<th>McNemar test</th>
<th>Zhang’s method</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>1,537</td>
<td>1,554</td>
<td></td>
</tr>
<tr>
<td>0.1</td>
<td>1,400</td>
<td>1,570</td>
<td></td>
</tr>
<tr>
<td>0.2</td>
<td>1,250</td>
<td>1,586</td>
<td></td>
</tr>
<tr>
<td>0.3</td>
<td>1,100</td>
<td>1,603</td>
<td></td>
</tr>
<tr>
<td>0.4</td>
<td>920</td>
<td>1,619</td>
<td></td>
</tr>
<tr>
<td>0.5</td>
<td>770</td>
<td>1,637</td>
<td></td>
</tr>
</tbody>
</table>

Conclusions
A feasibility study of computer-assisted input in a clinical trial required over 1500 inputs. It depends on the correlation of paired input by a CRC. In software validation, sample size estimation was less implemented so far. Binary outcome was well interpretable and we should note larger input trial was required for the performance evaluation.

Extracting Predictive Indicator for Prognosis of Cerebral Infarction Using Machine Learning Techniques

Yasunobu Nohara\textsuperscript{a}, Koutarou Matsumoto\textsuperscript{b}, Naoki Nakashima\textsuperscript{a}

\textsuperscript{a}Medical Information Center, Kyushu University Hospital, Fukuoka, Japan
\textsuperscript{b}Saiseikai Kumamoto Hospital, Kumamoto, Japan

Abstract

Identifying important predictive indicators for prognosis is useful since these factors help for understanding diseases and determining treatments for patients. We extracted important factors for prognosis of cerebral infarction from EHR. We analyzed EHR data of 1,697 patients with 1,602 variables using gradient boosting decision tree. Extracted factors include not only well-known factors such as NIHSS but also new factors such as albumin-globulin ratio.

Keywords: Prognosis; Cerebral Infarction; Machine Learning

Introduction

It is important to know predictive indicators for prognosis since these indicators are helpful to understand diseases and to decide treatments for improving patients’ outcome. Clinical information is entered into EHR systems by providers and ancillary systems such as radiology and laboratory information systems. In this paper, we extract predictive indicators for prognosis of cerebral infarction from EHR using machine-learning techniques.

Methods

A total of 1,849 patients were admitted to Saiseikai Kumamoto Hospital for cerebral infarction from October 2011 to October 2016. These patients were entered into a clinical pathway for mild cerebral infarction. We excluded patients who had incomplete data. Finally, we selected 1,697 patients for the study.

Objective variable

The modified Rankin Scale (mRS) is a scale for measuring the degree of disability in the daily activities of people who have suffered a stroke. The discharge mRS $\geq 3$, that means patients need assistance for daily activities, is typically defined as poor prognosis and we use this definition as the objective variable.

Explanatory variables

We used all EHR data that were available by the first day of admission as explanatory variables. We extracted 1,602-variables from five information sources: hospital discharge summary, discharge summary of neurology department, nurse observations and clinical inspection, and nutrition assessment.

Analysis methods

Since non-linear relationship exists in medical data and feature importance helps to interpret results, we use gradient boosting decision tree (GBDT) [1], one of the tree-based machine learning algorithms for making prediction model. GBDT also includes feature selection mechanism and is robust with many explanatory variables. A variable importance shows the strength of association between explanatory variables and the outcome; but does not show how they relate. We use a partial dependence plot (PDP) [1], which is useful to show the effect of the target explanatory variable for outcome [2].

Results and Conclusions

We generate a prediction model for poor prognosis using GBDT and extract important factors. The area under curves (AUCs) of the predictor is 0.839 and means excellent performance for prediction. Extracted important factors, of course, include many widely known predictive factors for prognosis of cerebral infarction such as pre-symptomatic mRS, NIHSS and age. Although not widely known, albumin-globulin ratio (A/G ratio) is extracted as the seventh important predictive factor. Figure 1 shows PDP for poor prognosis risk against A/G ratio. Patients with high A/G ratio (>1.5) belong to low risk group. This result is consistent with latest study by Tomasz et al. [3]. Machine learning techniques are useful to extract important factor for prognosis and understand how they relate to outcome.

Identifying Patients’ Smoking Status from Electronic Dental Records Data

Jay Patela,b, Zasim Siddiquia, Anand Krishnan,a, Thankam Thyvalikakathc

a Indiana University School of Dentistry, Indianapolis, IN, USA
b Department of Bio-Health Informatics, Indiana University School of Informatics and Computing, Indianapolis, IN, USA
c Center for Biomedical Informatics, Regenstrief Institute, Indianapolis, IN, USA

Abstract

Smoking is a significant risk factor for initiation and progression of oral diseases. A patient’s current smoking status and tobacco dependency can aid clinical decision making and treatment planning. The free-text nature of this data limits accessibility causing obstacles during the time of care and research utility. No studies exist on extracting patient’s smoking status automatically from the Electronic Dental Record. This study reports the development and evaluation of an NLP system for this purpose.

Keywords:
Smoking; Dental Records; Clinical Decision-Making.

Introduction

Smoking is a significant risk factor for initiation and progression of oral diseases such as periodontal disease, dental caries, and oral cancers. Therefore, it is crucial for dental clinicians to be aware of patient’s current smoking status and tobacco dependency [1]. This can help clinicians to make decisions and to take preventive measures as well as for treatment planning. In addition, this information can be used for conducting large scale research studies such as studies related to the association and correlation of smoking and oral diseases. However, due to free-text nature of the data, the access to this information can cause obstacles during the time of care and can be limiting for research purposes [2]. Historically, manual review is required in order to use this information. However, manual chart review can be labor intensive, expensive, and time-consuming. Natural language processing (NLP) can automatically extract patients’ smoking status from these histories to reduce human effort. Currently, no study exists on extracting patients’ smoking status automatically from Electronic Dental Record (EDR) data. This study reports on developing and evaluating an NLP system to identify patient’s smoking status from free text data in EDR.

Methods

This study was approved by the Indiana University Institutional Review Board (Study #:1611054551) and conducted at the Indiana University School of Dentistry (IUSD). We extracted de-identified clinical notes of patients who underwent oral examination at IUSD between December 31, 2011-January 1, 2012 from the EDR. Next, two clinicians trained in informatics manually reviewed and annotated 555 sentences describing patients’ smoking status as a smoker, non-smoker, or past smoker. We performed Cohen’s kappa statistical test to find the inter-annotation agreement (IAA) between the two annotators and any disagreement was resolved through discussion and consensus. We considered this dataset our gold standard and we divided this dataset into training (389) and testing (166) sets. We used the training dataset to develop our NLP algorithm. We evaluated the performance of NLP algorithm by testing its accuracy, precision, and recall on the test set.

Results

We observed an IAA of 92%. Our system achieved high precision (98%), recall (98%), and f measure (99%) in differentiating smokers and non-smokers. We observed 80% precision, recall, and accuracy when classifying patients into past smokers. The reason behind the moderate performance could be due to variations in documentations concerning past smoking status of patients in the EDR.

Conclusion

Our NLP system performed excellent in classifying patients’ smoking status into smoker and non-smoker and had moderate performance in classifying past smokers. In the future, we will annotate more smoking histories and increase the size of our training set. In addition, we will capture more variations in documenting past smokers. We will run this algorithm on bigger dataset and use this information for research purposes.

Discovery of Psychoactive Substance Addiction Patterns Based on Information Mining Engineering

García-Martínez Ramóna,b, Martins Sebastiánb, Bianco Santiagoa, Navas Hernánbc

a Information Systems Research Group, National University of Lanus, b Buenos Aires Scientific Research’s Commission, c Health Informatics Department, Sanatorium Finochietto, (Buenos Aires, Argentina.

Abstract
The evolution of Medical Data Mining has been possible from use of Health Information Systems. In Argentina, consumption of psychoactive substances is quantified through the National Survey on Prevalence of Psychoactive Substance of the National Institute of Statistics and Census. This paper presents the use of Information Mining Engineering as an alternative approach to identifying novel patterns.

Keywords:
Data Mining, Public Health Informatics

Introduction
Information Mining engineering (IME) covers the processes and methodologies used to order, control and manage the task of finding knowledge patterns in masses of information. Gervilla et al reports a study whose objective is to analyze and quantify the predictive value of different personal, family and environmental variables in cannabis use in adolescence. [1] In this context, our objective is to explore the use of IME as an alternative approach to identify patterns on the consume of psychoactive substance, to obtain qualitative answers to: i) Which are factors that describe whether a person tend to consume or not, marijuana? and ii) Which variables characterize different groups among the addicted people (and their level of incidence), allowing identify vulnerable sectors?

Methods
This research uses: a) Discovery of Behavior Rules (DBR): to identify the conditions that describe a specific outcome in the problem domain, b) Weighting of Group-Membership Rules (WGMR): to identify which are the conditions of membership to each of the classes of an unknown partition “a priori”. Involving the use of the combination of algorithms: Self-Organizing Map, Bayesian Networks and Decision Trees. [2]

Results
The database contains 34343 records. For the research question [i], the process DBR is implemented, using “Person consumes Marijuana” as Class Attribute. For question [ii], the process WGMR is implemented, filtering by people who consumes any psychoactive substance. The results are shown in Figure 1 and 2 respectively, describing the most relevant factors between parenthesis.

Conclusion
The discovery of psychoactive substance addiction patterns may be the cornerstone to identified state policies. When a information mining engineering protocol is established, the results of application of state policies may be revealed comparing patterns discovered in different editions of the same survey.

Bringing Knowledge to Users in One Click: Infobuttons in the Problem List of an EHR

Jose F. Rodriguez, Emilio S. Mole, Luciana Rubin, Sonia E. Benitez, Carlos M. Otero, Daniel R. Luna, Fernan Quiros

Department of Health Informatics, Hospital Italiano, Buenos Aires, Argentina

Abstract

The infobuttons allows the solving of information needs. In our study, the use of Infobuttons is described, analyzing the number of queries to UpToDate® from the problem list of an Electronic Health Record. There were 26419 requests in 8 months. The highest average use occurred in June. The links to knowledge bases can help to solve information needs, even before they occur.

Keywords: Electronic Health Records, Decision Support Techniques, Information Storage and Retrieval

Introduction

In medical practice it’s common for health practitioners to have doubts, especially regarding clinical cases which they deal with on a daily basis, particularly those related to diagnosis and treatment [1]. The availability of knowledge bases, such as UpToDate®, depends on a subscription by the user, and it also requires the accomplishment of a manual search, which presents a certain complexity in order to achieve the expected results [2].

The infobuttons are tools that allow different patient-specific data to be added to a search, allowing the user to obtain results with greater completeness and precision, using HL7 interoperability standards [3]. The purpose of this study was to describe the use of Infobuttons in our Electronic Health Record (EHR).

Methods

A descriptive, observational study was carried out analyzing the Infobuttons usage records in the problem list of the EHR. The data collection was performed from March 21, 2016 until October 31, 2016. The use was determined by each log accessing the tool taking into account the click on Infobuttons to access the response of UpToDate®.

Results

In the analyzed period, a total of 26410 queries were registered to the Infobuttons tool, of which 905 occurred during last 10 days of March, 3685 in April, 3462 in May, 4704 in June, 3685 in July, 3629 in August, 3216 in September, and finally 2963 in October. When we analyzed the tool use, discriminating by day of the week, it was possible to appreciate that the greatest number of requests to Infobuttons were made during Monday, Tuesday, Wednesday and Thursday, accounting for 4614, 5141, 4832, and 4873 interactions, respectively.

The analysis of use, according to schedule, showed that most of requests were performed in the morning hours between 9 am and 12 pm. A peak was detected at 11 am accounting for a total of 2348 requests to Infobuttons with a decrease to 214 at 5 am. Regarding to the daily average, 117.9 consultations per day were registered, while during the first month of the implementation of the tool was maintained in 90.5 queries per day. An increase was detected in the month of June to 156.8 per day, remaining at around 100 daily visits in the remaining months. The problems that more frequently needed the contextual help provided by Infobuttons as a clinical decision support were ‘Patient reviewed’, ‘Preoperative state’, ‘Clinical Finding’, ‘Patient currently pregnant’, ‘High blood pressure’, ‘Procedure related finding’, ‘Abdominal pain’, ‘Postoperative state’, ‘Nutritional support’, and ‘Tobacco dependence syndrome’.

Conclusion

In this study, we obtained an understanding of the online resources and the Infobuttons use in a problems list. The availability of these links to knowledge bases can help solve information needs, potentially improving patient care and decision making.

Laboratory of Health Education and Practices EA3412, Université Paris 13, Paris, France

Abstract
Continuing education is an imperative for professional nursing. E-Learning is one modality to support education and it has been extensively examined in a nursing academic context. An overview of quantitative, qualitative, and mixed-method systematic reviews were conducted to draw a broad picture of the effects of e-Learning and m-Learning used by registered nurses in a continuing education context.

Keywords:
Students, Nursing, Learning

Introduction
Continuing education (CE) is an imperative for nursing creating opportunities for nurses to acquire knowledge and develop competencies [1]. CE should improve the quality of care and patient health by changing the practice of providers [2]. E-learning represents a potential alternative way to learn and has positive impacts on nurses’ knowledge, skills, and satisfaction [3]. E-Learning technologies have been studied extensively for health professional students in an academic context (systematic reviews (n=22)) [4]. We found no overview of reviews focused on e-learning in a CE context for registered nurses (RN). We aim to systematically summarize evidence from qualitative, quantitative, and mixed method systematic reviews regarding the effects of e-learning and m-learning on nursing care. The methods and preliminary results will be presented.

Methods
The Cochrane methodology provides guidance overview preparation [5]. General health sciences (PubMed), nursing (CINAHL), and education electronic databases (ERIC) in addition to systematic reviews (Cochrane Database of Systematic Reviews, Epistemonikos) will be searched. The eligibility criteria are formulated using PICOS (Participants, Interventions, Comparisons, Outcomes, Studies). P: RN e-learning/m-learning. I: A variety of e-learning/m-learning interventions in a nursing CE context. C: comparing e-learning/m-learning with other learning. O: Conceptualize how e-learning/m-learning interventions could influence nursing. An organizational model will be used: the Nursing Care Performance Framework [6]. Outcomes include: Nursing resources (e.g., nursing staff supply, working conditions); nursing processes (e.g., work environment, nursing activities, satisfaction); and nursing outcomes (e.g., patient experience, quality of life, empowerment). S: Quantitative, qualitative, and mixed method systematic reviews published in English, French or Spanish from January 1, 2006 will be considered. Four reviewers will: independently screen the reviews to assess their eligibility, summarize the characteristics of reviews, perform data extraction and assess methodological quality. Data will be summarized using a narrative synthesis [7].

Discussion
This overview could elucidate the dimensions of nursing care with the potential to be supported, enhanced or constrained by the use of e- and m-learning in CE efforts.

Acknowledgements
This work is funded by the Quebec Nursing Intervention Research Network.

Using Human Phenotype Ontology for Phenotypic Analysis of Clinical Notes

Feichen Shen, Liwei Wang, Hongfang Liu

Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA

Abstract

Phenotypes are defined as observable characteristics of organisms. To facilitate the translation between genotype and phenotype, Human Phenotype Ontology (HPO) was developed as a semantically computable standardized vocabulary to capture phenotypic abnormalities found in human. In this study, we investigated the use of HPO to annotate phenotypic information in clinical domain by leveraging a corpus of 12.8 million clinical notes created from 2010 to 2015 for 729 thousand patients at Mayo Clinic Rochester campus.

Keywords:
Semantics; Human Phenotype Ontology, Phenotypic Analysis

Introduction

Phenotypes, defined as observable characteristics organisms, have attracted increasing attentions in the area of translational medicine by serving as the connectors between medical experimental findings and clinical practices. As a tool for annotating human phenotypic abnormalities, Human Phenotype Ontology (HPO) [1] has been developed as a controlled vocabulary for phenotypes by integrating phenotype knowledge from medical literatures and disease/gene databases. Here, we used HPO to annotate a large collection of clinical narratives consisting of all clinical notes generated from 2010 to 2015 at Mayo Clinic Rochester campus and assessed the distributional information of HPO terms.

Methods

Our annotation workflow is designed to leverage the Unified Medical Language System (UMLS) and corresponding NLP tool MetaMap. Figure 1 shows the overview of our annotation workflow. It includes two modules: i) the preprocessing module which leverages NLP techniques to extract key words from text; and ii) the semantic annotation module which maps the lexicon entries acquired from text to HPO terms.

Results

Demographic Phenotype Analysis- we grouped age 0-17, 18-35, 36-54 and >55 as children and teenagers, young adults, mid adults, and old adults age groups. 8 of the most popular HPO abnormality categories for each age group are shown in Figure 2. In addition, we found that Hypogonadotropic hypogonadism, Hirsutism, Basal cell carcinoma and Scarring alopecia of scalp are most significant phenotypes for male, female, White and Black or Africa patients, respectively.

Figure 1– Annotation Work Flow

Figure 2 – Distribution of Phenotypes across 4 Age Groups

Conclusions

In this study, we used HPO to annotate phenotypes from 2010-2015 clinical notes at Mayo Clinic. Phenotypic characteristics were collected for patients’ demographic and Wilson’s Disease.

Using a Simulation Modelling Approach to Manage Outpatient Department Waiting Time at the National Hospital of Sri Lanka

S.N.Silva\textsuperscript{a}, R.H. Hewapathirana\textsuperscript{b}, W.M.A.U. Jayatilleke\textsuperscript{c}

\textsuperscript{a}Head of Academic Affairs (International Institute of Health Sciences, Sri Lanka)
\textsuperscript{b}Chief Executive Officer (Health Informatics Society of Sri Lanka)
\textsuperscript{c}Senior Lecturer (Post Graduate institute of Medicine, University of Colombo, Sri Lanka)

Abstract

A simulation modeling approach was used to determine the optimal human resource solutions for the main functions of the OPD by observing 384 conveniently selected patients at the National Hospital of Sri Lanka. This work seems to be optimized by increasing the morning shift doctors, causing minimal disturbance and inconvenience to the administration and the workers.

Keywords:
Hospital Departments, Resource Allocation, Waiting Lists

Introduction

The Out Patient Department (OPD) at the National Hospital of Sri Lanka (NHSL) faces congestion due to overcrowding, leading to forming long queues and causing delays in patient care. The objectives were to identify an ideal resource allocation solution to reduce outpatient waiting time in Medical consultation, Phlebotomy and Dispensing processes at the NHSL OPD.

Methods

A process analysis was done using observations of the OPD process, and interviewing the key informants [1]. A times study to evaluate the OPD process was done observing 384 conveniently selected patients. The arrival and service times were calculated using the above data [2]. A Discrete Event Simulation using the ARENA software was carried out to model the current processes and to evaluate different scenarios that can reduce the delays. Each simulation was run 100 times.

Results

The most congested process in the OPD was the consultation and the most congested time was the weekday morning shift. The average inter-arrival time was 21 seconds at this time. The mean consultation time was 224 seconds and was considered a constant. For this process when the medical officers are increased from 12 to 15, the waiting time would reduce by 4 minutes and 30 seconds (66.1\% reduction) and the patients in the OPD queue reduced by 25 (81.2\%). Similarly when the doctors for the night shift was increased to 3, the waiting would reduce by 11.1minutes (77.6\%) and will shorten the queue by 80\%.

Abstract

The aim of this study was to use the Data Mining to analyze the profile of the use of contraceptive methods in a university population. We used a database about sexuality performed in the university population. The results obtained by the generated rules are largely in line with the literature and epidemiology worldwide, showing significant points of vulnerability in the university population. Validation measures of the study, as such, accuracy, sensitivity, specificity, and area under the ROC curve were higher or at least similar as compared to recent studies using the same methodology.

Keywords:
Contraception; Data Mining; Medical Informatics

Introduction

Data mining consists of applying algorithms to identify and analyze information in order to produce patterns or models [1]. In this context, the object of the study is sexuality, which is considered inherent to life and health and is expressed early in humans as one of the indices that measure the level of quality of life [2]. This paper presents the profile and experience of sexuality in a university population in southern Brazil generated using classification techniques.

Materials and Methods

This is an applied and technological study and was approved by the Research Ethics Committee on Human Beings. The database used for this study addressed the sexuality profile and the vulnerability regarding sexually transmitted diseases (STD) and syndrome immune deficiency acquired (SIDA) in a university population in southern Brazil. The classification of data was carried out using the J48 algorithm and the Waikato environment for knowledge analysis software (WEKA). Only the rules belonging in trees with at least 70% of the records correctly classified, and associations in 5% of the sample were used. For the evaluation of the knowledge generated, we used accuracy.

Results

After preprocessing, we generated 84 decision trees which have provided 3955 rules that were evaluated and selected according to the relevance to the objectives of the study. The accuracy is 78%, ROC area is 0.76 and the Kappa coefficient is 0.53. Sensitivity and specificity is 80.36% and 71.46% respectively; 80.38% instances were classified correctly and 19.64% instances were classified incorrectly. Among the evaluated rules it is highlighted that when selected as a class, the "use of condoms as a contraceptive method", it was found that the majority use condoms as contraceptive method, nor use sporadically as a form of prevention of sexually transmitted diseases , Did not use it in the last 5 sexual relations, not did they use the morning-after pill because they used oral or injectable contraceptives.

Conclusion

In conclusion, the results obtained by the generated rules are largely in line with the literature and epidemiology worldwide, showing significant points of vulnerability in the university population. Validation measures of the study, as such, accuracy, sensitivity, specificity, and area under the ROC curve were higher or at least similar as compared to recent studies using the same methodology.

Identifying Chemical-Disease Relationship in Biomedical Text Using a Multiple Kernel Learning-Boosting Method

Yueping Sun, Yu Zhang, Jiao Li

Institute of Medical Information & Library, Chinese Academy of Medical Sciences, Beijing, China

Abstract

Chemical-induced disease relations (CID) are crucial in various biomedical tasks. In the CID task of Biocreative V, no classifiers with multiple kernels have been developed. In this study, a multiple kernel learning–boosting (MKLB) method is proposed. Different kernel functions according to different types of features were constructed and boosted, each of which were learned with multiple kernels. Our multiple kernel learning–boosting (MKLB) method achieved a F1 score of 0.5068 without incorporating knowledge bases.

Keywords:
Matching Learning, Artificial Intelligence, Data Mining

Introduction

Chemical-disease relations are crucial in various biomedical tasks, such as developing new drugs and predicting potential toxicity. Automatic chemical-disease relation detection from free text remains challenging, and a key challenge in the task lies in integrating multiple types of data for accurate extraction. Recently, a chemical-induced diseases relation (CID) task and related corpus was provided by Biocreative V. Reviews of the team’s work shows that Support Vector Machines (SVM)-based classifiers are selected but no work incorporate multiple kernel learning into the classifiers.

Multiple kernel learning refers to a set of machine learning methods that use a predefined set of kernels and learn an optimal linear or non-linear combination of kernels as part of the algorithm. SPG-GMKL (Spectral Projected Gradient-Generalized Multiple Kernel Learning) developed by Jain et al [1] provides a state-of-the-art specialized optimization algorithm. In this work, SPG-GMKL is applied to different feature groups and a boosting algorithm is proposed in addition to the basic classifiers.

Methods

The training and the development data sets provided by BioCreative V are combined as a training set. The evaluation metrics include F1 score, precision and recall.

We systematically extracted the following features to train the classifiers, including: (1) Context words with position (-4,-3,-2,-1,1,2,3,4); (2) Context words with position in a co-occurring sentence; (3) Minimal middle string between chemical mentions and disease mentions; (4) Parser results of co-occurring sentences; (5) Binary features, including whether the chemical is head chemical, chemical in title, disease in title, etc. As shown in Figure 1, when the SPG-GMKL module was used for SVM implementations respectively for different features, the results of the basic classifiers are further boosted using algorithms such as linear function and voting function (MKLB).

Results

As shown in table 1, the best classifier is MKLB with voting as the boosting method, with F1 score of 0.5068, which is similar to the Entity plus Context score of CD-REST. [2]

</tbody>
</table>

Conclusion

We introduced a multiple kernel learning–boosting (MKLB) method to identify CID in biomedical text, and got a considerable F1 score without incorporating knowledge bases. This framework is extensible, making it more convenient to incorporate new features.

Automated Report Generation for Research Data Repositories: From i2b2 to PDF

Volker S. Thiemann, Tingyan Xu, Rainer Röhrig, and Raphael W. Majeed

Department of Medical Informatics, Carl von Ossietzky University, Oldenburg, Germany

Abstract

We developed an automated toolchain to generate reports of i2b2 data. It is based on free open source software and runs on a Java Application Server. It is successfully used in an ED registry project. The solution is highly configurable and portable to other projects based on i2b2 or compatible factual data sources.

Keywords:
Databases, Factual; Medical Controlling; Emergency Service, Hospital

Introduction

The AKTIN [1] project is a German national emergency department (ED) registry initiative. In this project we use i2b2 databases to establish local data warehouses for emergency room (ER) data in participating hospitals. One part of the project is to provide automated data reports intended for quality reports, research feasibility analysis and data entry controlling. The key requirements are (1) automatic execution on Java Application Server, (2) application of standard formats and tools and (3) free open source software (FOSS).

Methods

The data source for this project is an i2b2 database. It is based on PostgreSQL and contains factual data in a star schema, common for clinical data warehouses.

The export is done via the open source tool HIStream [2]. Based on a XML configuration file with details about the concept relations, HIStream exports the i2b2 data in a tabular (CSV) format.

The statistical evaluation of the data is done via script with the R project statistical computing software. The outputs of that script are vector graphic plots (SVG) and XHTML tables.

The PDF is then created using Apache Formatting Objects Processor (FOP). The XSL-FO transformation is broken down into steps to facilitate maintenance: (1) XSL-FO template, (2) XML template with text structure and content, (3) Client configuration file (e.g. hospital name), (4) File reference list for plots and tables.

Results

The developed reporting toolchain meets all requirements and was released to our clinical partners. It is currently used for three different reports in the AKTIN project. The reports can be requested in a web interface or they can be scheduled to be periodically sent via email. The modular structure allows to add reports by writing XML configuration and R scripts for plots and tables.

The execution time depends on the amount of data, the extent of the report and the hardware. It ranges from less than a second for simple reports to less than a minute for several pages and several thousand records.

Discussion

Within the boundaries of our requirements we could have used LaTeX as an alternative to produce the PDFs. We chose Apache FOP because it is less complex, has fewer dependencies and runs natively in a Java environment.

While there are other statistical software packages, the R Project was the only actively maintained free open source software. Additionally, it runs on all major operating systems and is very popular in the scientific community.

It can be argued that PDF is not the only possible output format. Yet, it is the cross-platform de-facto standard for archiveable ready-for-print documents. HTML was not favoured, because of its inferior print layout and its multiple files, which are unsuitable for emailing and archiving.

Conclusion

We were able to produce PDF reports from i2b2 data, using a generic, standards based approach. The reports are highly configurable and portable to other projects based on i2b2 or other clinical data sources.

Extraction and Evaluation of Medication Data from Electronic Dental Records

Yue Wanga, Zasim Siddiquia, Anand Krishnanb, Jay Patelb, Thankam Thyvalikakathc

a Dental Informatics Core, Indiana University School of Dentistry, Indianapolis, Indiana, USA
b Indiana University School of Informatics and Computing, Indianapolis, Indiana, USA
c Regenstrief Institute, Indianapolis, Indiana, USA

Abstract

With an increase in the geriatric population, dental care professionals are presented with older patients who are managing their comorbidities using multiple medications. In this study, we developed a system to extract medication information from electronic dental records (EDRs) and provided patient distribution by the number of medications.

Keywords:
Dental Informatics, Electronic Dental Record, Natural Language Processing

Introduction

Preoperative evaluation of dental patients’ medication history is a vital component that can significantly affect the dental care provided. Medication information extraction using natural language processing (NLP) was the theme for the 2009 Informatics for Integrating Biology and the Bedside (i2b2) challenge[1]. Following in the footsteps of the i2b2 challenge, we evaluated the medication lexical variants that existed in our dataset and the patient distribution according to the number of medications.

Methods

Cohort Identification

Electronic dental records (EDRs) were extracted from Indiana University School of Dentistry (IUSD) for adult patients who went under comprehensive oral evaluation from January 1st, 2009 to December 31st, 2011. A total of 11,220 unique patients de-identified records were used for this study.

Medication-related Term Identification and Extraction

Three data fields from medical history form was used for this study: “Do you take any medications?”, “What medications are you currently taking?” and “Have you taken any other medication in the past 5 years”. The data were first tokenized to generate singular terms and any duplications of these terms were removed. Two reviewers independently identified the medication related term (terms containing drugs name: either brand name or generic name) and non-medication related term (any term except medications such as noun (patients), verbs (taking), etc.). Any disagreement between them were resolved through discussion. These medication-related terms was then ran against the 11,220 patient records. Descriptive statistics were used for this study. Medication lexicon profile and patient distribution are presented.

Abstract
We constructed a novel prognostic model using an innovative method of Bayesian Network (BN) to predict Non-Small Cell Lung Cancer survival status within 5 years after operation in the Asian population. The proposed BN model could present the relationship between prognostic factors and showed the highest performance among other machine learning (ML) algorithms.

Keywords:
Bayes Theorem; Carcinoma, Non-Small-Cell Lung; Prognosis

Introduction
Lung cancer is the major cause of death for tumor patients, with approximately 83% of all lung cancer cases being Non-Small Cell Lung Cancer (NSCLC) and the overall 5-year survival rate is only 22.1% [1]. Physicians usually focus on scanty prognostic points but neglect other factors, which receive unsatisfactory prognosis prediction. We built this model in order to find the relationship between prognostic variables as well as predict the probability of patients’ 5-year survival status to solve the gap in knowledge about the NSCLC prognostic system.

Methods
The cohort included Asian NSCLC patients whose follow-up period over 5 years (N=683) from SEER collected by the National Cancer Institute. Datasets were randomly split in training set (n1=495) and test set (n2=188) with a ratio of 3:1. The Holdout method was used in learning data, testing the performance of this model. We filtered 5 prognostic factors from original factors, which involved 18 independent variables by statistical analysis through SPSS. After data processing, to enhance the applicability of prognostic model, we used a new form method of BN, which is combined Tabu Search (TS) and clinical experience that distinguish from the traditional method, which only depend on data learning. TS is a heuristic algorithm based on neighborhood structures and iteration to solve optimization problems [2]. We applied TS to construct our model at first, then referred to physicians’ advice to adjust the structure of the model by R. WEKA was for contrast experiment with other popular machine learning methods.

Results
STATUS is designated as “alive” if the patient can survive equal/longer than 60 months, or it is designated as “dead”.

Five high relative factors were generated by logistic regression form training set: grade, tumor size, stage, age, lymph nodes ratio (LNR). LNR was the advice from physicians which is mixed with two other relative variables in this study. The predictive accuracy, F-Measure, and AUC was (72.87%,0.719,0.67) obviously exceeded three other ML methods: Decision Tree(67.02%, 0.654, 0.568), Support Vector Machine (68.62%, 0.662, 0.611) and Artificial Neural Network(64.89%, 0.589, 0.615). Five variables were selected to construct the ultimate predictive model (Figure 1).

Conclusion
The most convincing procedure of modeling should be combined reliable datasets, proven methods, literature and experience from domain experts instead of merely applying conventional approaches. Compared with other network learning methods and main ML algorithms, the proposed BN prognosis predictive model showed outstanding performance, especially the accuracy, which could be considered guiding clinical decisions about the prognosis of neoplasm.

Comparison of Different Algorithms for Sentiment Analysis: Psychological Stress Notes

Sunmoo Yoona, Faith Parsonsb, Kevin Sundquistb, Jacob Julianb, Joseph E. Schwartzb,c, Matthew M. Burgd, Karina W. Davidsonb, Keith M Diazb

aSchool of Nursing, bCenter for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY, USA; cDepartment of Psychiatry and Behavioral Science, Stony Brook University, Stony Brook, NY, USA; dDepartments of Internal Medicine and Anesthesiology, Yale University School of Medicine, New Haven, CT, USA

Abstract

To visualize and compare three text analysis algorithms of sentiment (AFINN, Bing, Syuzhet), applied to 1549 ecologically assessed self-report stress notes obtained by smartphone, in order to gain insights about stress measurement and management.

Keywords:
natural language processing

Introduction

Psychological stress is linked to all six of the most common causes of death in the U.S. In psychology, content analysis methods derived from paper-and-pencil surveys have been applied to patient records to improve mental health outcomes. With the advance of technology, there is an increasing volume of patient generated free-text data reporting mental health symptoms and context. As a result, natural language processing-computer lingustics has been successfully applied to patient-generated free-text to gain insights from symptom and emotion management. A sentiment analysis package, ‘Syuzhet’, for processing free-text data has recently become publicly available. However, few studies have applied this package to free-text stress notes or diaries extracted from smartphone-based ecological momentary assessments [1].

This study aims to visualize and compare three algorithms for sentiment analysis (Syuzhet, AFINN, Bing) applied to 1549 ecologically assessed self-report stress notes using smartphones to gain insights into how the analysis of large volumes of stress diaries might inform emotion management.

Methods

We extracted 1549 free-text notes describing self-reported momentary stressful occurrences, which were collected daily from Jan 2014 to April 2015 from sixty participants. Natural language processing was applied using three sentiment analysis algorithms (Syuzhet, AFINN, Bing) [1]. Pearson correlations were calculated between each algorithm and the participant’s concurrently self-reported stress rating (0-10 scale).

Results

Figure 1 displays the pooled emotion scores from 1549 stress notes, each applying a different sentiment analysis. Pearson correlation coefficients among the three algorithms and self-rated stress scores are shown in Table 1. The correlations among the three algorithms are moderately high, but the correlations of algorithm scores with self-ratings are low. Positive emotion (lack of negative feeling) was detected from half of the corpora of stress notes. (e.g., “Excitement!” Syuzhet emotion score +1, Self-report stress score -4).

Figure 1 – Visualization of Distribution of Emotion Scores of Daily Stress Notes applying Different Algorithms

The Study of Hot Spots on Hepatitis B Dissertation Based on Co-Word Analysis in China

Zhang W*, Wang Y B*, Zhang X Z*, Duan H M*

* The School of Nursing, Beijing University of Chinese Medicine, Beijing, China
* Peking University of Software & Microelectronics, Beijing, China

Abstract

Doctoral dissertations and master's theses of "hepatitis B" (HB) in CNKI database were retrieved to explore the hot spots on HB research field in China, we processed, visualized the data above, and analyzed those data by using co-word analysis informatics method. Then, the figure for co-occurrence analysis of high-frequency keywords in theses on HB were plotted, which represented eight topics, could help health staff to understand hot topics in this field.

Keywords: Hepatitis B; Co-word analysis; Dissertation

Introduction

HB is a kind of the most wide-spread and most serious harmful infectious disease in China, which is caused by hepatitis B virus (HBV), has got more and more attention by clinical researchers[1]. In general, any doctoral dissertation and master's thesis is a complete and systematic presentation in a particular field, it is more profound and more professional than other type of literature of a particular field. Keywords are most reverent to the article which can reflect its core contents. So, to analyze the co-occurrence of high frequency keywords could represent hot spots in a particular research field[2].

Methods

We collected data from digital dissertations and theses indexed by CNKI (China National Knowledge Infrastructure) database in China. We retrieved the subject term "hepatitis B" OR subject term "HBV" from 1980 to April 10th, 2016. As a result, a total of 7430 papers were found.

The data was processed and analyzed mainly by computer programs, SPSS software (version 18.0). Firstly, we calculated high-frequency keywords after the removal of abnormal data. During this step, in order to get more precise results, general words with no actual meaning were removed and the synonyms of keywords were merged. For example, "hepatocellular carcinoma" and "liver tumors" are replaced by "liver cancer". After processing the keywords, word-frequency was calculated by computer programs and 65 high-frequency keywords were identified. Secondly, a 65*65 co-occurrence matrix was constructed with computer programs. The value of the matrix represents the co-occurrence of a pair of keywords. Using Ochhia equivalent co-efficient method, dissimilarity matrix was constructed to calculate dissimilarity between a pair of keywords. Thirdly, hierarchical cluster analysis was conducted based on the dissimilarity matrix above with SPSS software, dendrogram was plotted by euclidean distance.

Results

In total, 65 keywords were classified into eight categories according to their academic meanings, shown in Figure 1.

Conclusion

In general, we explore eight hot topics based on HB related dissertations and theses in CNKI database, which meet the contents in scientific research and clinical work of HB.

Nursing Informatics Pioneers Embrace Social Media

Juliana J. Brixey*, Susan K. Newbold*

*School of Biomedical Informatics and School of Nursing, University of Texas Health Science Center, Houston, Texas, USA

#Nursing Informatics Boot Camp, Franklin, Tennessee, USA

Abstract

The American Medical Informatics Association (AMIA) established the Nursing Informatics History Project to recognize the pioneers of nursing informatics. Central to the pioneers was dissemination of knowledge. The purpose of this review was to identify pioneers who have embraced social media as of 2016. It is suggested that the pioneers participate in the advancement of nursing informatics via social media.

Keywords:
Nursing Informatics; History of Nursing; Social Media

Introduction

The AMIA Nursing Informatics History Project was established to record and maintain the history of nursing informatics [1]. As part of the History Project, 143 individuals were designated as pioneers of which thirty three were interviewed and videotaped. Pioneers were defined as people who were innovators, trailblazers, or groundbreakers in some aspect of nursing informatics, first to open a new area and prepare a way for other nurses to follow [2, 3]. The designated pioneers advanced nursing informatics through innovation in health information technology (HIT), education, administration, and research. Central to their work was dissemination so that others could utilize their findings and technology to advance nursing and nursing informatics. This study is an extension of a systematic review used to identify manuscripts published by the pioneers in PubMed for the years 2010-2015 as evidence of continued contributions to nursing informatics [4]. Therefore, the purpose of this project was to identify contributions to the field of nursing informatics as evidenced by participation in social media – specifically Twitter and LinkedIn. These applications were deemed mostly likely to be utilized for a public professional presence.

Methods

A systematic examination of Twitter and LinkedIn was conducted using each of the thirty three pioneer’s first and last name to establish ownership of a social media account. Each Twitter account was analyzed to determine date joined, number of followers, number following, and the number of tweets sent. Each LinkedIn account was analyzed to establish the total number of connections and number of connections to other pioneers. Descriptive statistics were used to analyze the data from 1 to 2994. Similarly the pioneer followed from 6 to 277. The number of tweets ranged from 0 to 2775. A total of 28 pioneers were identified as having LinkedIn accounts with 21 fully accessible for analysis and 5 did not have a LinkedIn account. The average number of peer to other pioneers averaged at 9.5 with a range of 1 to 15.

Conclusions

Nurses use social media to share knowledge and ideas, debate issues, connect with communities, make announcements, and ask for information via professional social networking sites such as Twitter and LinkedIn.

The pioneers in nursing informatics continue to contribute to the dissemination of new knowledge in via social media. Moreover, the lack of use of social media by some pioneers could be attributed to the age of the pioneer, retirement, or lack of perceived value in participating in professional social networking. Future studies will include pioneers not interviewed to more fully quantify the use of social media for dissemination of knowledge.

Virtual Reality in Nursing: Nasogastric Tube Placement Training Simulator

Kup-Sze Choi

Centre for Smart Health, School of Nursing, The Hong Kong Polytechnic University, Hong Kong, China

Abstract

A virtual reality (VR) based training simulator developed for nasogastric tube (NGT) placement is presented. It leverages the advantages of VR technology – safety, flexibility, interactivity and quantitative assessment – to speed up the learning curve of NGT placement. The simulator demonstrates the potential of VR for nurse education.

Keywords:
Computer Simulation, Nursing

Introduction

Virtual Reality (VR) technologies have been advancing in the past three decades, which proliferates a wide range of applications. In health care, representative examples include virtual surgical simulators developed for training, pre-operative planning and rehearsal [3]. VR also finds applications in nursing. This paper focus on the use of VR on the training of nasogastric tube (NGT) placement, a common clinical skill.

NGT placement concerns the insertion of a plastic tube through the nose into the stomach. Since the tube cannot be seen during insertion, it may be accidentally inserted into the lung, which can lead to complications or even fatality. Training of NGT placement is conventionally conducted by practicing on humans, which causes discomfort, or on rubber manikins, which is static and does not replicate human anatomy and the insertion forces.

Method

To enhance the training, VR technology is employed to develop a computerized interactive training system. It is based on human anatomy and provides visual, audio and haptic feedback. A virtual patient (upper part of the body), a virtual NGT, and the virtual hand of the user are displayed on the screen. User can control the virtual hand using a 3D user interface, which is also a force feedback device that can produce real-time insertion forces. Verbal command can be used to instruct the patient to swallow (visualized by movement of Adam's apple) to facilitate the tube’s advancement. The virtual patient can gag or cough (by playing audio clips) depending on the position that the tube is reaching. The insertion forces are modelled based on physics using finite element methods [1] or expert experience using fuzzy inference [2]. Quantitative metrics including the tube’s location, speed and insertion force can be recorded.

Results

The VR-based NGT placement training simulator is shown in Figure 1. Nine clinical teachers were asked to comment on the system’s the feasibility for nurse training and the overall realism. A pilot study involving 80 nursing students was also conducted to evaluate system usability and their acceptance of the VR-based training approach. The feedback was positive in general, while suggestions to improve the user interface, to simulate more patient responses, and to extend the simulation for neonates were received.

Conclusion

Taking advantages of the VR technology, the novel NGT placement training simulator provides an automated and standardized method that can increase the learning opportunity and enables asynchronous self-learning. It has the potential to speed up the learning curve so that students can be well-prepared for practice and operation in reality sooner.

Digital Health Information Workforce Planning Through a National Census

Kathleen Gray\textsuperscript{a}, Kerryn Butler-Henderson\textsuperscript{b}

\textsuperscript{a}Health and Biomedical Informatics Centre, University of Melbourne, Melbourne, VIC, Australia,

\textsuperscript{b}Australian Institute of Health Service Management, University of Tasmania, Launceston, TAS, Australia

Abstract

This poster describes the rationale and method for the development of a minimum data set as the first step toward an Australian national health information workforce census. Critical importance is attached to open and inclusive models, and the early and extensive engagement of key stakeholders, to provide a solid base for broader research into this workforce.

Keywords:
Censuses, Health Manpower

Introduction

Progress to advance digital health is occurring in health systems around the world, and a specialised digital health information workforce is integral to such change. Countries vary in their understanding of the nature and scope of the workforce concerned [1-4]. In Australia, peak health information profession bodies held national joint summit meetings in 2015 and 2016, to share longstanding concerns over skilled workforce shortages, uneven career structures and uncertain future configurations [5-6]. Our census project responds to the need flagged at the 2015 summit, to accurately identify Australia’s current health information workforce, and lays a foundation for ongoing study of health information professions.

Method

A Health Information Workforce Census Management Group was formed, with representation from key associations and agencies - Australasian College of Health Informatics, Health Information Management Association of Australia, Health Informatics Society of Australia, Health Libraries Australia, State government health workforce officials, and the Australian Digital Health Agency – and also wider engagement with other interest groups. Whilst workforce censuses exist in a number of health fields, very little is published on the methodology used in each. After reviewing indirectly related work [7-12], we decided to use the WHO guidelines to develop a minimum data set, and to use a Delphi approach to gather expert input and consult widely about the data elements required.

Results

The development of the minimum data set for the health information workforce census is being conducted in six rounds of qualitative and quantitative data collection that started in February 2017. In round six, a survey instrument will be constructed based on the agreed minimum data set, and it will be uploaded into an online environment, where members of the Management Group, Expert Panel and Consultation Group will pilot test it prior to its full deployment in early 2018.

Conclusion

This project appears to be the world’s first aiming to use a national workforce census to generate empirical evidence about the health information professions broadly. It is a step toward improving knowledge about the specialised digital health expertise that is being developed in the health information professions, how this expertise is being deployed, and what effects it has on the safety and satisfaction of patients and clinicians, the sustainable management of health services, and the accountability of providers and funders of digital health initiatives. Given the globalisation that is facilitated by digital health, our research has implications for healthcare organisations and health systems internationally.

Development of a Data Collection Tool for MbHIS-QUAL: Evaluation of the Quality of Morbidity Data in Routine Health Information Systems (RHISs) in Hospitals

Lyn Hanmer\textsuperscript{a}, Edward Nicol\textsuperscript{a}, Debbie Bradshaw\textsuperscript{a}

\textsuperscript{a}South African Medical Research Council, Cape Town, South Africa

Abstract

The quality of morbidity data in multiple routine inpatient records in a sample of South African hospitals is being assessed in terms of data accuracy and completeness. Extensive modification of available data collection tools was required to make it possible to collect the required data for the study.

Keywords:
Health Information Systems, Data Accuracy, South Africa

Introduction

The evaluation of the quality of data in routine health information systems (RHISs) is an important component of assessing their potential to provide data to support planning, surveillance and patient care. The MbHIS-QUAL study is currently underway to assess the quality of morbidity data in routine inpatient records in South African public hospitals. While there have been multiple frameworks developed for collecting the actual data required for assessing the quality of data in RHISs, none of those identified was appropriate for this study. The closest model of the required data arose from guidelines for the structure and content of patient records [1], rather than from tools such as PRISM, which focus on the performance of RHISs at facility or higher organisational level [2].

Methods

The data collection tool for the MbHIS-QUAL study is being used to collect data from a sample of approximately 5780 routine patient records. The quality of the morbidity data in the records will be assessed in terms of accuracy and completeness. Data accuracy will be assessed at the hospital level by comparing information on patient functioning, procedures, and diagnoses recorded on paper-based systems (including routine patient medical records, discharge summaries, and ward registers) with the information captured in the electronic records for patients discharged during the study periods. Data completeness will be measured by assessing the proportion of discharge summaries that have all the required data fields completed by a clinician.

Results

Based on the guidelines for review of patient records defined by the Academy of Medical Royal Colleges [1] and other similar guidelines, the following data fields will form the basis of the review: patient ID, attending physician’s signature, admission diagnosis, discharge date, discharge (final) diagnosis, condition on discharge, and procedures.

Even when using the guidelines for record reviews, further detailed work was required to determine actual data items to be extracted from the records, and some data items are still to be defined on the basis of actual data found in routine patient records. Some examples of issues addressed are listed below:

- To ensure patient confidentiality, the patient ID is replaced by a study ID assigned by the research team.
- The ‘attending physician’ could be a medical specialist, or a specialist in training, or a general practitioner, depending on the hospital and the level of staffing.
- There is currently no standard for recording ‘condition on discharge’ in patient records. A free text field has been defined to allow for recording any available data related to the condition of a patient which is present in the record.
- Data on diagnoses and procedures are not necessarily coded. Provision is therefore made for recording both free text and codes for these data elements.
- A maximum of three (3) procedures will be recorded for each study patient.

Conclusions

The conversion of published guidelines and tools to an appropriate and practical data collection tool for the MbHIS-QUAL study required significant effort. Further details of the data collection tool are available from the authors.

Digital Divide and Health Disparities in China:
Data from a National Longitudinal Survey of CHARLS

Y. Alicia Hong¹, Zi Zhou¹, Ya Fang¹

¹School of Public Health, Texas A&M University, College Station, Texas, USA
²School of Public Health, Xiamen University, Xiamen, China

Abstract

The China Health and Retirement Longitudinal Study (CHARLS, 2013) data was used to investigate internet use and mobile phone ownership in older Chinese adults and examine digital divide and social economic status and mobile technology adoption and health outcomes associations. Results suggest a significant digital divide associated with not only individual characteristics, but also neighborhood resources. Future eHealth programs should consider the accessibility of mobile tools and develop culturally appropriate programs for different social groups.

Keywords:
Internet; Cell Phones, Digital Divide.

Introduction

A large percent of the global population has access to the internet; mobile phone ownership is almost ubiquitous. A digital divide exists in almost every society and is more prominent in developing countries. China tops the world in terms of population, internet users, and mobile phone users, but data on its digital divide are rather limited. This study investigates internet use and mobile phone ownership in older Chinese adults (≥45 years), a population typically known for slow in adoption of technologies. We also examine the relationship between the digital divide and social economic status, and the association of mobile technology adoption and health outcomes.

Methods

We drew data from China Health and Retirement Longitudinal Study (CHARLS), a nationally representative survey with a sample size of more than 18,000. CHARLS household data of 2011 and personal data of 2013 were linked to capture information at the individual and community level. Multi-level logistic regression models were employed for data analysis.

Results

We found that among Chinese adults older than 45 years, only 4.1% had used the internet in the past month, 23% household had broadband connection at home, and 82% household owned mobile phones. Our multivariate logistic regression models showed that internet use was strongly associated with one’s social-economic status (SES), rural-urban residence, neighborhood amenities, and community resources. Mobile phone ownership was strongly associated with SES and rural-urban residence, but not so much with neighborhood amenities and community resources. Internet use was a significant predictor of self-reported health status and having disability, even after controlling for potential confounders at the individual, neighborhood, and community level. By contrast, mobile phone ownership was not significantly associated with health status or having disability.

Discussion

This study is one of the first to examine the digital divide and its relationship with health disparities in China. It provides important data for developing interventions to bridge the digital divide. It also suggests that future eHealth programs need to consider different the accessibility of mobile tools and develop culturally appropriate programs for different social groups.

Conclusion

Our study suggests that despite a big population of internet users and mobile phone owners, a significant digital divide exists in China, especially in Chinese older adults. Internet access is still limited to people with higher SES, but mobile phones are adopted by the general population.

Patient Handovers – Cognitively Demanding: Does the Handover EHR Meet This Challenge?

Ursula Hübner, Mareike Przysucha

Health Informatics Research Group, University AS Osnabrück, Osnabrück, Germany

Abstract

Patient handovers are crucial to warrant continuity of care and patient safety. The handoverEHR is an instrument that allows users to depict the main features of a clinical case in cognitive maps. We were interested whether this tool had an effect on the task load. A cross-over study with 30 nursing students was therefore conducted. Mental demand showed a statistical trend to be lower in cognitive map handovers than in the other handover types.

Keywords:
Patient Handoff; Electronic Health Record; Psychology, Medical

Introduction

Patient handovers between shifts of care givers are a well defined mechanism to warrant information continuity between care teams and prevent adverse events. In addition to the safety challenge, there is a time challenge which poses an emotional and mental demand on the persons involved [1]. The main research questions of this study therefore was, whether the use of an electronic tool, the handoverEHR [2], affected the subjective task load.

Methods

In order to answer the research question, a randomised controlled cross-over design with the three experimental tasks was chosen: a) handovers without the help of any instruments (WITHOUT=control group), b) handovers with handoverEHR and list presentations (LIST) and c) handovers with handoverEHR and cognitive maps (MAP). Thirty young nursing students in their third study year (23 females/7 males, 21.9±2.9 years old) handed over four patients in groups of up to four study participants during each experimental condition. Following these tasks, they were asked to fill in the NASA Task Load Index Questionnaire (NASA TLX).

Results

The results of the NASA TLX dimensions "mental demand", "temporal demand", "effort" and "frustration" are shown in Fig. 1. “Mental demand” decreased from WITHOUT, over LIST to MAP (62.8±16.7; 59.0±16.2; 55.4±21.2). This effect showed a trend for significance (F=2.6, df=2;58, p=0.08). Despite decreasing means in “effort” from WITHOUT to MAP (29.4±14.8; 25.1±12.4; 23.8±12.1), this effect was not significant. The lowest values were obtained for “frustration”, however with a significant difference (F=4.03, df=2;58, p=0.04) between the tasks: WITHOUT (13.3±15.0), LIST (12.0±10.9) and MAP (25.9±30.6). “Temporal demand” nearly stayed the same in all groups: WITHOUT (31.7±19.2), LIST (32.3±14.5) and MAP (33.7±17.8).

Conclusions

We could demonstrate a trend for a positive effect of the handoverEHR on “mental demand”, “Effort” and “temporal demand” were unchanged, while “frustration” increased significantly. These findings will be contrasted by results on the cognitive functions memory and decision making, which had been tested in the same research design.

Evaluation of the Anonymity and Utility of De-Identified Clinical Data Based on Japanese Anonymization Criteria

Eizen Kimura\textsuperscript{a}, Satoshi Hasegawa\textsuperscript{a}, Koji Chida\textsuperscript{b}, Shoko Gamo\textsuperscript{d}, Satoshi Irino\textsuperscript{c}, Haku Ishida\textsuperscript{d}, Yukio Kurihara\textsuperscript{c}

\textsuperscript{c} Department of Medical Informatics & Decision Sciences, Yamaguchi University, Ube, Yamaguchi, Japan
\textsuperscript{d} Division of Health Informatics, Medical School, Kochi University, Kyoto, Japan

Abstract

We analyze the deterioration of clinical data quality due to anonymization. The result shows that data quality remained high with micro-aggregation and also verify the availability of noise addition to prevent illegal re-identification by matching another personal data.

Keywords:
Confidentiality, Anonymization, Privacy Preserving Data

Introduction

The Amended Act on the Protection of Personal Informationin Japan, scheduled to go into full effect in the May of 2017, will open a way to provide medical records to third parties by de-identifying personal data. For de-identifying data, the law mandates the processing of personal information in accordance with standards stipulated by the rules of the Personal Information Protection Committee (PPC) \cite{1} and the relevant guidelines. Currently, the PPC states that the five requirements must be met for the provision of data to a third party without personal agreement. At present, however, it is not clear what process will be sufficient to fulfill these rules because of the lack of technical guidelines for the anonymization process. The nature of an appropriate anonymization process may change depending on the content of the data and type of analysis. Our study examines use cases for clinical data to establish the best practice in anonymization.

Methods

We collected 7,200 quasi-healthy individuals with age, sex, and laboratory items: Hb, CR, ALT, RBC, WBC, aspartate aminotransferase, total protein, blood urea nitrogen, total cholesterol, and gamma glutamyl transpeptidase (GGT). Using the data, we examine various statistics, mean, standard deviation, quartile, the Mann–Whitney U-test (MW) and the Kolmogorov–Smirnov (KS) test for each group of the same age and sex as a case study. Based on the age hierarchy required by researchers, ages were converted into four classes using 5-year intervals: 50–54, 55–59, 60–64, and 65–69 years. As a requirement of the five rules, we evaluate k-anonymity assuming age and sex are quasi-identifiers. We also assumed that the exceptional description of a single attribute falls within three standard deviations (SDs) of all records and is within top and bottom 2.5% data within each same-sex group 5-year interval in age. We applied Maximum Distance to Average Vector (MDAV\cite{2}) for micro-aggregation. To reduce the possibility of identification by collating medical records with other data, we used Pk-anonymization\cite{3} with noise addition and the Post Randomization Method (PRAM\cite{4}).

Results

All data satisfied k=10 in the age and sex pairs. Therefore, k-anonymization processing was unnecessary for age and sex. We confirmed the errors were exceedingly small even if micro-aggregation withing 3 SDs is applied. The errors of RBC are smaller than those of GGT, the de-identified data with noise-addition cannot be used in either the basic statistics or hypothesis tests under existing conditions. The lower error rate of RBC compared with GGT may be attributable the wide range of GGT values, compared to the RBC values. Also, RBC has a closer distribution to the normal distribution.

Conclusion

We instantiated de-identified clinical data considering the requirements of Japanese anonymity criteria and verified the availability. Anonymization using only micro-aggregation maintained good data quality. However, we found that many sample data are required to obtain the statistical result with high quality for de-identified data with noise addition based on Pk-anonymity. In a future study, we will re-evaluate our results after improving the noise-addition algorithm and increasing the target data size, assuming large data processing.

Developing an Evidence-Based Web-Education Program Designed to Help Nurses Learn to Care for Acutely Ill Intoxicated Patients in Emergency Departments

Marita Koivunen*a,b, Eija Nopparic, Tiina Hakala*a,d, Anna-Kaisa Kauttoa

*a Satakunta Hospital District, Pori, Finland
*b Department of Nursing Science, University of Turku, Turku, Finland
*c Diaconia University of Applied Sciences, Pori, Finland
*d School of Health Sciences, University of Tampere, Tampere, Finland

Abstract
A significant part of the patients treated in an emergency department are under the influence of alcohol or drugs. It is important to identify individuals of patient groups who might benefit from an intervention to reduce drug use. The aim of the study was to develop an evidence-based web-education program aimed at enhancing nurses’ knowledge and skills in the care, assessment, and management of substance-related disorders among acutely ill patients in emergency departments.

Keywords:
Emergency Treatment, Substance-Related Disorders, Computer-Assisted Instruction

Introduction
It has been estimated that in emergency departments about one third of the patients are under the influence of alcohol or drugs or are alcohol abusers [1]. The hazardous use of alcohol is a major global factor contributing to disease, injury, and death [2]. It is therefore important to identify individuals or patient groups who might benefit from an intervention in emergency departments to reduce alcohol use [3]. The care of acutely ill or injured patients who are also intoxicated requires wide-ranging competence among nurses working in emergency departments [4].

The aim of the study was to develop an evidence-based web-education program aimed at enhancing nurses’ knowledge and skills in the care, assessment, and management of substance-related disorders among acutely ill patients in emergency departments.

Methods
At first, nurses’ competencies to care for intoxicated patients in emergency departments were clarified using a quantitative survey (N=1220, n=252) in twenty emergency departments in Finland. Second, according to findings of the survey the fields of knowledge, which should take account in the web-education program, were formulated. We conducted preliminary evaluation of the content and learning methods of the web-education program with four nurses.

Results
The contents of the program were designed using results of the survey. The web-education program consisted of three parts: 1) patient centered encounter of intoxicated patients in emergency care; 2) practical nursing methods in the care for intoxicated patients in emergency departments; and 3) developing quality of care for intoxicated patients in emergency departments. The preliminary evaluation showed that the program is easy to use and supports the nurses' knowledge.

Discussion
In practice, the nurses can complete the education program independently, but they have to get a feedback from the specialists. The nurses can seek information of the topic from the program. In addition, they can discuss on the web and use a diary, for example ethical questions that they were confronted with when they have cared for intoxicated patients.

Conclusion
The specific web-education program may be beneficial for nurses who care for the acutely ill intoxicated patients in emergency departments.

Privacy Policy Implementation on the Nation-Wide EHR in Japan for Hospitals and Patients

Naoto Kume*, Shinji Kobayashi*, Kenji Araki*, Hiroyuki Yoshihara*

*Department of Electronic Health Records, Kyoto University, Kyoto-city, Kyoto, Japan,
*Department of Medical Informatics, University of Miyazaki Hospital, Miyazaki-city, Miyazaki, Japan

Abstract

Shared clinical information is an important contribution to regional medicine. Clinical information sharing with patients is also recommended to motivate patients and promote health. On the other hand, the threat of information leaks, caused by internet connected records, is critical to hospitals. The traditional approach is complete isolation of hospital networks, instead of information sharing. The authors propose methods here to maximize information sharing by following hospital preferences for electronic health records.

Keywords:
Access to Information, Electronic Health Records, Patient Participation

Introduction

Sharing information among hospitals is necessary to achieve collaborative medicine. Also, sharing information with patients will be mandatory to prevent serious illness, especially in chronic diseases.

However, information sharing is also a risk from the viewpoint of hospitals. Information leaks and the unnecessary sharing of information must be prevented. For example, information related to clinical activities, and not clinical results, does not need to be shared. Therefore, in Japan hospitals have traditionally hesitated to share information or have tried to minimize sharing as much as possible.

The establishment of a nation-wide electronic health record (EHR) system in Japan must tackle the problem of sharing or not sharing between hospitals and patients through policy. Therefore, the authors propose a structural access control that reflects the decisions of each stakeholder by prioritizing their privacy policies and preferences.

Methods

The authors designed a nation-wide EHR as a centralized system. All clinical information of the partner hospitals is stored in the centralized database. Firstly, the priorities of the privacy policy are defined in the following order: hospital, patient, and collaborative hospital. Secondly, a privacy policy matrix is provided for the information-sharing hospitals. Thirdly, patients are provided an opportunity to declare their preferences using a user interface portal to their own medical records.

Privacy policy matrix for information-sharing hospitals

A hospital declares their policy on a clinical item and department matrix. Clinical items are provided by the document classification definition from Medical Markup Language (MML) [1]. MML 4.1.2 provides seventeen items. The number of departments depends on the hospital. A hospital provides a decision to each item as open or closed to patients and collaborative hospitals.

Privacy policy for patients

A patient can access the list of hospitals, which is on his/her clinical history. A patient declares which hospitals can provide their information to other hospitals. For instance, if a patient has one record that should not be shared with another hospital, the patient can stop sharing the record, even if the hospital allows sharing with collaborative hospitals.

Results

The methods are implemented on an EHR, which connects forty hospitals. Clinical information, including sharing policies, are uploaded from each hospital. A feasibility study of administration operation is underway.

Conclusion

Prioritized policy making structure with a simple privacy policy matrix are achieved so that the proposed methods provide convincing grounds to hospitals agree to share maxim items.

**Patient’s Adherence Level Determination System**

Taranik Maksim* a, Georgy Kopanitsa b

* Tomsk Polytechnic University, Tomsk, Russia, Tomsk State University for Architecture and Building, Tomsk, Russia

**Abstract**

The present paper deals with intellectual systems for patient’s level adherence determination. The most popular nowadays technique for adherence evaluation is interview. We advise a new automation approach, which compares direct patient data with treatment plan using fuzzy logic and standard ISO 13606. For this research data entered by users. The results can be useful for medical organisation with long-term patients.

**Keywords:**

Adherence, Informatics

**Introduction**

The quality of healthcare process and the results depend on the level of patient’s adherence. World Health Organization (WHO) mentions, that increasing the effectiveness of adherence interventions may have a far greater impact on the health of the population than any improvement in specific medical treatment [1]. The question of adherence is the most relevant for patient with chronic diseases, cancer, stroke etc. Among the methods of adherence level determination there are implicit: interviews, question lists and explicit: real counters (as pill counter). Both methods have human factor, which provides uncertainty. Therefore, medical specialist cannot be sure in the accuracy of patient’s answers. A great deal of modern adherence-based researches. However, the questions of automation of medical data acquisition and adherence level processing allowance of human factor, receive insufficient attention. Therefore, development of special intellectual automate systems for patient monitoring and adherence level evaluation is relevant modern issue. The presented paper deals with presentation, realization and evaluation of patient’s level determination concept based on the direct data in the scope of long-term healthcare in cardiovascular department.

**Methods**

The intellectual system is based on the following concept. The treatment plan is included in the system by a medical professional. The system determines and formalizes some knowledge on injected medical drugs, the right amount of sleep, physical activity, specific diet that influence the patient’s status. The system contains the objective data on patient’s status based on the data obtained through ongoing monitoring portable devices. The junior medical staff includes this information in the system. Enumerated list item. Based on the included data the system determines if the information matches the memorized treatment plan of the patient and assesses the treatment retention using fuzzy Mamdani algorithm. The obtained results are memorized. The duration of the present study on the treatment retention assessment was two weeks. We acquired the data of 20 patients at the age of 20-45 (13 men, 7 women) that have a hypertensive disease diagnosis. The study was in hospital environment of the Scientific Research Institute of Cardiology (Tomsk) in the arterial hypertension unit.

**Results**

The first step of intellectual system approbation was treatment plan determination for all patients. The system collected patient’s medical data and compared with treatment plan three times a day. As a result it was an evaluation (0-1). The mean of three evaluations was a day evaluation. After two weeks we calculated mean evaluation during the whole period (Table 1).

<table>
<thead>
<tr>
<th>Patient</th>
<th>Total evaluation</th>
<th>Patient state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patient 1</td>
<td>0,5</td>
<td>improvement</td>
</tr>
<tr>

</tbody>
</table>

We formalized patient’s states, adopted to scale from 0 to 1, and got further results: recovery (0,75-1), improvement (0,5-0,75), inconspicuous (0,35-0,5), deterioration (less than 0,3). Based on the presented results it is possible to conclude, that developed system determined accurate adherence level of researched set of patients.

**Conclusion**

Presented in the current paper research is a first iteration of the work concern of development of adherence level intellectual instruments with further decision support process. These results allow to increase the accuracy and quality of adherence level determination.

Report and Analysis of Web Portal oldagesolutions.org for Indian Old Age Persons

Sushil Kumar Meher\textsuperscript{a}, A.B. Dey\textsuperscript{b}

\textsuperscript{a} Department of Computer Facility, All India Institute of Medical Sciences (AIIMS), New Delhi, India, \textsuperscript{b} Department of Geriatric Medicine, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Abstract

Oldagesolutions.org is a web portal for older persons in India created as a part of Technology Interventions for Elderly (TIE) initiated by the science and society division for benefit of elderly people keeping in view of the National Policy on Older People (NPOP). This is a collative effort of the multidisciplinary team at All India Institute of Medical Sciences (AIIMS) comprising of doctors, genetic nurses, nutritionist and physiotherapists who provide their valuable collective insights for an elderly centric approach.

Keywords: Technology, National Health Programs, Aged

Introduction

India is home to 110 million older persons with high burden of diseases and disabilities and great need for access to affordable health care. The population of senior citizens in India is increased due to 60% increase in life expectancy in the last 60 years. Today India has the 2nd largest number of Elderly and every 7th senior citizen in the world is from India. There is a sharp increase in population of young-old 60 yrs to 69 yrs and old-old 80 yrs and above.

Oldagesolutions.org is a web portal for older persons in India created as a part of Technology Interventions for Elderly (TIE) initiated by the science & society division for benefit of elderly people keeping in view of the National Policy on Older People (NPOP). The web portal includes information related to health care and allied areas such as:

Recreation & Entertainment: indoor activities for seniors, outdoor activities for seniors, recreation centers

Physical Health: health and fitness, healthy eating, healthy bone, good sleep, taking care of your oral cavity, better sight in old age, immunization.

Mental Health: depression, living alone, worry & anxiety, cognitive impairment, bereavement.

Nutrition: nutritional considerations, nutritional requirements, dietary guidelines for life style, potential shortfall and over consumed nutrients, methods of assessment nutritional status.

Assistive Devices: occupational therapy, self care, mobility, house work, safety and security, leisure activities.

Facility: schemes & facilities, legal issues, safety of senior citizens a challenge. old age home directory, old age pension

Design & Environment: design & environment for elderly, barrier free environment

Methods

We propose 4-dimensional criteria to evaluate this website. The proposed criteria using a Likert scale are content quality, design quality, organization quality, and user-friendly quality. We have administered questionnaires to 272 participants.

Results

Analysis of the results of the 272 questionnaires is as follows:

1. Content quality: 48%- fully satisfied, 46% - satisfied, 5%- partial satisfied, 1% - not satisfied
2. Design quality: 42%- fully satisfied, 49% - satisfied, 07%- partial satisfied, 2% - not satisfied
3. Organization quality: 42%- fully satisfied, 46% - satisfy, 10%- partial satisfied, 2% - not satisfied
4. User-friendly quality: 40%- fully satisfied, 47% - satisfied, 12%- partial satisfied, 1%- not satisfied

Discussion and Conclusions

As per the above study, this web site provides a holistic service to ensure physical, mental, and social well being of senior citizens. More than 80% users are very satisfied with its content, design, and user friendliness.

Authenticating Unknown Doctors for Access to EHRs Based on Societal Trust

Kensuke Morris\textsuperscript{a}, Naoto Kume\textsuperscript{b}, Goshiro Yamamoto\textsuperscript{c}, Shinji Kobayashi\textsuperscript{b}, Kazuya Okamoto\textsuperscript{d}, Hiroshi Tamura\textsuperscript{ac}, Tomohiro Kuroda\textsuperscript{ac}

\textsuperscript{a} Department of Social Informatics, Graduate School of Informatics, Kyoto University, Kyoto, Japan  
\textsuperscript{b} Department of Electronic Health Record, Graduate School of Medicine, Kyoto University, Kyoto, Japan  
\textsuperscript{c} Division of Medical Information Technology and Administration Planning, Kyoto University Hospital, Kyoto, Japan

Abstract

Many isolated EHRs in Japan hinders the availability of patients’ clinical data who need treatment in a region outside the scope of their local EHR. We propose a timelier approach that increases availability of patient clinical data to unknown doctors and has the patient and their representative involved; they can grant access to doctors who are anonymous to the patients’ local EHR domain.

Keywords:
Access to Information; Electronic Health Records; Patient Participation

Introduction

Currently Japan has no universal health record system (EHR); many independent EHRs connect groups of healthcare institutions [1]. Prior work has been done to give patients mobile access to their clinical data. Our aim is to have an efficient access approach to patient data for anonymous doctors, which increases patient involvement.

Methods

Our system was designed with two scenarios, as shown in Figure 1. When the patient is unconscious, their representative (emergency contact) can vouch for the doctor using their mobile device. Scenario one (S1) was designed to illustrate our system design when the patient is conscious. Scenario two (S2) was designed for the situation where the patient is unconscious.

Results

A prototype was created to demonstrate our system design based on S1 and S2. When patient is unconscious, the representative(s) receives a push notification with a request, as shown in Figure 1.

Discussion

This research gives rise to two concerns; Eliminating all doubts in the representatives’ mind about the origin of the request and our system’s ability to control the responses of multiple representatives.

Conclusion

We propose an authentication scheme in health care that can increase the Japanese societal trust and involvement in healthcare data security.

Acknowledgements

Special thanks to my professors and colleagues at my laboratory for their guidance, especially Mr. Tuuka Karvonen.

**DOCtimer: A Timing and Event Recording Tool for Direct Observational Research**

Matthew E. Nolan, Brian W. Pickering, Vitaly Herasevich

*Division of Pulmonary & Critical Care, Mayo Clinic, Rochester, MN, USA
Department of Anesthesiology and Perioperative Medicine, Mayo Clinic, Rochester, MN, USA*

**Abstract**

Clinical research often requires direct observation of clinicians performing routine tasks, but few effective data collection instruments exist. We describe the development of DOCtimer - a web-based, platform-independent timing and counting application that allows researchers to easily record numerous tracking elements on a single screen, facilitating robust data collection for direct observational research.

**Keywords:**
Software; Data Collection; Medical Informatics Applications.

**Introduction**

The problem arose from our informatics research group’s study needing direct observation of physicians using electronic medical record information during new admissions. We required a tool that could log the duration and/or count for more than 80 data elements, while allowing the observer to remain mobile and unobtrusive to the physician’s workflow.

Several behavior timing/tracking solutions exist [1-3] but have shortcomings: lack of concurrently-running timer support, lack of task hierarchy support (i.e., group/subgroups), inability to log event sequences, inadequate interface for numerous items, lack of mobile-device compatibility, need for internet connection, or high cost. Therefore, we developed an easily configurable Direct Observation Counting timer (DOCtimer) instrument to solve this research problem.

**Methods**

We developed a time tracking/counting/sequencing tool using HTML5, CSS and pure javascript as a single “.html” file that runs on any modern browser, including tablets, without needing an internet connection. The researcher inputs the data elements of interest using a highly structured nested object template that defines the data element name, type, and display style, with the template sequence and hierarchy used to imply groupings and generate html code. There are two core element types: ‘timers’ record all start/stop datetimes, total timing duration, and elapsed time, while ‘counters’ record the count and datetime events.

**Results**

Using an efficient single-screen interface, our tool can display over 80 timing and counting elements that are quickly recorded with a single “click.” Hierarchical timing logic (‘child’ elements start their ‘parent’ elements) and mutual exclusivity (running timers stop when unrelated groups start) minimize user input requirements and improve recording speed. Results are output in CSV or JSON format, which can be directly pushed to a database via AJAX.

**Conclusions**

We developed a web-based, platform-independent timing and counting application that allows researchers to easily record numerous tracking elements on a single screen, facilitating robust data collection for direct observational research. Usability testing and comparative benchmarking against similar software are important next steps.

**Acknowledgements**

No specific funding or conflicts of interest to declare.

Health Digital Divide in the Era of Precision Healthcare: 
Taking Yunnan Province as an Example

Yan Peng, Li Yan, Liuwang Kuanghua, Guozheng Tang
Institute of Medical Information of Yunnan Province, China

Abstract
With healthcare coming into the era of Precision Healthcare, it will facilitate the development of health informatics from information processing, integration, analysis, application and other uses. If we ignore the e-health development of developing areas, it will bring a health digital divide. This study takes Yunnan province as an example, and analyzes the problems of e-health development in a developing area, hoping to get more attention from researchers and regulators.

Keywords: Digital divide, information services, delivery of health care

Introduction
Yunnan province is located in the southwest of China. The mountain area is about 94% of the total area. Due to economic, geographical conditions and other factors, information infrastructure, information technology application, information service capacity in Yunnan has lagged behind developed areas. In 2015, the Informatization Development Index of Yunnan was just 59.09, lower than the national average level (72.45), ranked 27th in 31 provinces [1]. This study analyzed problems of e-health development in Yunnan in the era of precision healthcare.

Methods
We investigated health administrators, health workers, patients by face-to-face interview in Zhenkang, Shangri-La, Yiliang, Wuding and Mengla, during October and November 2015. The interview outlines were determined by expert consultation method. Data from the interviews as well as information from literature review were aggregated and analyzed for themes.

Results
Interviews and literature review showed problems detailed below. First, some institutions, especially village clinics, cannot bear the cost of internet and computers, so that these institutions still do not access to internet. The health records created by village clinics cannot be accessed online. Second, data standards of information systems in the hospitals are not compatible, so it is very difficult to integrate and exchange of electronic medical records between hospitals. Third, health information systems in township hospitals are still at primary level, just for charge, financial management or pharmacy management. The electronic medical records are rarely used. The compatibility of health data is very poor. Fourth, because of low level of education, aging, minority languages and other reasons, it is difficult for patients or health consumers to find accurate health information by internet in these areas.

Conclusions
There is a big gap between the condition of e-health development in Yunnan and the basic conditions of precision healthcare. In order to reduce the new health digital divide, policy makers and researchers must pay more attention to developing areas, information infrastructure of health institutions, health information literacy of health care workers and consumer needs in order to improve as soon as possible.

Acknowledgments
This study was supported by Rule of Law Division, People’s Republic of China Committee on Health and Family Planning.

Measuring User Satisfaction with Clinical Information Systems: What Really Matters?

Jonathan L. Schaffer, Peter Haddad, Nilmini Wickramasinghe

Cleveland Clinic, Ohio, USA
Faculty of Health, Deakin University, Melbourne, Victoria, Australia
Health Informatics Management Unit, Epworth HealthCare, Richmond, Victoria, Australia

Abstract

The healthcare industry is increasingly investing in information systems / Information technology to enhance patient outcomes and organizational performance. This study qualitatively investigates the relationship between the overall satisfaction and five key aspects of clinical information systems. The results show that intuitive, easy-to-use, and collaboration enabling systems are more likely to satisfy users. The level of technical support and training also play key roles in determining user satisfaction in the clinical domain.

Keywords:
Information Systems, Personal Satisfaction, Health Care Behavior

Introduction

While examining IS/IT user satisfaction in healthcare has a lengthy history, measuring user satisfaction with clinical information systems lags behind. This is a major void in today’s healthcare environment given significant investments in CIS (clinical information systems).

Aim

To examine user satisfaction of four clinical information systems focusing on five key functionalities; efficiency of use, intuitiveness of graphical user interfaces (GUI), communications, collaboration, and information exchange, and interoperability and compatibility issues.

Methods

An online survey was designed, validated and then conducted to collect data on clinical IT user satisfaction at a large tertiary, not-for-profit, private healthcare group in Australia. The objective of this survey was to develop a valid measurement tool of clinical IT user satisfaction that can be applied for all CIS given that currently no such measurement tool exists. Descriptive and predictive statistical techniques were employed to analyze the collected data.

Results

A total of 107 respondents out of 250 answered the questionnaire. Responses ranged from satisfied to not very satisfied across the respective systems as well as frequency of use from multiple times a day to one or two times per month and varying technical proficiency. In addition, reluctance to contact IT help desk was a dominant response while significant differences between genders were not apparent but differences between level of proficiency and use were.

Discussion

Practically, the results of this study help executive decision makers including the CIO and CEO at hospitals to better understand the actual needs of clinical information systems’ users to better utilize CIS as a contemporary asset as well as have more informed and critical discussion with prospective IT vendors. This is crucial with the increased investments in CIS. Today, healthcare is ranked fourth in investing in IS/IT after retail, banking and securities, and education. The study also shows that CIS users are likely to be satisfied if the systems are intuitive, easy to use, and enable better access to medical information in a timely manner. Moreover, results show that decision makers will need to pay attention to training and technical support channels. The amount and quality of training are key aspects of user satisfaction as the results show. From a theoretical standpoint the developed assessment tool is one of the first to provide a comprehensive assessment of CIS user satisfaction.

Conclusions

This study set out to evaluate the overall user satisfaction with clinical information systems at an Australian tertiary, not for profit, private healthcare group. Different constructs were considered to evaluate the user satisfaction. The results show that intuitive, easy-to-use, and collaboration enabling systems are more likely to satisfy their users. The level of technical support and training seem to play key roles in determining user satisfaction in the clinical domain. Future research directions include fine tuning the survey to quantitatively determine user satisfaction based on its constructs in this study.

Prerequisites for International Exchanges of Health Information for Record Research: Comparison of Australian, Austrian, Finnish, Swiss, and US Policies

Hanna Suominena, b, Henning Müllerc, Lucila Ohno-Machadod, Sanna Salanteräb, e, Günter Schreierf, Leif Hanlena

a The Australian National University, Data61, & University of Canberra, Canberra, Australia, b University of Turku, Finland, c HES-SO & University of Geneva, Sierre/Geneva, Switzerland and Harvard Medical School, Boston, USA, d University of California, San Diego, USA, e Turku University Hospital, Turku, Finland, f AIT Austrian Institute of Technology, Graz, Austria

Abstract

The policies that address health information exchanges for research purposes in Australia, Austria, Finland, Switzerland, and the USA apply accountability and/or adequacy to protect privacy. Specific requirements complicate the exchanges: inform data subjects of data use purposes; assure that the subjects are no longer identifiable; destroy the data in the end; and not to use cloud computing without specific permission.

Keywords:
Electronic Health Records, Health Policy, Privacy

Introduction

A major risk in electronic health records is the possibility of compromising data subjects’ privacy, and this is particularly evident in analyzing text (i.e., inabilities to be fully convinced that all privacy-sensitive information has been removed) or big data (i.e., unforeseen possibilities to infer personal data after record linkages from multiple de-identified sources). Using EHRs for research purposes requires compliance with legislation, and governance.

Methods

We specified the legal frameworks, process of gaining access to EHRs, and restrictions for data exchanges across projects in five countries: Australian Commonwealth, its NSW, Austria, Finland, Switzerland (Valais), USA, and its CA. We used a published method [1] and extended its analysis from Australia and Finland to the EU more widely (Austria), non-EU Europe (Switzerland), and N. America.

Results

Requirements for data access and protection vary (Table 1, [2]). The frameworks apply accountability of the original data creator for regulatory compliance (e.g., Australia and USA) and/or the subsequent information receiver having to protect privacy adequately (e.g., Australia and EU) (Table 2, [2]). ICT can audit compliance with all frameworks [3]. The process of gaining access to EHRs for research has five steps (Table 3, [2]): 1) Preparations include: developing a research plan, group, and an ethics protocol. 2) The proper approvals and permissions are furnished. 3) Data are collected and de-identified and an informed consent is obtained from each subject. 4) Research, where the exchanged data are used only for these purposes, takes place. Exchanges of the original or secondary data across borders or projects are permitted if they have been addressed in Steps 1-3; the use of cloud services, which may store data in another country or legislation, without specific permission is not allowed. 5) All data are deleted or returned to their original creator at the end.

Conclusion

Capabilities to exchange health information are critical to accelerate discovery and its diffusion to practice. However, the same ethical and legal policies that protect privacy hinder these exchanges. Both legislation and technologies are available for overcoming these barriers [3].

Key Factors for the Successful Adoption of IS/IT in Healthcare: A Fit-Viability Perspective

Nilmini Wickramasinghe,a,b, Peter Haddad,a,b, Imran Muhammad,a,b

*Faculty of Health, Deakin University, Melbourne, Victoria, Australia
bHealth Informatics Management Unit, Epworth HealthCare, Richmond, Victoria, Australia

Abstract

The adoption of clinical information systems by healthcare organizations has become a strategic necessity today. For these situations to be successful, their fit becomes an important consideration. This research-in-progress study assesses the fit of three different clinical information systems in an Australian private not-for-profit healthcare group, and the readiness of this organization to adopt these systems. In so doing, it identifies key factors for the successful adoption of IS/IT in healthcare contexts. The study adopts a mixed methods approach using semi-structured interviews and an online survey.

Keywords:
Hospital Information Systems, Point-of-Care Systems, Telemedicine

Introduction

Adopting clinical information systems is becoming a strategic necessity for various levels of healthcare providers. The ultimate objective of most of these investments is to enhance patient outcomes with less cost. Many of these investments though, have not achieved the expected outcomes due to numerous factors as noted in the literature. These factors are mainly related to the readiness of healthcare organizations to adopt clinical information systems, and the fit of these systems into the organizational characteristics and objectives. This research-in-progress study assesses the fit of three different clinical information systems in an Australian private not-for-profit healthcare group, and the readiness of this organization to adopt these systems.

In order to assess the fit of these systems and readiness (viability) of the selected healthcare organization, this study uses the FIT-Viability Framework. The first system to be considered is an American developed computerized practitioner order entry (CPOE) system, the second is a European developed point-of-care system, and the third is an Australian made clinical auditing system. All of these systems are implemented by the selected case which operates in the Australian healthcare context.

Aim

The aim of this research is to build a framework that captures the factors that affect various clinical IS/IT solutions in the Australian healthcare context. In so doing, the study answers the following research questions:

1. What are the factors that affect the readiness of healthcare organizations to adopt sophisticated clinical IS/IT platforms?
2. How the domestication of internationally developed clinical IS/IT affect the fit of these systems in the Australian context?

Methods

This research is exploratory in nature, as it is planned to be a ‘broad-ranging, purposive, systematic, and prearranged undertaking designed to maximize the discovery of generalizations leading to description and understanding of the area of research’. It includes both qualitative and quantitative methods and thus it is a mixed methods study. For the qualitative component, the study subscribes to the directives of Yin who notes that such an approach enables conducting in-depth studies and research about a broad range of topics and at the same time provides greater latitude in selecting topics of interest.

Further, the study includes 28 semi-structured interviews with key informants in a large not-for-profit tertiary healthcare group in Australia. This hospital represents an exemplary single case study with multiple units of analysis. The interviewees are classified into four categories based on their occupations and organizational tasks, namely management and executives, IT, clinicians, and clinical IT. The last group comprises clinical personnel with sound IS/IT knowledge and experience. Further, the study employs an online survey to target a wider audience at the selected case. Both the interviews and survey are designed to capture data about the fit of clinical IS/IT solutions used by the healthcare group, and the viability of the selected case to adopt these and other IS/IT solutions.

Conclusion

Currently, we have developed the conceptual model. Now we need to test it to unveil the factors that affect the fit of clinical IS/IT into an exemplary Australian healthcare provider and the viability of this hospital to adopt clinical IS/IT systems. This is particularly crucial given the current increasing trend to use IS/IT to deliver superior healthcare operations. We then plan to test the model in other healthcare systems including Canada, China, Germany and US. Once all stages of testing are complete, the robustness of the proffered model would be established and hence its benefits to improving the readiness of healthcare organizations and the fit of IS/IT systems globally will be the primary contribution of this study to theory and practice.

Mobile Learning in Nursing Undergraduates in China: Current Status, Attitudes and Barriers

Qian Xiao¹, Qiannan Zhang¹, Lanlan Wang¹, Yanling Wang¹, Liu Sun¹, Ying Wu¹

¹School of Nursing, Capital Medical University, Beijing, China

Abstract

To explore the current status, attitudes and barriers of nursing undergraduates toward mobile learning, 157 nursing students were investigated. More than half of them used mobile learning frequently in past half year. The mean score of students’ intention towards mobile learning was 10.5 (ranged from 6 to 15), and it related to students’ gender, expected effect, ease of operation, influence of other students, self-learning management and perceived interest. Some barriers affected students’ mobile learning. Therefore, students had positive attitude and perception toward mobile learning, then we should create enough conditions to promote students’ mobile learning.

Keywords: Attitudes, Barriers, Mobile learning, Nursing undergraduates.

Introduction

With the popularity of smart phones, mobile technology had been integrated into nursing education[1]. Mobile learning, as a new form of learning, was effective, flexible, interesting and interactive, especially it can help students to learn anytime and anywhere[2]. Hence, this study aimed to explore the current status, attitudes and barriers of nursing undergraduates toward mobile learning.

Methods

Students who had more than 1 year study experience in university were eligible to participate in this investigation. The questionnaire mainly includes 3 aspects: 1) Students’ basic information, including age, gender, experiences of using smart phones and mobile learning. 2) Students’ attitude towards mobile learning: including 6 domain and 18 items with 5-point Likert score(from 1 to 5), designed on the base of Aizhen Xie’s UTAUT model of mobile learning[3]. The 6 domain focused on the intention to mobile learning and its related 5 possible factors: expected effect, ease of operation, influence of students around, self-learning management and perceived interest. 3) Barriers to mobile learning.

Results

157 nursing undergraduates participated in this study which included 18 male and 139 female students. All of them were in the age group of 18-22 years, and 77.8% of them had more than 2 years experiences of using smart phones. 53.7% students used mobile learning frequently in past half year. The score of students’ intention towards mobile learning ranged from 6 to 15, with an average of 10.5(SD, 2.3). The intention to mobile learning was related to students’ gender, expected effect, ease of operation, influence of students around, self-learning management and perceived interest (Figure1). The barriers to mobile learning were mainly reflected in the following three aspects: learning resources, features of smart phone and external support conditions (Figure1).

Discussion

This study showed that nursing students had the basis and positive intention for mobile learning, but decisive factors and barriers would affect their use of mobile learning. And it was clear what should pay attention to attract users for continuous adaptation and absorb more new users in developing mobile learning system and the mobile learning resources. It also contributes to the decision-making of teachers, and the formulation of policy on the promotion of innovative mobile learning.

Conclusion

Students had positive attitude and perception toward mobile learning, enough conditions to promote students’ mobile learning should be provided.

Figure 1 – Nursing undergraduates’ intention to mobile learning and its related factors and barriers

Secure Electronical Communications and Data Transfers in a Clinical Environment

T. Xu*, V.S. Thiemann*, R. Röhrig*, D. Brammen* and R.W. Majeed*

*Department of Medical Informatics, Carl von Ossietzky University, Oldenburg, Germany
*Department of Traumatology, Otto von Guericke University, Magdeburg, Germany

Abstract

As part of the German Project AKTIN, data security arises as an important issue. The context of this issue was detailed and the requirements were determined, with special focus on the hospital’s point of view. The solution is illustrated in this poster. Further use cases in other medical or study context are also discussed.

Keywords:
Computer Security, Electronic Mail

Introduction

In modern day medical context, there are increasing needs to transmit data also outside of complex study software. Ransomware brought new awareness to IT-security in clinical context and a healthy scepticism towards emails. During the early stages in the German Emergency Department Data Registry (AKTIN)[1], anonymised data is exported for evaluation of data quality. These data exports need to be transferred from the hospitals to our data analyst. Discussions with IT staff at the hospitals have shown the following environment at the hospitals: The common operating system is Windows. New software installations are difficult and should be avoided. Software must be usable with only little IT knowledge. Computers may not have direct internet access. Sceptical users want to verify that only the intended data is transmitted. This Poster presents our solution for secure data transfers from a clinical environment.

Methods

There are several possible approaches from Computer Science to ensure data safety and authenticity during communication: GPG encrypted mails, diverse asynchronous or certificate based methods, and secured channel transport. In this instance, a hybrid encryption scheme is chosen: Symmetric encryption is used for the potentially large data payload, while the symmetric key itself is encrypted via asymmetric algorithms. The software solution consists of Windows-Batch-Scripts and bundled dependencies which can be run without installation.

Results

Since the file for transmission (called F) can be of variable size, a symmetrical encryption with a reasonable large, randomly generated key Ks is used, generating F_enc. The recipient’s public key Kp is either stored in a local repository or retrieved from a trusted third server (with certificate) and used to encrypt Ks to Kp_enc. Both encrypted files are then compressed and sent, possibly with the sender’s signature, to the recipient. The recipient can then verify the sender by his public key and decrypt the K_enc, with his own private key kr. The encrypted file can be then decrypted with Ks.

With the hybrid encryption scheme, payloads of arbitrary length can be encrypted – independent of the asymmetric key block size. Transparency is provided by supplying not only the encrypted package, but also the original file and a software package for the physician to encrypt the file manually after checking the file to his satisfaction. All intermediate files are deleted at the end of encryption. The source code is available at https://gitlab.uni-oldenburg.de/AKTIN/secure-transmit

Discussion

The solution presented here will be used as an additional layer in the secured communication channels for the German Emergency Department Data Registry. There are other, already implemented methods in IT security fields. But these methods require additional software and management or are not fit for physician use, since they also require user training. Our solution provides data safety and prevents unauthorized data access. It also ensures data origin by signature. It can be extended or adapted for other projects and is easy to integrate into existing software. The only requirement is a trusted server. The possible senders and receivers need to create public and private key pairs and either register their public keys with the trusted server or exchange them with each other.

Conclusions

We presented a file encryption system by means of a small software package usable for most hospital IT environments, which improves data security compared to the commonly used unprotected channels.

Big Data in the ICU: experience in the Hospital Italiano de Buenos Aires

José Astudilloa, Javier Zelechowera, Francisco Traversaroa, Francisco Redelico, Daniel Lunac, Fernan Quiros, Marcelo Risk, Eduardo San Román

a Service of Adult Intensive Care Unit, Hospital Italiano de Buenos Aires, Argentina  
b Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina  
c Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract

Intensive care represents the critical care setting of a hospital, where fundamental, precise, and fast decisions have to be made. These decisions will affect the outcome of the patients in a matter of few hours. The knowledge of the therapeutic interventions applied in this setting is evolving, thus the perspective of Big Data may provide a new paradigm in the ICU. The conformation of a multidisciplinary team is essential to develop Big Data in the ICU.

Keywords:  
Intensive Care Unit, Critical Care

Introduction

Big Data is defined in many ways, especially given its origin in the economic and social sciences. The interest and application to the medical sciences is promising given the potential to generate a high volume and variety of data, and new knowledge in accordance with this abundance of information. In broad outline, and as other authors did, Big Data can be broken down into three fundamental aspects: Volume, Speed and Variety [1]. This approach is little known in the medical field and require the work of multidisciplinary teams, for their interpretation and application to clinical practice [2]. The objective of this poster is to propose a system of analysis of the vital signs and data of the Electronic Health Record (EHR) in critical patients.

Methods

The Hospital Italiano Buenos Aires has a mature EHR, developed entirely in our institution. All the interventions and tests of the patients are registered, regardless of the reason for consultation as well as the degree of complexity required in their care. We propose the formation of a multidisciplinary team composed of physicians, engineers and biologists, in order to develop this new approach of managing medical information.

This approach of using extensive medical information, which occurs during the hospitalization in the intensive care unit, the patients data is collected during their first 24 hours of hospitalization in the ICU. The sample of selected patients included immediate postoperative patients and shock patients with suspicion of septic etiology. It was collected from this population two severity scores Acute Physiology And Chronic Health Evaluation II, vital support requirements (vasopressors, mechanical ventilation, and sedation), and balance for the first 24 hours. It was also recorded, the duration of stay in both the ICU and the hospital, and infectious inter occurrence during hospitalization.

The pilot study have a total of 20 patients. We delight a total of 120 patients for the next 6 months. After that, we will process all the gathered information in order to obtain patterns of behavior towards sepsis. We expect this patterns will help us predict other patients evolution during their internment.

Discussion

The basic characteristics of Big Data would allow to, in the context of the critical patient, produce more accurate diagnostic impressions, based on the signals analysis from the vital signs and the records in the electronic medical record. In turn, the diagnostic impressions will lead, through algorithms based to a known institutional population, on the most relevant diagnostic tests and procedures. In this way, it would be possible to optimize resources and adjust the best procedures for any given patient.

In conclusion, this approach, combined with the genetic content of the patients, will allow the practice of precision medicine in critical patients [4]. Finally, through the knowledge of the outcome of similar patients undergoing similar treatments, Big Data could help to choose the most appropriate interventions. This is, to the extent of our knowledge, the first experience of this type of a multidisciplinary team work in an Argentinian Hospital.

Training of Students for Critical Evaluation of Mobile Health Applications

Jadranka Bozikov*, Mira Hercigonja Szekeresb

*Andrija Stampar School of Public Health, School of Medicine, University of Zagreb, Zagreb, Croatia.
*bUniversity of Applied Health Studies, Zagreb, Croatia

Abstract

Medical and nursing students need to be trained in critical evaluation of mobile health applications (m-health apps) in order to see their potential and to understand the need for their validation and certification. Students should develop positive attitudes but also critical views on such apps in order to be prepared for responsible and ethical use of m-health in their future professional practice.

Keywords:
Education, Medical; Mobile Applications; Telemedicine

Introduction

Health and social care systems are facing an upsurge in chronic diseases and multi-morbidity as a consequence of population ageing, at least when the European Union and broader European Region is considered. There is a growing need for supportive tools and practices that will enable elderly people to be active and independent. Mobile applications for health (m-health apps) have been recognized for their great potential to improve the health and wellbeing of patients by empowering them to take responsibility for their own health [1,2]. Likewise, m-health apps hold a promise for innovative health promotion interventions targeted at younger generations. Therefore, health professionals need to take into account the advantages of m-health apps, but also to be aware of their limitations and even harmfulness. Students need to be trained in critical evaluation of m-health apps in order to be prepared to utilize the potential of m-health in their future professional practice.

Methods

Fifth-year medical students and second year Master programme nursing students were asked to download m-health apps for smartphones and test them according to given guidelines. Each student has to review and report (in the form of an oral presentation accompanied with PowerPoint) on the selected application regarding the following points:

- target population: patients or healthy subjects
- aim and function: information and education only / health promotion / health care and disease control
- need of Internet connection: all the time or occasionally
- possibility of connecting measuring and tracking units (e.g. heart rate, Fitbit, belt, watch)
- communication with other persons: caretakers, healthcare personnel or social networks
- authors/publishers, availability, languages, price, etc.

Results

Students have proved their capability for testing m-health apps and understand the need for their evaluation, validation and certification. They successfully documented test results, presented them during seminars and have discussed the apps’ advantages and drawbacks, as well as their potential, from the perspective of health care.

Conclusions

Medical and nursing students should be trained in critical evaluation of m-health applications in order to:

- develop positive attitudes towards their use, but also critically view and understand the necessity for their validation and certification
- be prepared for the responsible and ethical use of m-health apps in future professional practice

\textsuperscript{b} freshEHR Clinical Informatics Ltd, Kettering, Northamptonshire, UK

Abstract

We present the first public openEHR archetypes and templates for physiotherapy, and the context of multidisciplinary academic–industry partnership that has enabled their production by a team led by a clinically trained student on the UCL health informatics MSc programme.

Keywords:
Electronic Health Records, Physical Therapy Specialty, Computer Simulation

Introduction

Given the clear assertions in published literature that physiotherapy needs, and will benefit from, electronic health records, it was surprising that the international repository for clinical models for the openEHR record architecture (the Clinical Knowledge Manager or CKM at openehr.org/ckm) made no reference to physiotherapy, and that other published modelling work had not used formalisms that provided for easy re-use. We set out to explore what would be involved in changing this.

Methods

With advice from another domain expert, a guideline for the assessment of ankle sprain by a physiotherapist [2] was selected. The guideline was chosen to be both generic (i.e. not from a specific hospital) and informed by established principles of structured record keeping (the International Classification of Functioning, Disability and Health).

Close reading of the guideline text enabled identification, extraction and enumeration of all data items mentioned or implied, and their datatypes. This included the tracing of recording requirements included in the guideline by reference (e.g. to particular tests or scoring systems).

The resulting document informed a “pair modelling” (cf. pair programming) process in which the student and an industry expert modeller worked side by side to organise the guideline content and build a corresponding openEHR template for ankle sprain assessment backed by existing and, where necessary, new openEHR archetypes.

The template and archetypes were then published on the UK national CKM (clinicalmodels.org.uk) for review, thus also making them available internationally for scrutiny and possible adoption by others.

Results

The Ankle Sprain - Assessment UCL.v0 template uses 41 archetypes, 25 of which were drawn from the international CKM. The CKM review was largely positive, raising some technical modelling questions and identifying some flaws in the original guideline.

Discussion

Imperfections notwithstanding, the real-world utility of the artefacts produced supports the hypothesis that clinical modelling is a field in which a student domain expert can – with appropriate support – develop sufficient expertise to make credible contributions to a public-facing knowledge resource.

Conclusions

Guideline authors should consider (and perhaps even specify) the consequences of their editorial decisions in relation to the record-keeping required in a multiprofessional, multi-agency service context. Taking a guideline, which already has some degree of clinical consensus, as a starting point significantly eases the process.

This kind of academic-industry partnership is rewarding for participants and aligns well with research-based education, for example as articulated in UCL’s Connected Curriculum [1].

Acknowledgements

We thank Dr Ibtissam Saab for expert advice on guideline selection and all who contributed time and expertise to the review process.

Exploiting Temporal Constraints of Clinical Guidelines by Applying OpenEHR Archetypes

Lilian Mie Mukai Cintho\textsuperscript{a}, Diego Garcia\textsuperscript{a}, Bruno Henrique da Silva Santos\textsuperscript{a}, Lucia Sacchi\textsuperscript{b}, Silvana Quaglini\textsuperscript{b}, Claudia Maria Cabral Moro\textsuperscript{a}

\textsuperscript{a}Health Technology Graduate Program, Pontificia Universidade Católica do Paraná, Brazil
\textsuperscript{b}Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Italy

Abstract

Studies describing Computer-Interpretable Clinical Guidelines (CIG) with temporal constrains (TC) generally have not addressed issues related to their integration into Electronic Health Record (EHR) systems. This study aimed to represent TCs contained in clinical guidelines by applying archetypes and Guideline Definition Language (GDL) to incorporate decision support into EHRs. An example of each TC class in the clinical guideline for management of Atrial Fibrillation was represented using archetypes and GDL.

Keywords:
Decision Making, Computer-Assisted; Decision Support Systems, Clinical; Decision Support Techniques

Introduction

Researchers have addressed issues related to the representation of clinical guidelines with TC specification using formalisms and tools to develop clinical decision support systems (CDSS). Although it is difficult to integrate them into the EHR, it is necessary to map the information. The integration of CDSS into EHR based in the archetypes architecture that is a standard to system interoperability and make possible to represent data and rules of CDSS, avoiding the mapping, was presented by [1], however not dealing with TC.

Accordingly, this work aims to represent the TCs contained in clinical guidelines with archetypes, and to use the GDL as a unifying language for representing both the EHR and CDSS.

Methods

An example from each type of TC class was identified: qualitative, quantitative and mixed, from the European Guideline for the Management of Patients with Atrial Fibrillation (AF). For patients with AF of ≥48h duration, or when the duration of AF is unknown, OAC therapy is recommended for ≥3 weeks prior to and for ≥4 weeks after cardioversion, regardless of the method (electrical or pharmacological), is an example of a mixed (qualitative and quantitative) TC. The data and rules related to each TCs were represented using archetype and GDL. The execution of each rule was validated manually, with 20 real cases from patients randomly selected.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure1.png}
\caption{Rules to represent TC in quantitative duration}
\end{figure}

Results

All the results of the rules execution are the same compared to the medical decision. Figure 1 shows part of the GDL rule created to represent a mixed TC.

Conclusion

The OpenEHR and GDL archetypes allowed to represent TCs contained in the CG.

Towards the Consideration of Diagnostic Delay in Model-Based Clinical Decision Support

Jan Gaebel, Mario A. Cypko, Steffen Oeltze-Jafra

Innovation Center Computer Assisted Surgery, Faculty of Medicine, University Leipzig, Leipzig, Germany

Abstract

Diagnostic delay involves the peril of information becoming outdated. It is a challenging task to quantify the up-to-dateness of clinical information and the consequences of diagnostic delay with the goal of considering them in clinical decision support. We propose an approach to integrating the up-to-dateness of clinical information in a model-based therapy decision support system.

Keywords:
Decision Support Systems, Clinical; Models, Statistical; Cancer Staging

Introduction

The diagnostic delay refers to the duration of the diagnostic process until the final treatment decision is made, e.g. for suspected tumors. Gómez et al. found a significant correlation between diagnostic delay and advanced tumor stages [1]. We propose 1) a temporal rating of measured diagnostic delays and evaluation of the up-to-dateness of clinical information as well as 2) the integration of this rating in a model-based decision support system (DSS) for the staging of laryngeal cancer.

Methods

We exemplarily analyzed 39 patient cases with laryngeal cancer from 2013. The median delay for neck CT scans is 35 days, for the histopathological reports the delay is 6 days. Data beyond this temporal threshold should have less impact on the therapy decision. To answer the question of how outdated information should be processed and in what scenario this would be applied, we integrate a temporal rating of measured delays into a clinical DSS using Bayesian networks (BN). A BN has the potential to represent complex decisions by a model including all relevant patient characteristics and decision options. In the model, characteristics and decisions are represented by variables, each with a number of possible states, see Fig. 1. A decision model can be instantiated with an amount of certainty reflecting the real-world situation [2]. Variables’ states can be instantiated, either with 100% certainty for one state (Fig. 1, left) or with probabilities distributed over multiple states (Fig. 1, right). They must always add up to 100%. If information is not given, this can also be specified, e.g. with an “unknown”-state. We employ the unknown state to reflect the uncertainty caused by diagnostic delay. For an outdated information, we set its probability to a value >0% depending on the temporal rating. For an initial analysis, we propose to set the uncertainty to 50% to halve the impact of the outdated information.

Results

Our approach connects the hospital information system with the therapy DSS for laryngeal cancer stating [3]. For testing purposes, we investigated a complex patient case: patient with 40 days old CT data and five days old pathological data. The DSS falsely computed a TNM staging of “T2 Nx Mo”. The CT data, in which no infiltration of lymph nodes was visible, interfered with the more current pathological data. With the reduction of certainty of the outdated CT data, as illustrated in Fig. 1, right, the DSS correctly calculated the stage “T2 N2b M0”. Setting “unknown” to 100% however gave no improvement. This shows that information cannot be discarded completely.

Conclusion

We conclude that this approach would be easily applicable to other diseases or problems with the proper amount of medical knowledge and modeling efforts. We will extend the calculation of the delay to all relevant diagnostic modalities to support the entire process and increase the quality of care. We will conduct a validation study on a larger patient data set.

Considerations of Human Factors in the Design and Implementation of Clinical Decision Support Systems for Tumor Boards

Carmelo Gaudioso\textsuperscript{a}, Peter Elkin\textsuperscript{b}

\textsuperscript{a}Department of Biostatistics, Roswell Park Cancer Institute, Buffalo, New York, USA
\textsuperscript{b}Department of Biomedical Informatics, State University of New York at Buffalo, Buffalo, New York, USA

Abstract

Critical decisions are made at tumor boards (TB). Further research is needed to guide the design and implementation of clinical decision support systems (CDSS) for highly interactive, fast-paced, and complex TB decision making. We highlight two key human factors that should be considered in the design and Implementation of CDSS for multidisciplinary deliberations: cognitive burden and trust.

Keywords:
Decision Support Systems, Clinical; Decision Making; Cognition

Introduction

TB are considered a standard of care and the use of information systems is recommended to support evidence-based decision making [1]. Multiple human factors must be considered in the design of CDSS for complex and fast-paced multidisciplinary decision making. To accomplish this, requires a shift in the approach to the design of information systems [2]. Tumor board systems need to present complex information from across many disciplines to a clinician treating the patient. In order to assure that human factors are taken into consideration, the interface design is going through much iteration of usability studies. The dynamic interactions between system and users, and communicative actions are key considerations in the design of actable CDSS [3].

Methods

Following a qualitative research method, including review of archival data, observation, interviews, surveys, and researchers’ reflection and discussion, through an iterative and incremental process [4], we designed an instance of a sub-class of CDSS for multidisciplinary decision making at breast cancer TB meetings. During testing, we observed and examined tumor board deliberations to characterize form, content, functional requirements, workflow, cognitive processes, and patterns of use of case-relevant evidence-based information with and without the aid of the CDSS. Semistructured interviews provided for more in-depth and targeted analysis of our observations yielding rich data.

Results

Given the limited time to review each case, users required that only case relevant clinical information be displayed on a single screen, organized in a case (problem) relevant and logical format. However, Radiology and pathology reports were to be displayed in their entirety rather than as a summary of findings. To this point, a medical oncologist said: “I want to read the report by myself. I don’t trust somebody else’s interpretation. These reports contain a set of critical information with details that are of different interest to different disciplines and tasks that have to be performed. Structure and synthesis are good for displaying discrete data (facts, i.e., clinical findings and laboratory results), but not for narratives like pathology and radiology reports.”

Conclusion

Human factors, including cognitive load, trustworliness and workflow inherent to dynamic and complex multidisciplinary decision making are critical considerations in the design of CDSS [5]. The design process must be one in which there is open communication and collaboration between the designer and the user and usability testing in real action bring to light critical form, content, and functional requirements.

Acknowledgements

The authors acknowledge the contributions of the tumor board members.

Usability Study of RSNA Radiology Reporting Template Library

Yi Honga, Ying Zhub, Selen Bozkurtc, Jin Zhangb, Charles E. Kahnd

Abstract

This study provides insights that could help to improve the Radiological Society of North America (RSNA) Reporting Template Digital Library, based on a usability evaluation. The results show that most users have been satisfied with the website. The general comments for the library are positive, although the participants suggested quite a few areas to improve. About 40% are returning visitors which means people often come back to the website.

Keywords:
Radiology Information Systems; Libraries, Digital; Program Evaluation.

Introduction

The Radiological Society of North America (RSNA) Radiology Reporting Template Library is a freely accessible digital library that incorporates metadata, standardized medical terminologies and health care industry standards to promote knowledge sharing of structured radiology reports [1]. Since the library was launched in December, 2009, it has received more than 4.2 million page views with its fast-growing collections of 252 reporting templates. The purpose of this study is to provide insights to improve the reporting template library website based on a usability evaluation, including an online survey, focus groups, web analytics, and transaction log analysis.

Methods

To get first-hand feedback from users, an ongoing online survey was posted on the library website. The web-based Qualtrics survey software was used to create the ongoing survey at https://milwaukee.qualtrics.com/jfe/form/SV_eR6Yawd3H. Two focus groups were formed to further gather users’ feedback on the template library. One group consisted of three medical informaticians, while the other group included three radiologists. A protocol was designed for the focus group interviews. The focus group sessions were conducted while the results were summarized and interpreted in a report. A Google Analytics account was set up to track the usage of the website, as well as monitor the number of visitors and their geographical location. The scripts that enable Google Analytics to collect data were added to the website to track users’ interactions with the website for a specific time. Approximately one year’s data from the web analytics and transaction logs were analyzed using the Web Log Explorer to further identify demographic profile of visitors, determine user behavior as related to the library website, find out what search terms were frequently used to find templates, and determine what templates are most popular.

Results

A total of 163 respondents participated in the online survey from February 2016 to April 2017; 135 completed all the questionnaires. The respondents were from Asia (35.58%), North America (31.90%), Europe (16.56%), and Africa (9.82%). Most of the respondents were male (63%). The survey results suggested that most users had been satisfied with the reporting template library website. About 80% of survey respondents rated the overall level of satisfaction for the library website as excellent/good, while more than 70% respondents rated each of the following specific features as excellent/good: Navigability 76%, Timeliness 75%, Ease of search 71%, Availability of information 70%, Organization 80%, Visual appeal 76%, and Uniqueness 76%.

The focus group interview results showed that the general feedback for the library was favorable, although the participants suggested quite a few areas for improvement. The participants thought that the goal of digital library was remarkable, while the quantity of templates was adequate. The medical informatician group had a higher overall level of satisfaction with the website, while the radiologist group seemed much pickier with the content of the templates. Both groups thought the online library tours were not simple enough to show how to use the template library and suggested that a video tutorial should be used. The results of web analytics showed that most visitors to the library website resided in the United States. In terms of visitor profiles, a larger proportion were new visitors (61.4%) vs. returning visitors (38.6%) and 12,246 of 113,618 users (10.8%) were active users.

As of April 6, 2017, the library website received 4,277,407 page views. The top five specialties that got most page views were Tomography, Chest Radiology, and Diagnostic Radiology.

Conclusion

This usability study provided insight into the evaluation of the reporting template library website, both methodologically and practically. It is the first study to perform a usability assessment for the radiology reporting template library. Our methodology could serve as an example for measurement development of other services in radiology reporting.

Evaluation of SNOMED CT as a Reference Terminology for Standardized Data Queries in the Arden Syntax

Robert A Jenders, MD, MS, FACP, FACMI

Charles Drew University & University of California, Los Angeles, California, USA

Abstract

Context: Arden Syntax is a standard that encodes knowledge as Medical Logic Modules (MLMs) but lacks a standard query data model and terminology. Objective: Assess to what extent SNOMED CT can represent MLM query data elements. Method: 340 MLMs containing 3268 queries were examined. Result: SNOMED can be used to represent all data elements except for clinical decision support system terms such as "alert." Conclusion: SNOMED CT adequately represents data queried using the Arden Syntax.

Keywords: Clinical Decision Support Systems

Introduction

Arden Syntax is a formalism supervised by Health Level Seven International (HL7) for representation of procedural medical knowledge to facilitate sharing units of knowledge known as MLMs that are executed in clinical decision support systems (CDSS). Some site-specific changes must occur in order for a knowledge base to be shared. The key to minimizing changes is the standardization of database linkages, which in turn requires at least a standard data model, terminology and query syntax. This is known as the “curly braces problem” of Arden because of the syntactic construct used to enclose these site-specific references [1]. Prior work [1] has established the utility of standards such as FHIR to serve as the standard data model for the Arden Syntax. SNOMED CT is a reference terminology used to encode health care data that, as such, can be used to standardize references to data used in knowledge interventions that can be represented as MLMs. The present work was undertaken to assess the utility of SNOMED CT as a reference terminology for queries in the Arden Syntax that, in conjunction with a standard data model, will help solve the curly braces problem.

Methods

A previously assembled convenience sample of MLMs was examined. The data query statements were extracted from these MLMs, and the data elements therein were identified. Each was assessed to ascertain whether it could be encoded using the September 2016 US Edition of SNOMED CT.

Results

A total of 340 MLMs were pooled from 5 source CDS systems, including 24 from 2 vendor knowledge bases and 316 from 3 academic medical centers. MLMs concerned with lab tests were the most common (138/340 = 41%), followed by clinical assessment (75=22%) and medication (45=13%). The remainder addressed administrative and miscellaneous topics. Each MLM contained at least one READ statement with a data query. A total of 3268 queries were identified, and the data elements therein were compared to concepts in SNOMED CT to assess if the former could be encoded by the latter. All the data elements in these queries could be encoded in SNOMED CT except for data elements referring specifically to aspects of CDSS (203 or 6.2% of all queries) such as alerts and intermediate blackboard-type results of preprocessing of data. Of note, the primary time of query data elements in Arden is an implicit attribute of every query variable and is not explicitly represented, but this can be encoded in SNOMED CT.

Conclusions

SNOMED CT is adequate to encode the data elements found in a large set of query statements in a corpus of Arden Syntax MLMs. The addition of concepts to SNOMED CT to represent CDSS constructs would improve its utility for this purpose. Consideration should be given for use of SNOMED CT to encode query data elements in a standard way in the Arden Syntax in order to facilitate knowledge sharing.

Building Interoperable FHIR-based Vocabulary Mapping Services: A Case Study of OHDSI Vocabularies and Mappings

Guoqian Jianga, Richard Kieferb, Eric Prud’hommeauxb, Harold R. Solbrigb

aDepartment of Health Sciences Research, Mayo Clinic, Rochester, MN, USA
bW3C/MIT, Boston, MA, USA

Abstract

The OHDSI Common Data Model (CDM) is a deep information model, in which its vocabulary component plays a critical role in enabling consistent coding and query of clinical data. The objective of the study is to create methods and tools to expose the OHDSI vocabularies and mappings as the vocabulary mapping services using two HL7 FHIR core terminology resources ConceptMap and ValueSet. We discuss the benefits and challenges in building the FHIR-based terminology services.

Keywords:
Reference Standards; Observational Study; Vocabulary, Controlled.

Introduction

The Observational Health Data Sciences and Informatics (OHDSI) Common Data Model (CDM) is a deep information model [1] that specifies how to encode and store clinical data at a fine-grained level, ensuring that the same query can be applied consistently to databases around world.

HL7 Fast Healthcare Interoperability Resources (FHIR) [2] is emerging as a next generation standards framework for facilitating health care and electronic health records (EHRs) data exchange. The objective of the study is create methods and tools to expose the OHDSI vocabularies and mappings using the FHIR-based terminologies services.

Methods

We examined both the OHDSI Vocabulary CDM version 5.0.1 [3] and the STU3 Ballot version of the FHIR core terminology resources [2]. We created mappings between the Vocabulary CDM and two FHIR terminology resources with high maturity level – ValueSet and ConceptMap. We used FHIR extension mechanism to capture those fields in CDM (e.g., domain_id, vocabulary_id) that do not have corresponding mappings in FHIR. We installed an OHDSI virtual machine (VM) based on the CDM 5.0.1 version, which contains the full OHDSI Technology Stack and is loaded with the standardized vocabularies. We then created a Java-based transformation tool that invokes the HAPI-FHIR API to transform the OHDSI vocabularies and mappings as the instances of the FHIR ValueSet and ConceptMap, and loaded the instances into a local FHIR server.

Results

The OHDSI VM is loaded with 3,316,702 unique concept ids, in which 1,052,060 concepts are marked as “standard concepts” which have mappings asserted. These concepts are classified by 32 domain ids, 61 vocabulary ids and 210 concept class ids. We have successfully created tools to generate the ValueSet instances that capture the metadata of concepts and the ConceptMap instances that capture the metadata of concept mappings (an example in Figure 1). We loaded 1000 ConceptMap instances and 2000 corresponding ValueSet instances in a FHIR server and examined the search capability enabled by FHIR.

Discussion

The OHDSI Vocabulary CDM and its implementation have been successfully used in supporting clinical observational data integration and systematic data characterization. It has provided a collection of valuable terminology service requirements that can be generalized to address the similar needs of broader scientific communities. The FHIR terminology resources and tooling provide a standard mechanism to enable interoperable vocabulary mapping services for the OHDSI vocabularies and mappings.

Mapping HL7 CDA R2 Formatted Mass Screening Data to OpenEHR Archetypes

Shinji Kobayashi, Naoto Kume, Hiroyuki Yoshihara
The EHR department of Biomedical Informatics, Kyoto University, Kyoto, Japan

Abstract

Mass screening of adults was performed to manage employee healthcare. The screening service defined the data collection format as HL7 Clinical Document Architecture (CDA) R2. To capture mass screening data for nationwide electronic health records (EHR), we programmed a model within the CDA format and mapped the data items to the ISO13606/openEHR archetype for semantic interoperability.

Keywords:
Electronic Health Records, Semantics, Mass Screening

Introduction

Mass screening of adults has been performed for the early detection of diseases, and to limit healthcare expenditures by preventing lifestyle-related diseases in Japan. This screening service defines the data collection process as HL7 Clinical Document Architecture (CDA) R2 [1] and uses data for personal lifestyle prevention.

An electronic health record (EHR) project based on the ISO 13606/openEHR archetype was performed to use healthcare data for research purposes. To capture the mass screening data, we programmed a model within the CDA format and mapped the data to ISO13606/openEHR archetypes for semantic interoperability.

Methods

Datasets were initially analyzed to identify possible mass screening items. Subsequently, archetypes and templates were designed by the openEHR Archetype Editor and Ocean Template Designer, respectively. The archetypes were mainly derived from the openEHR Clinical Knowledge Manager with or without modifications. Since some concepts only concerned the usage of mass screening processes in Japan, they were newly designed to express such specialized concepts. We then mapped the HL7 CDA elements with the OID table to the path of elements in the openEHR template that was designed for capturing mass screening data.

Results

In accordance with mindmap analysis, mass screening data were recorded using an openEHR template, which was designed with 36 archetypes. The main part of the CDA had a simple structure including item names and values. Each element was parameterized using items from a questionnaire and an OID table was mapped to concept models. For the mass screening CDA, doctors' evaluations of health were categorized as an OBS Reference Information Model (RIM), but mapped as the Problem/Diagnosis archetype derived from the “EVALUATION” Reference Model (RM) within the openEHR archetype.

Discussion

To build EHR systems, standards are necessary to construct an interoperable data repository. Connected to the standardized data was a common problem, and we established mapping rules between the openEHR archetypes/templates and HL7 CDA. To efficiently and accurately establish mapping rules [2], terminology binding should be considered; however, no such terminology is available in Japan.

HL7 CDA-formatted data were transformed to openEHR archetypes/templates, thus establishing a possible method for building interoperable EHRs.

Conclusion

Mapping rules between HL7 CDA-formatted data and openEHR archetypes/templates was successfully performed in this study. For efficiency, such terminology should be widely adopted throughout Japan.

Implementation of an Archetype Data Set to Reuse Electronic Health Record Data in Clinical Decision Support Systems

Georgy KOPANITSA

Institute Cybernetic Center, Tomsk Polytechnic University, Tomsk, Russia
Tomsk State University for Architecture and Building, Tomsk, Russia

Abstract

The efficiency and acceptance of clinical decision support systems (CDSS) can increase if they reuse medical data captured during health care delivery. High heterogeneity of the existing legacy data formats has become the main barrier for the reuse of data.

Keywords:
Decision Support Systems, Clinical; Telemedicine; Electronic Health Records.

Introduction

Medical insurance companies perform quality assessment of medical treatment in Russia. The results of the quality control influence the payment that a clinic will get for the certain case of treatment. The quality assessment process is a well-formalized process performed by medical experts based on clinical standards and personal experience. However, different interpretation of clinical standards especially in regards of optional medical procedures add bias to the process. To avoid bias and to make the process transparent and independent the task of quality assessment can be delegated to a decision support system [1-6]. However, most of CDSSs still are stand-alone systems that require import-export routine with HISes. The goal of this paper is to present the development of an archetype based dataset for a CDSS–HIS data exchange.

Methods

Our study is based on the approach proposed by Marcos et al [7] where archetypes are used as a standardized mechanism for the interaction of a CDSS with an EHR. We used LinkEHR archetype editor to design archetypes. In our project, clinical data in EHR systems was stored in proprietary formats. All the HISes participating in the project provide routines that can import/export XML data with known XML schema. We have transformed this data into the openEHR standard format following the constraints defined in archetypes. To perform this transformation we used LinkEHR studio. Using LinkEHR studio we have defined mapping rules between an EHR data schema and CDSS archetypes. After the mapping has been completed, an XQuery script for each of the 10 HISes has been generated to transform the source data instance into an XML document compliant with the target archetypes.

Results

We have used archives of treatment cases from 10 clinics in Tomsk, Russia, participating in the pilot project. Each HIS database stores a complete electronic health record for each patient. On the first step, we have reviewed the openEHR archetype repository (Clinical Knowledge Manager (CKM)) for the archetypes that could be reused in our project. Although, the found archetypes had many of the necessary fields, there still was a need to design new archetypes and to add some of the fields useful for payment information and CDSS purposes like nonconformity, transfer summary and inference coefficients.

Conclusions

We have defined a set of archetypes to represent concepts for exchanging and analyzing interaction with insurance companies.

Correcting Ontology Errors Simplifies Visual Complexity

Hao Liu, Ling Zheng, Yehoshua Perl, Yan Chen, Gai Elhanan

Department of Computer Science, New Jersey Institute of Technology, Newark, NJ 07102-1982 USA

Abstract

In previous research we have shown that hierarchically complex overlapping concepts have a higher error rate of errors versus control concepts. In this paper we show an example from Neoplasm concepts of the NCI thesaurus(NCIt) demonstrating that erroneous overlapping concepts, reflected in the partial-area units of a partial-area taxonomy, display visual complexity. Furthermore, correcting these erroneous concepts causes visual simplification.

Keywords:
Ontology Quality Assurance; Ontology Visualization.

Introduction

In a current study of Quality Assurance of Neoplasm concepts of the NCIt, we have shown that hierarchically complex concepts have higher error rate than control concepts. Those complex concepts are called overlapping concepts, since they belong simultaneously to multiple units/groups called partial-area of similar concepts in a partial-area taxonomy[1] (taxonomy for short) of the NCIt Neoplasm subhierarchy. Such overlapping concepts are semantically complex due to the compound semantics originated from different partial-areas. For formal definition see [2]. In this paper, we bring an example which illustrates a correlation between erroneous overlapping concepts and their visual complexity. To show this we demonstrate that the impact of correcting the errors of these overlapping concepts brings to the visual simplification of the complexity reflected for the erroneous concept.

Methods

For visual reflection of the complexity before and after the corrections, we utilize Venn Diagrams. Figure 1(a) displays an excerpt of six concepts of Neoplasm subhierarchy structure in the area with three roles {Disease Has Abnormal Cell, Disease Has Associated Anatomic Site, Disease Has Finding, Disease Has Primary Anatomic Site}. That is, each of the six concepts has exactly these roles. The concepts of each unit (partial-area) are enclosed in a bubble of a different color. Visual complexity is reflected by the existence of concepts which belongs simultaneously to several bubbles. For example in Figure 1(a), the two concepts Recurrent Childhood Central Nervous System Neoplasm and Recurrent Childhood Spinal Cord Neoplasm are overlapping concepts in the audited sample. They belong to both the red partial-area rooted at Childhood Central Nervous System Neoplasm and the green partial-area rooted at Recurrent Central Nervous System Neoplasm.

Furthermore, when the two overlapping concepts are corrected by adding the role Disease Has Primary Anatomic Site, the modeling changes. When looking at the same concepts after remodeling, the view through the prism of a taxonomy reflects a simpler visual presentation. In particular these two concepts are no longer overlapping concepts of the two partial-areas in Figure 1(a). After the remodeling, they appear in a separate area with four roles {Disease Has Abnormal Cell, Disease Has Associated Anatomic Site, Disease Has Finding, Disease Has Primary Anatomic Site}. A new blue bubble(partial-area) rooted at the concept Recurrent Childhood Central Nervous System Neoplasm, contains the two corrected concepts.

Results

What we see in Figure 1, is that in contrast to the visual complexity in Figure 1(a) reflecting errors in modeling, the corresponding visual complexity of the partial-areas of the six concepts, following the remodeling, is simpler. That is, corrections of the modeling errors in overlapping concepts leads to visual simplification, when reviewing the taxonomy compact representation of the ontology. A future study is planned to confirm the following hypothesis: The visual presentation of erroneous overlapping concepts in a taxonomy, is simplified when the errors are corrected.

The future study will investigate in what percentage of erroneous overlapping concepts, a visual simplification is obtained by correcting the errors.

Conclusion

In this poster we demonstrate how erroneous concepts are manifested by visual complexity. Correcting them leads to visual simplification.

Using Semantic Technologies to Extract Highlights from Care Notes

Vanessa Lopez*, Grace McCarthy*, Joao Bettencourt-Silva†, Marco Sbodio*, Natasha Mulligan*, Fabrizio Cucci*, Stephane Deparis*, Ciaran Hennessy*, Nagesh Yadav†, Karie Kelly†, Russell Olsen†, Conor Cullen†, Spyros Kotoulas*

*IBM Research Ireland, Dublin, Ireland, †IBM Watson Health, Dublin, Ireland

Abstract

We propose a cognitive system for patient-centric care that leverages and combines natural language processing, semantics, and learning from users over time to support care professionals working with large volumes of patient notes. The proposed methods highlight the entities embedded in the unstructured data to provide a holistic semantic view of an individual. A user-based evaluation is presented, showing consensus between the users and the system.

Keywords:
Health Information Systems, Artificial Intelligence

Introduction

The adoption of electronic health records have contributed to a growing volume of data while promising to improve quality of care and reduce costs. However, in a system of record, insights about a patient with multiple clinical and social issues are often scattered among several notes. New methods are needed to provide automated extraction of highlights and insights to relevant information to care practitioners [2]. Our system captures knowledge from care professionals’ observations, often in an unstructured form, to create a holistic patient-centred view, consisting of entities with explicit semantics extracted from notes. Care professionals are then presented with highlights on the most relevant entities, helping them making informed and personalised decisions.

Methods

The system first annotates raw case notes associated to patients to extract entities. The annotation component consolidates the annotations from different text annotators. Currently, we use Advanced Concept Insights (ACI), a clinical IBM annotator based on ICD-10 terminology and AlchemyAPI to annotate concepts not included in ICD-10 – mainly social determinants. Second, the terminology service maps the annotations from the text to semantic entities in well-defined ontology models. Third, the note highlights component learns to rank over time the relevant determinants of health for a patient based on users’ feedback. A key challenge is to deal with the diversity of the social and clinical domains. The terminology service is built by creating a Lucene index over: (1) the ICD-10 clinical hierarchy; (2) a Linked Data subset of Freebase and DBpedia, covering the following semantic types: clinical (procedures, medication, symptoms, etc), care services and social determinants (risk factors, activities of daily living, etc). The added value behind using a terminology service is that: (1) having a URI gives a global meaning to abstract from the annotators heterogeneous models of choice, e.g., representing synonyms like Eye-drops and Ocular lubricant with the same entity; (2) a semantic type is used to filter the entities that are most likely to be relevant for the user and for organizing them into views.

Results

We created a gold standard to measure whether our system can extract similar entities from notes as to what users will choose. We selected 20 patient cases based on social and clinical collections of notes [1] and real care workers’ notes anonymized and de-identified. To create the relevance judgments, 15 evaluators were asked to highlight all relevant keywords (user annotations) and select the top 10 highlights for a case. On average each case had 91 entities and was evaluated by 3 evaluators to measure agreement: in 80% of the cases, more than two evaluators highlighted an entity. We measured an F1 score of 0.67 (i.e., the system ability to find all relevant and only relevant annotations), with 0.86 Precision and 0.56 Recall for all the entities extracted by the system with respect to all user annotations with at least moderate agreement. If we only consider the entities with strong agreement and the top-n annotations, R (coverage) increases up to 0.78, indicating that with enough learning, the performance can improve for the entities that matter the most. While 25% of entities were not assigned a semantic type due to the lack of models’ coverage, if only a clinical annotator is used (i.e., ACI) P increases to 0.94 but R drops to 0.27, showing the importance of including social concepts.

Conclusion

The system targets an interdisciplinairy care team. While social aspects are not as well defined as clinical, we show promising results to provide a semantic view on top of patient notes, based on a shared terminology that reuses well-known heterogeneous ontologies. In the future we expect to determine whether notes highlights offer a better experience for care professionals than simply reading case notes.

Challenges in Archetypes Terminology Binding Using SNOMED-CT Compositional Grammar: The Norwegian Patient Summary Case

Luis Marco-Ruiz, Rune Pedersen

Norwegian Centre for e-Health Research, University Hospital of Northern Norway, Tromsø, Norway

Abstract

In order to cover the requirements for interoperability in the Norwegian context, we studied the terminology binding of archetypes to terminology expressions created with the SNOMED-CT compositional grammar. As a result we identified important challenges categorized as technical, expressivity, human, and models mismatch.

Keywords:
Systematized Nomenclature of Medicine; Vocabulary, Controlled; Terminology.

Introduction

In order to fulfill the interoperability requirements of the Norwegian national health IT strategy in a scalable manner, machine-interpretable representation of an archetype’s clinical semantics is needed. As a result, we studied the feasibility of using SNOMED-CT compositional grammar to build semantic models that distilled the implicit ontology contained in archetypes [1] (i.e. leaving data constraints aside).

Methods

In collaboration with the National Editorial Group of Archetypes (NRUA) we selected the most representative archetypes of the Norwegian patient summary. For each archetype, terminology binding was attempted by creating a projection of its clinical semantics using the SNOMED-CT compositional grammar. When some element/section of the archetype could not be represented using a SNOMED-CT expression, we defined a new expression and tagged the cause. Additionally, when an impediment caused by the complexity of the process, lack of tooling etc. was found, we tagged it. Afterwards we reviewed all the tags and classified them into categories of challenges.

Results

Four types of challenges were identified:

Technical challenges were related to: a) lack of support in archetypes to include verbose post-coordinated expressions in their term bindings section; b) lack of tooling to assist the binding process suggesting valid concepts/attributes while building the terminology expression.

Expressivity challenges were related to: a) variation of the original meaning of the archetype element introduced by the terminology concept; b) lack of expressiveness of SNOMED-CT context model; c) lack of candidates in SNOMED-CT to represent some archetype elements.

Human challenges were related to: a) doubts in determining which sections of the archetype should be represented in the SNOMED-CT expression; b) selecting the appropriate terminology hierarchy (e.g. whether to represent blood pressure with the concept from Observable Entity or Clinical Finding hierarchies).

Models mismatch challenges were related to: a) alignments of the archetype contextual information and the SNOMED-CT context model; b) low coverage in SNOMED-CT for the attributes in the protocol section; c) overlap of semantics in the archetype (the archetype Problem_Diagnosis corresponds to two concepts from different hierarchies in SNOMED-CT).

Discussion

The results show that major challenges are present when representing an archetype’s clinical semantics as SNOMED-CT expressions. First, technical challenges show that clinical modelers need to clarify if post-coordinated expressions should be placed within the archetype definition. An alternative is to let terminology specialists maintain complex expressions in external repositories and use Linked Data principles to reference them [2]. Second, expressivity challenges show that better guidelines elicited by archetypes and SNOMED-CT editors are needed to determine what elements can be bound to SNOMED-CT expressions, and what elements should be bound to other domain ontologies (if needed). Third, technical and human challenges show that defining and binding SNOMED-CT expressions requires the development of support tools. However, further investment in these tools [3] is needed to allow them supporting such functionalities.

Terminology Status APIs – Mapping Obsolete Codes to Current RxNorm, SNOMED CT, and LOINC Concepts

Lee Peters, Thang Nguyen and Olivier Bodenreider

U.S. National Library of Medicine, Bethesda, MD, USA

Abstract

We created the Terminology Status Application Programming Interface (API) to assist users in mapping obsolete codes to current RxNorm, SNOMED CT and LOINC concepts. Use cases include support for information retrieval, maintenance of value sets, and analytics of legacy clinical databases. Our terminology status APIs typically receive over 4 million calls per month on average.

Keywords:
RxNorm; Systemized Nomenclature of Medicine; Logical Observation Identifiers Names and Codes

Motivation

In medical terminologies, new releases introduce new concepts, remove obsolete concepts and reorganize others through remapping. Managing change in large terminologies can be burdensome to users. We created the Terminology Status Application Programming Interface (API) to assist users in mapping obsolete codes to current RxNorm, SNOMED CT and LOINC concepts.

Terminology Status APIs

The status APIs have been developed to help manage change in three major medical terminologies, whose use is required for the Meaningful Use certification criteria: RxNorm, SNOMED CT and LOINC. While the RxNorm service has been part of the RxNorm API for several years, we developed equivalent services for SNOMED CT (including concepts specific to the U.S. extension of SNOMED CT) and LOINC more recently, for the purpose of validating value sets for clinical quality measures.

The RxNorm status API [1] returns three elements: Status – active, “alien” (i.e., present in one of the source terminologies, but without an RxNorm type), remapped, retired or unknown; Last active release date; and Concept information for active and remapped status.

The SNOMED CT status API [2] returns three elements: Current status – retired, active or moved; Effective time – the version of the latest change; and SNOMED CT identifiers for remapped concepts.

The LOINC mapto API [3] returns an array of LOINC identifiers when the original identifier is remapped.

All three APIs are available in two flavors, SOAP-based and RESTful. Each API also has a version function so that users can determine which version of the data set is being used. The services are updated as new terminology versions become available. Figure 1 shows an example of query to the SNOMED CT status API (RESTful version), along with the information returned.

Use Cases

Use cases for these status APIs include: 1) Supporting information retrieval systems that accept concept identifiers as queries (e.g., MedlinePlusConnect uses this service); 2) Determining outdated or remapped drug concepts in clinical drug databases (e.g., updating value sets); and 3) Supporting analytics of older datasets coded to past versions of the terminologies. Our terminology status APIs typically receive over 4 million calls per month on average.

\textsuperscript{f} WHO Collaborating Center for International Classifications in French Language, Paris, France
\textsuperscript{g} WHO Collaborating Center for International Classifications in the Netherlands

Abstract

The International Classification of Health Interventions (ICHI) alpha2 2016 Section 1 Interventions on Body Systems and Functions is based on ISO 1828 international standard named categorial Structure (CAST). This is not sufficient to represent the meaning of ICD9-CM Volume 3 labels. We propose to modify it by using the SNOMED CT concept model.

Keywords: Vocabulary, controlled, Systematized nomenclature of Medicine

Introduction

We propose to apply ontology methods \cite{1-3} for building a new generation international classification of procedures.

Methods

305 ICD9-CM volume 3 codes mapped many to one out of 113 The International Classification of Health Interventions (ICHI) codes. ICHI coding system displays the following:

- PZX DB AF means PZX Any site DB Application of Pharmaceuticals including chemotherapy AF
- Percutaneous transluminal /Transparietal intraluminal access ICD-9CM volume 3 mapped codes are different for implantation (00.10), infusion (00.11), injection (00.13), immunization (99.12). We compare ICD9 CM codes titles with SNOMED CT (SCT) procedure concept model to identify required modifications.

Results

The following modifications are proposed:

- The ICHI axis Action should be duplicate to express the intent and the deed.
- The ICHI Target axis should be extended to pathology as calculus, and to medical devices as pacemaker.
- The ICHI Target axis should be duplicate in Direct Target and Indirect Target.
- The ICHI Means axis should be extended to medical devices and drugs.

Conclusion

The analysis of the SCT concept model provides a method to increase ICHI semantic interoperability.

Acknowledgments

The WHO FIC network.

POLE.VAULT: A Semantic Framework for Health Policy Evaluation and Logical Testing

Arash Shaban-Nejad, Anya Okhatovskaia, Eun Kyong Shin, Robert L. Davis, David L. Buckeridge

* UTHSC-Oak Ridge National Lab (ORNL) Center for Biomedical Informatics,
  Department of Pediatrics, University of Tennessee Health Science Center, Memphis, TN, USA

b McGill Clinical & Health Informatics, Department of Epidemiology, Biostatistics and Occupational Health,
  McGill University, Montreal, Quebec, Canada

Abstract

The major goal of our study is to provide an automatic evaluation framework that aligns the results generated through semantic reasoning with the best available evidence regarding effective interventions to support the logical evaluation of public health policies. To this end, we have designed the POLicy EVALUation & Logical Testing (POLE.VAULT) Framework to assist different stakeholders and decision-makers in making informed decisions about different health-related interventions, programs and ultimately policies, based on the contextual knowledge and the best available evidence at both individual and aggregate levels.

Keywords:
Public Health Systems Research, Program Evaluation, Evidence-Based Practice

Introduction

Root cause analysis (RCA) [1] is a technique for detecting and describing the causality path for a problem and recommending remedial actions. Using contextual knowledge captured in ontologies, we analyze public health programs and policies and discuss how context influences outcomes. To evaluate public health programs, we begin by studying their impacts on target populations/communities and the local and global environment (e.g., changed public knowledge, a situation or behavior). The stakeholders (i.e., public health institutions, policy-makers and advocacy groups, practitioners, insurers, clinicians, and researchers) often need to consider several factors and collect information from multiple resources to answer questions regarding the effectiveness of public health interventions. The POLicy EVALUation & Logical Testing (POLE.VAULT) Framework aims to facilitate knowledge-based evaluation of public health interventions and policies.

Methods and Results

POLE.VAULT evaluates public health interventions by assessing their logic models that represent the logical relationships between resources, activities, outputs, outcomes and impacts of a public health program. This is important because, regardless of whether evaluations are process- or outcome-oriented, or qualitative or quantitative, they need to assess whether critical program components or activities were implemented and whether they had an impact on mediating outcomes, important behaviors and overall health goals.

To evaluate different sections and components of logic models, we developed a set of semantic queries that examine whether a program/intervention had the anticipated impact(s) in the population health status (positively, negatively, or unchanged). Then we align the logic model with the semantic knowledge platform and the conceptual model created using best available evidence in the domain.

For example, using PopHR [2], a knowledge-based population health record, we deploy evidence that captures knowledge about the burden of a disease due to specific causes (causal, correlational, and explanatory knowledge) and then combine it with evidence related to guidelines and protocols regarding the effectiveness of interventions and policies, confronting those causes, along with information about the target populations and their environments.

Discussion and Conclusion

The POLE.VAULT platform allows assessing public health programs/interventions and their outcomes through a set of individual and group level indicators. It also intends to assist in the comparative analysis of effectiveness and cost of different public health interventions and policies. Moreover, in the future our platform intends to evaluate programs based on their coverage and effectiveness by highlighting the proportion of the defined objectives and goals that a program is capable of addressing, within a specific resource range (e.g. time period, budget bracket and human resources).

c ... Vienna, Austria
d Section for Artificial Intelligence and Decision Support, Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University of Vienna, Spitalgasse 23, A-1090 Vienna, Austria

Abstract
Evidence-based clinical guidelines positively effect physician decision-making. Actionable clinical guidelines that actively trigger alerts, reminders, and instructive texts will increase effectiveness. We applied Activiti, a Business Process Model and Notation language system to model a clinical guideline for the prevention of mother-to-child transmission of hepatitis B as a computerized clinical workflow. Furthermore, we implemented an interconnected Arden-Syntax-based medical rule engine, which is part of the ARDENSUITE software.

Keywords:
Practice Guidelines; Decision Support Systems, Clinical; Pregnancy Complications.

Introduction
This study addresses the (partial) implementation of the “Hepatitis B in pregnancy” guideline: a clinical workflow providing evidence-based instructions on preventing mother-to-child transmission of hepatitis B during delivery. The guideline is in use at the Department of Obstetrics and Gynecology at Vienna General Hospital, Austria (Figure 1).

Methods

Business Process Model and Notation: the open-source workflow platform Activiti for the development of Business Process Model and Notation (BPMN) workflows [1, 2].

Arden Syntax: data access and knowledge-based clinical guidelines were implemented in HL7’s standard notation Arden Syntax part of the ARDENSUITE solution [3-5].

Results

BPMN translation permitted automation or the provision of reminders to the pediatrician of the following tasks:
- Active and passive immunization after childbirth
- Specific breastfeeding recommendation depending on the results of HBeAg and hepatitis B PCR testing
- Availability of order forms for in-house or external lab testing for HBsAg or HBeAg and/or hepatitis B

Conclusion

We presented a clinical workflow implementation connecting a BPMN-based workflow using the ARDENSUITE. This simplifies complex clinical guidelines by dividing them into workflow, knowledge processing, and data access steps and separates patient data access and knowledge-based decisions from the actual workflow/workflow decisions. This is essential for integrating evidence-based clinical guidelines into the patient care process.

CoMetaR: A Collaborative Metadata Repository for Biomedical Research Networks

Mark R. Stöhr, Gudrun Helm, Raphael W. Majeed, Andreas Günther

UGMLC, German Center for Lung Research (DZL), Justus-Liebig-University, Giessen, Germany

Abstract

The German Center for Lung Research (DZL) is a research network with the aim of researching respiratory diseases. To perform consortium-wide queries through a single interface, it requires a uniform conceptual structure. No single terminology covers all our concepts. To achieve a broadly accepted and complete ontology, we developed a platform for collaborative metadata management “CoMetaR”. Anyone can browse and discuss the ontology while editing can be performed by authenticated users.

Keywords:
Metadata; Terminology; Intersectoral Collaboration

Introduction

The DZL is a consortium of multiple lung research institutions. We collectively pursue the goal to find ways of preventing and curing respiratory diseases. There are many different local data storing systems in use, e.g. CentraXX, Filemaker etc. This circumstance hinders researchers from performing consortium-wide queries quickly and with least effort. Therefore, a central data warehouse (i2b2) is used to which every site uploads their data. Semantic integration of lung research data requires not just one but multiple existing terminologies like LOINC and SNOMED-CT, in addition to custom lung research specific concepts. The OBO Foundry lists four principles for developing a new ontology [1]: (i) be developed in a collaborative effort, (ii) use common relations that are unambiguously defined, (iii) provide procedures for user feedback and for identifying successive versions and (iv) have a clearly bounded subject-matter. Aim of this project is to realize a platform that visualizes the DZL metadata ontology and enables medical documentalists and researchers from all participating institutions to take part in the development process.

Methods

Our requirement analysis resulted in the following statements: The ontology has to be visualized and searchable through an user interface, which is accessible by any person without additional software. Medical documentalists need to maintain the ontology, which should be possible without additional software. The description format has to be extendable. Any DZL member should be able to contribute expertise. Every term of the ontology needs to be discussable and discussion history itself accessible. Trained specialists from anywhere should be able to take part in editing the ontology independently and simultaneously. Changes to the ontology need verification, e.g. every concept needs to be labeled and properly integrated into the hierarchy. Investigation of existing solutions [2,3,4] did not lead to satisfying results.

Results

We developed a platform for independently maintaining an ontology from different sites combined with a web interface for visualization and concept related discussion. The web interface is based on standard technologies in order to guarantee accessibility. All metadata concepts can either be explored through an expandable tree or a search form. For each concept the user is offered details and a discussion board. RDF was chosen as ontology description format because of it’s basic purpose for graph description, it’s extensibility as well as the possibility of editing in simple text editor. Concept hierarchy is realized through the Simple Knowledge Organization System (SKOS) relations “broader” and “narrower”. All RDF files are stored in a GIT repository, to which any person with access can upload data. Transmissions are verified through syntactical and semantical tests. Afterwards, the updated ontology is immediately loaded into the i2b2 server and a triple-store. The latter provides all information for the web interface via AJAX and standard SPARQL queries.

Discussion

During development we focused on using existing standards. CoMetaR may be used for arbitrary SKOS ontologies. It is especially suitable for management of biomedical and other evolving ontologies. Additional functionality may be integrated into the web interface through javascript extensions.

Conclusions

We developed a software for collaborative management of metadata ontologies. Specialists from all participating institutions are able to view and contribute. All source code is open source and available at https://github.com/dzl-dm/cometar.

Using an Ontology-Based Approach to Handle Author Affiliations in a Large Biomedical Citation Database

Haixia Sun\textsuperscript{a}, Junlian Li\textsuperscript{b}, Yingjie Wu\textsuperscript{a}, Lei Wang\textsuperscript{a}, Kin Wah Fung\textsuperscript{b}

\textsuperscript{a}Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China
\textsuperscript{b}National Library of Medicine, Bethesda, MD, USA

Abstract
To handle differences in affiliation names submitted with biomedical journal articles, we build an affiliation knowledge base named Authority File for Affiliations (AFA) based on ontology principles. There are currently 113,700 affiliation concepts with about 583,700 affiliation names. The AFA becomes an essential tool in managing citation information and data analysis.

Keywords:
Databases, Organizational Affiliation, Information Management

Introduction
CBM (Chinese Biomedical Database) contains more than 9 million abstracts of journal articles since 1978, covering over 1,800 Chinese biomedical journals. We build an affiliation ontology (Authority File for Affiliations, AFA) to manage author affiliation information. Previous work on affiliation information management mostly focused on organization names and synonyms, such as the work by Jonnalagadda et al. [1]. Our conceptualization of the AFA enables us to represent attributes of affiliations, their evolution (e.g., splits and merges) and relationships (e.g., subsidiary, associated hospital).

Methods
We developed a web-based application using Java and SQL database to support AFA editing. Original affiliation names were extracted from citations, then cleaned and normalized. Each affiliation concept contained three kinds of names: official name, preferred name and synonyms. The preferred name was the most frequently used name in the citations. Attributes were added to the affiliation concepts, such as organization type, location and specialty. Relationships between affiliations included division_of, school_of, renamed_from, merged_from, and affiliatedHospital_of etc. Affiliations were linked to their citations through their unique identifiers (UI).

Results
There are currently 113,700 affiliation concepts with 583,700 affiliation names, originating from more than 2 million unique original affiliation strings and 7 million abstracts. Each affiliation has one or more organization types.

Discussion
We anticipate that AFA will greatly enhance our ability to handle variations and resolve ambiguity in affiliation names related to different styles of usage, non-standard abbreviations and occasional typos. It facilitates searching and retrieval by providing a rich set of synonyms. The explicit representation of inter-affiliation relationships and attributes also enables us to perform analysis at different levels of granularity (e.g., at the university, school or department level), and according to certain properties of the affiliations (e.g., organizational type).

Conclusion
An ontology-based approach is an efficient way to handle lexical variations in affiliation information and will facilitate data retrieval and analysis.

Self-Reported eHealth Literacy Among Undergraduate Nursing Students in Selected Districts of Sri Lanka

Shaluni Tissera, Nishan Silva

School of Nursing, International Institute of Health Sciences, Welisara, Sri Lanka
Academic Department, International Institute of Health Sciences, Welisara, Sri Lanka

Abstract
Nurses as the largest Health Care Workers group, are extremely important in promoting eHealth. Before promoting eHealth in a structured system, personal use of eHealth like as for Health Information Seeking; is important. Therefore study was done on the use of electronic health information sources among the Sri Lankan Nursing students. It showed that though they do use a wide range of sources, but they are unable to use them specifically and reliably.

Keywords: Telemedicine, Health Literacy, Computers

Introduction
The Ministry of Health in Sri Lanka is leading several initiatives to digitalize the National health system. These include familiarizing both Health care workers and the public with the electronic health and using electronic sources to access health information. However, the current levels of eHealth literacy and the related practices of the Sri Lankan nurses, the largest category of professional health care workers, is not known [1]. So the objectives of this study were to assess the eHealth Literacy and among 3rd year Nursing Students and its relationship with their other IT practices.

Methods
A descriptive cross sectional study was conducted among 136 conveniently selected 3rd year students from few selected Nurses training schools in Sri Lanka (Matara from the southern, Ampara from the eastern and Kandy from the centran provinces) in 2016, using the eHEALS self reported eHealth Literacy Scale [2].

Results
88 (64.7 %) uses only their mobile phones to access internet and 20.6 % uses multiple devices at multiple locations. 27.9 % (32) of the nursing students used internet only to access social media. Only 16.2 % used internet for their daily routine work. Cronbach’s alpha for the scale was 0.845. Mean eHEALS score (min 8; max 40) was 30.8 with a standard deviation of 3.479. The mean scores for individual scale items were most for knowing where to find helpful health resources (3.96 out of 5) and least for being able to discriminate between high and low quality resources (3.63). The mean eHEALS score does not depend on the duration of internet use (p=0.532).

Conclusion
The eHealth literacy among 3rd year Nursing students was fairly satisfactory. But the ability to use electronic resources reliably seems to be questionable.

Acknowledgements
The Authors would like to acknowledge the support of the Administration of all the visited Nursing Schools.

The Analysis of Medical Adverse Events Related to Electronic Health Records in Nursing Services

Mika Tomita, Natsumi Kishi, Mariko Iwasawa

Abstract
This pilot study investigated problems of electronic health records (EHR), which have been used by nurses as a clinical decision tool. The investigation was conducted based on case records retrieved from the national database of medical adverse events. Detailed data related to nursing services must continue to be collected to establish a clearer linkage of EHR data and scholarly information.

Keywords: Nurses, computerized medical records systems, safety management.

Introduction
Electronic health records (EHR) contribute to the collection of a large amount of patient data and thus are useful to provide effective nursing care. Data collected from the EHR can also be used to perform high-quality safety management of patients. Moreover, EHRs are expected to play an important role in connecting the scholarly information map [1] with nurses’ information behavior that we previously proposed. The purpose of this pilot study is to analyze problems of EHR when it is used as a clinical decision tool for nurses.

Methods
The case records in this study were acquired from the “National Database of Medical Adverse Events” [2, 3] provided by the Japan Council for Quality Health Care on its website. Among the case records, this study selectively acquired data on adverse events related to nurses by using the keywords of “EHR” or “information system”. The searched records were analyzed through a natural language processing using the software called Text Mining Studio version 5.1 (Mathematical Systems Inc., Tokyo, Japan).

Results
The number of the full text case records retrieved from the initial search was 138. Five cases that had no direct relation to EHR were removed.

The results of the text mining for abstraction about EHR are displayed in Table 1. The actions of individual nurses that were considered to cause an adverse event were mainly identified as: failure to doublecheck, poor collaboration among health professionals, poor judgement on events in clinical settings, failure to observe patients’ conditions.

Conclusion
We analyzed medical adverse events data related to EHR in nursing services. More data that detail medical adverse events related to nursing services must be collected to create a meaningful linkage between EHR data and scholarly information. When that is realized, EHRs with comprehensive data will be a powerful clinical decision tool for nurses.

Abstract

The objective of this research is to propose to develop an innovative distance function, called SNOMED distance, which captures the nature of the semantic distance within the topological structure of SNOMED, to identify semantic similarity between clinical trials.

Keywords: Systematized Nomenclature of Medicine (SNOMED), Semantics, Clinical Trials

Introduction

One of the most widely used methods to group similar trials is called “clustering.” Significant research efforts have been devoted to produce clusters with low intra-cluster distance (high intra-cluster similarity) and high inter-cluster distance (low inter-cluster similarity). There are quite a few structural similarity measures between concepts used in natural language processing, and the Jaccard similarity coefficient [1] is considered the best one for calculating pair-wise structural similarity as it can assess both similarity and diversity. However, the semantic similarities among clinical trials are not adequately studied. In this research, we propose to develop an innovative distance function, called SNOMED distance, which captures the nature of the semantic distance within the topological structure of SNOMED, to identify semantic similarity between clinical trials. We expect that the application of SNOMED distance would lead to more reasonable trial clusterings.

Methods

The proposed SNOMED distance that captures semantic distance between concepts. Here “semantic distance” refers to the relative closeness between two concepts of interest from a terminology or concept-oriented view. The SNOMED distance we proposed illustrated in Figure 1, where three cases (a) (b) (c) are considered. In particular, case (b) is a special case of (a).

![Figure 1. Illustration of SNOMED Distance in SNOMED terminology topological structure](image)

We use filled gray circle to represent the root of SNOMED terminology called “SNOMED CT Concept”. The shaded circles represent the root of a hierarchy. Un-shaded light blue circles represent SNOMED concepts. In the case of multiple paths connecting two concepts, only the shortest path will be considered. As shown in Figure 1(a), two nodes A and B are within the same hierarchy, and the SNOMED distance is defined as the shortest path between A and B. Therefore, it is one. Figure 1(b) is a special case of (a) when we calculate the SNOMED distance between B and C, because the shortest path must contain the lowest common ancestor of B and C. In this case is the hierarchy root (the shaded node), therefore, the SNOMED distance between B and C is three. Figure 1(c) represents the case that two nodes A and B reside in different hierarchies, and their SNOMED distance is close to infinity.

Given two clinical trials, each of which is represented by a set of SNOMED concepts, such as Clinical Trial 1 (CT1): \( S = \{s_1, s_2, \ldots, s_n\} \) and Clinical Trial 2 (CT2): \( T = \{t_1, t_2, \ldots, t_m\} \). We calculate the distance between these two clinical trials using SNOMED distance (sct_dist) as follows.

\[
\text{Distance (S, T)} = \text{Median}(d | d = \text{sct_dist}(s_i, t_j), s_i \in S, t_j \in T)
\]

Results

Let us take the following two clinical trials as examples. Assuming CT1 is represented by \{Electronic dental anesthesia, Pregnant woman, Rheumatic heart disease\}, and CT2 is represented by \{Long menstrual cycle, Heart disease, Woman\}. The SNOMED distance between each pair of SNOMED concepts appearing in two different clinical trials are shown in Table 1. Due to the space limitation, we are not able to show the SNOMED distance for all pairs of concepts. It is calculated- ed that the SNOMED distance sct_dist(CT1, CT2) is 12, sct_dist(CT2, CT3) is 10012, and sct_dist(CT1, CT3) is 10012.

![Table1 Example SNOMED distance between pairs of SNOMED concepts in CT1 & CT2](image)

Conclusion

One limitation of the research is that the comparison between the proposed methods with existing distance function should be compared. We would like to show that SNOMED distance function can surpass existing distance function for the clustering in terms of accuracy and efficiency.

Terminology Adoption in Family Medicine Service – Start of Journey

Austen Wong, Maggie Lau, Vicky Fung, Dorothy To

Health Informatics Section, Hospital Authority, Hong Kong, China
Tuen Mun Hospital, Hospital Authority, Hong Kong, China

Abstract
A proposal on terminology adoption for the Problem and Encounter Reason capturing in the Hong Kong Hospital Authority Family Medicine Module was suggested. Given the complexity of the project, mapping had been conducted as preparatory work in the early phase of development.

Keywords: Primary care, Standardisation, Mapping

Introduction
With the popularity of advanced information technology and informatics development in recent decades, clinical data documentation should be tailored to suit clinicians’ workflow so as to offer them conveniences for facilitating their work. The Family Medicine Module (FM Module) in Hong Kong Hospital Authority (HA) was developed more than 20 years ago. A plan on reforming the Problems and Encounter Reasons capturing, with terminology adoption in particular, was suggested.

Methods
Implemented in 1995, the FM Module is a clinical system currently being used in more than 80 General Out-patient Clinics, Family Medicine Specialist Clinics and Staff Clinics within the territory under HA’s management. Problem Oriented Medical Record (POMR) was adopted, which patients’ individuality was emphasised by the list of problems specific to the person. Encounter Reasons for each episode of care would also be documented. Free text entries were being captured as Problems while International Classification of Primary Care-2 (ICPC-2) was adopted for Encounter Reason input.

In relation to the advancement in terminology development in HA for the past 10 years, review was conducted on the data capturing approach in FM Module. It was suggested to transform the Problem and Encounter Reason capturing to a complete adoption of Hong Kong Clinical Terminology Table (HKCTT). HKCTT embraces international reference terminologies and has been used for diagnosis and procedure reporting by other clinical modules within HA since 1995. It is sensible to align the terminology used in FM with the main stream in order to achieve interoperability within the organisation.

In the preparatory stage, a mapping of ICPC-2 terms to HKCTT had been conducted.

Results
After studying on the data distribution of Encounter Reason captured in the past, all 686 items in ICPC-2 Component 1 (Symptoms and complaints) and Component 7 (Diseases and diagnoses) were added into the HKCTT. As HKCTT is concept-based, ICPC-2 items that refers to a single clinical meaning were being handled differently with those carrying multiple meanings.

For ICPC-2 code which referred to a single clinical meaning, an attempt of locating a HKCTT concept with equivalent meaning was made. New HKCTT concepts with status indicator being “Active” were added for instances where the meaning being represented by the ICPC-2 item was not readily present, which denoted that the concept had been made available for future data capturing.

For ICPC-2 code that corresponded to more than one meaning, a new HKCTT concept with status indicator being “Inactive” was created. Further data capturing with that newly created concept would not be plausible. Nevertheless, the concept creation was necessary for preserving the processibility of historical data documented with ICPC-2. HKCTT concepts for individual split part of those “combined concepts” were created with concept status “Active” when an equivalent concept was not readily present in the table.

Table 1 shows the number of HKCTT concept mapped from a single ICPC2 item. 510/686 (~74%) of ICPC2 items were mapped to a single HKCTT concept.

Conclusion
Patients care always comes first. Clinical documentation should be designed as seamless as possible. Yet, balance between convenience and data quality should be struck. Structured data should be adopted in view of the reusability that demonstrated. The enriched HKCTT would serve as a good fundamental for more work to come on the future development of the FM Module.
Application of Information Technology in the Outpatient Service Optimization

Zhang Xiaoying

School of Information, Nanjing University of Traditional Chinese Medicine, Nanjing, Jiangsu, China

Abstract

In a hierarchical diagnosis and treatment policy local tertiary hospitals assume the majority of clinic service, improving patient medical experience and enhancing service quality. Information technologies such as comprehensive self-services, and palm medical APPs can help solve these problems.

Keywords:
Quality of Health Care; Service optimization; Delivery of Health Care; Telemedicine.

Introduction

The Outpatient clinic is the first hospital window directly connected to the hospital’s image [1]. The National Health and Family Planning Commission of the People’s Republic of China has explicit requirements for tertiary hospitals: enhance working efficiency of outpatient clinic, optimize outpatient medical service procedures, shorten medical-therapy-seeking time, and increase visit satisfaction. Information technology is an efficient means to strengthen the hospital’s scientific management and enhance the medical quality. Optimizing the outpatient clinic treatment procedure can help solve the “three longs and one short”. Here, we monitor service quality promotion in the outpatient clinic by comparing the original flowchart to a new flowchart.

Methods

Service Optimization of Outpatient Clinic

Implementing the All-Purpose Card at the Outpatient Clinic. The all-purpose card integrates patients’ basic information. It enables patients to pay a security deposit in advance, complete registration, make payments, receive diagnoses/treatments, get medications, and check inspection reports.

Time-Segmented Appointment-Making and Registration. Average treatment time is computed by the information system, which can be used to reduce registration and wait time.

Outpatient Clinic Payment/Appointment Implementation. Doctors can directly accept payments, care for patients, and schedule appointments reducing patient time in queue.

Carrying out Multiple Self-Services

To optimize the service and reduce the occurrences of “three longs and one short” multiple self-services are rendered.

Adopting Multiple Registration Forms. Appointment or registration by cellphone, website, official Wechat, on-site self-feeder, and manpower provide can reduce operational costs.

Self-Help Medicine Getting. Self-help medicine is used to help patients make payments and receive medications, reducing the time to fill prescriptions.

Self-Service: Result of Laboratory Chemical Examination. Self-service reporting machines, set outside of clinical laboratories provide inspection and impact reports reducing reporting errors and patient wait time when receiving results.

Electronization of Outpatient Clinic/Information Sharing

Electronic prescription, medical record, and application forms can improve fee collection transparency and patient assurance.

Supporting Multiple Fee Charging Methods

Make payments with all-purpose card or bank cards or cellphone APP.

Mobile Health

Palm medical therapy has multiple integrated functions: registration/fee collection, online result access, payments, expert introduction, online consulting, satisfaction evaluation, and hospital maps.

Results

In the original flowchart of the outpatient clinic service process patients spent too much time in registration, waiting for treatment, making payments, filling prescriptions and waiting for results. The new system reduced treatment time and improved patient satisfaction and hospital service quality.

Conclusion

The optimization of outpatient clinic service by information technology shortens medical-therapy-receiving time, and enhances work efficiency, and quality of hospital outpatient clinic service solving the “three longs and one short” phenomenon rendering a superior medical-therapy-seeking experience.

An Open Metadata Schema for Clinical Pathway (openCP) in China

Wei Xu, Yanxin Zhu, Xia Wang

Department of Medical Informatics, Second Military Medical University, Shanghai, China

Abstract

China has issued and implemented standard clinical pathways (Chinese standard CPs) since 2009; however, they are still paper-based CPs. The aim of the study is to reorganize Chinese standard CPs based on related Chinese medical standards, by using archetype approach, and develop an Open platform for CP (openCP) in China.

Keywords:
Clinical pathway; archetype; data element.

Introduction

By the end of 2011, 331 standard CPs in 22 specialties have been developed in China and implemented in more than 3000 hospitals since a trial version of the Guiding Principle of CP was issued in October 2009[1]. However, Chinese standard CPs are still paper-based CPs, which hindered efficient development and use and was difficult to adapt to computer-based or even web-based environment[2]. The aim of the study is to reorganize Chinese standard CPs based on related Chinese medical standards, by using archetype approach, and develop an Open platform for CP (openCP) in China.

Methods

We chose 43 diseases covering 7 departments of internal medicine as samples and source materials including Respiratory, Gastroenterology, Neurology, Cardiology, Radiology, Endocrinology, and Hematology, and we followed the 4 steps in reorganizing Chinese standard CPs and developing openCP: reorganize and develop the structure of Chinese standard CPs, add data groups, structure and standardize data elements, and create openCP.

Results

A four-level structured CP information model has been developed, basic data elements have been structured and standardized according to Chinese health related standards, creation rules for data elements have been set, and an Open platform for Clinical Pathway (openCP) has been built.

Structure of CP information model

CP information model in openCP has four hierarchical levels including Document, Section, Data Group, and Data Element. Document contains the top level structure, the CP, which consists of metadata about CP identifier, access, and status and top level sections for CP content. Sections in openCP include Basic Information, Main Care Activities, Main Orders, and Main Nursing from original Chinese standard CPs.

Basic Information Section presents the state or situation of the patient, which includes demographic information, patient ID, diagnoses, processes, implementation time, and etc. Main Care Activities Section contains a series of care plans, observations, actions, and assessments. Most of data groups have corresponding ones in Chinese EHR Standard. Both Main Orders Section and Main Nursing Section can reuse data groups and elements in Section of Main Care Activities.

Structure and standard of CP data elements

Data items in original Chinese standard CPs has not structured or standardized. If the data item is generic and has corresponding data element in Chinese health related standards, we adopted the data element directly. If there were no corresponding data elements, we created new names for the data items according to WS/T 303-2009 (Rules for data element standardization)[3]. As to the specific data items dedicated to CPs of specific diseases, we divided them into 2 categories and standardized them respectively. One can be transformed into common data elements plus specific data value. The other can not be transformed into common data elements, and we standardized them as specific data elements used for CPs of particular diseases.

Discussion and Conclusion

OpenCP has been developed and local CPs can be easily created or revised based on Chinese standard CPs. Adopting philosophy of openEHR archetype, we reorganized Chinese Standard CPs. The reorganization involved two steps: optimizing the structure of CP information model and standardizing the data elements. CP developers can create a CP by extracting data elements from these modules or add new data element according to the creation rules. It is an efficient way to develop a standardized, modularized and computerized CP.

Integration of Japanese Medical Device Adverse Event Terminologies

Ayako Yagahara\textsuperscript{a,b}, Takumi Tanikawa\textsuperscript{a,b}, Katsuhiko Ogasawara\textsuperscript{a}, Hideto Yoko\textsuperscript{c}

\textsuperscript{a} Faculty of Health Sciences, Hokkaido University of Science, Sapporo, Hokkaido, Japan,  
\textsuperscript{b} Faculty of Health Sciences, Hokkaido University, Sapporo, Hokkaido, Japan,  
\textsuperscript{c} Department of Medical Informatics, Kagawa University Hospital, Kida-gun, Kagawa, Japan

Abstract

The purpose of this study is to integrate Japanese medical device adverse event terminologies for evaluating terminological consistency. We represented hierarchy and relations among terms using Resource Description Framework (RDF). There were 3521 classes and 14650 properties. As a result of evaluating the consistency of the description in SPARQL, it was evident that the same notations existed within different terminologies (category terms and terms) and some terms had plural definitions.

Keywords: Terminology; Equipment and Supplies; Medical Errors

Introduction

The Ministry of Health, Labour and Welfare announced the official Japanese medical devices adverse event terminologies (JMDAET) in March 2015 [1]. These are 90 terminologies for each medical device developed by 13 groups in the industry, who are members of The Japan Federation of Medical Devices Associations. The current terminology categories that have been announced are medical device problems, patient problems, and components. The 13 industry groups independently constructed each terminology by bottom-up method, conversely international terminologies were developed by top-down method. JMDAET was constructed to facilitate communication between users at all levels. The purpose of this study is to integrate these 90 terminologies to evaluate their terminological consistency.

Methods

The subject of this research included the categories of medical device problems and patient problems. The 90 terminologies recorded on separate Excel sheets were integrated onto one CSV file. The field names in CSV were as follows: category of terminology, terminology ID (which represented the industry and medical devices), category terms, preferred terms, definition, synonym, FDA code, and FDA source PT. We described the relations to fulfill the variables in the following fields using Resource Description Framework (RDF) (Figure 1). We used Google Refine 2.5 and Protégé 5.1.0 to describe and represent the relations. Finally, we evaluated the consistency of description in SPARQL, an RDF query language.

Results

There were 3521 classes and 14650 properties. The maximum number of hierarchies, when the hierarchy between the category terms and preferred terms was represented, was 4. This meant that the same notation existed in category terms and preferred terms under different terminologies. In addition, we proved that the same notations had a maximum of 7 definitions. There were 109 terms that were both a category term and a preferred term, and 88 that were both a preferred term and a synonym. We considered integrating the defined representations or dividing the terms to ensure consistency. We could easily identify inconsistencies by visually representing the integrated terminology using SPARQL. It may be a useful tool to discuss the revisions in terminology among industry groups and to validate the consistency of the used terms.

Conclusions

In this study, we integrated JMDAET and found some points of inconsistency. Based on the results, we will consider editing JMDAET for consistency. In future work, this method may be used for consistency evaluation of terminology mapping between international terminologies and JMDAET.

Infrastructure for Big Data in the Intensive Care Unit

Javier Zelechowera, José Astudilloa, Francisco Traversaroa, Francisco Redelicob, Daniel Lunac, Fernan Quirosc, Eduardo San Romanb, Marcelo Riskb,c

*a Service of Intensive Care Unit, Hospital Italiano de Buenos Aires, Argentina
b Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina
c Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract

The Big Data paradigm can be applied in intensive care unit, in order to improve the treatment of the patients, with the aim of customized decisions. This poster is about the infrastructure necessary to built a Big Data system for the ICU. Together with the infrastructure, the conformation of a multidisciplinary team is essential to develop Big Data to use in critical care medicine.

Keywords:
Intensive Care Unit, Vital Signs

Introduction

The application of Big Data [1] to the Intensive Care Unit [2], involves of both infrastructure and team work, this poster is about the first subject. The current technology of the monitor devices in the ICU, allows the capture of the vital signs beside the bed of the patient, and this monitors are capable of being connected to the computer network of the hospital. The objective of this poster is to propose a system for the infrastructure to build a Big Data system for the intensive care unit.

Methods

There are a number of fundamental issues that were resolved in order to carry out this kind of project: connectivity of equipment, internal communication system, control center, and server database. The figure 1 shows the diagram of the infrastructure, where the monitors are connected to a router, then the information flows through the network of the hospital, in the other end are connected the database server of the vital signs and the server of the EHR.

Among the components of the infrastructure the connectivity of the monitors is fundamental. In the absence of a standard communication protocol, each manufacturer has its own protocol, which means having to develop a specific interface for each of them. This part is one of the most complex to solve, since the information provided for the manufacturer is scarce. For this reason, in this study a multi-parameter monitor was selected due to its highest quality information gathered.

In order to generate the information volume, the measurement is repeated in a previously selected sample of patients. The internal communication system is solved using the network of the hospital, owing to the capacities that it possesses with respect to the transmission of large amounts of information. Through the use of routers and with a planned subnetting, it is possible to identify each of the components in the network. There is a computer in charge of functioning as the Control Center. In this computer runs a processes to capture the data coming from the monitors. These processes analyze each captured data, perform its relevant decoding, and give them an appropriate format suitable for storage.

Due to the large volume of data that is generated by each patient, it is necessary to work with a dedicated database. For this reason there is a server located in a data center, in which it is stored, under a structure preferably designed, all the acquired information. Thus, allowing that this information can be later collected for subsequently analysis. This database also receives additional information from an electronic medical record, thus providing a large amount of static data. It must be taken into account that the personnel in charge of the monitors is instructed in order that the measurements of the parameters are not interrupted or are wrong, thus achieving the best possible quality of the acquired data. The database server of the vital signs runs a MongoDB software, this database was used because is non relational and therefore suitable for the kind of data generated by the monitors.

Discussion

The infrastructure propose in this paper has proven to be useful to store large amount of data from the monitors in the ICU. Then this data combined with the EHR, and analyzed by a multidisciplinary team, may help to a better assistance of the patients in the ICU.

Information Model Construction of EBM Resources

Yanxin Zhu, Wei Xu, Xia Wang

Department of Medical Informatics, Second Military Medical University, Shanghai, China

Abstract
To build evidence-based medicine (EBM) databases in China, we developed a semantic structure of EBM database information model by top-level, middle-level, and bottom-level structure. Top-level structure was composed of three modules including Literature Characteristics, Treatment Process and Evidence Levels. We further specified each top-level module based on international and national metadata and health related standards. Finally, we developed a complete information semantic model of EBM resources by an ontology tool. It can provide a reference for semantic construction of Chinese EBM database.

Keywords:
Evidence-Based Medicine, Metadata, Semantics

Introduction
It is often difficult for Chinese medical workers to obtain useful resources due to the lack of useful EBM databases. Our study is to establish a semantic structure of EBM information model, to better manage and organize the clinical literature which is a kind of important clinical evidence and to provide better EBM information service for medical personnel.

Methods
We used archetype method to construct complicated medical information into separate modules, whose elements were selected by literature guarantee principle. We built three combinable multi-level archetypes, and formed a complete information semantic model of EBM resources based on ontology.

Results
Top-level structure
EBM information needs of medical staff are multi-dimensional. In addition to the traditional but leading information needs known as literature characteristics, there’s also needs for EBM evidence level and treatment process [1]. Therefore, we constructed the top-level structure into three separate modules: Literature Characteristics, Treatment Process, and Evidence Levels.

Middle-level structure
In the module of Literature Characteristics, we adopted Dublin Core Metadata Element Set [2] to organize and describe the middle-level semantic structure for better information sharing. Within the 15 data elements in Dublin Core, we chose and standardized 6 commonly used data elements such as title, description, source, language, subject, and creator. In the module of Treatment Process, the data elements were mostly obtained from requirements research [1] and well-known EBM databases abroad, such as disease, ICD-10, diagnosis, treatment, drug, symptoms, etiology, prognosis, patient information, etc. For future integration to EMR system in China, we also consulted Date group and data element dictionary of CDA of electronic medical record for reference.

In the module of Evidence Levels, we selected data elements such as trial design, intervention, outcomes, sample size, sequence generation, allocation concealment mechanism, blinding and diagram, based on randomized controlled trial (RCT) standard CONSORT 2010 [3].

Bottom-level structure
In bottom-level structure, we described each data element by Chinese standard WS363.1 (Health data element directory-Part1: General specification) [4], which is the standard for medical information data element attribute description.

Conclusion
We developed a complete information semantic model of EBM resources based on international and national metadata and health related standards. It can provide a reference for semantic construction of Chinese EBM database.

V. Quality and Safety, and Patient Outcomes
A Hospital Nursing Adverse Events Reporting System Project: An Approach Based on the Systems Development Life Cycle

Yingjuan Caoa, Marion Ballb

*Department of Nursing, Qilu Hospital of Shandong University, Jinan, Shandong, China
bJohns Hopkins University, Senior Advisor IBM Research, Baltimore, Maryland, U.S.A

Abstract

Based on the System Development Life Cycle, a hospital based nursing adverse event reporting system was developed and implemented which integrated with the current Hospital Information System (HIS). Besides the positive outcomes in terms of timeliness and efficiency, this approach has brought an enormous change in how the nurses report, analyze and respond to the adverse events.

Keywords: Informatics; Nursing; Patient Safety

Introduction

An adverse events reporting system facilitating to respond to the events in a timely and efficient way is profound in enhancing patient safety and nursing care in all levels of health care institutes [1]. Many hospitals in developing countries like China are encountering a transitional phase in terms of building up a comprehensive and advanced hospital based medical informatics system. It is reported that the nursing adverse events reporting system is under developed which serves as one of the main barriers in promoting a patient safety culture among hospital staff in China [1]. To this end the Systems Development Life Cycle (SDLC) has been developed and implemented to ensure quality systems design and implementation [2]. This study was undertaken to develop and implement a hospital based nursing adverse events reporting system integrated with the current Hospital Information System (HIS).

Methods

This was a prospective study conducted in a tertiary teaching hospital in Jinan, P.R.China.

The SDLC was used to develop a nursing adverse events system in the study setting. The implementation process started in early 2013 and has followed the SDLC recommended plan. First, a team was assembled which made up of a few nursing unit managers and bed-side nursing staff as well as members of the hospital’s quality and patient safety nursing subcommittee. Consequently, the functional requirements of the upcoming adverse events reporting system was assessed according to the hospital’s local and national protocols and guidelines. This approach was followed by selecting a design approach, specifying the system’s requirements.

Results

A nursing adverse events reporting platform was accomplished by working with the Information Technology (IT) company engineers and front-line nursing staff and managers, installing and training, operating the system, and continuously evaluating and improving the system to achieve the defined goals and system requirements.

The average time saved to report an adverse event via the system, compared with the traditional filling in and hand-in way was more than 50%. An additional finding as a consequence of the systems implementation in 2014, has been a dramatic increase in the number of reported adverse events by nursing staff due to more accurate data now available.

There are six main modules including:

- Patient demographic characteristics
- History of disease
- Risk assessment (e.g. falls, pressure ulcers, unplanned extubation, venous thromboembolism)
- Adverse events report
- Root cause analysis and action plan, and
- Statistical analysis data

Conclusions

The reporting system has brought an enormous change in how the nurses report, analyze and respond to the adverse events. Using this approach has made it possible for different levels of nursing managers, administrators, and bed-side nurses to detect those patients who are at high risks of adverse events, and to share and respond to adverse events in a timely and efficient manner.

Data Quality of the Chinese National AIDS Information System: A Critical Review

Hong Chen a, b, Ping Yu a, David Hailey a, Tingru Cui a

*Centre for IT-enabled Transformation, School of Computing and Information Technology, Faculty of Engineering and Information Sciences, University of Wollongong, Wollongong, NSW, Australia, *Jiangxi Provincial Centre for Disease Control and Prevention, Nanchang, Jiangxi, P.R. China

Abstract

Thirty-nine electronic English and Chinese articles on data quality assessment of the Chinese AIDS information system were critically reviewed. Some performance assessment related indicators of data quality have improved since the system was launched in 2008. After a thematic analysis of the factors that may affect data quality, four domains were identified. They are data management, data collector, information system, and data collection environment. The findings are useful to guide data quality improvement effort.

Keywords:

Data quality; AIDS; information system.

Introduction

We conducted a critical literature review to explore data quality assessment in Chinese AIDS Comprehensive Response Information Management System (CRIMS): the status of and the influential factors of data quality.

Methods

English and Chinese electronic literature databases were searched, such as Scopus and CNKI with keywords “AIDS”, “data quality” and “China”. Thirty-nine articles were critically reviewed and thematically synthesized to conceptualize the factors that may affect data quality.

Results

Some performance assessment related indicators of data quality have improved since the CRIMS was launched in 2008. By 2013, the case follow-up rate and the case epidemiological survey rate were greater than 98.0%. The rate of data consistency in laboratory testing of CD4+ T cell counting was maintained above 90.0% except for 2010 [1]. However, non-compulsory items remained incomplete, e.g., identity number, workplace, and contact phone number [1, 3].

The factors associated with CRIMS’s data quality were identified and grouped into 14 categories under four domains: data management, data collector, information systems, and data collection environment (see Figure 1). Data management is of particular concern when the annual national data-driven performance assessment is used to compare data quality at all levels of the CRIMS [1]. A further concern is the data collection environment in which health service clients sometimes could inhibit data quality in data collection process. Inadequate communication with the clients by data collectors is reported. Automatic data entry checking function is welcomed in the field but may increase the uncertainty of data elements [2].

Figure 1 - Factors that may affect data quality in the CRIMS

Conclusions

High-level data quality for performance assessment related indicators was reported in the CRIMS, although the problem of the incompleteness of non-compulsory data remained by 2013. The factor affecting data quality can be grouped into four domains: data management, data collector, information system, and data collection environment. Further research needs to investigate how the four domains affect the quality of the data collection process.

\textsuperscript{c} Department of Nursing, Central Clinic Hospital, Taipei, Taiwan, China
\textsuperscript{d} Department of Nursing, Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan, Taiwan, China

Abstract

The purpose of this study was to evaluate the Clinical Nursing Information System (CNIS) in Taiwan regional hospital. In 2016, a total of 333 nurses responded to the Technology Acceptance Model-based questionnaire after 15 months of CNIS implementation. The results showed positive acceptance toward CNIS, especially among those nurses who were younger, those who worked as administrative managers or in non-critical care units, and had advanced computer skills.

Keywords: Computer Systems, Nurses, Taiwan

Introduction

Clinical Nursing Information Systems (CNIS) improve the communication between health care team to enhance the healthcare quality and work efficiency. In June 2015, an 862-bed regional hospital in Taiwan implemented CNIS, including a total of 19 sub-systems such as pain assessment etc (see Figure 1). The purpose of this study was to investigate nurses’ perception toward the CNIS and as a reference for the similar healthcare institutes in the future.

Methods

A cross-sectional study was conducted in 2016 after 15 months CNIS implementation. To collect data, a questionnaire consisted of 13 demographic variables, 52 Technology Acceptance Model (TAM) based items \cite{1} with five-point Likert scales and 3 open questions was developed and validated (Cronbach $\alpha$ was 0.89). Half of the nurses were randomly sampled to fill out the questionnaire and there was a total of 333 valid respondents, the effective return rate was 99.4%.

Results

The respondents were mostly female (96.6%); 31.8 years old in average; 52.6% with bachelor degree; 67.6% work in non-critical care units, and 46.5% self-report the level proficiency in computer skills was intermediate. The average score of overall CNIS satisfaction was 3.50. Subjects were most satisfied with “CNIS helped me to save writing time” (3.72) and most unsatisfied with “screen switching, storage, delay-prone and crash” (1.97). Nurses who were younger, as administrative managers, work in non-critical care units and had advanced computer skills were most satisfied with CNIS. Those 19 sub-systems were all reached at least 3.40 satisfaction score in average. Nurses’ perceived usefulness, perceived ease of use, and attitude toward using all had a positive influence on the willingness of use and satisfaction (see Figure 2). The frequently narrative descriptions from open questions showed that CNIS reduced the writing time, increased efficiency and convenience, realized the patient dynamics and situations quickly, and increased the interaction between care team.

Conclusions

The results showed that nurses had positive acceptance toward CNIS. However, the stability of the system should be improved first. For those unsatisfied staff (e.g., critical care units), it will be recommended that more advanced information (e.g., qualitative interview) should be collected and analyzed in the future. Improving the problems occurred frequently could also help to satisfy users. Consequently, the implementation of CNIS was really beneficial to nurses’ work efficiency and quality.

Acknowledgements

The research team thank Taoyuan General Hospital, Ministry of Health and Welfare for funding this study.

Personalizing Longitudinal Care Coordination for Patients with Chronic Kidney Disease

Theresa A. Cullen, MD, MS\textsuperscript{a}, Suranga N. Kasthurirathne, BEng\textsuperscript{b}, Jenna M. Norton, MPH\textsuperscript{c}, Andrew S. Narva, MD\textsuperscript{d}

\textsuperscript{a}Regenstrief Institute, Indianapolis, IN, USA; \textsuperscript{b}School of Informatics and Computing, Indiana University, IN, USA; \textsuperscript{c}National Institutes of Health, Bethesda, MD, USA

Abstract

Chronic care coordination efforts often focus on the needs of the healthcare team and not on the individual needs of each patient. However, developing a personalized care plan for patients with Chronic Kidney Disease (CKD) requires individual patient engagement with the health care team. We describe the development of a CKD e-care plan that focuses on patient specific needs and life goals, and can be personalized according to provider needs.

Keywords: Precision medicine; Renal Insufficiency, Chronic

Introduction

Chronic kidney disease (CKD) is a significant medical challenge that affects between 8-16% of the world’s population [1]. CKD patients are often faced with multiple medical problems, the management of which may be impeded by poor interoperability of digital information and insufficient communication amongst providers and with patients. CKD patients are prescribed many medications, require frequent procedures, are at high risk for acute events, and experience frequent transitions across multiple care settings [2]. Due to its complexity and severity, CKD patients may hold different life goals that should significantly influence decision-making points that occur throughout their illness. In each case, it is essential to tailor treatment and care plans to meet patient specific life goals. The National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), one of the National Institutes of Health of the USA, sought to personalize care for CKD patients via an e-care plan tailored to capture patient specific needs that could be transferred across multiple care sites.

Methods

The NIDDK’s Kidney Disease Education Program convened an expert working group comprising of patients, nephrologists, and primary care physicians to facilitate the development of an e-care plan to facilitate a longitudinal transfer of key patient data across providers and health care settings using HL7 Consolidated Clinical Document Architecture (C-CDA) [3]. It also conducted a series of patient phone interviews to inform this process via the identification of significant decision points and CKD care goals of value to patients.

Results

We identified 55 indicators for inclusion in the CKD e-care plan. These indicators range from measurements such as serum creatinine levels to other predictive clinical factors, renal replacement therapy decisions, evaluation for mental health status (including depression), functional status, activities of daily living and achievement of personal health goals. For each indicator, we assigned numeric and categorical priority scores based on the working group’s recommendations. We also identified appropriate clinical terminology spread across LOINC, SNOMED, ICD-10 (diseases) and CPT codes (procedures). We found that many data elements essential to optimal CKD care lack appropriate clinical terms for information sharing across settings. This included specific patient focused terms such as choice for renal replacement therapy, patient education, patient goals and much more. Standard codes were used. Where standard LOINC codes were unavailable, we contacted LOINC to create new codes. A draft data set was published online [4] and welcomes feedback. Out next step is to pilot and test the data set at multiple settings.

Conclusions

A common data set is essential for developing an e-care plan. However, the plan must also have the flexibility to allow multiple views of the data, including a personalized patient perspective as well as functionality for individual providers to create personalized templates or dashboards that present the common set of data elements based on the needs of their clinical disciplines. The e-care plan must also find an appropriate balance between brevity and comprehensiveness. It should also be person, and not solely disease-centric. A disease-based focus could yield numerous, uncoordinated plans for people with multiple chronic conditions. Many data elements essential to optimal CKD care lack standards and codes for sharing information uniformly across settings. Additionally, global issues with interoperability, inadequate clinical terminology, inconsistent health information exchanges, and medication and other clinical reconciliation challenges pose problems for implementing the care plan.

A Guide for Constructing Bayesian Network Graphs of Cancer Treatment Decisions

Mario A. Cypko\textsuperscript{a}, Matthaes Stoehr\textsuperscript{b}, Steffen Oeltze-Jafra\textsuperscript{a}, Andreas Dietz\textsuperscript{b}, Heinz U. Lemke\textsuperscript{c}

\textsuperscript{a} Innovation Center Computer Assisted Surgery (ICCAS), Medical Faculty, University of Leipzig, Leipzig, Germany
\textsuperscript{b} Department of Head Medicine and Oral Health, Head and Neck Surgery, University of Leipzig, Leipzig, Germany
\textsuperscript{c} International Foundation for Computer Assisted Radiology and Surgery (IFCARS), Kuessaberg, Germany

Abstract

In complex cancer cases, Bayesian networks can support clinical experts in finding the best patient-specific therapeutic decisions. However, the development of decision networks requires teamwork of at least one domain expert and one knowledge engineer making the process expensive, time-consuming, and prone to misunderstandings. We present a novel method for guided modeling. This method enables domain experts to model collaboratively without the need of knowledge engineers, increasing both the development speed and model quality.

Keywords: Decision Support Systems, Clinical; Bayes Theorem; Expert Systems

Introduction

Bayesian networks (BN) has a great potential in patient-specific therapeutic decision making [1]. However, networks require knowledge from domain experts but they are usually neither BN experts nor able to use the often complex BN-specific modeling tools. Furthermore, BNs allow for very flexible knowledge representations; modeling attempts by two experts are likely to create different models despite a shared understanding of physiological mechanisms and causalities. Therefore, domain experts require teamwork with at least one knowledge engineer making the process expensive, time-consuming, and prone to misunderstandings. A computer system can supersede the knowledge engineer and enable an user-unspecific modeling.

Methods

A BN represents the decision model by a directed, acyclic graph (DAG) with conditional probabilities [1]. A DAG consists of nodes representing random variables and directed edges between nodes representing their direct causal dependency. An exemplary network for the treatment of laryngeal cancer is represented in Figure 1. The therapy decision network includes all relevant characteristics of the target disease, therapy options, and therapy effects. Based on a network and a set of observations (patient information), an inference algorithm computes the likelihood of occurrence for the network’s remaining unobserved characteristics. The larynx model resulted from three-year teamwork of ENT clinician and knowledge engineer (both authors of this poster) [2]. The domain expert externalized medical knowledge and experiences, while the knowledge engineer translated it into a network structure.

Figure 1 – Bayesian network of the therapy decision for laryngeal cancer, with over 900 variables and over 1200 dependencies [2].

Results

From the long term teamwork as well as weekly expert meetings, we elaborate a guided modeling approach tailored to clinical understanding. The general idea was, to transform complex and flexible BN modeling tasks into a natural language questionnaire from with a predefined modeling process. Our approach comprises 1) the questionnaire form facilitating a structured input of clinical knowledge, i.e. variables and their causalities 2) a nomenclature of clinical terms, supporting model exchange, comparison and search as well as distributed modeling and 3) a graph representation of the knowledge, which shows the modeling status and is automatically built as a background task.

Conclusion

With an appropriate web-based modeling framework, collaborative modeling between domain experts will be possible, would expedite the model development of other diagnosis and therapies, and allow for discussing domain-specific decision.

Modeling a System for Generating Structured Reports

Lorena Dutra da Costa, Marcos Cordeiro d’Ornellas

Department of Applied Computing, Federal University of Santa Maria, Santa Maria, Rio Grande do Sul, Brasil

Abstract

The purpose of this research is to make the medical report generation process more practical, fast and reliable, both for the health professional and for the patient. We created an ontology and modeling of a structured report (SR) Standard DICOM SR.

Keywords:
Reports, Radiology, Informatics

Introduction

The work of health professionals has been changing in recent years. The information previously stored on paper first consisted of digital files, with this, the need arose to normalize and standardize clinical information through reliable and efficient systems. Most healthcare institutions do not use SR, as a consequence, the management and retrieval of this information becomes a complex challenge that demands a lot of service time. This makes it difficult to extract relevant information and especially the comparison between reports, and the variability between structures used can easily lead to confusion and lead to medical errors. SR reduces the possibility of errors that could occur if performed with free text. The data output of these systems will be in a specific structure, since medical assistants use common terminology and pathways to generate reports and interpretation is performed in a guided way using that model used. The time for producing a report using defined templates is reduced, and the productivity of the radiologist increased intensified, thereby improving departmental [1].

Method

Create an ontology for structuring the content contained in radiological reports of computed tomography of the skull, and create models / reports templates that can be used in the system to be modeled. A bibliographical research was conducted on structured reports that sought the state of the art and the systems being developed as SR editors.

Result

The system to be modeled allows the creation of structured medical reports from models. The standard followed is the DICOM SR standard, an international standard used for storage and sharing of medical reports. Patient information is encoded in the form of objects that can contain text, DICOM images, audio files, and other information. Table 1 shows some studies in which systems have been developed for this purpose.

Table 1 – State of the art - Structure Report

<table>
<thead>
<tr>
<th>Name</th>
<th>Objective</th>
<th>Ref.</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Institute of Telematics</td>
<td>View, edition and storage.</td>
<td>[2]</td>
<td>Not fully structured</td>
</tr>
<tr>
<td>Perceptive Express Reporter</td>
<td>Transforms reports into DICOM SR.</td>
<td>[3]</td>
<td>Paid</td>
</tr>
</tbody>
</table>

Conclusion

In the system modeled here each part of the final report created constitutes a subtree of the structure, the system constructs the final structure by automatically mounting the sub-trees according to preconfigured rules. The possibility of errors is diminished and therefore customer service is also improved. With the bibliographic research already done, it was possible to notice that many studies are being done about SR [5]. In most cases, comparisons are made between the use of SR and free text, the results show that the readability and linguistic quality of the reports are improved, leading to greater satisfaction among the professionals involved, but do not extend to until the development of system for creating SR.

Event Notification in Support of Population Health: The Promise and Challenges from a Randomized Controlled Trial

Brian E. Dixona,b, Kenneth S. Boockvardc,e

a Indianapolis VA Medical Center, U.S. Department of Veterans Affairs, Indianapolis, Indiana, USA
b Richard M. Fairbanks School of Public Health, Indiana University, Indianapolis, Indiana, USA,
c Center for Biomedical Informatics, Regenstrief Institute, Indianapolis, Indiana, USA
d James J. Peters VA Medical Center, U.S. Department of Veterans Affairs, Bronx, New York, USA
e Icahn School of Medicine at Mount Sinai, New York, New York, USA

Abstract

Event notifications are real-time, electronic alerts that have the promise of improving population health by exchanging critical information to a patient’s extended care team. In a trial of event notifications in U.S. Veterans Affairs facilities, we seek to understand the impact of notifications on health care utilization within 30 and 90-days. Lessons from the trial have implications beyond the evidence by informing strategies to develop and implement event notifications in other health systems.

Keywords:
Health Information Exchange; Organization and Administration; Veterans

Introduction

Event notification is the real-time, electronic, automatic alerting of providers to their patients’ contact with other health care facilities [1]. Also referred to as an alert or subscription service, event notifications are messages triggered by specific patient activities, such as a visit being registered in a hospital’s admission-discharge-transfer (ADT) system. Triggers often involve an inpatient admission, discharge, or emergency department visit. Event notification systems fall under the broader category of health information exchange (HIE).

Event notification holds promise for improving population health. Event notifications are a source of information about patients, thereby increasing providers’ general awareness of patients’ complex medical histories. Additionally, informing the provider by event notification creates opportunities for immediate intervention where appropriate. For example, care coordinators may be able to contact the emergency department prior to inpatient admission to provide insights that may prevent unnecessary utilization of resources. Likewise, if the patient is still at the emergency department or hospital, the ambulatory primary care (PC) provider could support the coordination of post-discharge transitions and services, potentially improving the quality of care for a patient. Event notification may also help identify patients for referral into care coordination programs. The evidence base for the effectiveness of event notifications is just beginning to grow. Few studies have examined these systems in real-world settings.

Methods

We are conducting a cluster randomized trial in two geographically diverse medical centers within the U.S. Department of Veterans Affairs (VA) to examine the impact of event notifications for non-VA on quality of care following acute events. Older Veterans (≥65 years of age) are randomized to one of two arms based on their PC provider: 1) event notifications to PC; or 2) event notifications plus a 30-day care coordination intervention designed to engage Veterans in managing their health. The trial seeks to understand the impact of even notifications and the intervention on 30-day and 90-day readmissions. We further seek to understand the acceptance of event notifications by patients and providers.

Results

The trial began in mid-2016 with an emphasis to date on patient recruitment and development of the event notification services. Event notifications are delivered to the VA using two different technical architectures. In the Bronx, New York, event notifications are delivered to a provider portal in which staff at the VA log into to view details about non-VA events. In Indianapolis, Indiana, notifications are delivered to VA systems using the Direct standard, and details of the non-VA events are entered as clinical notes in the VA electronic health record.

Conclusion

While event notification services hold much promise, to date there have been challenges to introduce them within the VA. Providers are wary about the utility of notifications as they perceive them as a new ‘alert’ that may interrupt workflow. Patients generally view them favorably, although many Veterans do not perceive the need for them as they do not believe they will consume non-VA care (an assumption not supported by available evidence). Lessons from this trial will be of use to other health systems that seek to leverage event notifications in support of population health.

Automatic Loading of Problems Using a Comorbidities Subset: One Step to Organize and Maintain the Patient’s Problem List

Santiago Márquez Fosser, Alejandro Gaiera, Carlos Otero, Sonia Benitez, Daniel Luna, Fernán Quiroz

Departamento de Informática en Salud, Hospital Italiano de Buenos Aires

Abstract:
An accurate and updated problems’ list is critical in a problem-oriented Electronic Health Record (EHR). The lack of organization and maintenance of the problems limits its value. Certain problems have a larger effect on the clinical evolution of the patient, these are known as Comorbidities. The aim of this paper is to evaluate the impact of the automatic loading of comorbidities in the organization and maintenance of inpatient problems’ list using a comorbidities subset.

Keywords
Comorbidity; Medical Records, Problem-Oriented; Cost of illness.

Introduction
The problem of conceptualizing and organizing patient data in the electronic health record (EHR) around problems is a challenge [1]. An accurate and updated problem list is critical in a problem-oriented EHR. However, keeping a precise problems list can be a challenge; an inaccurate or incomplete problem list has deleterious effects on several patient care functions [2,3]. The comorbidities are problems that affect the clinical evolution of the patient and are associated with worsened health outcomes, more complex clinical management, and increased health care costs [4]. The objective of this study is to analyse the impact of automatically loading problems during the problems reconciliation in admission summaries for the organization and maintenance of the inpatient problem lists using a comorbidities subset.

Methods
Since 1998, the Hospital Italiano de Buenos Aires (HIBA) has run an in-house developed health information system. Its EHR is an integrated, problem-oriented, patient centered system recently certified by HIMSS as level 6+ [5]. All recorded problems use SNOMED CT. We use a previously developed set comorbidities [6] of 672 concepts in hospital admissions during problem reconciliation to allow automatic loading of problems. On 7/14/16, automatic loading of outpatient comorbidities was deployed on all admission summaries for reconciliation by the attending physician. A pre- and post-deployment analysis was performed based on the amount of structured problems. We evaluated a period of 150 days pre- and post-implementation, calculated the mean of recorded problems, and analyzed the status modification (deletes/passed to error) in each hospitalization to evaluate the maintenance of the inpatient’s problem list.

Results
A total of 39239 hospitalization were analysed. Patients had an average age of 47 years (21621 females) and the average length of stay was 2.74 days. There were 19577 pre-deployment hospitalizations (mean of 130 daily admissions), 20183 structured and coded problems (mean of 135 daily), with an average of 1.03 per hospitalization. There were 19662 post-deployment admissions (average of 131/day) and 92828 problems (mean of 619 records/day) with a mean of 4.72 daily. There was a 386% increase (316 pre/1219 post-development) in structure problems with professional status modification (passed to error/resolved), during hospitalization. The most registered pre-development problems were: High blood pressure (1042), Newborn (632), Labor (388), Scheduled Caesarean (302), Hypothyroidism (273), Diabetes Mellitus type 2 (232), Fiber (221). Post-deployment problems included: High blood pressure (6303), Dyslipidemia (3417), Tobacco Abuse (2247), Hypothyroidism (1637), Obesity (1293). The most frequent status modification pre-deployment were: High blood pressure (10), Rituximab (6), Bone marrow transplant (5), Hepatic biopsy (5), Fiber (4), New born to term (4), Stroke (4), Pneumonia (3), New born to term with adequate weight (3). Post-deployment: High blood pressure (83), Dyslipidemia (53), Tobacco abuse (38), Stroke (31), Ischemic stroke (30), Diabetes Mellitus (25), Valvulopathy (20), Cataract (20), Chronic renal failure (19).

Conclusion
The development of a comorbidities subset based on the WHO’s Global Burden of Disease measure using disability-adjusted life years (DALY) lead to more meaningful/actionable problems being added to the problem and more frequent problem list reconciliation (i.e., removing inaccurate/outdated problems). We conclude that more studies are necessary to obtain a complete and adequate problem-oriented EHR.

Using Health Information Technology to Enhance Care Outcome Accountability Through Bundled Payments

Rima Artonian Gibbingsa, Nilmini Wickramasingheb

a University of Illinois in Chicago, Chicago, USA,
b Deakin University and Epworth HealthCare, Melbourne, Victoria, Australia

Abstract

Eventhough the US expenditure on health care is almost twice of the Organization for Economic Co-operation and Development (OECD) average, the care quality indicators in the US unfortunately are not reflective of such extra spending (Baird, 2016). To revise this cost and quality imbalance, new models have been recommended (and partially implemented) that will tie health care reimbursement with efficient outcomes. This study offers a technology enabled solution to calculating appropriate bundles.

Keywords:
Bundled payment

Introduction

The CMS’s Innovation Center (IC) has initiated the Bundled Payments for Care Improvement (BPCI) initiative to measure the degree of success in improving quality of care and reducing cost with selected organizations [2]. In reviewing the several models suggested through the BPCI, the focus is to determine a retrospective bundled payment arrangement that will reconcile the actual rendered care services’ cost with the CMS’s targeted price for a given episode of care. In addition to CMS, twenty major health systems including payers, providers, patients, and purchasers have joined forces in forming an industry consortium called the Health Care Transformation Task Force.

Background

Health care expenditure is claiming 18 percent of the entire US GDP and is projected that by 2023 this share will experience a sharp rise of an additional 28% to consume the fifth of the nation’s GDP [3]. Policymakers are scrambling to reduce “wasteful spending” by targeting administrative and clinical inefficiencies resulting in improved quality and accountability. Replacing fee-for-service with pay-for-performance (P4P) is aimed at rewarding health care facilities who provide higher quality of care with reduced cost. The main goals of P4P (value-based purchasing) is ensuring that health care facilities will be able to determine units that are continuously underperforming based on the new payment classification model.

Method

The research method is based on a design science research methodology to develop a technology solution. The study is based on categorizing medical procedures based on predetermined CMS bundled payments. Further, it examines the role of developed technology solution to assist with promoting accountability in the VBP. The study focuses on enabling health care facilities to determine bundled payment encodings and reflects the codes in the payment process. Facilities will be capable in identifying the procedural charges of clinical processes according to CMS bundle settings. The outcome of facility payment categorization will improve strategic planning and provide standardization incentives. Health care facilities will be able to determine units that are continuously underperforming based on the new payment classification model.

Results

This is a research in progress study. The main idea in this study is to assist health care facilities in creating road maps prior to adopting bundled payments. The bundled payment model has only been adopted in portion of pilot hospitals so far. The accurate implementation of bundled payments will provide valuable knowledge to facilities that will identify critical changes to their service delivery methods based on the outcome. Currently the conceptual model and first parts of the technology solution have been developed.

Can Video Conferencing Facilitate Better Discharge Processes and a Superior Patient Experience?

Jeremy Grummet*, Nilmini Wickramasinghe*a,b, Peter Haddad*a,b, Louise O’Connor*a

*a Epworth HealthCare, Melbourne, Victoria, Australia
*b Faculty of Health, Deakin University, Melbourne, Victoria, Australia

Abstract

Video conferencing is emerging as a useful clinical tool. Its application has extended to cover home monitoring, psychotherapy, managing patients with chronic diseases, and other various applications. However, utilizing video conferencing capabilities to facilitate discharge processes has to date been sparsely researched. This study explores the possibilities of video conferencing to facilitate better patient discharge processes at a large Australian not-for-profit tertiary healthcare group.

Keywords: Hospital Information Systems, Point-of-Care Systems, Telemedicine

Introduction

For patients undergoing surgery in a multi-day admission, a standard care scenario requires that their surgeon will review the patient post-operatively to check on their progress. This is usually done by the specialist attending in person before they may be discharged. However, in the Australian setting, most specialists work at multiple institutions. As a result, reviewing ward rounds, especially of post-operative patients, can be delayed for numerous reasons, which in turn delays management decisions and discharge and may lead to lower patient satisfaction among other problems.

To prevent such delays, an often-used alternative is a “phone round”, where the specialist checks their patient by speaking with the patient’s nurse by phone. However, a phone round does not allow the specialist to perform the clinically important end-of-the-bed inspection, and does not provide the patient with the reassurance that they have been reviewed by their doctor. Telemedicine, whereby doctors consult via Internet video offers a potential solution. This technology could also be used in the inpatient post-operative setting as an adjunct to the current in-person ward rounds.

This study answers the research question: How can video conferencing facilitate a superior discharge process? The underlying issues to be addressed in this study have arisen from practice and the solution designed focuses on enabling a better patient experience.

Aim

The research aims for this study include:

1. Proof of concept of video conferencing capabilities as an adjunct for post-operative inpatient review.
2. If using video conferencing as an adjunct for post-operative inpatient review will provide improved patient, staff and surgeon satisfaction, more efficient/effective discharge including 70% of patients discharged by 10 AM, and will provide cost savings.

Methods

A clinical trial will be used to assess the benefits of the developed bespoke telemedicine discharge tool. Specifically, a two arm non-blinded study is designed where 100 patients will experience current standard care for discharge while the 100 patients in the intervention arm will experience standard care and the developed solution. At the completion of the discharge experience all patients will be asked to complete an on-line survey designed and validated to assess patients’ level of satisfaction with their discharge experience. Standard statistical techniques will be employed to analyze the survey data.

Doctors (urologists) and nurses (on the chosen wards) make up the clinicians involved in this study. They perform their normal duties regarding discharge in both arms of the study. The only difference being that the intervention arm utilizes discharge with the telemedicine/video conferencing solution. The designed solution will be developed in consultation with a subset of clinicians who will form a focus group, subscribing to a Design Science Research Methodology, which will serve to comment on key design features so that the final solution can then be developed. All clinicians participating in the study will be interviewed to ascertain their level of satisfaction with the developed solution over the standard care approach to discharge. Standard thematic analysis techniques will be employed to analyse the collected interview data.

Conclusion

The proposed use of video conferencing capabilities as an adjunct method for surgeons to conduct inpatient post-operative reviews will lead to a higher patient satisfaction, higher doctor satisfaction, higher ward staff satisfaction, greater efficiency of care delivery, discharge time to 70% by 10 AM, and cost savings.

A New Essential Functions Installed DWH in Hospital Information System: Process Mining Techniques and Natural Language Processing

Masayuki Honda, Takehiro Matsumoto

Department of Medical Informatics, Nagasaki University Graduate School of Biomedical Sciences, Japan

Abstract

Several kinds of event log data produced in daily clinical activities have yet to be used for secure and efficient improvement of hospital activities. Data Warehouse systems in Hospital Information Systems used for the analysis of structured data such as disease, lab-tests, and medications, have also shown efficient outcomes. This article is focused on two kinds of essential functions: process mining using log data and non-structured data analysis via Natural Language Processing.

Keywords:
Data Mining, Natural Language Processing

Introduction

Hospital Information Systems (HIS) and Electronic Medical Records (EMR) have been developed for a few decades in Japan. The HIS at Nagasaki University Hospital was updated in January 2015 to include a constant securing of system response. In addition, a secondary usage system of patient information (data warehouse (DWH) system) was built to enable the analysis of structured data including diseases, lab-tests, and medications. [1] Several kinds of event log data produced in daily clinical activities, have not been used for improving hospital activities. Process mining techniques that leverage log data should be introduced into the DWH. One of the problems in the research field of medical informatics is the extraction of knowledge and outcomes from unstructured data. In this article, we focus on the process mining technique "iKnow", which is a Natural Language Processing (NLP) tool developed by InterSystems Corporation.

Methods and Results

Process Mining

By applying process mining techniques to several kinds of event log data derived from HIS we can discover, monitor, and improve clinical processes. Process mining techniques are available in the current HIS [2]. Process mining techniques are necessary in the field of medical information and have been applied to several fields in the HIS [3]. New functions using process mining techniques were constructed and updated in the DWH system in the Nagasaki University Hospital. We used PDCA cycles of the following four steps using the open source framework of "ProM" and the extraction tool "XESame": (1) Extraction of event log data, (2) Applied process mining techniques, (3) Evaluation of daily clinical processes, (4) Visualization of processes. Several kinds of event log data, such as log-in time and place of system users, patients moving information, and access point of Wi-Fi data were used.

NLP

Traditional NLP systems are top-down and leverage a thesaurus, ontology, and statistical model. "iKnow", is a bottom-up system that does not require a thesaurus and can automatically index valuable information from the original data independent of the length or semantic complexity of the data. Preliminarily discharge summary data was analyzed; "iKnow" was used to extract data from discharge summaries and the progress notes. Cosine similarity for both entities was calculated. Differences were found in clinical department data as well as in individual patient data.

Conclusions

Process mining techniques can obtain the real-time status of patients. This study aimed to improve activity efficiency, system security, and to provide efficient patient service. The context information provided by "iKnow" can be useful for capturing similar terms or terms with similar meaning. We plan to evaluate the features of "iKnow" and other NLP tools. Lastly, we believe that the quality of medical informatics research will be improved by the findings from this study.

A Study of Evaluation and Automation Instruction of Management by Law of Community Health Service in China

Hongpu Hu¹, Yue Zhang⁰, Yao He², Fan Yu³, Minjiang Guo⁴

¹ Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China
² School of Management, Beijing University of Chinese Medicine, Beijing, China

Abstract

The goal is to explore a concrete mode for the health administrative department to manage community health service. On the basis of existing health laws and regulations, the study synthesized computer technology, set up the automation system of community health service supervision and management, drew up management norm, management procedure, evaluation system, designed corresponding software, and then completed the spot usage. Four changes of community health service management are realized.

Keywords:
Community Health Services; Automation; Software

Introduction

The Community health service (CHS) is the best health care mode which is selected by developed countries through several decades’ explosions [1]. At present, CHS business in China is at the stage of system frame construction after launching and expanding pilots [2]. With no or little uniformity in the laws governing CHS and how CHS is managed, the goal of this study was to explore a concrete mode for the health administrative department to manage CHS.

Methods

First, research the relevant laws, regulations and theories of CHS, analyze the questions, and combine current management situations to build up the norm of supervision and management. Second, conduct a cross-sectional survey of managers of CHS organizations. Then select and build up an expert's database to conduct the expert consultation and select the indexes to evaluate CHS management. Next, the automation software was designed with 4 components: the administration management system, evaluating system, searching system, and analytical system. The last two systems generate forms automatically on the basis of the first system according to the analytical form designed in advance. The field implementation includes preparing experiment, designing investigation questionnaires, and field application. Field application: Two districts in Beijing are chosen as the trial spots and other two districts as the control ones. This research objects mainly involve 4 district health bureaus, 4 CHS centers and 16 CHS stations.

Results (Planned data analysis)

All investigation questionnaires are inputted and checked by the trained graduate students of Capital Medical University.
Using a Mobile Device Application to Support Emergency Clinicians in Diagnosing Pulmonary Embolism

Chun Yen Huang, Po Liang Cheng, Po Lun Chang

Abstract

Pulmonary embolism is a difficult disease to diagnose in the emergency department. It may be fatal if the diagnosis is missed. Clinical practice guidelines and textbooks publish pretest diagnostic tools and algorithms that facilitate the diagnosis of pulmonary embolism. We developed and administered a questionnaire that determined that such tools can be difficult to remember to use. We also designed an Android application to facilitate diagnosis of pulmonary embolism and used a questionnaire to evaluate the application.

Keywords:
Pulmonary embolism; Decision support systems, clinical; Mobile applications.

Introduction

The symptoms and signs of pulmonary embolism are non-specific, from asymptomatic to shock or death [3]. The mortality rate of pulmonary embolism without proper treatment is up to 25-30% [2]. But if timely anticoagulant treatment is administered, then the mortality rate can be reduced to 2-8%. Therefore, early diagnosis of pulmonary embolism and treatment is very important [1].

Systematic application of existing algorithms or pretest tools published by guidelines or textbooks, such as Wells’ score, Geneva score and PERC rule, can support accurate and timely diagnosis [3; 4]. Because assessment can be complex, time-consuming, or inconsistent, routine usage may be challenging.

We designed an Android application that integrates the symptoms, risk factors, algorithm, pretest tools of pulmonary embolism. Then, we developed a questionnaire intended for emergency physicians to identify barriers in diagnosing pulmonary embolism and evaluate the feasibility of the application designed.

Methods

We designed an Android application using MIT App Inventor 2 beta. The context includes the symptoms, risk factors, algorithm, pretest tools derived from the 2014 ESC Guidelines on the Diagnosis and Management of Acute Pulmonary Embolism, as well as from Tintinalli’s Emergency Medicine - A Comprehensive Guide, 8th edition. We developed and administered a 10-item questionnaire using Google Forms. The questionnaires were completed by emergency physicians in Far Eastern Memorial Hospital (FEMH) in Taiwan after using the application for 2 weeks.

Results

We sent out the questionnaire to 38 emergency physicians and 26 physicians filled it (68% response rate). The main reason for non-responders were that they used iOS and not Android. Most physicians thought pulmonary embolism is difficult to diagnose in the emergency department (77%), most physicians agree that pretest tools are helpful in diagnosis (61%), and difficult to remember (84%). After using the application, most physicians felt the application is easy-to-use (77%), facilitates rapid decisions about ordering computed tomography or pulmonary embolism treatment (64% < 6 minutes). Finally, most physicians agree the application is helpful in diagnosing pulmonary embolism (77%). The application will be implemented in a medical center and nurse practitioners will help physicians to use the application for selected patients. Further evaluation of the usability of the application in a real emergency department is in progress.

Conclusion

Timely and accurate diagnosis of pulmonary embolism is clinically significant. The application we designed appears to be user-friendly and acceptable by emergency physicians. It will be piloted in the FEMH emergency department.

The Impact of PACS on Radiograph Interpretations in an Orthopedic Outpatient Clinic

Petter Hurlena,c, Arne Borthnea,b, Pål Gulbrandsenb,c

*Department of Diagnostic Imaging, Akershus University Hospital, Lørenskog, Norway
bFaculty Division Akershus University Hospital, University of Oslo, Oslo, Norway
cHelse Sør-Øst Health Services Research Centre, Akershus University Hospital, Lørenskog, Norway

Abstract

We found no significant change in the accuracy of clinicians’ reading of skeletal radiographs before and after PACS introduction. The level of inter-rater agreement between clinicians and radiologists was high in both periods, but they disagreed in significantly more cases after PACS.

Keywords:
Radiology Information Systems, Diagnostic Errors, Program Evaluation

Introduction

It is suggested that diagnostic accuracy may be maintained when images are viewed on monitors rather than on film under optimal conditions [1], [2]. A previous study of chest radiograph interpretation before and after the introduction of a Picture Archiving and Communication system (PACS) indicates that this may apply also in a “real life situation” [3]. This study assesses the impact of PACS on the accuracy of clinicians’ radiograph interpretation at an orthopedic emergency outpatient clinic. The study was approved by the Norwegian Social Science Data Service (NSD).

Methods

The basic design of this study was a before-after study using two cross-sectional data collections. Clinicians’ and radiologists’ assessment of the same images were classified independently as either positive (certain or possible skeletal injury) or negative (all others). Cases where the clinician and radiologist disagreed were independently reviewed by two radiology specialists. Cases with agreement and the results of the review constituted the gold standard.

Differences were analyzed using the independent samples T-test, inter-rater agreement using Cohen’s kappa. Significance levels (predetermined at α < 0.05) are reported.

Results

Table 1 presents the clinicians’ interpretation of the radiographs before and after PACS. There was no significant difference between pre-PACS (0.95) and post-PACS accuracy (0.93, p=0.36).

Comparing Inpatient Falls Guidelines to Develop an ICNP®-Based Nursing Catalogue for ENRs

Miran Junga, Insook Chob, Jisun Chaea, Jihye Kima, Yeunhee Kim

a Asan Medical Center, Seoul, Republic of Korea
b Nursing Department, Inha University, Incheon, Republic of Korea

Abstract

This study compared and synthesized clinical guidelines for inpatient falls with the aim of developing an ICNP®-based nursing catalogue for use in electronic nursing records. The identified content will influence nursing services provided to patients and the associated documentation.

Keywords:
Nursing Records; Accidental Falls; Patient Safety

Introduction

The rapid adoption of electronic health records means that electronic nursing records (ENRs) could provide data for reporting nursing quality metrics. Content design issues for ENRs are important for determining how nursing services are represented, recorded, and aggregated. Korea adopted the ICNP® (International Classification for Nursing Practice) early in 2000 as a national standard. Our research team planned to develop an ICNP® catalogue for the patient safety domain, specifically for inpatient falls. The Patient Safety Act established nursing care laws that limits the bedside visits of family members and private caregivers. This situation has led to inpatient falls becoming a high-priority need area. To develop an appropriate catalogue, we reviewed and compared the current evidence in order to identify key nursing components. The presented findings can be used to develop an inpatient fall ICNP® catalogue for use in ENRs.

Methods

Inpatient falls are governed by complex factors, but there is a considerable body of literature on fall prevention and reduction. We assembled the seven resources and toolkits suggested by the Joint Commission with the knowledge gained through research and quality improvement initiatives from six leading organizations. The practice guideline developed by the Korean Hospital Nurses Association and a local guideline of Asan Medical Center were also included. The international classification of patient safety framework [1] was used as a theoretical basis and consensus-based content analysis was employed.

Results

We identified 11 key care components and 98 relevant concepts in 3 categories (Table 1). Several gaps between the two Korean guidelines and other guidelines were identified.

<table>
<thead>
<tr>
<th>Category</th>
<th>Key care components</th>
<th>Number of concepts &amp; examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patient characteristics</td>
<td>Physical</td>
<td>22 (e.g., age, diagnosis, gait, dizziness, INR)</td>
</tr>
<tr>
<td></td>
<td>Behavioral</td>
<td>8 (e.g., agitation, irritability, delirium, dementia)</td>
</tr>
<tr>
<td></td>
<td>Social</td>
<td>4 (e.g., fall history, drinking, smoking)</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td>Therapeutic risk</td>
<td>7 (e.g., medications, Foley catheter, operation, IV line)</td>
</tr>
<tr>
<td>Actions taken to reduce risk (interventions)</td>
<td>Universal</td>
<td>13 (e.g., toileting, education)</td>
</tr>
<tr>
<td></td>
<td>Impaired mobility</td>
<td>9 (e.g., walking aids, safety aids, helmet, hip protector)</td>
</tr>
<tr>
<td></td>
<td>Behavioral</td>
<td>5 (e.g., triggers of agitation)</td>
</tr>
<tr>
<td></td>
<td>Observation &amp; surveillance</td>
<td>7 (e.g., regular rounding, alarm, pain management)</td>
</tr>
<tr>
<td></td>
<td>Communication</td>
<td>9 (e.g., visual indicator)</td>
</tr>
<tr>
<td></td>
<td>Environmental</td>
<td>7 (e.g., nonslip mat, floor)</td>
</tr>
</tbody>
</table>

Discussion

The available resources and toolkits were found to have a high degree of commonality with each other. However the Korean guidelines had no addresses on communication requirements between clinical disciplines.

Conclusion

The application of both top-down and bottom-up approaches has identified comprehensive evidence-based care components and core concepts for use in nursing statements for ENRs.

* Iwamizawa City, Iwamizawa, Hokkaido, Japan
* Hamanasu Information CO., LTD, Iwamizawa, Hokkaido, Japan

Abstract

The aim of this research is to quantify individual willingness-to-pay (WTP) to test effectiveness of Digital terrestrial broadcasting elderly tele-care system. We used contingent valuation method (CVM) to estimate the WTP for this system among 400 citizens living in Japan. The median WTP for this service’s monthly fee is estimated to be 431 JPY. The finding suggests that people who cares their health were pay more to use this system.

Keywords:
tere-care system, digital terrestrial broadcasting, WTP ;(willingness to pay)

Introduction

In Japan, over the past few years, attention has been increasingly focused on solitary death in relation to the aging society and the

trend towards the nuclear family. Hokkaido University, TV-Asahi, and Iwamizawa-City have implemented a prevention measure with Digital terrestrial broadcasting elderly tele-care system. Although this system is provided for free of charge as a demonstration test, determining the appropriate price is required for Sustainable operation of the service. The aim of this research is to quantify individual willingness-to-pay (WTP) to test effectiveness of Digital terrestrial broadcasting elderly tele-care system.

Methods

We used contingent valuation method (CVM) to estimate the WTP for this system among 400 citizens living in Japan. A questionnaire survey was conducted for people from age 18 to 100 according to Japanese age distribution. To elicit WTP we adopt a “double-bound dichotomous choice method” for asking the respondents whether they are agree or against the price we offered.

Results

The median WTP for this service’s monthly fee is estimated to be 431 JPY. The finding suggests that gender (0.66, p=0.014), health consciousness (1.08, p=0.013), willingness to use (2.38, p<0.000), and seeing others less than once a week (1.00, p=0.057) made a positive effect on WTP.

Development of a Quick SOFA-Based Sepsis Clinical Decision Support System in a Tertiary Hospital Emergency Department

Youn-Jung Kim\textsuperscript{a,}\textsuperscript{b}, Jae-Ho Lee\textsuperscript{a,}\textsuperscript{b}, Sang-Wook Lee\textsuperscript{c}, Ming-Young Jung\textsuperscript{b}, Won Young Kim\textsuperscript{a}

\textsuperscript{a}Department of Emergency Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea, \textsuperscript{b}Department of Biomedical Informatics, Asan Medical Center, Seoul, Republic of Korea, \textsuperscript{c}Medical Information Office, Asan Medical Center, Seoul, Republic of Korea

Abstract

New definition of sepsis introduced quick sequential organ failure assessment (qSOFA) score. A qSOFA-based sepsis decision support system was designed and developed in an emergency department. The system has functions of automatically retrieving qSOFA score, 3 and 6 hours of sepsis and septic shock treatment bundle, semi-automatic calculation of SOFA score, etc. Early usage and user requests are needed to find aspects of improvement.

Keywords:
Sepsis, Emergency Medicine, Decision Support System

Introduction

The quick sequential organ failure assessment (qSOFA) was introduced as a simple tool to suspect sepsis in emergency departments (ED) by new definition of sepsis and septic shock [1]. The qSOFA is simple and easily retrieved from electronic medical records (EMRs) of ED. To help ED physicians detecting sepsis early and guiding sepsis diagnosis and treatment, a sepsis clinical decision support system (CDSS) was designed and developed in a tertiary hospital ED.

Methods

The research team was composed of ED physicians, a medical informatician, a programmer, and a registered nurse. New sepsis guidelines were reviewed and items which could be included in the sepsis CDSS were selected. Data were retrieved from EMRs and semi-automatic calculation of SOFA scores (different from qSOFA) was performed. This study was performed from March to June, 2016.

Results

A qSOFA-based sepsis template and CDSS were implemented to the EMR of ED Jun 2016. qSOFA score of ≥ 2 was retrieved from nursing information note at ED admission by automatically calculating variables of mental change, heart rate, and systolic blood pressure. Patients with qSOFA score of ≥ 2 score at ED admission were marked as “S” at the end of their names in the list of EMR. Confirming ‘suspected infection’ process was added to the sepsis CDSS template (Figure 1). The template contained a patient list of qSOFA score of ≥ 2, initial vital signs, entry field of suspected infection foci, 3 hours and 6 hours of the sepsis and septic shock bundle, semi-automatic calculation of SOFA score, and dispositions. Data and contents were reviewed and corrected.

Discussion

Active alert system of new suspected sepsis case could be an alternative to adding “S” to end of patient name. ED physicians had to check “Infection or not” because there was no way to identify such information automatically at the time of their visits. SOFA score calculation support was done semi-automatically due to its complexity coming from qSOFA. Initial qSOFA variables were used to calculate qSOFA score because continuous monitoring of vital signs could use large resources of the EMR system.

Conclusion

The qSOFA-based sepsis CDSS was developed to help ED physicians. Researches of early usage and user requests are needed as a next step.

Abstract

Hospital Information systems (HIS) provide efficiency in clinical practice, and give users the chances of systemic feedback, recommendations based on evidences. However, HIS without consideration of usability or patient safety could make adverse events. In this study, we suggest safety/usability guideline of HIS, extracted via systemic review of related articles. We categorized the guidelines and recommendations by clinical workflow.

Keywords:
Hospital Information Systems, Patient Safety, Workflow

Introduction

The implementation of hospital information systems (HIS) is known to improve patient safety and quality of care. However, the lack of consideration in ergonomic aspects could result in new problems that could compromise patient safety. The Joint Commission in the United States presented 120 HIT-related errors and their types in the 'Sentinel Event Alert' report in March 2015, titled 'Safe Use of HIT'. In this report, the usability of HIT was pointed out to have correlation with patient safety. Though the HIS in Korea were highly adopted and even exported to other countries, there is no inherent guideline or recommendation for the safety or usability of HIS. Therefore, the guideline for safety and usability is required for the design, maintenance and improvement of HIS.

Methods

The search was conducted based on English literature published since 2000 through the literature search database (PubMed, Cochrane, Embase, Web of Science, CHINAL). The search terms were classified into three categories: Guideline, Healthcare information technology, and Safety / usability. Two researchers independently reviewed the article title and abstract. In case no agreement was reached, consensus, the decision was made through consultation with the third researcher or the advisory group.

Results

A total of 7,411 articles were identified through the literature search, and 6,222 documents without duplication were reviewed. 51 documents were selected for full-text review. Based on the final selection of 14 eligible documents, 402 usability / safety guideline bases were extracted and listed. Extracted guidelines were reclassified according to the workflow of clinical practice. That included the 'Display & Identification' for the user's information perception and selection, the 'Action' of the user's work behavior, the 'Feedback' of the alarms provided by the system after the user's work behavior, 'Communication' corresponding to the exchange of information between the medical personnel or system, and the 'Management' for update of the information required for system operation, user monitoring and maintenance.

Conclusions

By reclassifying the existing guidelines according to the workflow of the user's clinical practice, rather than the existing conceptual and system-based classification, it is expected to be more effectively used to improve the usability and safety of HIS in actual clinical work.

The Role of Technology in Medication Safety Incidents: Interpretative Analysis of Patient Safety Incidents Data

Valentina Lichtnera, David Gerrettb, Ann Slec, Noreen Gulb, Tony Cornfordd

Abstract

This is a study of medication safety incidents reported to the NHS in England (UK) associated with the use of digital technology. An interpretative analysis of 888 incidents reports offers insight into uses and features of this technology associated with medication errors and potential patient harm.

Keywords:
Patient safety; Drug therapy, Computer-assisted.

Introduction

Electronic medicines management systems (e.g. Computerised Provider Entry Systems - CPOE) are increasingly used worldwide, giving rise to availability of related patient safety data. A number of studies have provided classifications of the types of errors with this technology and contributing factors. Schiff et al [3], for example, queried incidents reported to the United States Pharmacopoeia; more than 63 thousands were classed as related to CPOE. Test case scenarios were generated and used to assess vulnerabilities in current systems. CPOEs were found to lack adequate barriers to protect against wrong orders, or their design made data entry-error prone. In Australia, a study of medication incidents in primary care [1] found IT impacted on patient care, including harm or near misses, disrupted clinical workflow, created inefficiencies and user frustration. Although for some incidents risks had always been present, others were more likely to occur with IT, and some were ‘unique to IT’ [1]. We undertook a sociotechnical analysis of patient safety incidents reported to the National Reporting and Learning System (NRLS) in England and Wales [2] to better understand the role and impact of digital systems on medication safety in the English National Health Service (NHS). The NRLS contains voluntary anonymised reports from all areas of healthcare.

Methods

The aim was to carry out a qualitative analysis of NRLS data to investigate: the role of the technology in medication incidents; issues with the design or implementation of the technology that are incident-prone; if there are specific types of medications involved. The analysis was informed by a set of principles and theoretical assumptions, as follows:

1. Safety is an emerging property of systems; errors are ‘normal’ in complex systems.
2. Technology influences the risk of errors occurring. Technology can be made ‘safer by design’. Through forcing functions or effective display of information, some human errors can be prevented.
3. Human factors principles and heuristics can aid in the design, evaluation, and configuration of systems.

Data were extracted from the NRLS, to retrieve reports of incidents related to the use of a range of digital systems for the supply and use of medicines over five years. It included all incidents reported in the period from 1/1/2012 to 31/12/2015 (based on date of incident), irrespective of associated degree of harm, incident type and care setting of occurrence. A total of 24,889 records were retrieved. A sample of 888 (approximately 4%) were analysed and coded. Thematic extraction (by VL) was based on initial opportunistic identification and follow up scoping to produce a spectrum of issues until saturation was reached. Content validity was achieved by inspection and ratification by remaining authors. The sample lead to identification of 50 themes, and 6 overarching categories: Design, Data, Software, Hardware & Network, Use and Mix-ups. IT related medication safety incidents were across hospital, primary care and community settings, involving a number of IT systems, beyond CPOE. In one case, related to Hardware & Network infrastructure, patient harm was reported as severe.

Using Modified-ISS Model to Evaluate Medication Administration Safety During Bar Code Medication Administration Implementation in Taiwan Regional Teaching Hospital

Pei-Luen Maab, Yan-Wun Jhengac, Bi-Wei Jhengd, I-Ching Houa

a School of Nursing, National Yang Ming University, Taipei, Taiwan, China
b Department of Anesthesia, Sijih Cathay General Hospital, New Taipei City, Taiwan, China
c Department of Nursing, Taipei Veterans General Hospital, Taipei, Taiwan, China
d Department of Nursing, Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan, Taiwan, China

Abstract

Bar code medication administration (BCMA) could reduce medical errors and promote patient safety. This research uses modified information systems success model (M-ISS model) to evaluate nurses’ acceptance to BCMA. The result showed moderate correlation between medication administration safety (MAS) to system quality, information quality, service quality, user satisfaction, and limited satisfaction.

Keywords:
Information systems success model, BCMA, Medication administration safety

Introduction

Medication administration safety (MAS) is the first priority for clinical nurses and one of the BCMA implantation’s purposes is to help the clinical nurses reducing the medication error. Therefore, we used the M-ISS model[1] with MAS facet added (e.g. modified-ISS model) to discuss the relationship between MAS to system quality, information quality, and service quality in one Taiwan regional teaching hospital with 862 beds after the BCMA implementation in 2015 (Figure 1).

Results

We received 350 questionnaires with 96.6% effective response rate. The descriptive statistic result showed 96.8% participants were females, the mean age was 31.7 with a bachelor degree, and the consciousness of computer ability was between good and average. The MAS was moderate correlation to system quality, information quality service quality, and user satisfaction (Figure 2). After analyzing the open questions, the advantages of BCMA include reducing the medical administration time, quick inquire the medication information and identify easily. The disadvantages include slow connection, poor sensitivity of the bar code sensor, and system crashes.

Conclusions

This study shows MAS was affected by system quality, information quality, service quality, and user satisfaction, which has good explanatory power. According to the open questions, MAS will be promoted by renewing the medication data in real time, and elevating the system’s efficacy

Decision Support System for Medical Care Quality Assessment Based on Health Records Analysis in Russia

Taranik Maksim*, Georgy Kopanitsa*a,b

*Tomsk Polytechnic University, Tomsk, Russia,
*b Tomsk State University for Architecture and Building, Tomsk, Russia

Abstract

The paper presents developed decision system, oriented for healthcare providers. The system allows healthcare providers to detect and decrease nonconformities in health records and forecast the sum of insurance payments taking into account nonconformities. The components are ISO13606, fuzzy logic and case-based reasoning concept. The result of system implementation allowed to 10% increase insurance payments for healthcare provider.

Keywords:
Standards, Case Based Reasoning, Quality Assurance

Introduction

Medical care process in Russia was unified [1] and medical standards were implemented. Standard describes the necessary medical services and drug prescriptions for groups of diagnoses. Medical services contain coefficients, which determine the probability of application. This fact identifies medical standard as reference document with uncertainty and makes fuzzy logic [2] as a relevant tool to work with them. Medical organizations (MO) have to provide their activity with standards. Insurance companies (IC) makes evaluation for MO’s medical care by inspecting health records. On the result of evaluation, IC makes an invoice document that contains data of insurance payment for a medical service. However, this evaluation can be based not only on standards, but also on medical expert’s personal experience. Expert produces a document, which presents all nonconformities. This document evaluates the quality of medical care specifies the sum of insurance payments for the analyzed treatment case. Medical care quality assessment based on health records evaluation by expert. Expert can evaluate using medical standards (explicit knowledge) and personal experience (implicit knowledge). In the Russian practice, the use of implicit knowledge is more common. We propose a concept of a decision support system for medical aid quality management, which allows healthcare providers to detect and reduce medical nonconformities in health records taking into account uncertainty and forecast the sum of insurance payments.

Methods

The object of the research is planned surgical treatment in the Institute of Microsurgery (Tomsk, Russia). We acquired a set of health records of 2015 inspected by medical experts and the results and conclusions of their evaluation. Combinations of treatment cases of 2015 and results of expert evaluation determined a training set. Linking the medical conclusions to the results of the expert evaluation allowed us to formulate the logical inference rules. We used the Euclidean metric to limit the set of cases and Mamdani algorithm to determine the probability coefficients. Using developed models, we determined how many medical documents are required at each step of the medical care process. Mamdani algorithm was used to evaluate the quality of treatment case and to forecast insurance payments based on the detected nonconformities.

Results

The system implementation in Institute of Microsurgery’s treatment process in the beginning of 2016 would allow to significantly decrease the total sum of deduction from insurance payments (table 1) by detecting nonconformities in health records and insurance payments forecasting.

The key results of intellectual system implementation:
• The possibility of the insurance payments forecasting;
• The insurance payments for medical care were increased by correction of health records;

Conclusion

The methods presented this research has demonstrated an effectiveness on insurance payments forecasting. Presented concept can be also applied to others solution in public health, hybrid inference method based on fuzzy logic and CBR can be used for different relevant problems, which require decision-making process.

Method to Identify Diagnostic Rules for Pancreatic Cancer Using Laboratory Data Based on Bayesian Estimation

Shirou Manabe, Yoshie Shimai, Taizo Murata, Ayumi Fujii, Kanayo Ueda, Akito Nakagawa, Toshihiro Takeda, Naoki Mihara, Yasushi Matsamura

*Department of Medical Informatics, Osaka University Graduate School of Medicine, Osaka, Japan

**Department of Medical Informatics, Osaka University Hospital, Osaka, Japan

Abstract

Early diagnosis and treatment of pancreatic cancer is challenging. We attempted to find diagnostic rules for pancreatic cancer from laboratory data in the Osaka University Hospital’s data warehouse using Bayesian estimation. We calculated the pretest odds based on the number of laboratory tests and the cutoff value at which the diagnostic accuracy is over 20%. By this method, we identified diagnostic rules of 6 types for one item and 79 types for 2 items. Pancreatic cancer is difficult to detect from only general laboratory tests. However, this method may be promising in early diagnosis.

Keywords:
Bayes Theorem; Pancreatic Neoplasms; Chemistry, Clinical

Introduction

To treat pancreatic cancer, it is most effective to find it early and start treatment. However early detection of pancreatic cancer is difficult. Earlier diagnosis may be achieved if guidelines will be developed from accumulated test data and electronic health record systems to alert doctors when cancer is suspected. Research for pancreatic cancer using pathological data has been reported. We tried to identify such diagnostic guidelines by Bayesian estimation using both laboratory test and cancer registration data.

Methods

During a set time period, the pretest odds for each cancer laboratory test can be calculated from the numbers of the tests of cancer and non-cancer patients. When two kinds of tests are measured at the same time, the pretest odds can be similarly calculated from the number of the test where these two items are measured at the same time.

Bayes’ theorem is expressed as follows. (LR+; a likelihood ratio for a positive test result)

\[
\text{Posttest odds} = \text{pretest odds} \times LR^+ \]

By dividing posttest odds by pretest odds, the target positive likelihood ratio for obtaining posttest odds is obtained. When the sensitivity is 0.1 or higher, the positive likelihood ratio at which the posttest odds are 0.25 or higher was adopted as the target positive likelihood ratio. The cut-off value that exceeds the target positive likelihood ratio was defined as a diagnostic rule of pancreatic cancer in one laboratory test item.

When two independent laboratory test items are performed consecutively, the posttest odds can be obtained by the following formula using the Naive Bayes model. (LR1+, LR2+ are positive likelihood ratios of test 1 and test 2)

\[
\text{Posttest odds} = \text{pretest odds} \times LR1^+ \times LR2^+ \]

However, in most cases, the two laboratory test items were not independent. Therefore, the posttest odds in such cases were corrected using the correlation coefficient r.

\[
\text{Posttest odds} = \text{pretest odds} \times LR1^+ \times LR2^+ \times (1 - (1 - 2 / (LR1^+ + LR2^+)) \times r) \]

When examining all the combinations between two items, the amount of calculation becomes enormous. Therefore, it was decided to make a combination using five kinds of values, which are the minimum value, the 25% value, the median value, the 75% value, and the cutoff value having the sensitivity of 0.1 for each test item. Of the combinations exceeding the target positive likelihood ratio, the combination with the lowest value was taken as the diagnostic rule for that pair of laboratory test items.

Results of 38 laboratory tests such as biochemistry, blood count, and tumor marker were obtained from 17,202 patients (include 288 pancreatic cancer patients) in January 2013. Their data was used to obtain one or two items’ pretest odds and correlation coefficient for each test for pancreatic cancer. 176 pancreatic cancer patients registered from January 2007 through December 2011 were selected as the patient group. And 21,106 patients registrations from the same period for other diseases were defined as a control group. For the 38 laboratory test items, a cut-off value, at which posttest odds is 0.25 or greater and sensitivity is 0.1 or higher for each test, was calculated from the maximum value within a month prior to diagnosis.

This study was approved by the Institutional Review Board at Osaka University Hospital.

Conclusions

In clinical decision support systems, timeliness of diagnosis and diagnostic accuracy are important. Using Bayesian estimation appears to be a useful method in facilitating pancreatic cancer diagnosis.

The Evaluation of the Health Information Exchange with the Number of Usage and the Introduction of Outpatient to the Hospitals at Nagasaki Japan

Takehiro Matsumoto, Masayuki Honda

Department of Medical Informatics, Nagasaki University Graduate School of Biomedical Sciences, Japan

Abstract

Health Information Exchange (HIE) has been gradually spreading in Japan. But the effect and evaluation of these systems have not been proven. The aim of this study is to examine the effect of the Japanese HIE through the evaluation of the clinical activities in Nagasaki University Hospital. The electric medical records of 5335 patients were shared in the Ajisai-net, which was Japanese HIE in Nagasaki, from 2009 to 2015. And the number of shared patients increased every year, and the annual average number was 762.1. On the other hand, the number of the patients who was introduced from clinics to our hospital and whose medical records were shared in the Ajisai-net increased every year. In conclusion, the usage of Japanese HIE is useful for the clinical consultation and medical care, and these systems have the good effect on the hospital management in Japan.

Keywords:
Health Information Exchange; Electronic Health Records

Introduction

Health Information Exchange (HIE) has been gradually spreading in Japan. The Japanese Medical Association reported the number of these networks were at least 245 all over Japan, and were increasing in 2015. Though most network has started recently, the effect or evaluation of these networks were not proved yet. Ajisai-net, one of the most popular HIE, has been used since 2004. The electric medical records of 31 big hospitals of Nagasaki Prefecture are shared among hospitals, clinics, pharmacies and other medical institutions, the number of the medical institutions were over 300. The aim of this study is to examine the effect of the HIE of Japan through the evaluation of the clinical activities in Nagasaki University Hospital which joined Ajisai-net in 2009.

Methods

The electric medical records of 5335 patients were shared with their consent in this Ajisai-net from 2009 to 2015. We evaluated the number of electric medical records of Nagasaki University Hospital in Nagasaki city which were shared in this Ajisai-net from 2009 to 2015. And we compared the rate of introduction to our outpatient clinic after usage of Ajisai-net each year. And we also evaluated the rate of the usage of this system from inside and outside of Nagasaki city in Nagasaki Prefecture.

Results

The number of shared patients increased every year, and the annual average number was 762.1. And the number of last year, 2015, was 1,018. The annual average number of the usage of this system was 10.7. The average rate of the patients who was introduced from clinics to our hospital was 42.2%, and this rate also increased every year (Table 1). The rate of 2015 was 53.2% which was the largest among study year. On the other hand, the average rate of the usage from outside of Nagasaki city was 11.7%, and this rate had been gradually increasing tendency every year. Of the participating clinics which is inside of Nagasaki city, the average rate of facilities actually used was 72.3% a year.

Discussion

The number of usage had been increasing every year. And the rate of introduction of the same patient to our hospital had been increasing every year too. And the usage of the clinics outside of Nagasaki city had been increasing. These results show that Ajisai-net is useful for most users, and has incentive effect on the patient introduction. We estimate that massive and high quality medical information and data from large hospitals will be useful for clinical consultation and medical care every day. Furthermore the rate of usage from outside of Nagasaki city had been increasing. This result and the increase of introduction patients show Japanese HIE has the effect on the stabilization of hospital managements.

Conclusion

These results show the usage of Japanese HIE like Ajisai-net in Nagasaki is useful for the clinical consultation and medical care, and also show these systems has the good effect on the hospital management in Japan.

Computerized Cognitive Rehabilitation: Comparing Different Human-Computer Interactions

Silvana Quaglini\textsuperscript{a}, Anna Alloni\textsuperscript{b}, Barbara Cattani\textsuperscript{b}, Silvia Panzarasa\textsuperscript{a}, Caterina Pistarini\textsuperscript{b}

\textsuperscript{a} Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Italy
\textsuperscript{b} IRCCS Foundation Hospital Salvatore Maugeri, Pavia, Italy

Abstract

In this work we describe an experiment involving aphasic patients, where the same speech rehabilitation exercise was administered in three different modalities, two of which are computer-based. In particular, one modality exploits the “Makey Makey”, an electronic board which allows interacting with the computer using physical objects.

Keywords:
Computer-Assisted; Aphasia; Rehabilitation.

Introduction

Linguistic communication deficits resulting from brain damage have a strong impact on patients’ daily life. The purpose of cognitive rehabilitation (CR) is the return to an acceptable quality of life, which can be obtained by stimulating the language production and comprehension, while improving other cognitive functions. CR, which has been traditionally paper-based, can now be supported by computers. This allows generating exercise sessions characterized by high variety, minimizing the risk of boring patients, and increasing their compliance. It also allows automatic detection of patients’ performance, as well as data storage for further analysis. Finally, patients, once trained at the hospital, could continue their rehabilitation plan at home with a telemedicine system. These properties, which in principle could benefit the entire CR process, unfortunately collide with some practical problems, such as the lack of familiarity of many patients with computers. To mitigate this problem, we have experimented a new interface, where the patient interacts with the computer through physical objects. The new modality has been integrated into CoRe, a system for computerized rehabilitation we developed during last years [1].

Methods

We exploited the Makey Makey (MM), an USB electronic board running on top of the Arduino system. It represents an alternative to keyboard and touch-screen, since it allows to “map” any physical conductive object to elements of the keyboard. As a first test, we implemented an exercise for aphasic patients, namely a “complete the word” task. The patient must choose among 6 options (3 consonants and 3 vowels), to complete a word (e.g., APPLE), given its picture and initials (e.g., “AP”). In our trial, three patients with Broca’s aphasia, aged 38, 46 and 69 years old respectively, performed several sessions of the exercise in three modes. First, using paper; second, using the touch screen; third, using MM, with the picture and initials shown on the screen while the 6 option letters, large and chromed, were fixed on a mobile lectern (Figure 1). The order of the modes was changed from session to session to avoid bias in subsequent statistical analysis (the patient may decrease its performance in the last minute of the session because of tiredness). Each session consisted of a set of 20 stimuli, always different, consisting of two-syllable words with their images, to be completed in a 7-minute time limit. Thus, 420 stimuli (7 set x 20 stimuli x 3 modes) were selected avoiding verbs and digraphs and employing high-definition images with neutral background. For each session we measured total running time, accuracy (number of words completed without errors), any aid provided by the therapist, and mistakes. At the end of each session we asked patients to rate the 3 modalities in order of preference.

Results

The rehabilitation sessions went smoothly and did not require additional time by the therapist for the preparation of the rehabilitation setting. Performance was quite similar among the 3 modalities, confirming that a different interaction does not affect the result. All patients, in time, have improved execution times, particularly with the PC-based modes. Patients were also positively affected by the unusual unfolding of sessions. All patients preferred the computerized mode to the paper: P1 was indifferent between touch-screen and MM, while P2 and P3 slightly preferred touch-screen.

Discussion and Conclusion

This work showed feasibility and ease of use of PC and MM applications in aphasic patients. However, our three patients, before the injury, had a good familiarity with the PC, and this probably did not allow to fully assess the MM possible benefits. The trial will thus continue with patients with older age and lower computer literacy as well as exercises that involve the use of conductive objects other than chrome letters, such as fruits, vegetables or even graphite drawings.

In Vitro Comparative Study Between Conventional and Computer-Assisted Surgery Methods for Planning and Resection of Bone Sarcomas

a Virtual Planning and Navigation Unit, Department of Health Informatics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.
b Institute of Orthopedics “Carlos E. Ottolenghi”, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.
c National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina
d Instituto Tecnológico de Buenos Aires, Buenos Aires, Argentina

Abstract
This poster aims to achieve an “in vitro” comparative study between three methods: 2D digital images planning and execution without navigation (freehand with ruler and caliper), 3D planning and execution without navigation (freehand with ruler and caliper) and 3D planning and execution guided with navigation. 3D planning and navigated procedures potentially improve sarcoma resection.

Keywords:
Informatics, Virtual Navigation, Sarcoma

Introduction
Surgeons plan surgeries using bi-dimensional images from magnetic resonance and tomography to define the tumor extension and then handle standard tools intraoperatively (caliper and ruler) to resect bone sarcoma. We wonder if surgeons have more information about the spatial tumor situation before and during the surgical procedure would it reduce the risk of potential sarcoma recurrence? Thus, the aim of this comparative study is to reach ideal “in vitro” conditions with an experimental design to answer these questions: Which type of planning method is safest for planning an oncologic margin? Which type of executing method is safest for sarcoma resection?

Methods
Two surgeons specialized in bone tumors unfamiliar with computer-assisted techniques and a 2nd year resident were evaluated to measure the accuracy and the impact in bone sarcoma resection according to the tools used. Plastic bones: a proximal femur, a distal femur, a humerus, a pelvis considering iliac wing and acetabulum. The methods evaluated were 2D digital images planning and execution without navigation (freehand with ruler and caliper), 3D simulation scenario planning and execution without navigation (freehand with ruler and caliper) and 3D simulation scenario planning and execution guided with navigation.

Results
Surgeon A, B and C did not remove the tumor when planning in 2D and executing with the freehand method based on those plans. The 3D planned and freehand guided resections exceeded the 3mm threshold a 66% of the times, while the navigated assisted resections a 20% of the times. For the 5mm threshold, the 3D planned and freehand guided resections exceeded it 41% of the times while the 3D planned and navigated assisted resections a 3% of the time. There is no apparent difference between 3D planned non-assisted resections and 3D planned assisted resections when evaluating safe margin violations. The navigation-assisted resections are closer to the target resection.

Conclusions
The 2D planning derived in a wrong resection, leaving tumoral tissue inside the patient. The 3D planning method potentially improved the results. There is no significant difference between 3D planned non-assisted resections and 3D planned navigation-assisted resections. The proposed model is on its experimental stage. The model allows physicians to compare advantages and disadvantages of tools and methods used in oncologic surgeries. 3D planning and navigation are potential assets in order to acquire accuracy and to reach an optimum margin in tumor resections.

Effects of Computerized Guideline-Oriented Clinical Decision Support System on Glycemic Control in Diabetic Patients: A Systematic Review and Meta-Analysis

Ryota Sakurai\textsuperscript{a}, Kazuhiko Ohe\textsuperscript{b}

\textsuperscript{a} Department of Healthcare Information Management, The University of Tokyo Hospital, Tokyo, Japan
\textsuperscript{b} Department of Biomedical Informatics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Abstract

In a meta-analysis of 4 trials, computerized guideline-oriented clinical decision support system (CDSS) for healthcare providers showed a similar change in glycated hemoglobin (HbA\textsubscript{1c}) from baseline to follow up (weighted mean difference (95\% confidence interval (CI)): -0.29 (-0.74, 0.16), \(p=0.212\)), but a reduced proportion of patients with HbA\textsubscript{1c} \(\geq 7.0\%\) at follow up (odds ratio (95\%CI): 0.85 (0.74, 0.97), \(p=0.014\)) compared with the control group, suggesting the need for the development of multifaceted computerized CDSS.

Keywords:
Computers, Guideline, Meta-Analysis

Introduction

A computerized guideline-oriented clinical decision support system (CDSS) for healthcare providers is expected to improve clinical outcomes in patients with chronic diseases, such as diabetes. However, it has not been well characterized whether this type of CDSS is effective for diabetic care. Therefore, we conducted a systematic review and meta-analysis of clinical trials comparing computerized guideline-oriented CDSS with control on glycemic control in diabetes.

Methods

The search terms included “guidelines,” “clinical,” “decision,” “support,” “system,” and “diabetes” in PubMed, the Cochrane Library, and Web of Science. The same terms or relevant studies were also queried on the website of the U.S. National Institute of Health and relevant reviews. The endpoints were a change in glycated hemoglobin (HbA\textsubscript{1c}) from baseline to follow up and a proportion of patients with HbA\textsubscript{1c} \(\geq 7.0\%\) at follow up. The computerized guideline-oriented CDSS for healthcare providers was defined as that which provides any clinical advice or recommendations automatically generated by computer, according to clinical guidelines.

Results

A total of 4,008 patients (2,037 patients allotted to the intervention group and 1,971 to the control group) in 4 studies (2 randomized controlled trials (RCTs) and 2 cluster RCTs) were included in this study. While the change in HbA\textsubscript{1c} in the intervention group was not statistically significant compared with the control group (weighted mean difference (95\% confidence interval (CI)): -0.29 (-0.74, 0.16), \(p=0.212\)), the proportion of patients with HbA\textsubscript{1c} \(\geq 7.0\%\) was significantly lower in the intervention group than in the control group (odds ratio (OR) (95\%CI): 0.85 (0.74, 0.97), \(p=0.014\)).

Conclusions

In this meta-analysis, computerized guideline-oriented CDSS for healthcare providers was partially effective on glycemic control in diabetic patients as compared to control. To achieve more improvement of clinical outcomes in diabetic patients, it seems that the development of a multifaceted computerized CDSS, in which not only healthcare providers but also patients could participate and cooperate, would be more effective.

In addition, it might be useful to perform a sensitivity analysis, such as a trial sequential analysis, to adjust for random error risk in a meta-analysis including a small number of trials [1].

Acknowledgments

The authors thank Heidi N. Bonneau for her editorial review. The authors have nothing to disclose regarding this study.

Use of an Off-the-Shelf Corporate Information Tool to Track a High-Level-Disinfection Process

*Carolina Salazar, *Jaime de los Hoyos, *Francisco Izurieta, *Daniel Jara, b,cDaniel Capurro

*Salud UC CHRISTUS Healthcare Network, Pontificia Universidad Católica de Chile, Santiago, Chile  
bDepartment of Internal Medicine, School of Medicine, Pontificia Universidad Católica de Chile  
cDepartment of Biomedical and Health Informatics, University of Washington, Seattle, USA

Abstract

High-Level Disinfection (HLD) of endoscopic equipment is a critical process to ensure patient safety. Although commercial tracking software is available, here we demonstrate the successful design and implementation of a HLD tracking system using pre-existing corporate information tools. After a brief development and implementation stage, the HLD unit is successfully tracking the process and are able to create simple visualizations to monitor and improve the existing procedures.

Keywords:
Infection Control, Health Information Systems

Introduction

Endoscopic procedures are first-line diagnostic and therapeutic tools. Given the structure and thermolabile nature of their components, endoscopic equipment cannot go through common sterilization processes; they are considered semicritical equipment, they must go through a process called High-Level Disinfection (HLD)[1].

HLD is a complex, unidirectional process that requires strict supervision of every step. The main steps in HLD include a) washing and decontamination b) disinfection, and c) packaging and delivery. Complete traceability of this process is paramount.

Our local HLD unit used a paper-based traceability system, which hindered the re-use of the captured information to monitor the process, detect failures and implement quality improvement actions. Although equipment-tracking softwares are available for purchase, we sought to implement one using our already available corporate information tools.

Methods

Our unit documented the current, paper-based HLD process with key users. We modelled the corresponding business facts and structured data needed to support said process Microsoft InfoPath. Once validated, the form was loaded and made available as a Microsoft SharePoint site, and specific user accounts were created. We conducted a week-long testing period, in which users simultaneously documented HLD equipment check-in and check-out in both the paper-based method, and the new SharePoint site. Finally, the HLD process began using the SharePoint site exclusively to support and document their workflow. Designated users can readily extract all records into a Microsoft Excel spreadsheet for review and analysis.

Results

As of December 2016, the HLD SharePoint site has over 2,800 records, and continues to be successfully used to track the HLD process, and our institution was to extract and analyze related information. This enables the creation of quick analyses to make informed decisions based on error rates, turn-around-times, etc. Figure 1 offers a quick visualization of the distribution of equipment admission times to the HLD unit which could inform future decisions on staffing.

Conclusion

This experience demonstrates the practical possibility to use already available corporate information tools to solve practical healthcare information-related problems.

Acknowledgements

We would like to thank the HLD personnel for their collaboration on the HLD process modelling and validation

Using Fast Healthcare Interoperability Resources (FHIR) for the Integration of Risk Minimization Systems in Hospitals

Kutaiba Saleha, Stephan Stuckeb, Alexandr Ucitelic, Sebastian Faulbrück-Röhrb, Juliane Neumannd, Kais Tahrac, Danny Ammonb, Tobias Schmidtb, Thomas Neumurthd, Andreas Bestingb, Frank Portheinec, Heinrich Herrec, André Kaedingb and Martin Spechta

Abstract

With the growing strain of medical staff and complexity of patient care, the risk of medical errors increases. In this work we present the use of Fast Healthcare Interoperability Resources (FHIR) as communication standard for the integration of an ontology- and agent-based system to identify risks across medical processes in a clinical environment.

Keywords:
Standards; Decision Support Systems, Clinical; Harm Reduction

Introduction

Current studies provide an estimation of more than 400,000 lethal harms due to preventable medical errors during hospital treatment per year, with 10- to 20-fold serious harms occurring [1]. Clinical decision support systems (CDSS) can assist in preventing such errors, but have not yet integrated the new messaging standard Fast Healthcare Interoperability Resources (HL7 FHIR [2]). In the research project “OntoMedRisk”, we developed an agent-based system to identify risks based on a special ontology [3]. This system aims at supporting medical staff with risk detection and error prevention. A requirement for practical demonstration is the integration of this system into an existing hospital IT infrastructure, which was carried out at Jena University Hospital (JUH).

Methods

Cochlear Implantation (CI) has been chosen as a first exemplary clinical treatment process. To detect risks during CI treatment, relevant medical information from clinical subsystems must be extracted and processed by the system. In our concept, we combined the data retrieval agent of the DSS with a FHIR server to extract data either directly from the clinical subsystems or via communication server to systems which do not yet support FHIR.

Results

We implemented a FHIR server at JUH for medical data collection for risk detection in the CI treatment process, where singular data is extracted and processed in a timely manner. For communication and storage, certain clinical data key performance indicators relevant for risk detection like age of the patient, cranial thickness, or duration of deafness, were modeled using FHIR resources like “patient”, “observation”, “encounter” and processed by the agent system. Through the use of an ontology, alerts are generated during treatment as a support to the clinical staff. Since FHIR is a new standard, many relevant clinical systems might not be providing a correspondent interface. In these cases, the use of a communication server is a transitional solution.

Conclusions

We obtained as findings that CDSS can collect medical data from existing clinical information systems through the use of modern communication standards like FHIR. The “OntoMedRisk” system relies on real-time access to discrete data generated in different subsystems, and we could provide these as FHIR resources for risk detection and presentation of the results to clinical staff. Further investigation on the usability of this software at JUH is planned. In the future, we plan to extend system functions to other treatment processes.

Acknowledgements

This work has been funded by the BMBF under the project “OntoMedRisk” (grant no. 01IS14022).

Development of Observation Support System Using Integrated Nursing Practice Data

Ryoma Seto, Toshitaka Inoue, Nobuyuki Koeda, Sayuri Yamashita, Kotaro Komino, Takahiro Yasoshima

Division of Healthcare Informatics, Faculty of Healthcare, Tokyo Healthcare University, Tokyo, Japan
Department of Social Welfare Science, Faculty of Health and Social Welfare, Nishikyushu University, Saga, Japan
Secretariat, Yao Municipal Hospital, Osaka, Japan
Department of Nursing, Municipal Fussa Hospital, Tokyo, Japan
Department of Primary Care, Sapporo Dohto Hospital, Hokkaido, Japan

Abstract

The purpose of this study was to develop a prototype nursing observation support system using integrated nursing practice data with nursing records, prescription data, and nurse call logs. These data show that the present observation system has improved. The system has the potential to provide improved observations of chest symptoms and pain management.

Keywords:
Hospital Information Systems, Nursing Record, Patient Safety

Introduction

Inpatient care support systems are rapidly getting integrated with patient care devices (PCDs) [e.g., nurse call system, fall prevention sensor, electrocardiogram (ECG) monitor]. However, these integrated systems function mainly to alert nurses and are not used to predict patient conditions. Observation is one of the most important roles in nursing care. Therefore, a “structured observation function with PCDs” is required for future inpatient care systems. The purpose of this study was to develop a prototype nursing observation support system using integrated nursing practice data with PCDs.

Methods

Data were collected at a private “A hospital (105 beds)” with internal medicine and surgical units. Nursing progress notes from May to November 2015 were analyzed using the text-mining method and converted into qualitative data. The notes were integrated with the prescription order log and the nurse call log. The nurses’ work flow was visualized via patient topics (e.g., pain, chest symptoms). The work flow from those data was discussed with an inter-professional team, and a prototype prediction algorithm was developed. This study was approved by the managing board under A hospital’s protocol.

Results

Observation of Chest Symptoms

Among 237,202 nursing records from May to November 2015, 1,942 records were related to ECG. Of the ECG-related records, 582 were normal sinus rhythm (NSR), but only 38 (6.5%) were written as “chest symptom.”

Observation of Pain

Among 237,202 nursing records from May to November 2015, 1,990 were related to “nurse call.” Text-mining picked 4,546 key terms (noun) as top 10 nouns from all “nurse call” records. Most nouns were related to humans or materials (e.g., “nurse” and “bed”); the only noun relating to symptoms was “pain.” From May to November 2015, “nurse call” was related to “pain” in 457 patients (49 patients in November). In 49 patients, the prescription data and nurse call log were connected to their nursing records. Consequently, only 12 patients (33.3%) used pain-relief medication (e.g., non-steroidal anti-inflammatory drugs). However, two stages of pain were written in their records: able or unable to bear.

Development of Observation Recommendation

The nursing practice data showed nursing observation to be improved. The inter-professional team discussed the algorithm of nursing intervention. If a nurse records information about ECG, the prototype system provides recommendations for observation, including chest symptoms. If the nurse call rings often and the nursing record includes pain, the system asks the nurse whether the patient feels pain.

Discussion

PCDs have a huge potential to increase opportunities of nursing observation. Electronic medical records also increase the quality of nursing care. However, the results of this study indicate that the nurse cannot use these patient data at full value. Therefore, the “cognitive limit” of nursing observation should be considered in the development of inpatient care systems using PCDs.

Conclusions

An observation support system using integrated nursing practice data can improve nursing observation, and the system is useful for patient safety and improvement of the quality of nursing care such as pain control.

Abstract

The aim of this study was to evaluate the accuracy of decision support systems in the diagnosis of breast cancer by means of a systematic review and meta-analysis of studies of diagnostic accuracy. The first step of the research, which consisted of the initial research of abstracts and titles identified from the research strategy in the databases was performed by two researchers independently. In this stage, 622 references were retrieved in the databases and, through a consensus meeting, 183 articles were selected for full reading.

Keywords: Decision Support Systems, Clinical; Review; Meta-Analysis

Introduction

Historically to the present day, the reason for a technology not being used in clinical practice may be the lack of a robust evaluation, high cost, or because it presents itself as a very invasive method. Considering the importance of the issue in the global context, some countries in the Americas, Europe and Asia have turned their attention to the evaluation of technologies applied to the health context and implemented government agencies that specifically focus on this issue [1].

On the other hand, due to population aging in the next 20 years, the estimate for cancer cases generally suggests a 75% increase in prevalence [2]. Considering this information and in addition to the fact that breast cancer is very common among women, the concern is that there will be growth of breast cancer cases in Brazil and in the world. According to the World Health Organization (WHO) prevention strategies can not extinguish most of the cases that occur in low- and middle-income countries, where the diagnosis of the disease is made in advanced stages, so early diagnosis is necessary In order to improve the prognosis [2].

This paper presents the initial results of the accuracy of decision support systems in the diagnosis of breast cancer by means of a systematic review and meta-analysis of studies of diagnostic accuracy.

Materials and Methods

An exhaustive search of Medline, Embase, and Gray Literature was performed for publications between 1970 through 2016, and were included diagnostic accuracy studies that evaluated individuals with breast cancer (target condition) by means of decision support systems (test in evaluation).

Results

The first step of the research, which consisted of the initial research of abstracts and titles identified from the research strategy in the databases was performed by two researchers independently. In this stage, 622 references were retrieved in the databases and, through a consensus meeting, 183 articles were selected for full reading.

Conclusion

The present project is being developed with the following steps, reading the full articles, developing the meta-analysis and evaluating the methodological quality of the included studies, which will be done through the tool Quadas 2.

Accessibility of Mobile Devices for Visually Impaired Users:  
An Evaluation of the Screen-Reader VoiceOver

Berglind Smaradottir\textsuperscript{a}, Jarle Håland\textsuperscript{b,c}, Santiago Martinez\textsuperscript{b}

\textsuperscript{a} Department of Information and Communication Technology, University of Agder, Grimstad, Norway  
\textsuperscript{b} Department of Health and Nursing Science, University of Agder, Grimstad, Norway  
\textsuperscript{c} Kongsgård School Centre, Kristiansand, Norway

Abstract

A mobile device’s touchscreen allows users to use a choreography of hand gestures to interact with the user interface. A screen reader on a mobile device is designed to support the interaction of visually disabled users while using gestures. This paper presents an evaluation of VoiceOver, a screen reader in Apple Inc. products. The evaluation was a part of the research project “Visually impaired users touching the screen - a user evaluation of assistive technology”.

Keywords:
Visually Impaired Persons, Medical Informatics

Introduction

Mobile technologies with touchscreen allow users to interact with the interface through hand gestures. Touchscreens may represent a significant accessibility and communication barrier to users with visual disabilities since this type of interaction does not usually provide audio or tactile feedback by default. However, there currently are in the market solutions that enable visually impaired users to use technology using voice commands. An example of this technology is the VoiceOver by Apple Inc., developed for iOS devices such as iPhone and iPad. VoiceOver synchronizes speech feedback with user hand gestures. This work presents a user evaluation of the screen reader VoiceOver, with the aim of exploring the challenges that visually disabled users experience when they interact with a touchscreen using hand gestures.

Methods

A usability evaluation in the Usability Laboratory [1] at the Centre for eHealth and Healthcare Technology at the University of Agder, Norway, was made with 6 visually impaired participants. They were asked to use a series of gestures to solve tasks related to the use of a smartphone (i.e., iPhone). Quantitative (time and attempts per gesture) and qualitative (pre- and posttest semi-structured interviews) measures were used for the analysis of the data collection.

Results

Participants reported that most of the hand gestures were generally easy to perform. However, several gestures were described as “challenging” or requiring user-training in advance. The system responded mainly correctly to the set of gestures, but a few times the system did not respond to the hand gestures performed on the user interface (UI). For instance, several participants had problems with ending a phone call. In addition, the speech feedback responded appropriately to the gestures. However, one particular gesture (swipe gesture) was inconsistently interpreted across the tests. The speech feedback provided sufficient information to enable participants to navigate through the UI. Only a few times there was a lack of information in the speech feedback or expressions that were not understood by participants.

Conclusion

Mobile device touch screens are widely used by heterogeneous user groups, which emphasizes the importance of key human-computer interaction concepts such as accessibility and usability. Accessibility and usability evaluations are essential to improve the interface design and the interactions between mobile devices and users with physical, cognitive and/or sensory limitations. This work has summarized an analysis of the usability of the gesture-based speech-assisted interface navigation system, Apple Inc. VoiceOver. The findings showed that, in general, the system feedback was appropriate, but there were some specific functions and speech expressions that could be improved to increase effectiveness, efficiency and user satisfaction of visually impaired users.

Acknowledgements

The authors thank the visually disabled people for their disinterested participation in this study.

Advancing Towards a CDA-Based Trauma Registry Data Submission

Martin Staemmler\textsuperscript{a}, Alexander Nischwitz\textsuperscript{a}, Markus Blätzinger\textsuperscript{b}, Johannes Sturm\textsuperscript{b}

\textsuperscript{a}Medical Informatics, University of Applied Sciences, Stralsund, Germany, \\
\textsuperscript{b}TraumaRegistry\textsuperscript{®}, Academy of the German Society for Trauma Surgery, Munich, Germany

Abstract

This poster presents an assessment to which extent the data submission to one of the largest trauma registries worldwide can be structured compliant to the clinical document architecture (CDA) and semantically annotated. Overall, complete annotation was achieved for 75\% of the items, for the remaining ones annotation failed due to missing codes or concepts for individual items or values of value sets.

Keywords:
Registries, Semantics, Electronic Health Records

Introduction

Data submission to trauma registries relies either on web-based forms or files holding the items entered using a standalone application or an application integrated with a clinical information system (HIS, EMR) [1, 2]. Usually the data representation is proprietary, registry dependent, lacks semantic annotation and/or conformance to established standards regarding data types, structure (e.g. entries, sections) or building blocks (e.g. templates). The objective of this paper is to assess to which extent the data submission to one of the largest trauma registries worldwide, the German TraumaRegistry\textsuperscript{®}, can be represented compliant to the above requirements.

Methods

The analysis of the trauma registry data submission revealed five sections reflecting the phases: trauma and demographic data, pre-hospital, emergency room/operating theatre, intensive care unit, diagnosis and outcome. Some of these phases include subdivisions e.g. laboratory, diagnostic procedures, emergency interventions, anticoagulation. The data types of the ca. 100 items comprise of free text, single and multiple values, scores and structured items with defined value sets. To assure maintainability the open-source tool ART-DECOR\textsuperscript{®} was used. It supports the specification of data sets by providing access to HL7 templates, value sets, data types as well as to classifications and nomenclatures. The structure of the submission data set was mapped to a document template with sections for the phases and the subdivisions. For each item a data type was selected using the HL7 CDA set of data types. Furthermore, each item was semantically annotated based on the concept of coded values. This annotation has also been extended to individual values of value sets. Project related object identifiers were assigned to items and values sets provided that there was no existing assignment. Overall, a table was used to monitor the status of each item regarding semantic annotation for later assessment.

Results

The phases and subdivisions were reflected in CDA sections. Items led to entries. Semantic annotation was achieved using ICD-10, LOINC and SNOMED CT (only precoordination). Overall, 75\% of all items could be annotated completely, exhibiting the highest rates with the pre-clinical and the emergency room/operating theatre phases. Reasons for annotation failure were missing or inapt codes for items (21\%) or values within a value set (4\%). For example, the NACA score is missing in SNOMED or LOINC, values of the value set "type of accident" could not fully be mapped to existing SNOMED concepts. ART-DECOR\textsuperscript{®} was versatile for structuring and semantic annotation, its specification file (decor.xml) serves for later verification and instantiation of a CDA document.

Discussion and Conclusions

In 2016 HL7 published a CDA implementation guide for trauma registry data submission for the NTDS [3], taking a similar approach, but based on a partially different sets of items. The more extensive Canadian approach [4] uses proprietary data types but lacks semantic annotation. Other, mainly IHE profiles e.g. XDS-MS, EDR in the PCC domain [5] rely on CDA but are focused on the emergency department. As a result, the two CDA based approaches better comply to the registry requirements while taking the different realms into account.

Patient Accessibility to Hospitals in Winter Road Conditions: GIS-Based Analysis Using Car Navigation Probe Data

Takumi Tanikawa*, Hisateru Ohba*, Ayako Yagahara*, Katsuhiko Ogasawara*

*Faculty of Health Sciences, Hokkaido University of Science, Sapporo, Hokkaido, Japan,
*Graduate School of Health Sciences, Hokkaido University, Sapporo, Hokkaido, Japan

Abstract

The purpose of this study was to estimate geographical patient flow to hospitals during winter seasons using simulation analysis. We used probe data collected from car navigation systems and performed a Geographical Information System (GIS)-based analysis to determine the relationship between travel time to hospitals and winter road conditions. Accessibility to hospitals based on travel time in summer and winter was overlayed on a map to demonstrate the increase in travel time during winter.

Keywords:
Health Services Research, Transportation

Introduction

In snowy areas, road surface conditions can significantly deteriorate in the winter. The decline in traffic flow due to snowfall and freezing of roadways leads to a decreased accessibility to hospitals, and increase in travel time can be very problematic during an emergency. In this study, we analyzed the difference in travel time to hospitals based on weather and road conditions in summer and winter.

Methods

We examined 21 secondary medical service areas (geographical administrative unit for health policy) of Hokkaido Prefecture, Japan. It was assumed that outpatients traveled for their hospital visit by car. Several weather scenarios were defined to determine cost factors. The area examined was also classified into urban and suburban areas to set a cost value. Travel time in winter equaled that in summer multiplied by the cost value. Based on the scenario, the cost was set to 1 for roads in summer and from 1 to 3 for roads in winter. Additionally, actual cost values were determined using probe data of a week in each of summer and winter collected from a car navigation system.

We used the geographic information system ArcGIS 10.1 and road network data from ArcGIS data collection 2013 (Esri). The 15-min to 120-min travel time areas were projected on a map, and the population coverage ratio in each area was calculated by each secondary medical service area.

Results

In winter, throughout Hokkaido, the cost value calculated using probe data was 1.15 in urban areas and 1.29 in suburban areas. The population coverage ratio for the 60-min travel time area was decreased from 90.4% in summer to 87.9% in winter in the Sapporo medical service area, while for the 30-min area, it was decreased from 71.5% in summer to 64.8% in winter.

Discussion

Data used for formulating medical plans is usually derived from investigations during the summer season. However, weather and road surface conditions in winter may restrain patient visiting behavior; thus, winter conditions in snowy areas should be considered while formulating medical plans. The results of this study provide a visual demonstration based on the weather scenario and the probe data that patient travel time to core hospitals becomes longer in winter than in summer. A limitation of this study is that only two weeks probe data was taken, thus the cost value may change depending on collected periods.

Conclusions

In this study, we used GIS data to create a map displaying the increase in travel time to core hospitals in Hokkaido in winter. We also estimate the time required to travel to core hospitals based on weather and road conditions in winter as well as the population coverage ratio for the secondary medical service area based on weather scenario and car travel data.

Implementation of an Outsourced Transnational Service of Clinical Decision Support System

Vania Teixeira\textsuperscript{a}, Luciana Rubin\textsuperscript{b}, Romina Rebrij\textsuperscript{b}, Alvaro Tamborindegu\textsuperscript{a}, Rodrigo Martineza, Juan Carlos Bacigalupo\textsuperscript{a}, Daniel Lunab

\textsuperscript{a}Universal Soluciones Tecnológicas, Uruguay, \textsuperscript{b}Department of Biomedical Informatics, Hospital Italiano de Buenos Aires, Argentina

Abstract

The aim of this study is to describe the implementation and evaluation of an outsourced Clinical Decision Support Systems (CDSS) service of drug-drug interaction (DDI) alerts in an Uruguayan outpatient healthcare network. A cross-sectional study was developed. 1.5 alerts were triggered of every 1000 prescriptions. Clinicians accepted 44% of the total alerts. In conclusion, the implementation of CDSS was achievable.

Keywords: Decision support systems, Clinical; Drug Interactions; Outsourced Services

Introduction

DDI are causes of preventable adverse drug events (ADEs). DDI type D can produce major ADEs and type X may be mortal. DDI are related to 2%-3% of the hospital admissions [1]. CDSS can reduce ADEs caused by DDI, by alerting the physician about them [2]. Universal Soluciones Tecnológicas (UST) is a company that provides IT to an Uruguayan private healthcare network with 300 thousand consumers. Systematization of medical terminology has been introduced in the Electronic Medical Records (EMR), consuming Hospital Italiano de Buenos Aires (HIBA) terminology web services. The purpose of this study was to implement and to evaluate an outsourced CDSS service of DDI alert in an outpatient healthcare network.

Methods

A cross-sectional study was carried out taking 5 months before and 5 months after the implementation of the IDD alerts, in the health network of UST in Uruguay. The EMR was audited in case of overridden DDI alerts to evaluate user's override's motives. The prevalence of DDI was compared before and after CDSS implementation. Data analysis was done with EPIDAT version 3.1 with 95% confidence level.

Results

CDSS services including DDI alerts of type D and X was developed by HIBA and uploaded to a web service. UST started consuming from a development environment and following HIBA design guides, for the graphic alert's interface. Two months later with the satisfactory tests, the CDSS services went live. EMR users (physicians) received capacitация through the application itself. During the 5 months after CDSS implementation 1.5 DDI alerts were triggered every 1000 prescription. Physicians cancelled 44% of prescriptions with DDI alert and override 54%. Override justifications were: 42% “other” explained by free text, 32.5% “limited time”, 13% “benefits/risks”, 7% “tolerance” and 5.5% “no alternatives available”. Compared to prescriptions performed before the CDSS implementation, DDI after CDSS alerts implementation were approximately 80 % lower (RR: 0.21; CI\textsubscript{95%}: 0.18-0.26; P<0.0001). The prevalence of patients with DDI over the total of patients with any drug prescription was 0.50% before CDSS alerts compared to 0.30 % with CDSS alerts (RR: 0.68; CI\textsubscript{95%}: 0.57-0.82; P<0.0001).

Discussion

The outsourced CDSS service was effectively and efficiently implemented. The overridden alerts were mainly attributable to a gap between knowledge and practice. Further investigations are necessary to improve the acceptance. A decrease in the DDI prevalence was associated to the implementation of CDSS alerts. However, analytical studies need to be conducted to investigate the potential causality. CDSS showed to be a tool for learning and updating knowledge for a variety of users across national and institutional boundaries. Users trained virtually had heterogeneous knowledge and capabilities and resulted in a minor limitation in the implementation.

Conclusion

The implementation of the outsourced CDSS was feasible, without major technical or professional difficulties.

Acknowledgments

Authors thank Sonia Benitez and Daniel Rizzato for their support in this writing process.

Center, Houston, TX

Abstract:
Clinical decision support systems, when used effectively, can improve the quality of care. However, such systems can malfunction, and these malfunctions can be difficult to detect. In this paper, we describe four methods of detecting and resolving issues with clinical decision support: 1) statistical anomaly detection, 2) visual analytics and dashboards, 3) user feedback analysis, and 4) taxonomization of failure modes/effects.

Keywords:
Expert Systems, Electronic Health Records, Safety Management

Introduction
Significant evidence suggests that clinical decision support (CDS) systems, when used effectively, can improve healthcare quality, safety, and effectiveness [1]. However, unintended consequences and safety issues around CDS have been reported [2]. In prior qualitative studies, we identified several cases where CDS systems failed, in many cases without being detected [3]. Here, we focused on studying the identification, causes, and effects of CDS failures.

Methods
CDS systems issues were identified using many approaches:
1. Statistical anomaly detection on alert firing logs
2. Visual analytics/dashboards for knowledge engineers
3. Free-text analysis of user feedback to identify problematic logic
4. Taxonomization of failure modes and effects to help us develop prevention strategies

These methods have been used at six healthcare systems, including a mix of academic medical centers, integrated delivery systems, and community health care systems.

Results
Statistical anomaly detection: A mix of simple heuristic anomaly detection, Poisson change-point analysis, and Seasonal Trend decomposition using Loess identified potential issues from alert firing logs. Issues included errors due to changes in underlying trends, system upgrades, and service malfunctions.
Visual analytics and dashboards: Several dashboards for visualizing CDS alert firing and acceptance rates using D3.js and Google Charts were developed. Detected issues included misconfigured alerts firing too often, and system upgrade errors.

User feedback analysis: Rules and sentiment analysis were used to identify user free-text comments from override reasons in response to CDS alerts suggesting anger or frustration. These methods have identified failures related to order detection, medication classification, and clinical logic errors.

Taxonomization of failure modes and effects: From analyzing 70 known CDS malfunctions, we developed a tri-axial taxonomy of causes, modes of discovery, and effects. This taxonomy can identify best practices for preventing and detecting CDS malfunctions.

Conclusions
A multi-modal approach is necessary for preventing, detecting, and studying CDS malfunctions. Our methods detected a range of issues at six sites as well as identified malfunctions other methods missed. We are now identifying best practices for avoiding CDS malfunctions, including system testing, log file monitoring, CDS governance, organizational policies and procedures, developer and user training, and new analysis and visualization tools.

Data Mining on Numeric Error in Computerized Physician Order Entry System Prescriptions

Wu Xuea,b, Wu Changxuc

a Peking University, School of Nursing, Beijing, China, b Institute of Psychology, Chinese Academy of Sciences, Beijing, China, c Department of Industrial and Systems Engineering, State University of New York (SUNY)-Buffalo, NY, USA

Abstract

This study revealed the numeric error patterns related to dosage when doctors prescribed in computerized physician order entry system. Error categories showed that the ‘6’, ‘7’, and ‘9’ key produced a higher incidence of errors in Numpad typing, while the ‘2’, ‘3’, and ‘0’ key produced a higher incidence of errors in main keyboard digit line typing. Errors categorized as omission and substitution were higher in prevalence than transposition and intrusion.

Keywords

Medical order entry systems; Medication errors; Numeric

Introduction

Computerized physician order entry (CPOE) system can significantly reduce certain types of prescription errors. However, prescription errors still occur. Various factors such as the numeric input methods in human computer interaction (HCI) produce different error rates and types. This study aimed to categorize the types of errors on different numeric keys when doctors prescribed using CPOE. Several error patterns in this study were compared with Salthouse’s findings [1] and Lin & Wu’s research [2].

Methods

Data mining techniques, including clustering and classification, were used to explore the incidence of four error categories. All the errors were categorized into four types [1]: 1. (Omission), e.g. the target number was 50, while the entry number was 5, recorded ‘0’ key occurred 1 Omis error; 2. (Substitution), e.g. the target number was 50, while the entry number was 55, recorded ‘0’ key occurred 1 Subs error; 3. (Transposition), e.g. the target number was 25, while the entry number was 52, recorded ‘2’ key occurred 1 Trans error; 4. (Intrusion), e.g. the target number was 50, while the entry number was 500, recorded ‘0’ key occurred 1 Intru error. The error rate of 0-9 key in Numpad and main keyboard digit line was calculated respectively.

Results

A total of 41,100 dosages were collected from a simulated CPOE system, of which 954 sets of numbers involving 1,737 numeric errors were identified. Measuring the composition of errors, omission and substitution were higher than transposition and intrusion (Figure 1). The ‘6’, ‘7’, and ‘9’ key had a higher incidence of errors using the Numpad, while the ‘2’, ‘3’, and ‘0’ keys had a higher incidence of errors in main keyboard digit line typing (Figures 2 & 3).

Conclusions

The omission and substitution error rates were higher than transposition and intrusion. Significant difference existed in error rates of each key between keyer layouts.

Development of Multiple Wireless Network Environments for Hospitals

Yoshinori Yamashita*, Tatoku Ogaito*

*Department of Medical Informatics, University of Fukui Hospital, FUKUI, Japan

Abstract

The use of smart devices in medical information systems is progressing. In addition, correspondence of communication functions in medical equipment is advancing. For this reason, and in order to establish the ubiquitous environment in hospitals, we developed an environment in which multiple wireless communications can be used.

Keywords:
Wireless Technology; Risk Management; Management Information Systems.

Introduction

In our hospital, the private cloud system has changed with virtualization of the hospital information system [1]. As a result, the miniaturization of terminals and the use of smart devices has expanded. In addition, data acquisition from medical devices by wireless communication has been accumulating. In particular, we have developed a communication infrastructure to utilize communication with smart devices and medical devices. However, in communications from medical devices and communication from event monitoring devices, it is necessary to reduce electric power in communication, so the use of power saving communication is required. For this reason, we can no longer use the Wifi communication that we have used so far and must switch to a system like IEEE 802.15. With this system we are able to collect data, alarm events, and identify location information [2].

Methods

We have made it possible to use the following as multiple wireless communication in the hospital:

1. Using Wireless LAN (Wifi)
2. Communication by IEEE 802.15
   (IEEE 802.15.1 Bluetooth & IEEE 802.15.4 ZigBee)
3. Function for Indoor GPS(IMES)

We developed a gateway device called "IoT gateway" that relays these communications to each other (Figure 1). By using this gateway device, we collect data by relaying information from medical equipment and sensors. Also, it is possible to perform positioning with BLE beacon or GPS radio waves for smart devices.

By installing this gateway device at 1000 places throughout the hospital (i.e. in each room and hallway in the hospital), we can obtain the position with the collected data.

Figure 1 – Scheme of Gateway Device

Results

In previous methods, communication methods other than Wifi were operated on a point-to-point basis, but with this it was possible to establish as an infrastructure that could be used all the time. We have been able to handle data by wireless communication anywhere in the hospital. Therefore, it is possible to utilize a medical device with a communication function. In addition, because it has the function of providing location information, it is now possible to specify the location where data is collected. As another use, it was also possible to restrict data access by location. As a result of the development of this gateway device, wireless communication for embedded devices can be used steadily and expansion of wireless compatible devices in the future can also be done. Furthermore, it is possible to collect data with location information.

Conclusion

With this method, location information can be obtained together with collected data, so that data analysis can be performed along with location. Therefore, it can be used for analyzing accidents and workflow information. By using the results from this study we were able to change the work of nurses and succeeded in reducing overtime.

Yoshinori Yamashita : e-mail: yyama@u-fukui.ac.jp
Abstract

A content analysis was performed to investigate core curriculum in master degree programs for patient safety. Twenty programs from six countries and 179 core curriculum/modules were extracted and reviewed. The curricula were compared to the topics recommended in WHO’s Multi-professional Patient Safety Curriculum Guide and the core content relevant to patient safety issues in IMIA/AMIA recommendations for health informatics education. The differences between the identified curricula with those addressed in the aforementioned Guide/Recommendations were examined.

Keywords:
Patient Safety; Education; Curriculum

Introduction

Some master degree programs have been established to target all healthcare professionals recently. Studies indicating the ways in which “patient safety” are incorporated within such programs are still limited. So far, there is no consensus exist in this domain. WHO’s Multi-professional Patient Safety Curriculum Guide[1] is considered as the gold standard. Meanwhile, IMIA and AMIA also addressed some core content relevant to patient safety issues in their recommendations on education for health informatics [2] [3]. In this study, we conducted a content analysis to investigate core curriculum developed in the master degree programs for patient safety, in general, to understand: 1) the coincidence degree of the existing curricula with the WHO’s Guide; 2) the differences between these curricula with those addressed in the aforementioned Guide/Recommendations.

Methods

We searched the literature using Pubmed and Google Scholar to collect and extract the study subjects. We excluded those curricula, which were developed either in certificate programs or in residency training/fellowship programs. Then we drew up a list of the identified curriculum/modules for evaluation. Program Title, Name of the Univerisity/Institute, Country, Study Type, Durations, Degree Structure, Course Name were used to describe each program. Finally, we reviewed the contents of each curriculum and compared them with the topics recommended in WHO’s Guide. Also, we examined the differences between the identified curricula with those addressed in the corresponding Guide/Recommendations.

Results

Twenty master degree programs from six countries were identified: US (8), UK (7), Canada (2), Spain (1), Japan (1) and United Arab Emirate (1). 179 core curriculum/modules were extracted and reviewed. The coincidence degrees with WHO’s recommendations were: “Using quality improvement methods to improve care” 100%; “What is patient safety?” 70%; “Understanding and managing clinical risk” 65%; “Understanding systems and the effect of complexity on patient care” 50%; “Being an effective team player” 50%; “Why applying human factors is important for patient safety” 45%; “Learning from errors to prevent harm” 45%; “Engaging with patients and carers” 45%; “Improving medication safety” 20%; “Infection prevention and control” 5% and “Patient safety and invasive procedures” 5%, respectively. Health informatics topics, e.g. electronic health records, clinical informatics, decision support processes, human-computer interface design, and usability were involved in 40% of these curricula. Beyond topics covered by WHO’s Guide and IMIA/AMIA recommendations, research methodologies, social issues regarding policy/leadership/legal/law/regulatory topics were typically focused in the existing curricula.

Conclusions

The identified curricula in the existing programs reflect the educational trends in the field.
