AIHA included significantly fewer patients in categories (2)–(6). From th(1) to th(6), the changes in the numbers of TP, FP, FN, and TN patients and the changes in performance were smaller than for common diseases. The changes for T2DM were intermediate; the recall and NPV decreased by 9.73% and 2.12%, respectively, and the precision and the specificity increased by 39.3% and 4.49%, respectively (Figure 4(i)). Figure 5 shows that the changes in performance of naïve algorithms, which exhibited the same patterns as in Figure 4 except for the decrease in recall from th(1) to th(2) for essential HT.

**Discussion**

Our experiments showed that for each of the four chronic diseases, it was necessary to determine how to annotate CASEs by dividing possible patients from definite CASEs and classifying each type of possible patients, to avoid research teams’ inclusion of different characteristics in their CASEs. Consequently, the changes in performance of phenotyping algorithms following the alteration in annotation criteria differed among the diseases; this was considered to be independent of the type of algorithms, that is, GB or naïve algorithms. We suggest that these results support the importance of sharing annotation criteria in detail to reproduce algorithms.

**The characteristics of possible patients**

The different distributions of patients among the diseases (Figure 3) are clinically plausible. Clinicians can diagnose T2DM willingly by a combination of simple lab tests or symptoms [15]; many clinicians were assumed to diagnose T2DM with strong conviction (category (1)) or describe information that inferred T2DM (category (2)). Essential HT is a diagnosis by the exclusion of secondary HT [16]; most clinicians only describe “HT” when referring to essential HT. This was assumed to be the reason for the peak at category (4). PBC and AIHA are rare diseases; then, specialists diagnose most patients with strong conviction (category (1)) [17, 18]. Further, the upper disease of AIHA (acquired hemolytic anemia) is rare, while that of PBC (fibrosis and cirrhosis of liver) cannot be sometimes diagnosed with certainty even by specialists because it is relatively common; then, PBC had a relatively higher proportion of possible patients compared to AIHA, and AIHA did not include the patients in categories (5) and (6).

The detailed annotation criteria according to the degrees of disease conviction recorded by the clinicians reflect patient characteristics and clinicians’ rational assessments (Tables 3(a)–(c)). We considered that clinicians could neither diagnose patients with low HbA1c certainly nor describe the definite disease name for such patients, and the average of the maximum HbA1c of each patient in DA categories (4) or (6) for T2DM was relatively low. Similarly, it is suggested that the clinicians’ choices of lab tests, medications, or billing codes are affected by the clinicians’ conviction of the diseases. It seems one reason no elements tended to be unequal among the categories for essential HT was that they included antihypertensive medications for other diseases and the corresponding billing codes, independent of the conviction of essential HT.

**Annotation criteria influence the reproducibility of phenotyping algorithms**

Many studies have applied phenotyping algorithms to multiple institutions and identical performance has not been achieved [19, 21]. Our findings suggest that even if the research teams used the same annotation criteria, the ambiguities of the criteria and the corresponding different annotation results could lead to the different performance. This is a critical limitation when other teams attempt to reproduce published performance for different datasets. Without detailed annotation criteria, other teams could not judge whether the different performance arises from differences in annotation criteria, the different characteristics of the study population, or the differences in available data or tools. Our results can guide researchers on this limitation; the robust metrics in terms of changing annotation criteria, such as the NPV of rare diseases, would be preferable for reproducing algorithms without shared annotation criteria. In addition, failure to share annotation criteria could lead to erroneous interpretations of published performance. For example, the precisions of the GB algorithm for T2DM were 39.3% different between th(1) and th(6) (Figure 4(i)).

We confirmed that these issues do not depend on the particular phenotyping algorithm; although only for essential HT, the decrease in recall by 50% from th(1) to th(2) was dependent on the GB algorithm. One simulation study showed that different gold standards led to the different sensitivity or specificity in diagnostic studies [22]. Our results were consistent with this, and presented the first assessments of the different gold standards led to the different performance. This is a critical limitation when other teams attempt to reproduce published performance for different datasets. Without detailed annotation criteria, other teams could not judge whether the different performance arises from differences in annotation criteria, the different characteristics of the study population, or the differences in available data or tools. Our results can guide researchers on this limitation; the robust metrics in terms of changing annotation criteria, such as the NPV of rare diseases, would be preferable for reproducing algorithms without shared annotation criteria. In addition, failure to share annotation criteria could lead to erroneous interpretations of published performance. For example, the precisions of the GB algorithm for T2DM were 39.3% different between th(1) and th(6) (Figure 4(i)).

We confirmed that these issues do not depend on the particular phenotyping algorithm; although only for essential HT, the decrease in recall by 50% from th(1) to th(2) was dependent on the GB algorithm. One simulation study showed that different gold standards led to the different sensitivity or specificity in diagnostic studies [22]. Our results were consistent with this, and presented the first assessments of the different gold standards led to the different performance. Without detailed annotation criteria, other teams could not judge whether the different performance arises from differences in annotation criteria, the different characteristics of the study population, or the differences in available data or tools. Our results can guide researchers on this limitation; the robust metrics in terms of changing annotation criteria, such as the NPV of rare diseases, would be preferable for reproducing algorithms without shared annotation criteria. In addition, failure to share annotation criteria could lead to erroneous interpretations of published performance. For example, the precisions of the GB algorithm for T2DM were 39.3% different between th(1) and th(6) (Figure 4(i)).
Because the annotation criteria are to be determined according to the research purposes, they will naturally differ among studies. Thus, sharing annotation criteria in detail is critical in reproducing EHR-based studies.

Limitations and future work

To assess our results’ generalizability, we must evaluate them with patients with other diseases at other hospitals in several countries. Lower weighted $k$ statistics would be obtained from this study. Nevertheless, when applying the same phenotyping algorithm to different datasets, the strength of our DA method will not change because it clearly shows that the different results will arise from the different characteristics of the study population, or the differences in available data or tools. Assessment of the impact of clinicians’ diagnostic errors is outside the scope of this study and must be done in the future work. We aim to evaluate phenotyping algorithms developed using other techniques. For machine learning, one study indicated that the precision was almost unchanged but the recall differed according to the different training data [21]; thus, different results would be obtained from this study. We will report on which elements used in the DA method can be extracted automatically in the near future. This will lead to a systematic strategy for the development of phenotyping algorithms [12].

Conclusion

Our results confirmed that if researchers do not share annotation criteria in detail for classifying possible patients separately from definite CASES and for classifying each type of possible patients, the characteristics of CASEs would differ among research teams; although phenotyping algorithms emphasize reproducibility, we cannot expect reproducible performance of the phenotyping algorithm. This was clinically rational for the four chronic diseases. In this study, we annotated EHRs using the DA method. This could increase reproducibility of retrospective EHR-based studies because it achieves annotations with low ambiguity by using information not directly referring to target diseases. We expect that our results will guide researchers on the reproducibility of EHR-based studies.

Analysis of Historical Medical Phenomena Using Large N-Gram Corpora

Zdenko Kasáč, Stefan Schulz

Abstract
Historically, numerous indirect references to real world phenomena have been conserved in literature. High-quality libraries of digitized books and their derivatives (like the Google Ngram Viewer) have proliferated. These tools simplify the visualization of trends in phrase usage within the collective memory of language groups. A straightforward interpretation of these frequency changes is, however, too simplistic to draw conclusions about the underlying reality because it is affected by several sources of bias. Although these resources have been studied in social sciences and psychology, there is still lack of user-friendly, yet rigorous methods for analysis of phenomena relevant for medicine. We present a methodological framework to study relationships of observable phenomena quantitatively over periods, which span over centuries. We discuss its suitability for knowledge extraction from current and future large-scale, book-derived, n-gram collections.

Introduction
It is a common in science for the phenomena of interest to be observed by proxy. Appropriate tools and methods are needed whenever direct measurement or inspection are unavailable or too complicated. A well-known example in the field of climatology is the analysis of ice core records for the estimation of atmospheric carbon dioxide [1]. Measuring the proportion of air gases trapped in polar ice allowed approximating parameters of atmospheric conditions along the last 800,000 years. Such information has redefined our understanding of the Earth’s climate. In this case, nature did the scientist’s job of archiving samples of air for hundreds of thousands of years, until our species developed and created a method to analyse the precious archived sample bank.

We seek to develop an analogous method for studying relevant phenomena for medicine and health. The described method would be also easy to exploit in other fields, e.g. in social sciences. A phenomenon might be anything (e.g. event, thing, situation, idea or sensation) that might be observed. On one hand, using the current epidemiological tools to research past phenomena would introduce recall bias and hide many environmental exposures because one simply forgets what happened many years ago. In other words, asking individuals about their exposures much earlier in their lives just would not work. For similar reasons, asking the respondents about the risk factor exposure of their great-grandparents would not work at all. It is therefore hard to analyse long-running health-related phenomena of the past directly. On the other hand, the extraction of retrospective data from medical records is overly limited, because the current form of medical documentation is recent, having started approaching its current form only in the run of the last century [2]. In addition, medical language has constantly evolved, as did the concepts in physiology and pathology. Many aspects of health today considered important, and thus relevant for research, were granted low priority in earlier decades. Diagnostic criteria frequently change, and diagnostic tools evolve rapidly, which further complicates the evaluation of long-term epidemiological data. Finally, the availability of medical care constitutes an additional bias whenever studying medical records.

Therefore, to approximate and plot the temporal change in presence of a phenomenon, a source of coherent data is required. An ideal source must retain six properties of the ice core, viz. i) Populated with contemporary data; ii) Conserved unchanged until analysed; iii) Sufficiently large for an evaluation iv) Attributable to a certain population; v) The circumstances of data entry are homogeneous; vi) The process of data entry is self-organized, not institutional (to avoid group bias).

It seems that such a dataset exists. It is scattered across the world in the form of books in libraries. These books were written by authors who unwittingly – associatively (in fiction) or deliberately (non-fiction) reported on what they themselves saw/experienced (direct) or heard/read about (indirect observation) prior to writing. Once the books are digitized, their content can be reprocessed into databases of yearly n-gram frequencies [3]. By “n-gram”, we mean a space-delimited sequence of 1-grams. In this text, we use l-gram interchangeably with token to denote a string of characters not separated by a space – mostly a word like “syphilis” or “antibiotic”. Regarding syphilis, Figure 1 depicts the frequency of its mention in literature, growing in the era of industrialization and peaking during wars, accompanied by its then most popular mercurial therapy. Both the disease and the useless therapy were slowly extinguished after the discovery of penicillin.

![Figure 1 – The three plots, each sum of n-gram frequencies, from top: syphilis; traditional therapy; and effective therapy.](image)

In the following, we propose and discuss a method to study real-world phenomena by systematic analysis of their mentions in literature over time. After cautious exclusion of potential confounders, we expect this mirroring in literature can be used for a quantitative visualization of the change in the real-world presence of certain phenomena – e.g. illnesses, observable factors of environment, etc. – as shown in the following.
Methods

Source

We used the freely available English (E), German (G) and Russian (R) Google Books n-gram data (V.20120701) as an input for used examples, documented in each caption as Src:E/G/R. Just the English version of the library used to create the Google n-grams contained 361 billion words derived from a nearly 5.2 million books large subset of Google Books library – approximately 4% of all books ever published [4]. The creators of Google Ngram published descriptive statistics of 1-grams, 2-grams, 3-grams, 4-grams and 5-grams (text fragments, which contained 0-4 spaces) in these books. This resulting n-gram database consists of yearly counts of every n-gram and counts of books containing it. Our method requires precise metadata of the resource, in particular, precise publication date. Some kinds of publications notoriously contain older text, thus their publication date is imprecise. An example of these are periodicals and books that aggregate more works – such as anthologies or collected works by a given author. To improve the accuracy of the publication dates the corpus the creators had removed these. After the filtering, a sample of book metadata had been verified by a human annotator (n=1000, sampling five books for every year between 1801 and 2000) and the rate of books with a publishing date outside a five-year range of tolerance was found to amount to 5.8% [4]. Though not required for the proposed method but justified by the propaedeutic character of this paper, we selected only few marker n-grams for the examples. In most cases, we averaged data over three years for our figures. If the span of moving average differed, we specified it in the caption (as MAavg=n), where n is the number of years. As explained later in this section the absolute ordinate value (n-gram frequency) is not relevant and is therefore usually relative, but always of linear scale starting from zero.

There is a broad topic spectrum of books in libraries and they do not come from a single group of authors. We appreciate this as such “institutional” origin could amplify group think bias [5]. There is yet another reason why we prefer books to news articles or abstracts of research papers: Due to Heaps’ Law [6], the longer the text (book vs. article), the higher the number of distinct n-grams in it. Similarly, also the number of topic-unrelated reports will follow the text length sub-linearly.

Arguably, trends in word usage are not merely due to phrases and words going in and out of fashion as seen in Figure 2. It is also, because their referents (the real-world phenomena) change in frequency and salience. Huge amounts of data have been generated by analyses of millions of digitized books [4]. The data has been applied in other fields, such as in language research [4, 7-8] , social sciences such as measuring social functions and even predicting wars [9-10] and in psychology for measuring emotions, individualism or misery [11-13]. Yet it has remained virtually untouched by medical research.

One might wonder why this opportunity has been missed – it could have at least served as a cost-effective tool for the generation of population level hypotheses or for further observation of already known causal relationships.

There are objective reasons for this mistrust. Apart from its novelty, it may be explained by the uncertainty about whether the detected trends and correlations in word frequencies are really caused by the (i) changes in the domain of reference (real-world phenomena), or by (ii) linguistic and other confounders (Figure 2). We will discuss both in the following.

The division we just introduced is slightly different but not entirely unlike the division provided by Michel et al. [4] into “two central factors”: (i) cultural and (ii) linguistic change, such as the changing likelihood the author describes the referent by “X-ray” vs. “radiogram” [8]. We had to define these groups differently, as many cultural factors – albeit important for others – confound or hide what we seek.

Let us shortly discuss the major linguistic origins of signal cancellation, noise or confounding. Aside from new words coming (word birth) to compete and eventually replace the current ones (which might face word extinction) just like seen in Figure 2, they might acquire new spellings or meanings, lose old referents and undergo shift in their meanings (see Figure 4). Interestingly, not only vocabulary gradually changes, so do parameters of the language dynamics. To provide an example, in Figure 3 we show a marked shortening of our collective working memory over the past two centuries. This supports the finding reached by other means by Petersen et al. [8]. Although we do not expect this to interfere with the method, it might still be important to keep this plot in mind when interpreting any trends in n-grams generated from that period.

![Image](https://via.placeholder.com/150)

**Figure 3 - Frequencies of 9 strings marking years starting with “1793” by increments of 20. A linear coefficient was used, so that the peak of each string would reach f=0.014%.
**The black dots that follow each peak show inverse values of the coefficient used (roughly approximating the original amplitudes). The time for the recall to fall to 25% of the peak frequency notably shortens over the last 200 years. Apart from the “shortening of recall” a common “oscillation in recall” of these markers with a period of 20-25 years is visible. (Src:E).

In order to study the underlying real world phenomena, we should suppress the confounding linguistic effects. We can do this by appropriate selection of only high-precision marker n-grams, as described in the following section. Afterwards, we can approximate the environmental factor – the phenomenon.

A phenomenon in a domain is mirrored in literature by a marker set = a set of high-precision marker n-grams. E.g., phenomena of means of transportation in the real world are mirrored in books by a marker set Src:means of Transportation = Smot:

Marker set is not to be confused with the term topic used in n-gram analysis by others [14-15]. While a topic is defined by a group of n-grams that denote various phenomena and which typically occur together in a discourse on a theme, a marker set includes only the tokens that have a high precision (not just recall or sensitivity) in denoting the phenomenon of interest.

In our example, we assign a few case-insensitive strings to the example marker set for “Means of transportation” (Smot):
We used “...etc.” as a wildcard for further possible marker subsets (\(S_{\text{Mot}}\)) or n-grams, such as “travel” or “transport”, which have good precision to \(S_{\text{Mot}}\) but do not fit in any of the subsets. In contrast, a token like “balloon” would not properly fit into \(S_{\text{Mot}}\). It is imprecise for \(\text{MoT}\) because it could just as well denote a hot air balloon as an inflatable toy balloon.

N-grams belonging to a marker set can be assigned to categories called subsets (sS). We demonstrated this by dividing the set \(S_{\text{Mot}}\) into the following subsets and populating them:

\[
S_{\text{Means of transportation}} = S_{\text{Mot}} \begin{cases} 
S_{\text{Human-powered MoT}} \\
S_{\text{Animal-powered MoT}} \\
S_{\text{Motor-powered MoT}}
\end{cases}
\]

Some of the n-grams truly belong to a marker set only during a certain era; e.g. more and more bicycles are now equipped with an electric motor. Therefore, if we are to define a subset: sSExclusively Human-powered, we would have to replace “bicycle” with a higher-precision synonym, or alternatively, limit the analysis to the time when “bicycle” meant solely an exclusively human-powered vehicle. For this reason, it is important to state the mutual exclusivity of the marker subsets.

A typical example of an n-gram unfit for a marker set due to a non-intuitively low marker precision is “rigid bronchoscope”, shown in Figure 4b. Since the introduction of bronchoscopy until 1960s, all bronchoscopes used to be rigid. In spite of this, or better to say: exactly for this reason, the term “rigid bronchoscope” did not need to exist. With introduction of fibre optics, flexible bronchoscopes became standard. To denote these flexible ones specifically, authors could now use terms “bronchofiberscope” and “flexible bronchoscope”, but often, they would use the umbrella term. Due to this bandwidth steal, the “flexible bronchoscope” seems to be less frequent. Similarly, the name “First World War” (instead of “Great War”) came to use only after advent of the Second World War – when a distinction was required. Such terms might decrease recall.

Now it is clear that for an n-gram to be added to a set, it must have a high marker precision – not to be confused with meaning precision, the mere absence of polysemy. Marker precision is a property of an n-gram that defines how well it reflects the phenomenon of interest across the whole period of analysis, by its frequency change in a given corpus, without detecting unrelated phenomena. If only highly precise marker n-grams are present in the set, the set will mirror its phenomenon in a reliable way.

Non-precision might be also constant in time. This applies also for “disease” (see Figure 4a) which is astonishingly unspecific to human health, being also used for plants and animals. In contrast, the less popular “illness” shows both meaning and marker sensitivity to human medicine. We show another example in Figure 5, which highlights how cultural and political differences between the studied language groups have to be accounted for, like state censorship in the Soviet Union.

![Figure 5 – The effects of politics on the literature [until 1917], first mentions during the February Revolution (blue), “особный рынок”, Src: R] and soaring interest in the following 8 years, immediately interrupted in the year of Lenin’s death (1924). In red is the English “free market” (Src: E) which continued rising steadily until the mid ’90s. (MAvg=1)

In the following paragraphs, we explain the steps by which noise and confounding effects can be minimised. As a result, the marker sets and subsets should be “clean” enough to relate quantitatively to the changes in the underlying phenomena.

**Data pre-Processing**

**Creation of the “candidate” n-gram sets and subsets:**

After selection of the phenomena for the observational analysis, we can define the future marker sets and subsets for these; e.g. as shown above: \([C_{\text{MoT}}, sC_{\text{H-MoT}}, sC_{\text{H-MoT}}] \text{ and } sC_{\text{H-MoT}}\).

**Mechanistic token selection [inclusion criteria]**

Here we describe how to populate the main candidate sets of n-grams by potential marker n-grams. Then we propose how these could be cleaned from “noisy” n-grams by applying exclusion criteria on each of the “candidate” n-grams.

Firstly, we select the potential marker n-grams by:

1. extraction from defined and cited literature,
2. search of a comprehensive dictionary or thesaurus,
3. variation of the grammatical or lexical form,
4. a proposal from any of the co-authors, validly argued by the rules 1-3, and/or validated through full-text analysis.

Even though meaning precision mostly implies marker precision, this is not always the case. As an alternative to the “mechanistic” selection of words described above, in some contexts it would be also viable to use token selection by questionnaire as done by others [13]. This approach is more useful for hard-to-define parameters or phenomena, such as emotions, attitudes or concerns because we cannot easily extract these from a dictionary. Even here, it must be reflected that like any other dimension of language these parameters are subject to change. If a word, such as “terrific” is charged with a positive emotion in 2016, this does not necessarily imply it was positive in 1916.

**Definitions**

In the next step, the timescale of analysis is defined and exclusion criteria are defined, which must filter out:

1. N-grams discovered that frequently denote unrelated phenomena (homographs) or have low precision.
2. N-grams with a high noise to signal ratio, as with rare n-gram tokens or in older books due to OCR errors. Where needed, the manual verification of precision for an n-gram might be performed by human annotator on a sample of full-text books – similar as performed by Michel et al. [13].

Analysis
A measurement of n-gram frequency in a single point in time does not predict the contemporary expression of the related phenomenon in the real world by itself. It is also influenced by the salience of the phenomenon and the popularity of a given expression at that time. This introduces noise and makes a trend of the single marker n-gram hard to interpret. The shifts in popularity and the resulting noise can be suppressed by using the marker sets, thanks to the increased sample size.

As only the dynamics of the frequency of an n-gram tells the interesting story, the absolute amplitude of its trend is irrelevant for our analysis. We can linearly scale it without interference. In other words, the information is in the shape of curve, such as the positions of the local maxima, minima and trends. To extract knowledge, we propose the following approach.

For the first of the marker sets to be quantified (the reference set, usually the simplest one) and its subsets; if any, the plots of the member n-grams are added by simple summation.

Linear Fitting
Firstly, we plot the frequencies for each n-gram that belongs to the other sets (referred to as independent sets). We adjust their amplitudes by mutually independent coefficients, defined by a fitting algorithm. This algorithm uses the linear (!) coefficients with the goal to find the best alignment of the independent set to the reference set – measured by G (goodness-of-fit, see the section: Measurement).

If studying causalities with delayed effects (Figure 7), a proper adjustment of a whole (sub-) sets on the x-scale may be required as well, before proceeding with the following section.

Measurement
Now as we have fitted the curves of the independent sets $S_i$ (or sets) to the reference set $S_0$, we can measure two parameters. The first parameter is the goodness-of-fit ($0 < G < 1$). For a curve of each set $S_i$ (or subset $sS_i$), the area under its curve $A_i$ (or $A_{i,c}$) is calculated. We define the goodness-of-fit as:

$$ G = \frac{A_{S_0} \cap A_{S_i}}{A_{S_0} \cup A_{S_i}} $$

An ideal correlation of two marker sets would have a goodness-of-fit $G=1$. Furthermore, a value of $G$ for a set compared with a constant function (e.g. $x=1$) presents a calibration value $G=1$ for the given set. $G=1$ means “exactly no measurable association”. $G$ lower than the calibration value is a negative correlation, higher $G$ is a positive correlation.

The second parameter, called share, can be derived if $G$ is close to 1. We define it as the fraction of the height of the reference set made up by a fitted independent subset in a time point. This correlates with the partial association of the respective sub-phenomenon (a category) in the respective time. Thus, we can use it to reflect a partial influence in case of a multifactorial causal relationship.

Results
In Figure Six, we compare asbestos use according to CDC with the frequency of mentions of asbestos cement in literature. The similarity of shape (growth in 1910, 1920s, and 1940) is still clear. Unlike the CDC data above, the mentions of “asbestos cement” are not limited to industrial and construction use of asbestos. The n-gram data can also report on demolitions, encounters in environment, daily use, etc. These would well explain the asynchrony in curve descent as even nowadays it is easy to come across aged asbestos containing materials. On the other hand, our single token did not account for other uses than reinforcement of concrete (such as braking systems, stove lining, etc.). Analysis using more n-grams would address this.

Here comes up another aspect, viz. a possible amplification of “asbestos cement” by medical and legal literature over the last decades. The recognized causality causes a backwards flowing influence, where these terms do increasingly co-occur. Unlike the underlying aetiological connection, which is delayed, this amplification is immediate: when an author states that a mesothelioma was caused by exposure to asbestos cement. Two possible solutions are at hand: i) to use a resource that allows for excluding books containing both n-grams, thus suppressing the effect, or ii) to limit the inference to the “naive” era, when the causality was not widely known. Not doing so would decrease sensitivity of the method and the goodness-of-fit.

To extend the example of asbestos, we used two simple sets $S_0$ and $S_0$ (see Figure 7) on a different population (German language group). Here, the patterns expected for this causality are obvious. There are three major peaks in frequency of the marker set $S_0$ (1913, 1937, and 1996). For mesothelioma, there are two peaks (1962, 1978) followed by a rising trend filling the last 2 decades of this plot. German epidemiological data confirm this late growth [17]. More interestingly, the two peaks for the marker set $S_0$ follow first two peaks of marker set $S_0$ with a lag of 49 and 41 years, respectively. This is in accord with the generally accepted latency of incidence for this malignancy between 40 and 50 years [17–18]. We expect the next peak of $S_0$ between 2036 and 2046.

Discussion
The precision of the method critically depends on the elimination of unrelated influences. Therefore, very popular but lexically ambiguous (homonymous) tokens need to be sacrificed (Figure 4a). Even when excluded, these n-grams might soar in...
popularity at expense of used markers, which could lower the sensitivity. Thus, in the language where this happens, correlations of certain phenomena might stay hidden (false-negativity). There is certainly much space for improvement of the existing n-gram corpora, as pointed out by Pechenick et al. [19]. One of the good critiques raised, is that the dataset does not measure true popularity of ideas, but the frequency with which they are generated [19]. In our case, what is bug for culutromics becomes a feature: popular beliefs and fashions would only confound what we study, viz. the incidental observations by authors of books, whether related or unrelated to the topic or author popularity¹.

A second critique raised against the Google n-gram corpora, less relevant in our context, points out the unequal distribution of popular vs. scientific content underlying the English corpus [19]. For our goal, the genre is of little importance if the size of a sampling unit (length of book vs. article) is retained and attention to corpus homogeneity is paid when highly technical terms are used as marker n-grams for observations. An unequal genre/topic distribution could interfere with the sensitivity of this method. However, we doubt the validity of this criticism; namely, we doubt that there is indeed a growing fraction of scientific literature in the 2012 English n-gram resource. A simple search in English Fiction for the token “research” shows a steep and continuous rising trend for the entire 20th century. This suggests that the growth might not stem from a sampling error but rather from a similar culturological process as shown in [10] – a social function shift in favour of research.

A more relevant critique points at the OCR errors, which are quite prevalent in the pre-1800 texts [4, 19]. This may be improved in the future by more reliable OCR techniques. In this case, which would enable digging far into the past, new evidence regarding lexical changes, social stigmatization, censorship etc. may be found.

Conclusions

We described the main issues in the extraction of information about observable real-world phenomena from changes of n-gram frequencies in large time-indexed n-gram corpora, with the focus on establishing a standardized method for exploitation of these data in, but not exclusively, the public health research. We plan to make a user-friendly tool based on this method available to other researchers and authors.

We demonstrated some of the possible applications on examples of use relevant for the public health and we have shown how already some very simple marker sets might well reflect the related real-world phenomenon in its parameters.

¹ Maybe this text does not really belong to the “culutromics” field created by the authors of the NGram Viewer, as the culture is not our focus. Thus, a better fitting name for this approach would be “exponential” as it examines the observable exposures of a population (the “exponente” of a population - as opposed to the exposome, which measures all the exposures of an individual).
An Incremental Adoption Pathway for Developing
Precision Medicine Based Healthcare Infrastructure for Underserved Settings

Abstract

Recent focus on Precision medicine (PM) has led to a flurry of research activities across the developed world. But how can understaffed and underfunded health care systems in the US and elsewhere evolve to adapt PM to address pressing healthcare needs? We offer guidance on a range of sources of healthcare data / knowledge as well as other infrastructure / tools that could inform PM initiatives, and may serve as low hanging fruit easily adapted on the incremental pathway towards a PM based healthcare system. Using these resources and tools, we propose an incremental adoption pathway to inform implementers working in underserved communities around the world on how they should position themselves to gradually embrace the concepts of PM with minimal interruption to existing care delivery.

Keywords:

Precision Medicine; Vulnerable Populations; Health Information Systems.

Introduction

The need to offer providers a more complete picture of an individuals’ health has led to the advent of precision medicine (PM), which is defined as an emerging approach to optimize clinical decision-making by taking individual variability in genes, environment and lifestyle into account [1]. By harnessing measurements from multiple modalities such as clinical and genomic evaluations, environmental exposures, behavioral patterns, and many others, we can develop a far more comprehensive view of the patient’s health status and its trajectory over time.

Despite the recent emergence of the PM initiative, its core underlying principals have been known for decades [2], and manifested over the years in various forms such as personalized medicine [3] and the learning healthcare system [4]. Further, PM inspired activities such as the delivery of patient specific allergy alerts [5] and tailored immunization guidance [6] have been routinely used for many decades. A notable difference between these and more recent PM initiatives is the intensified focus on so-called “-omics”: which includes the study of a body of information such as the genome, proteome, metabolome (metabolites), transcriptome (RNA transcripts), autoantibody profiles, etc., [7] made possible by the sequencing of the human genome [8] and rapid advances in high-throughput laboratory technologies and systems approaches across the fields of computer and biological sciences [9].

While -omics based therapeutics have gained widespread publicity and demonstrate significant potential [10], there remain barriers to translating and broadly implementing these discoveries in the care delivery process. For example, -omics based PM therapeutics are expensive and resource-intensive activities that currently are ill-suited for large-scale clinical care [11,12] because breakthroughs in many -omics based therapeutics will not be available for use until research and discovery activities progress over the next 5 - 10 years [13].

By definition, the scope of PM is much larger than -omics. PM promises to provide a more complete picture of an individuals’ health by capturing actionable information detailing individuals’ health status and their socioeconomic context to inform provider decision-making. Thus, the core concepts of PM are relevant to modern medical care and beneficial for both developed and underserved settings. Examples of easily implementable low cost PM-based care that do not rely on -omics based data include the identification of high-risk patients based on socioeconomic factors and the detection of adverse drug events based on demographic and racial/ethnic factors.

While -omics based PM initiatives are typically cost intensive and, thus, currently unsuitable for widespread use, the overall aims of PM are relevant and invaluable for healthcare delivery. Thus, all healthcare systems, even those of the underserved world, stand to learn from this approach. Recent focus on PM has led to a flurry of research activities across the developed world. How can understaffed and underfunded health care systems in the US and elsewhere evolve to adapt PM to address pressing healthcare needs? Which PM based solutions are most suitable for use across underserved settings, if any? Also, which needs should be prioritized as implementers begin the thought process leading toward a PM based healthcare system?

We advocate that PM is heavily dependent on leveraging both novel and existing data and knowledge sources to ensure the accessibility and availability of information surrounding an individual and their environment. Thus, not all PM based activities may be cost and resource intensive. In this paper, we offer guidance regarding the wide range of sources of healthcare data and knowledge, as well as other infrastructure and tools that could inform PM initiatives. Such elements may serve as low hanging fruit easily and incrementally adopted on a pathway towards a PM based healthcare system. Using these resources and tools, we propose a progressive adoption pathway to inform implementers across the underserved world on how they should position themselves to gradually incorporate the principles of PM with minimal interruption to existing healthcare delivery.

Methods

We identified data and knowledge sources that could be
leveraged to support PM-based care delivery based on findings of the Precision Medicine initiative cohort program [14] and seminal publications [1,15,16]. However, these cannot operationalize PM based care without appropriate supporting systems and processes. Thus, we also identified a list of key infrastructural components that would enable the use of data and knowledge sources for delivering appropriate PM based care.

Next, based on our own expertise and these seminal publications, we sought to describe an incremental adoption pathway for underserved settings that seek to adopt PM initiatives by proposing when each of the aforementioned data, knowledge an infrastructure components should be integrated into exiting healthcare systems. We considered five criteria to evaluate where each component fit into our proposed adoption pathway:

1. The availability of robust technical tools / platforms for ready use (Availability): Are mature toolsets with demonstrated evidence of use available for adoption?
2. The level of provider and user education / training required for adoption (Workforce capacity): Does the tool/approach require specialist technical skills? How difficult is it to manage and operate these systems?
3. The practicality of integrating it into the existing health ecosystem and workflows (Integration to healthcare): Can the component be feasibly integrated into existing/emerging infrastructure? Will it lead to disruptions, and does it require significant behavior changes for use?
4. Cost burden/sustainability: How sustainable is care delivery using these new components?
5. Clinical impact: Does robust evidence indicate this element meaningfully improves clinical outcomes?

We adopted the ThoughtWorks Technology Radar (TTR) [17] to present our incremental PM adoption pathway. The TTR is a living document prepared by the ThoughtWorks Corporation, a leading software development company, to assess the risks and rewards of existing and nascent technologies, and the strategic importance of each of these for their organization at a specific point in time. TTR presents a concise overview of techniques, tools, platforms/languages and frameworks (four quadrants of a circle), and recommend their strategic importance to technology organizations by allocating each of these to one of four bins - adopt, trial, asses and hold (four concentric rings of a circle). Given its intended purpose, TTR has won widespread interest across the technology industry. Its ability to represent the changing technology landscape also makes it ideal for visualizing the evolving PM domain.

In adopting TTR for our own needs, we modified it as follows. Rather than the four quadrants presented in the TTR, we propose three slices (data, knowledge and infrastructure) that are more suitable to represent the needs of PM delivery. (b) Rather than the four rings presented in the TTR, we presented three: Adopt (highly significant components that must be adopted immediately), Aspire (components that should be focused on only after the adopt phase is competed) and Hold (components that should be held off for a future date where further advances are made). We selected these rings as they better represented the needs of a rapidly evolving healthcare system and stakeholder needs.

As our model is intended to represent a static snapshot the current state of PM-based research, and not serve as a ‘living document’, we will forgo TTR’s ‘new’, ‘moved’ ‘or no change’ icons to indicate how the influence of each component has shifted over time.

Results

Various components and their adaption

We identified the following data components (Table 1), knowledge components (Table 2) and infrastructure (Table 3) as necessary for enabling PM based care systems. The information presented in Tables 1, 2 and 3 were fit into a PM technology radar (Figure 1) based on the five evaluation criteria presented above. The PM technology radar is comprised of three slices (data, knowledge and infrastructure) and three concentric circles (adopt, aspire and hold).

Description of the PM Technology radar

The Data Slice

As step 1 we recommend collecting various unstructured and structured clinical data from EHR, PACS and LIMS systems that may already co-exist within a healthcare facility. As step 2, we recommend investigating and integrating other healthcare data such as various registries and other geospatial information sources that may already exist outside the borders of the immediate healthcare facility. This facilitates the use of non-clinical socioeconomic and public health data that could be used to paint a better picture of patients’ overall health. Step 3 consists of -omics data and personal data sources such as social networks and smart phones, wearable and home based devices. We also note that some data types such as patient demographics and contact information may be obtained from multiple sources that belong to different stages. In such an event, we recommend that data sources are adopted incrementally over each stage, with patient demographics captured from EHR systems in stage 1, and gradually supplemented with registry data during stage 2.

The Knowledge Slice

We recommend adopting drug-drug interaction information as step 1. All other knowledge sources are based on -omics, and thus, should be held off until step 3.

The Infrastructure Slice

As step 1, we advocate adopting core health IT components such as EHR, PACS and LIMS systems, together with medical terminology/vocabularies and messaging standards for collecting clinical data. Step 2 consists of incorporating different health infrastructure components that together, form a robust health ecosystem; ideally a fully functional health information exchange. We recommend that -omics based infrastructure components be placed on hold, to be enabled together with genomic based data and knowledge sources after appropriate advanced are made in the field.

Discussion

Enabling PM based care systems can be seen as two distinct but related challenges: (a) optimizing the use of existing sources of readily available data and knowledge spread across clinical, socioeconomic, and public health spheres, and (b) the integration of -omics based therapeutics and other data obtained from smart devices and additional sources outside of the traditional healthcare delivery domain.

A fundamental requirement for all PM-based systems is the efficient management and use of structured information to inform providers’ view of patients’ health status. Thus, basic EHR systems that are widely used within underserved settings can serve as an initial stepping-stone on the incremental pathway toward building a more complete PM based healthcare system. To ensure comprehensive adoption of PM-based systems, readily obtainable clinical and behavioral data must also be sustainably captured and appropriate infrastructure components must be built to ensure that this data, together with additional sources of knowledge, are available for actionable use.

In evaluating the PM technology radar, it is evident that our selection of priorities for each step matches a specific pattern; the collection of data, knowledge, and infrastructure defined as step 1 (adopt) implies that the first step in enabling PM based care delivery lies in consolidating standardized data collection within a healthcare facility. As per figure 1, it is also evident that a significant portion of infrastructure resources should be implemented during the early stages of the process, as terminology and messaging standards are crucial to ensure standardized data collection.

The components assigned to step 2 (aspire) characterize expansion of data collection to resources that may lie beyond traditional disconnected healthcare facilities and towards a greater Health Information Exchange (HIE) spreading across a larger demographic area and resources. Adopting an HIE represents significant investment. However, many tools and platforms that enable HIE-based infrastructure have been in existence for years, and are available free of charge [24].

There is also significant value in shifting towards an HIE as these components can contribute to, and inform many other needs beyond PM based care delivery. In comparison, resources identified as step 3 (hold) represent a consolidation of -omics and other resources that have the potential to significantly impact healthcare delivery, but are too immature and/or expensive for adoption at current time.

The PM technology radar also indicates that for underserved settings, early efforts should focus on using PM based initiatives to improve more common care delivery needs such as identifying patients at higher risk, better clinical decision support and medication adherence, as opposed to introducing new treatment processes for specific and less common diseases.

While strategies for adopting resources defined under step 1 are increasingly well understood, step 2 may not be as simple, and would require significant buy in and policy changes. Our approach includes significant emphasis on realizing a concordant HIE. However, this may be restricted by national or regional scale policies or law. For example, U.S. legislation bans creating a unique national patient identifier that could be used to effectively identify patients across the healthcare ecosystem.

Our reasons to delegate -omics based therapeutics as 'hold' for underserved settings are manifold, and based on practical, financial and policy based limitations rather than disagreement on the benefits of PM. Currently, genomic testing is available for approximately 2,000 clinical conditions in the U.S., and the number of available diagnostic tests is increasing exponentially [16]. However, genetics are only responsible for 20% of an individual’s overall health status. Healthy behaviors (50%), environment (20%) and access to care (10%) pose significant impact on health, and are also relatively cheaper and easier to adopt [25].

Further, existing health information systems may not be geared to manage -omics based care. Research suggests that EHRs have poor support for online test ordering and provide limited decision support for genetic testing, interpretation of test results, and potential impact of results on patients and their families [26]. There is also significant need to develop, deploy, and adopt data standards to ensure data privacy, security, and integrity in managing PM based care delivery across these systems [27].

-Omics based treatment also raises significant questions regarding patient confidentiality and health payer rights and policies. In the U.S., these concerns led to the signing of the Genetic Information Nondiscrimination Act (GINA) [28]. However, other countries have been slow to follow. Given these considerations, and that projection that -omics based PM initiatives focused on discovery of disease risk factors, pharmacogenomics, disease biomarker discovery, loss-of-function mutations, new classification of diseases and clinical trials of targeted therapies are not expected to be realized over the next 5 to 10 years [13], we recommend that these components are placed on hold.

The use of smart devices for fitness and monitoring purposes is enjoying significantly greater interest and adoption in comparison to -omics based resources. However, we have assigned it to step 3 (hold) as; (a) smart devices do not contribute as significantly as other components and resources. These data often may also be collected via EHR systems or questionnaires, thus reducing their value; (b) despite tremendous interest, smart devices have not matured adequately to be robustly integrated with healthcare infrastructure, and may lead to security vulnerabilities. However, we acknowledge that smart devices present considerable potential, and may be moved to step 2 shortly.

Conclusions

The advent of PM represents the continuation of research
principals that have manifested in many forms over recent decades. Despite overemphasis on -omics based therapeutics, effective PM based care delivery also involves the efficient use of existing sources of clinical and public health data that are less expensive and easily integrated into existing healthcare infrastructure, and thus serve as 'low hanging fruits' for managing PM based care delivery. We present a PM technology radar that informs implementers on how they could gradually shift towards enabling better PM based care delivery.

Diagnostic Machine Learning Models for Acute Abdominal Pain: Towards an e-Learning Tool for Medical Students

Piyapong Khumrina, Anna Ryanb, Terry Juddb, Karin Verspoora

* Dept of Computing and Information Systems, School of Engineering, University of Melbourne, Melbourne, Australia.
b Dept of Medical Education, Melbourne Medical School, University of Melbourne, Melbourne, Australia

Abstract

Computer-aided learning systems (e-learning systems) can help medical students gain more experience with diagnostic reasoning and decision making. Within this context, providing feedback that matches students’ needs (i.e. personalised feedback) is both critical and challenging. In this paper, we describe the development of a machine learning model to support medical students’ diagnostic decisions. Machine learning models were trained on 208 clinical cases presenting with abdominal pain, to predict five diagnoses. We assessed which of these models are likely to be most effective for use in an e-learning tool that allows students to interact with a virtual patient. The broader goal is to utilise these models to generate personalised feedback based on the specific patient information requested by students and their active diagnostic hypotheses.

Keywords:
Decision Support Systems, Clinical; Formative Feedback; Artificial Intelligence

Introduction

Diagnostic reasoning is the cognitive process of deriving a correct diagnosis from a patient’s presenting clinical problem. The development of diagnostic reasoning skills in medical training starts with a disease-oriented approach by learning common presentations of different diseases [1]. Given this knowledge, students approach patients with a presenting problem and hypothesise the most likely diagnosis. They gather patient information through the steps of history taking, physical examination, and consideration of the results of laboratory procedures and other investigations. Students accumulate the information to prune and prioritise possible diagnoses until they get to a final diagnosis [2]. During medical training, students practice diagnostic reasoning skills with patients under expert supervision, called “bedside teaching”. Students gather patient information and present their diagnostic reasoning to the expert. The expert identifies errors, misconceptions and inadequacies and formulates suitable feedback to help students to reconstruct their knowledge [3]. Personalised feedback is a key element of learning and instruction [4-6] and bedside teaching is known to improve diagnostic reasoning skills. However, its use is declining due to a range of factors, including increased patient turnover, concerns with patient privacy, increased technology in the diagnostic process, increased numbers of students, and limited availability of experts [7; 8].

E-learning systems can help to address some of these challenges and when used effectively, in conjunction with traditional approaches, can aid in the development of diagnostic reasoning skills [9-11]. However, tailoring the feedback from e-learning systems so that it is both effective and fits the needs of individual students is difficult [4; 12]. Effective feedback should help the student to identify what they already know or have mastered, where potential knowledge gaps or misconceptions lie, provide an indication of their learning progress, and support them to achieve their learning goals [13].

Clinical Decision Support Systems (CDSS) are computer systems that assist doctors to make decisions and are typically used in either the diagnostic process or to support clinical management. CDSS synthesise information based on patient data and use the information to generate a prediction. Prior research has demonstrated that using a CDSS to assist physicians’ diagnostic and treatment processes can improve both the effectiveness and efficiency of patient care [14-16], a clear example being the management of acute abdominal pain [17]. Applying the concept of a CDSS, we aim to use machine learning models to produce personalised feedback within an adaptive game-based learning tool intended to support the development of medical students’ diagnostic reasoning and decision-making skills. The learning tool will allow students to interact with a virtual patient, and revealing relevant patient information and diagnostic predictions in response to the students’ actions and requests.

This paper presents the development of the machine learning model that underpins the e-learning tool. It describes the collection and processing of a large corpus of patient data, and the development, training, testing and comparison of alternative machine learning models based on these data. A preferred model is identified and the rationale for its selection in the context of the e-learning tool explained. We also discuss how this model may be leveraged within the tool to generate personalised and appropriate feedback for medical students.

Methods

Phase 1: Data collection

Electronic patient records were collected to train the machine learning models. We captured and processed de-identified medical data from three disparate but complementary sources; 1) Student log cases 2) Student entered Electronic Health Records (created by medical students at our university as part of their course and stored within their curriculum delivery system 3) Electronic health records within the public hospital affiliated with our university’s medical school. The data were used to develop clinical scenarios to be presented within the learning tool and to train machine learning models for the learning tool’s embedded CDSS. All data collection was approved either by our university’s Health Sciences Human Ethics Sub-Committee or by the affiliated hospital’s Human Research Ethics and Research Committee.
Phase II: Case selection

We selected cases from the electronic systems with the following inclusion and exclusion criteria:

**Inclusion criteria**
1. A principal diagnosis of one of five key conditions (appendicitis, gastroenteritis, urinary tract infection, ectopic pregnancy, or pelvic inflammatory disease).
2. The treatment protocol for the principal diagnosis was completed.

**Exclusion criteria**
1. More than one of the conditions of interest were diagnosed in an individual patient in the same admission.
2. A previous history of other conditions or procedures or treatments that would rule out one or more of the key diagnoses (e.g. appendectomy for appendicitis).

Two hundred and ninety-eight clinical cases were identified by applying the query criteria. Ninety cases were excluded leaving 208 valid clinical cases (see Table 1).

Phase III: Data pre-processing

PK manually extracted data from the selected cases and transformed the information into an array of features. Seventy-five features were extracted from history taking (n=48), physical examinations (n=13), laboratory and investigation results (n=13), and a target class (n=1).

Phase IV: Machine learning training

We used pre-processed clinical features from Phase III to train machine learning models for classifying the features into one of the five target diseases. We utilised Weka version 3.8 [18] for the training process using 10-fold cross validation on a training set to evaluate alternative algorithms: testing Naïve Bayes, Support Vector Machine (SVM), Neural Networks (NN), C4.5 decision tree (J48), and Logitboost (using DecisionStump as a classifier). We used the correlation attribute evaluation to rank the level of feature relevance to predict a diagnosis. We intend to use one or more of the machine learning models to predict diseases when students raise possible diagnoses on the basis of clinical observations. We plan to transform the prediction of the classifier to a suitable form of feedback to represent the likelihood of diagnosis based on present findings. The rank of a given feature’s relevance in the model will be used to guide students’ feature selection.

We grouped the target classes in two ways. First, we treated the entire dataset as a single group and targeted classification of the five diseases considering all diagnoses together, which is a “multi-class classification” scenario. Second, we divided the target classes into two groups, to create a “binary classification”. In this case, the first group contains one of the target diseases, with all others being assigned to the second group. The diagnoses in the second group are then merged into a single class – e.g. the classifier makes a decision between “appendicitis” and “not appendicitis”.

**Results**

**Multi-class classification result**

Table 2 shows the percentage of overall correctly classified instances from six machine learning models. ZeroR (majority class classifier) provides a baseline performance. All classifiers predict better than the baseline but the top three classifiers were Logitboost, NaïveBayes, and Neural Network, shown in bold.

Binary classification result

Table 7 shows the F1-measure score of binary classifications for individual diagnoses, using the NaïveBayes and LogitBoost classifiers. The first and second sub-columns under the classifier column represent the first and second groups in the binary classification, respectively. The last sub-column is the average F1-measure in the first two sub-columns. LogitBoost classifies all target diagnoses with good accuracy whereas NaïveBayes registers a significant drop for EP.

Feature selection

Feature selection on multi-class classification

The most highly ranked features with respect to the multi-class classification were a history of left abdominal pain and the patient’s age. The top ten features, all of which returned a percentage relevance of at least 15% are listed in Table 8.

Feature selection on binary classification

We also measured the correlation of features to individual diagnoses, based on the binary classification model. Table 9 shows selected features across the five diseases. Symptoms such as age, gender, location of abdominal pain, characteristics of pain, fever, gastrointestinal, urinary tract system, and gynaecological histories are useful in distinguishing between the different diseases. Right lower abdominal pain and pain migration are more specific to AP. Diarrhea is more specific to GE. Urinary tract symptoms are more specific to UTI. UPT and serum hCG are most specific to EP, while gynaecological symptoms and laboratory result for sexual transmitted diseases are most strongly correlated with PID.

Discussion

Retrospective vs prospective data collections:

We used a retrospective data collection method to collect clinical cases for training machine learning models. Unlike prospective approaches, this meant we were unable to constrain the records within a single template. Further limitations of this method included the variable formatting and structure of records, missing values, and temporal data. Our reliance on different data sources (even within the one hospital it is not unusual for different clinical departments to use different electronic health record systems) created a range of data entry and processing issues related to feature definition, type and sequence as well as clinical interpretation. This variation introduced considerable noise, reducing data validity and complicating data pre-processing. Many of these issues would undoubtedly have been reduced in the case of prospective data collection, as requirements or recommendations around record creation can be more closely defined and monitored. However, prospective data collection would have required considerable additional planning on our part, and carried substantial additional time and administrative costs that are likely to have been unacceptable to hospital staff given their heavy workloads.

Table 10 shows pros and cons of retrospective and prospective data collection. In summary, retrospective data collection is simpler with lower costs and does not impact on patients’ treatment. Prospective data collection, on the other hand, provides higher quality data and data validity but is likely to involve unacceptable costs.

For this study, we utilised case records provided in three different digital formats: plain text, scanned documents (images), and Word documents. The majority of these were extracted from the hospital’s record databases. The number of records available to us were sufficient for our purposes except in the cases of EP and PID, because patients diagnosed with those two diseases tend to be admitted to a specialist women’s hospital rather than the general hospital involved in our study. Inclusion and exclusion criteria were used to filter the cases because certain histories have a critical impact on formulating a list of possible diagnoses. For example, a patient who has had their appendix or ovaries removed should never be
diagnosed with AP or EP, respectively. Those histories provide a spot conclusion rather than enhancing the development of diagnostic reasoning processes.

Data pre-processing
Before PK started extracting data, he listed common presentations of the five diseases from medical standard textbooks [19-23]. He used standard medical terms from UMLS [24] and SNOMED CT [25] to identify and organise features and synonyms. Seventy-two (72) of 75 available features contained some missing values (only age, gender, and target diagnosis were complete). Missing values commonly occur because admitting doctors deem it as self-evident, unnecessary or irrelevant. For example, doctors will never ask questions about menstrual history, or order a urine pregnancy test and serum hCG for male patients. Similarly, a normal urine finding typically infers a negative finding in relation to all abnormalities of the urinary tract.

Symptoms also typically change over time. For example, the location, severity and quality of pain, and whether the pain is relieved by medication, can all change as a disease progresses. In the case of the location of pain, we divided pain location into two episodes – prior to and at admission. If these were different then the pain had migrated. More generally, we only used symptoms and signs from records created in the emergency department or on first admission to a hospital ward to reduce the effects of timing and treatment.

Clinical interpretation of classification results
The top three classifiers were Logitboost, NaïveBayes, and Neural Network, which all had a predictive accuracy above 80% (see Table 2). The Logitboost algorithm improves the results of a classification by reweighting mis-classified samples and taking a weighted majority vote to form training data [26]. It returned a significantly higher overall predictive accuracy than either NaïveBayes or Neural Network classifiers due to its superior predictive performance for EP (see Table 3). The classification performance for EP was low for all other algorithms due to a combination of low record numbers and missing data. We believe that Logitboost performed well despite these issues because of its use of a Decision Stump; a subroutine within Logitboost that analyses patterns of missing data to develop rules for classification.

When we considered the distribution of misclassified EP over other diseases predicted by NaïveBayes (Table 4) and Logitboost (Table 5), the models were more likely to misclassify EP as either AP and PID, which have a number of overlapping symptoms, rather than UTI or GE. By way of comparison, in a series of early studies, de Domal and colleagues [27; 28] used a CDSS employing a Bayesian classifier to predict abdominal pain within 600 prospectively collected clinical cases. They reported an overall diagnostic accuracy of 91.8%.

Table 11 compares the research methods and classification results for the current and these earlier studies when using a similar classification approach [27]. In this case, the machine learning model developed by de Dombal had the higher overall classification accuracy. We noted the key success factors in the de Dombal study were sufficient samples, equal distribution of sample, and the quality of input data.

While all classifiers apart from the baseline (ZeroR) provided more accurate predictions than the J48 algorithm, it is the only one that produces human-readable output. Its decision tree style output is easily interpreted and has the potential to provide useful feedback to users during the decision-making process.

Key features
For multi-class classification, left abdominal pain appears to be a key feature as it positively selects for those diseases presenting with lower abdominal pain – appendicitis, ectopic pregnancy, and pelvic inflammatory disease. Gastroenteritis and urinary tract infection are less likely to be selected because the pain position for these two diseases is more diffuse. However, a history of left abdominal pain reduces the probability of appendicitis and indicates more strongly ectopic pregnancy or pelvic inflammatory disease. Age is also an important factor, with appendicitis, ectopic pregnancy and pelvic inflammatory disease most strongly associated with younger patients. In the case of the binary classification, we were able to identify key diagnostic features associated with each disease. We will use this information to help medical students to identify strongly relevant clinical information to support their diagnostic decisions.

Machine learning model selection
Our final choice of machine learning model for use in the proposed learning tool is informed by two requirements: clinically appropriate predictions; and classification performance. We give precedence to clinical interpretation because proper development of the diagnostic reasoning process is more important than maximising the number of correct decisions. Binary classification is preferred because it provides a better sense of scaling of the likelihood level than multi-class classification. And, while the overall prediction performance of NaïveBayes is slightly inferior to Logitboost, the NaïveBayes predictions are more reflective of actual clinical judgements. For example, Logitboost predicts zero probability of ectopic pregnancy on a female patient presenting with right lower abdominal pain, which is clinically inappropriate. Accordingly, we selected the NaïveBayes classifier in combination with binary classification as our preferred model.

Feedback representation
We plan to use the machine learning model to provide two types of feedback (interim and final) within the proposed learning tool. Interim feedback will be based on the interpretation of predictive correlations between selected patient information and top three most likely diagnoses following the history taking, physical examination, and laboratory and investigations steps. Final feedback will present the correct diagnosis, and generate a user score based on how often the correct diagnosis is selected in the differential diagnosis list, correlation to the correct diagnosis, and the inclusion of key patient information.

We plan to use an overlap model to assess students’ performance (and potential learning gains) while using the tool [29]. This treats the student’s decisions (student model) as an incomplete model which can be compared to the machine learning model (complete model). The more similar these two models are, the higher the assessment of the student’s performance.
Conclusion

Timely and clinically appropriate personalised feedback is key to the development of students’ diagnostic reasoning skills. E-learning has a role to play here, through the provision of personalised and appropriately scaffolded feedback on students’ diagnostic decision-making on virtual patient cases. We propose to use diagnostic models derived through machine learning as the basis for giving relevant feedback. In this paper, we describe how we trained machine learning models using a large corpus of real clinical cases to develop differential diagnoses related to presentations of abdominal pain. We selected a model that combines a Naïve Bayes classifier with binary classification for further use in the learning tool based on a combination of its predictive performance and the clinical relevance of that model’s predictions.

Developing Methodologies to Find Abbreviated Laboratory Test Names in Narrative Clinical Documents by Generating High Quality Q-Grams

Abstract

Laboratory test names are used as basic information to diagnose diseases. However, this kind of medical information is usually written in a natural language. To find this information, lexicon based methods have been good solutions but they cannot find terms that do not have abbreviated expressions, such as “neuts” that means “neutrophils”. To address this issue, similar word matching can be used; however, it can be disadvantageous because of significant false positives. Moreover, processing cost is longer as the size of terms is bigger. Therefore, we suggest a novel q-gram based algorithm, named modified triangular area filtering, to find abbreviated laboratory test terms in clinical documents, minimizing the possibility to impair the lexicons’ precision. In addition, we found the terms using the methodology with reasonable processing time. The results show that this method can achieve 92.54 precision, 87.72 recall, 90.06 f1-score in test sets when edit distance threshold(τ)=3.

Introduction

There are several ways to find similar words. The most representative case would be edit distance. However, its calculation cost is significant; therefore, existing studies apply q-gram based filters to filter the words that are not most likely to be involved the query term preferentially. Q-gram refers to substrings of words moving a window that is the size of q. For example, “folate” can generate q-grams of “fol”, “ola”, “lat”, “ate” where q=3.

Counter filtering can filter out terms that do not have common q-grams less than threshold of counter filtering= (max(|s|, |t|) - q + 1) - q· τ. For example when q=3 and edit distance threshold(τ)=1, if “folder” generates “fol”, “ole”, “lde” and “der”, threshold of counter filtering would be 1. There is a common q-gram between terms “folate” and “folder”; hence, they are treated as similar terms. The terms that passed this test successfully were compared to the query word by using the edit distance calculation in next step.

However, counter filtering approach has an error. In its formula, “(max(|s|, |t|) - q + 1)” means the size of q-grams and “q· τ” is the limit of differences between two words. Therefore, threshold of counter filtering means that the least common q-grams to judge two words are the same. If words are short, the threshold can become negative and generate a massive false positive. Therefore, in this study, we modify algorithms to generate less false positives and to make them faster.

Methods

Developing Algorithms

We describe counter filtering in 2-dimensional space. In Figure 1, the x-axis represents the number of q-grams and the y-axis represents common q-grams with the query term. The query word draws a virtual line, the “standard line” on both figures. If distances between the point of the target word and standard line reach a threshold line or over it, the target word is filtered out.

Orthogonal Distance Filtering

This filtering concentrates on distances between two words from the perspective of q-grams. For example, consider q-grams of query word (QQW) : neutrophils= [neu, eut, utr, tro, rop, oph, phi, hil, ils] q-grams of target word (QTW) : neutrophilx = [neu, eut, utr, tro, rop, oph, phi, hil, ilx]. The different q-grams are “ils”, “ilx”. Here, q· τ is the limit of differences between two words. Therefore, distances between two of them should be equal or less than q· τ. Thus, the condition to judge them as similar is (QQW-CQ) + (QTW-CQ) ≤ q· τ. (CQ: common q-gram). We expressed equations QQW-CQ as ILQ (insertion of lacked q-gram), QTW-CQ DRQ () for convenience. Here, to simplify the problem as vertical distance, the equation should be changed as follows: ILQ ≤ q· τ – DRQ

Modified Q-Gram Filtering

This filtering concentrates on distances between two words from the perspective of q-grams. For example, consider q-grams of query word (QQW) : neutrophils= [neu, eut, utr, tro, rop, oph, phi, hil, ils] q-grams of target word (QTW) : neutrophilx = [neu, eut, utr, tro, rop, oph, phi, hil, ilx]. The different q-grams are “ils”, “ilx”. Here, q· τ is the limit of differences between two words. Therefore, distances between two of them should be equal or less than q· τ. Thus, the condition to judge them as similar is (QQW-CQ) + (QTW-CQ) ≤ q· τ. (CQ: common q-gram). We expressed equations QQW-CQ as ILQ (insertion of lacked q-gram), QTW-CQ DRQ () for convenience. Here, to simplify the problem as vertical distance, the equation should be changed as follows: ILQ ≤ q· τ – DRQ

Orthogonal Distance Filtering

A modified q-gram generates a massive false positive when it finds “neuts” as “neutrophils”. Therefore, orthogonal distance filtering was suggested to solve this problem. In this algorithm, substrings from the 0-th to i-th character in query words are treated as exemplary terms such as “neu”, “neut”, and “neutr”. Therefore, the standard line in Figure 1 tilts 45 degrees to become Figure 2. For this reason, all distances are multiplied by $1/\sqrt{2}$. This is shown in Figure 2 (left).
Triangular Area Filtering
We assumed that orthogonal distance filtering has a massive error in short terms; therefore, triangular area filtering was suggested. In this method an area of a triangle is given by $\frac{1}{2} d_n \times l_n$. The area of a triangle is a fixed value such that the bigger value is $l_n$ and the smaller value is $d_n$. Therefore, a strict threshold could be applied to the short term. This is shown in Figure 2(right).

Modified triangular area filtering
We added a safety lock to the triangular area filtering. In the filtering, the area of the triangle gets increases or decreases as the value of $l_n$ changes to prevent a huge false positive near the area of the long expressions. This is shown in Figure 3.

Experiment
Datasets
The suggested algorithms were compared with existing counter filtering. We extracted laboratory test names in the 500 Document (i2b2 2014) documents and 400 Korean diabetes clinical documents that were derived from Seoul national university hospital (snuh_diabetes). In the former, 400 documents were used as a training set, and 100 documents were used as a test set, whereas, in the latter 200 were used as a training set and the rest were treated as a test set.

Lexicon
Lexicons consist of laboratory test names that were derived from the laboratory test online site (https://labtestsonline.org/). Lexicons were refined using the training sets to achieve precision of 89.85, recall of 73.42, and f1-score of 80.81 in i2b2 2014, and 95.11, 75.28, 84.04 in snuh_diabetes.

Preprocessing
All documents were pre-processed to generate 1-4 q-grams. Then, all words related to clinical terms and all ordinary words that incur massive false positive were eliminated. All `"'`, `[,]`, `[+]`, `[{'}, {']`, `[']`, `['], `[']`, `[']`, `[']`, `[']`, `[']`, `[']`, `[']` were eliminated to reduce the distance between query words and target words. These steps are shown in Table 1.

Additional Filters
If edit distance or suggested algorithms were applied to all words in the documents, it would take over 400 hours to process all documents. Therefore, additional filters such as length filter and prefix filter were applied to each algorithm. Q-grams containing white spaces were ignored because they can incur massive false positives. For example, “abcdef”, “abc def” can generate three different q-grams, “bc”, “c d”, and “de”.

Results
Quality of Q-Grams
We evaluated q-grams by adopting notions of precision, recall and f1-score. We analyzed results to find that all algorithms’ f1-score was dependent on precision. In other words, algorithms that generate less false positives could yield good quality q-grams.

Edit distance achieved a stable result; however, it was always inferior to the triangular area filtering and modified triangular area filtering. This was because these algorithms could identify abbreviated terms like “neuts’ and “chol” that are not listed in the lexicon. Though orthogonal distance filtering generated most variety in the terms, it generated the biggest false positives at the same time. Modified q-gram filtering generated better q-grams than traditional counter filtering because traditional threshold of counter filtering can be a negative or zero value.

Triangular area and modified triangular area filtering yielded 92.54 precision, 87.72 recall, and f1-score of 80.81 in i2b2 2014 test sets, and 86.23, 81.92, 84.02 respectively, when $\tau=3$ in snuh_diabetes test sets, and 86.23, 81.92, 84.02 respectively, when $\tau=3$ in i2b2 2014 test sets. They ranked highest among algorithm scores. These trends were consistent for all datasets that were used in this study.

Calculation Time
Modified q-graam was always faster than traditional counter filtering in the test sets. Because Preprocessing of Table 1 could save time as much as appearance times of whitespaces.

Modified triangular area and triangular area filtering were slower than edit distance. This was because suggested algorithms generate more terms like “neuts” and “chols” so they were slower than edit distance in Figures 8, 12, 16 and 20. Actually, these algorithms were faster when they process the same words (Figure 4). Therefore, modified triangular area filtering and triangular area filtering are faster but deal with more terms than existing algorithms to ensure the quality of q-grams at a sacrifice of their speed.
Discussion

For a long time, there have been attempts to reduce the time of similar string matching. [1] reduced processing time by building a special inverted index. [2] concentrated on how to make a systemic inverted index; therefore, introducing a graph shaped inverted index. [3] concentrated on mismatching q-grams to speed up the algorithm. [4] split words, then applied prefixes to words to generate similar strings in documents. These works are not interested in precision but the increased speed of the algorithm, because the q-gram has been treated like as a preprocessing-step before edit distance. However, a massive false positive in candidate set 1 can raise the cost of the rest of the calculation steps like edit distance. Therefore, we developed our proposed algorithm.

Although the suggested algorithm used a more strict threshold, it could cultivate entities, many as existing algorithms with less false positives and within a reasonable time. This algorithm can be helpful to researchers who want to cultivate features from documents so that the burden on subsequent processing such as the validation step and semantical classification can be reduced, as the number of input entities was reduced.

Conclusion

We developed a novel algorithm successfully by modifying existing filtering algorithms based on q-gram techniques. The modified triangular area filtering and triangular area filtering generated good quality q-grams even cultivating abbreviated laboratory terms within moderate time. These algorithms have substituted existing counter filtering and edit distance because they are faster and generate better quality words. This work will be helpful to researchers who want to find similar strings in documents rapidly with lower calculation time and fewer candidate words.

Abstract

Scientific advancement and the development of new research fields bring uncertainties about what the current topics of research emphasis are and thus, what new knowledge might need to be represented. The exposome is an example of one such new field for which these uncertainties exist. The exposome is the analogue to the genome, from an environmental exposure perspective; research on the exposome has gained momentum only since 2011. In this work, we propose a generally applicable methodology that aims to characterise the landscape of a new research area based on linguistic analysis of its associated publications. Using abstracts of 261 exposome research articles, we illustrate a methodology that combines (1) inductive analysis based on word frequency counts, and term analysis to identify the topics, methods and applications of the new field and (2) deductive analysis using the NCBO Ontology Recommender to identify to what extent this new area is covered by current knowledge representation tools. Applying this method to the exposome literature, we uncover both the current focus of exposome research and the ontologies that are most relevant to the domain.

Keywords:
Environmental Exposure; Medical Informatics, Text Mining, Biomedical Ontologies

Introduction

The role of environmental factors in health and disease along with the controversial “nature versus nurture” debate have been ongoing themes in science and research for over a century [1], [2], [3]. With the development of precision medicine, the relevance of both themes and the need to consider both in research have been explicitly acknowledged [4], [5]. This represents an attempt to satisfy the equation “Phenotype = Genome x Environment”. The “nature” component of this equation, the genome, has experienced a formidable boost in the last two decades. It has also fostered the development of what are known as “omics” approaches (proteomics, metabolomics, etc.) to characterize molecular phenotypes. A commonality among these approaches has been their reliance on recent technological advances to generate very large data sets. On the other hand, the “environmental” aspect of the equation was typically studied with population or environmental health approaches, until 2005 when C.P. Wild coined the term “Exposome” and further defined it as an exposure-oriented analogue of the genome [6]. The exposome represents the sum total of exposures an individual receives over time, from both internal and external sources. Similarly to what has happened with the development of other “omics” approaches, study of the exposome is benefiting from recent advances in technology, especially with the development and reduction in cost of sensors. These new technologies have opened the door to the development of new strategies that shift research focus from population-based exposure assessment to more individualised approaches [7].

The concept of the exposome was initially established over a decade ago, and has gained significant attention only recently with the establishment of several large research projects [8-11], due in part to its demonstrated relevance to the new paradigm of “precision medicine” [12]. As a consequence of this increased focus, the body of knowledge and the volume of literature associated with the exposome have grown continuously over the last six years (Figure 1). Although still young, this is a rapidly evolving research field.

![Figure 1](image)
describe exposome related knowledge. We believe that this methodology is applicable not only to the exposome but also is transferable to any new or developing research field.

Methods

Our characterization of the exposome research landscape is based on a literature review to discover the extent of relevant articles, followed by two different and complementary approaches to content analysis of their abstracts (Figure 2):

- An inductive approach based on text mining to identify the most relevant words and terms;
- A deductive approach based on identifying the most relevant ontologies, i.e. those that offer the best coverage of terms.

The literature selection was performed by searching for papers published between January 2005 and April 2016 with the term "exposom*" in the title, abstract or keyword fields. Searches were undertaken in the CABI, CINAHL, EMBASE, PubMed and Web of Science databases. Articles were excluded if they were written in a language other than English, if they were an e-book, or if they were related to research in non-human subjects. 22 items were excluded under these criteria, resulting in a total of 261 documents that were finally used in these analyses. Abstracts of the selected documents were then retrieved and stored in a database to form a corpus for analysis.

The inductive stage of the analysis was performed applying two different strategies. In the first strategy, “technical terms” were identified in the corpus using Termine [16], a tool that approaches novel multi-word term identification using statistical methods. The second strategy consisted of calculating word frequency counts in the corpus applying a natural language processing (NLP) protocol developed “in house” using Python’s Natural Language Tool Kit (NLTK) [17].

Using Termine, abstracts were concatenated into a single file in order to provide enough text for effective processing in one pass. Prior to this concatenation, a preprocessing step on the individual abstracts was carried out to improve the final outcomes and the submission process, as follows: Copyright notices were removed from the text; they were converted to lowercase and they were lemmatized to reduce the number of duplicated terms (for example “exposure” and “exposures” were grouped together); and finally sentences were tokenized (using the NLTK method) and replaced with new lines.

Word frequency analysis was performed in the following fashion. Abstracts were concatenated first, then converted to lowercase, and punctuation characters were removed. A frequency distribution was then produced using the nltk.probability.FreqDist procedure. This result was stored and then manually curated to limit the terms considered potentially relevant (for example, discarding closed-class function words such as ‘the’, ‘of’ and ‘by’).

For the deductive analysis, we used the repository of biomedical ontologies found at the National Center for Biomedical Ontology (NCBO). This resource currently catalogues more than 500 ontologies. The NCBO Ontology Recommender tool API [18] was applied in order to identify what ontologies covered this new field. An automatic process was used to pass each abstract separately to the API and record the ontologies recommended in each response.

Results

Inductive Analyses

Word count analysis identified 7061 unique words with a range of counts between 1 and 2844. The count distribution shows a Zipfian-like distribution, where only 12.7% (897) of the words have a word count greater or equal than 10. We further filtered these results applying a minimal word-count threshold of 10 followed by manual filtering of the remaining words. This filtering step, designed to remove frequent general English words and other words irrelevant for this field based on our own linguistic knowledge, resulted in a final list of 427 relevant words with word frequencies between 10 and 614. Of these 427 words, the top 25 showed a word frequency >100 (Table 1).

Termine identifies complex and technical terms comprising two or more words. These results are then ranked according to their frequency and an internally calculated score (c-value) that is derived from statistical and linguistic information [16]. This analysis resulted in the identification of 12,947 terms with c-values ranging between -1 and 105.8 and frequencies between 1 and 107. Of those terms identified, 95% occurred at a very low frequency (<2), and only 1% had a frequency of ten or greater. Table 2 shows the top 25 terms identified.

Deductive Analysis

The NCBO Ontology Recommender tool uses four separate scores for each ontology based on internal calculations measuring the “coverage”, “detail of knowledge”, “specialization” and “acceptance” of the proposed ontology. These four categories are weighted to produce a default ranking. Using the NCBO default settings, the weights employed are Coverage: 0.55, Detail of Knowledge: 0.15, Specialization: 0.15 and Acceptance: 0.15. These analyses returned a list limited to the twenty five (25) most highly ranked ontologies for a supplied abstract.

A total of 164 different ontologies were recommended, across the 261 abstracts. To better interpret these results we calculated a measure, the ontology recommendation frequency percentage (ORFP), to represent how often an ontology was recommended for this dataset. Applying an arbitrary threshold of ORFP > 50, only 17 (~10%) of the 164 suggested ontologies were recommended for more than 50% of abstracts (Figure 3 and Table 3).

To further refine these results, we aggregated all 164 recommended ontologies and calculated a new combined ranking for the 17 ontologies above the threshold. This was performed by means of computing a “corrected rank” for each ontology, taken as the average rank it received for each individual abstract. If an ontology was not recommended for a given abstract, it was given an arbitrary rank of 26.

Table 3 – 17 ontologies recommended by the NCBO Ontology Recommender with ORFP > 30, showing their average and corrected ranks.

To check for consistency between our inductive and deductive results, we added a deductive step where we used the list of multi-word terms filtered from Termine as input to the NCBO Ontology Recommender tool. This resulted in 25 recommended ontologies, all of which also appeared in the list of 164
ontologies derived from the deductive analysis of complete abstracts. These 25 ontologies matched 15 out of the 17 ontologies with an ORFP >50, demonstrating the overall representativeness of the inductive terms as compared to the broader literature. The two missing ontologies were EDAM and RH-MESH (Figure 4).

Figure 4 – Consistency Between Two Sets of Ontologies Recommended for Exposome Abstracts: 25 Recommended for Filtered Multi-Word List from Inductive Analysis, and 17 Recommended from Deductive Analysis of Whole Abstracts.

Discussion

The proposed methodology is based on two different and complementary approaches, an inductive strategy aiming to unveil unknown aspects associated with the terms and words (eventually concepts) that might characterise exposome research, and a deductive method that attempts to identify what existing elements in the biomedical knowledge representation space can be used to annotate exposome related published research.

The two inductive analyses were complementary to each other. The word frequency method resulted in the identification of individual words such as “environmental”, “exposure” or “biomarker” whereas the use of Termine focused on the identification of more complex terms and concepts such as “environmental health”, “environmental exposure” or “metabolic profiling”.

The word frequency approach was applied to identify the most frequent words in the literature and gave insights into individual elements that provide an overall perspective on the field. Although Table 1 shows only the top 25 results, this analysis enabled the identification of other relevant words in this context that show different areas where research has focused such as “epigenetic”, “metabolomic”, “maternal” or “lead” (a metal) and even more specialised words such as “adductomics”.

The second inductive approach, using Termine, allowed us to identify more complex terms and concepts that elude the simple word count approach. The reason why Termine analysis identified a large number of terms, greater than the individually identified words, is because the results include terms of different length (word 
grams, or multi-word terms) that are sequences of individual words (i.e. “environmental factor”, “environmental factor environome” and “environmental factor such investigation”). The results in Table 2 clearly show the complementarity to those identified by word count. The analysis of terms allowed us to identify methodologies (such as “cohort studies” or “genome wide association studies”) and techniques (“mass spectrometry” or “metabolic profiling”) that are relevant in exposome research. They thus identified terms which correspond to important concepts in this emerging field.

The approach based on deductive analysis using the ontology recommender allowed us to contextualise current formal knowledge representation of the exposome. Based on this analysis, only a small portion of the overall recommended ontologies are broadly useful in this field of research at this point. More importantly, none of the ontologies that were frequently recommended had major associations with the science of environment or exposures, suggesting that there is a need to bridge interdisciplinary research gaps to build knowledge in this field.

Limitations

In spite of having successfully applied this methodology to the characterisation of exposome research with complementary and consistent results, this study has several limitations in its current form. One of these is connected with the use of abstracts rather than full text content in the analysis, since abstracts highlight the key aspects of the full-text content of the document but are not intended to be exhaustive summaries. However, since many full text publications are not available for analysis, this limitation is balanced with more exhaustive coverage of relevant literature using abstracts.

Another limitation lies in the use and interpretation of the results from the proposed automatic analyses with regard to the ambiguity of terms; the tools do not have the capacity to disambiguate different meanings. For example, in the inductive analysis the word “lead” would be equally counted regardless of whether it is acting as a noun (a metal) or as a verb (to precede). In the deductive analysis there is a similar problem with different ontologies recognising the same term but without contextualising it. In the aforementioned example “lead” is defined by NCIT as “Be in charge of; a position of leadership” whereas in CRISP it is defined as a “Soft grayish blue metal with poisonous salts; symbol, Pb, atomic number 82”.

General Application of the Approach

Scientific advancement and the development of new research areas bring uncertainties about how new knowledge can be or should be represented. The methodology proposed here enables objective assessment of such questions and thus facilitates analysis of the evolution of new fields of biomedical science, including those driven by new technologies.

For example in this study of exposome research, the deductive analysis showed the relevance of toxicogenomics in exposome research in the form of a number of genomic and bioinformatics related ontologies (GO, EDAM, EFO and HUPSON).

Our suggested method combining induction and deduction is generalisable and suitable to be applied in corpora of literature derived from other biomedical fields. The inductive stage is “blind” to the origin of the corpus used, and independent of any existing knowledge resources. Therefore it can equally applied in any area with an identifiable body of literature, allowing the most relevant words and terms that characterise the new field to surface and thus providing insight into the current methods, applications and general interests in the field – as well as the gaps. On the other hand, the deductive stage relates the corpus to existing knowledge encoded in the form of ontologies, and maps the places where aspects of current knowledge overlap with research in the new field of interest, or where there is no intersection.

Future Work

In future work, we plan to analyse full texts of articles from the literature instead of just abstracts. In addition, more complex natural language processing strategies will be applied in order to reduce the disambiguation problem. These results will eventually be combined with the results generated from the deductive approach to improve the interpretation of the latter. This will support eventual comparison between the results from the analysis of exposome research literature and the results of...
analysis of representative bodies of literature from related fields (for instance, other omics research). This may determine which features of exposome research are particularly novel and thus may help to direct further research.

Conclusion

We have developed a methodology that combines inductive and deductive approaches for the characterisation of the landscape of terms or concepts and availability of formal knowledge representation tools in a relatively new area of biomedical research. When applying this methodology to the study of exposome research, results from the inductive and deductive approaches are consistent and complementary, allowing us to identify different sets of terms, concepts and ontologies that describe the current status of human exposome-related knowledge. This is a major first step towards enabling development of informatics tools to support systematic comprehensive integration of exposome data into precision medicine.

The use of automated tools and methods like the ones described in this work adds to the growing body of work to address the limitations of the current processes in systematic reviews of this kind [19; 20]. Our methods could enable the generation of an overall perspective of research scope, and characterisation of the most relevant topics under investigation, in new disciplines. The approach further facilitates the assessment of whether new formal knowledge representation tools are required for the new discipline.

Abstract

The objective of our study was to assess the feasibility of gathering data stored in primary care Electronic Health records (EHRs) in order to create a research database (PRIMEGE PACA project). The software for EHR models of two office and patient data management systems were analyzed; anonymized data was extracted and imported into a MySQL database. An ETL procedure to code text in ICPC2 codes was implemented. Eleven general practitioners (GPs) were enrolled as “data producers” and data were extracted from 2012 to 2015. In this paper, we explain the ways to make this process feasible as well as illustrate its utility for estimating epidemiological indicators and professional practice assessments. Other software is currently being analyzed for integration and expansion of this panel of GPs. This experimentation is recognized as a robust framework and is considered to be the technical foundation of the first regional observatory of primary care data.

Keywords

Electronic Health Records; Database; Information Dissemination

Introduction

Computerization of general practitioners (GPs) has been developed over the last 20 years [1]. The use of electronic health records (EHRs) and e-prescribing are priorities in General Practice [5]). These development efforts have enabled the creation of voluminous databases allowing multiple publications.

In France, there is no similar model currently in operation. Consequently, unlike the hospital sector for which the established diagnoses are known, thanks to the PMSI (Program of Medicalization of the Information Systems), the morbidity supported in primary care is not well known [6].

The objective of our study was to assess the feasibility of gathering data stored in primary care EHRs in order to create a research database (PRIMEGE) PACA project: Plateforme Régionale d’Information en Médecine Générale en Provence-Alpes-Côte d’Azur [7].

Methods

Data Definition

In a preliminary study, we identified the data provided by an EHR system. From the recommendations of the ANAES (Agence Nationale d’Accréditation et d’Evaluation en Santé) [8], concerning medical records in general medicine in addition to a study led by the departments of General Medicine at the University of Nice Sophia-Antipolis and Lyon 1 [9], we established a list of data to be collected. These data concern the episode of care, but also include data useful to evaluate and improve the practices (such as the ICPC2 code (international classification of primary care) enabling standardization of the reason for encounter and diagnoses). Data allowing patient identification (such as name, surname, address, etc.) were excluded.

Database Design

The modeling of a problem (i.e., the passage of the real world to its computerized representation), includes the integration of data into a relational database management system (SGBD-R) and allows for the manipulation of the data using SQL language (Structured Query Language) [10]. Classically, the data modeling process includes two phases: realization of a conceptual model and translation into a relational model. To establish the conceptual model, we used an entity-association (E-A) graphical formalism (widely used for the design of SGBD-R). We first built an E-A model centered on the visit (Figure 1). To be compatible with the the POMR (Problem Oriented Medical Record) software formalism, we built a second model that was centered on the problem of interest. The only difference between the first and second models was the visit table; start date and end date fields as well as a possible link to a parent problem were added. The two E-A models were then merged into the relational model (Figure 2). To link the CIP (Classification of Instructional Programs) code (drug table) with the corresponding ATC (Anatomical Therapeutic Chemical) class, a supplementary table (drug booklet) was added. The cross-reference table was supplied by Thériaque®. To be able to directly reach the reasons of encounter, diagnoses, and drugs prescribed for a given patient, additional access was added (represented by dashes on the relational model).
The PRIMEGE PACA database was developed under MySQL (version 5.1.73). PhpMyAdmin (version 3.5.2.2) was installed providing a graphical interface and to facilitate database management. The database is hosted at the CHU of Nice on a Linux SSH (Secure Shell) access. PuTTY was installed to access the server in command mode and transferring files to the server is made via SFTP (SSH File Transfer Protocol).

**Extraction Procedure**

One of the most frequently used data management software systems by French GPs was analyzed using a workstation provided by a medical office [9]. Its structure was analyzed, and tables and fields of interest were identified. Once this work was completed, SQL queries to collect data were developed. To reduce interference with the GPs’ work, extraction queries were run in batches, as background tasks, to generate needed .TXT and .CSV files.

Data extraction was realized using two methods. The first method involved the physician office where data were recovered on USB key. The second method was performed remotely using certified remote control software. This extraction procedure could be extended for use with other software.

**Recruitment of the Investigators**

Initially, internship supervisors working with one of the two software systems were contacted via the department of general medicine of the Faculty of Medicine of Nice. Upon agreement (all the partners of the contacted GPs agreed to participate), we went to their offices to explain the project in detail.

**Data Importation**

After quality checks performed, data were imported into intermediate tables corresponding to the structure of the software from which they were extracted. Once the data was imported into the intermediate tables, other scripts were used to convert the data into the PRIMEGE data model. During the process, copy tables were created, allowing the ability to return to the previous state in case any problems were encountered. Additionally, log files were generated to monitor the progress of the scripts and to analyze any errors encountered. A final script allowed copy tables to be removed and intermediate tables to be reset.

To ensure unique identifiers, a code corresponding to each medical office was concatenated onto the EHRs identifiers.

**Automatic Coding**

During extraction, few codes capturing the encounter and diagnoses reasons were found. “Coded” data are needed to standardize the ways that clinical concepts are represented. To solve this problem, we developed an automatic coding procedure based on the ICPC2 (recognized by 2003 as the international reference classification for primary care). This procedure compares the wording supplied with a list of strings (established from the reference document: treatment of medical information by the ICPC2 [11]) and stops at the first match found (Figure 3).

**Legal Aspects**

A declaration was made to CNIL (French supervisory authority for the protection of personal data registration no. 1585962). An informative poster intended for the patients and
explaining the modalities of access and rectification of the data was arranged among the member physicians.

Results

Eleven physicians agreed to participate. The inclusions and data collection began in 2012. Finally, we collected four years of data (2012 to 2015) (Table 1, 2).

Although reasons of encounter and diagnoses where poorly coded by GPs (14.60% and 1.88%), the automatic coding procedure allowed us to associate main reasons of encounter and diagnoses with an ICPC2 code (97.05% and 96.83%).

Discussion

Our study assessed the feasibility of gathering data stored in primary care EHRs in order to create a research database.

Strengths

Data Validity
To evaluate data quality, we considered the following criteria:

- Internal validity: 10 files per GP were randomly selected and searched for the corresponding data in the PRIMEGE database. In case of missing data, we returned to the extraction procedure to correct the problem.
- External validity: data volume was coherent since the number of annual consultations per GP was close to that indicated in the IRDES (Institut de Recherche et Documentation en Economie de la Santé) report on the GPs’ working time (4667 vs 4225) [12].

Potential Impact
Secondary use of EHRs offer many perspectives:

- Clinical perspectives: These data could be used to improve quality of care, especially chronic disease management, [13] and could be used to assess professional practices. For the GPs, a better knowledge of the main problems encountered would allow for continuous learning. These data could also be used to evaluate the impact of the recommendations.
- Public health perspectives: Data from EHRs would facilitate public health surveillance by allowing for the estimation of epidemiological indicators and providing better data to guide public health interventions [14-15].

Interoperability
Our data model was conceived regardless of any medical software constraints. Intermediate table creation and data reprocessing to be compatible with the PRIMEGE model enables future adaptation to different medical software and ensures interoperability of the model.

Weaknesses

Automatic Coding Procedure Evaluation

Although the reliability of our automatic coding procedure was not formally established, an initial validation was carried out. For this, we compared the codes obtained with those found in ECOGEN (étude des Eléments de la COnsultation en médecine GENérale) [16] as well as those provided by the CISMeF (Catalogue et Index des Sites Médicaux de langue Française) team in Rouen using the same labels. In case of divergence between the codes, the reference document [11] was re-examined by analyzing the inclusion and exclusion criteria. In the future, an additional evaluation will be performed as part of a thesis (a representative sample of reasons of encounter and diagnoses will be manually coded and the results will be compared with those of the procedure to determine their accuracy).

Missing Data
The variability in completeness of data across patients and time requires careful consideration; restriction to those with complete data may result in biased analyses [17]. One solution would be to encourage contributing practices to maintain a certain level of data quality through financial and/or intellectual incentives. In addition, some missing data could be collected via automatic cross-reference between prescriptions, laboratory results, and ICP2 codes [18]. Our automatic coding procedure could also be used to extract information from notes provided in free text fields by doctors.

Perspective
Other software is currently being analyzed for integration and expansion with this first panel of GPs. This regional model could be created as a network of regional observatories thus providing a representative panel of general practitioners' "data producers". Linkage to hospital data would enable the tracking of patient trajectories. To link PRIMEGE PACA data with hospital data we intend to use a probabilistic matching procedure as described in an IRDES’ study [19].

Conclusion

This experimentation is recognized as a robust framework that could be adapted to increase data storage. This framework could be considered the technical foundation of the first French regional observatory of primary care data.

As far as we know, this is the first French data consolidation work in primary care. Currently, we use the ICP2, but other international classifications like SNOMED and ICD10 should complement this model to refine the results of epidemiological investigations and practice assessment.

Abstract
It is increasingly necessary to generate medical evidence applicable to Asian people compared to those in Western countries. Observational Health Data Sciences and Informatics (OHDSI) is an international collaborative which aims to facilitate generating high-quality evidence via creating and applying open-source data analytic solutions to a large network of health databases across countries. We aimed to incorporate Korean nationwide cohort data into the OHDSI network by converting the national sample cohort into Observational Medical Outcomes Partnership-Common Data Model (OMOP-CDM). The data of 1.13 million subjects was converted to OMOP-CDM, resulting in average 99.1% conversion rate. The ACHILLES, open-source OMOP-CDM-based data profiling tool, was conducted on the converted database to visualize data-driven characterization and access the quality of data. The OMOP-CDM version of National Health Insurance Service-National Sample Cohort (NHIS-NSC) can be a valuable tool for multiple aspects of medical research by incorporation into the OHDSI research network.

Keywords:
Delivery of Health Care; Medical Informatics Application; Database

Introduction
Use of existing observation data to generate medical evidence is rapidly increased in terms of quantity of data, diversity of data sources, and the transparency [1]. Observational Health Data Sciences and Informatics (OHDSI) is an international collaborative consortium which aims to facilitate generating high-quality evidence via creating and applying open-source data analytic solutions to a large network of health databases across countries [2]. The OHDSI adopted distributed research network (DRN), which mediates observational studies to be conducted using multi-site database, while confidential personal health data remain within the original data holders [3]. The standardized same data structure, called the Observational Medical Outcomes Partnership Common Data Model (OMOP-CDM), is imperative to create network-wide results through the DRN by running the same analysis program for cooperating organizations. The OMOP-CDM was first developed in 2008 for drug surveillance study and has expanded its capacity to other research area. It supports various types of studies such as drug/procedure safety, drug/procedure comparison, and medical cost analysis.

South Korea adopts a compulsory social insurance program, covering the whole population living in the country [4]. The National Health Insurance Service (NHIS), the institution for the Korean health insurance service holds the health claim database for all Koreans. In 2015, The NHIS released the NHIS-National Sample Cohort (NSC) database, which is a population-based sample cohort as the representative of the population as a whole.

In this paper, we present the converting process of the NHIS-NSC database into the OMOP-CDM and the result, focusing the executing phases.

Methods
Data Source
Korean public health insurance system for all citizens was initiated in 1963. Universal healthcare coverage was achieved in 1989. In 2000, the NHIS was launched as a single-insurer system by integrating more than 366 medical insurance organizations, for efficient system operation in Korea. The NHIS maintained national records for healthcare utilization and prescription over 98% of Korean whole population as of 2006. The NHIS established the NHIS-NSC, which was population-based cohort to provide representative, useful health insurance and health examination data to public health researchers and policy makers in 2015. About one million subjects, 2% of the Korean whole population, were selected by stratified random sampling from 2002 Korean health insurance database. Longitudinal health records in these population were collected for 11 years from 2002 to 2013. To preserve total number of subjects in the cohort, a representative sample of newborn was added annually as expired or emigrated subjects were excluded. The NHIS-NSC database can be assessed on the website [http://nhiss.nhiss.or.kr/bd/ab/bdaba021eng.do].

Code Mapping
The NHIS uses Korean national medical code system. The 6th Korean standard Classification of Diseases (KCD-6) code is used for the diagnoses, which was originated from ICD-10 code. The NHIS has its own code system, electronic document...
interchange (EDI) codes for drug, procedures and measurements.

The OMOP-CDM uses OMOP Standard Vocabulary (hereafter OMOP code), which requires transformation process from the local medical code system. OMOP code is based on RxNorm for medical drug and SNOMED-CT for medical diagnosis. Figure 1 shows how a drug code from Korean local drug code system is transformed to standard OMOP code. To consolidate the meaning of multi-site data, code transformation system is essential.

![OMOP code](image)

**Figure 1** - The example of transformation process from Korean local drug code to OMOP code.

We adopted the Korean Code Mapping Dictionary (KCMD) as a means of transformation from the NHIS codes to the OMOP codes. The KCMD is the code mapping dictionary between Korean local codes and the OMOP codes, which is developed by the authors. It shows 99% coverage for the diagnoses (KCD-6), 95% for drugs (EDI codes), and 99% for procedure (EDI codes) by the number of patients treated. For measurement, we additionally developed a mapping dictionary.

### Extraction, Transformation, Loading (ETL) process

The OMOP-CDM embraces a variety of medical data such as patients, encounters, diagnoses, drug exposures, procedures, devices, results from laboratory tests, anthropometric measurements or questionnaire, and medical costs.

We converted the original data necessary for drug safety monitoring into OMOP-CDM with priority. Therefore, the seven tables in OMOP-CDM were generated: person, death, visit occurrence, condition occurrence, drug exposure, procedure occurrence, and location. With these converted tables, the various research including drug effect analysis, pharmacovigilance analysis can be performed.

The logical ETL mapping rules between the NHIS-NSC and OMOP-CDM were first defined. There were problems in developing ETL mapping documents. First, the NHIS-NSC provides subjects’ age as a form of five-year-interval age group. Therefore, the approximate birth year of each subject had to be presumed. Second, all treatments such as drugs, procedures, and medical devices were stored in a single table in the NHIS-NSC and there was no reference data to accurately distinguish the type of treatments. We had to execute ETL by applying the KCMD for each treatment to source data.

We developed the physical ETL scripts as a form of Standard Query Language (SQL) and performed them as actual ETL process.

### Data Characterization and Quality Management

ACHILLES (Automated Characterization of Health Information at Large-scale Longitudinal Evidence System) is a open-source OMOP-CDM-based data profiling tool, developed by the OHDSI community. The ACHILLES creates a data-driven characterization and visualizes this result, by generating high-level aggregating statistics in a database based on the OMOP-CDM. The quality of the data can be assessed by the ACHILLES Heel, which is a subcomponent of the ACHILLES.

It is possible that mistakes in ETL processes occur [5]. To verify that the transformed data is equivalent to the original cohort data, we used statistical results from the ACHILLES to compare the population-level statistics with the previous reported cohort profile [6]. The ACHILLES Heel was also conducted to evaluation the data quality. The ACHILLES Heel generates two types of notifications: errors and warnings. “Errors” indicate more serious data quality issues, while “warnings” represent faults anticipated to have smaller impact.

### Results

#### CDM Conversion Performance

Table 1 is the result of ETL, which shows counts of converted database records and conversion rates for OMOP-CDM tables. All data in the NHIS-NSC equivalent to subject, death, hospital visit and location were totally converted, resulting in 100% conversion rate. For the condition table, 89.4% diagnosis codes were mapped to SNOMED-CT and 99.9% of condition data were converted to OMOP-CDM with the mapping diagnosis codes. This means that 89.4% of codes showed the 99.9% prevalence in condition data. For drug and procedure, the total about 975 million data were converted to OMOP-CDM. Among them, drug and procedure comprised 53.6% (525,575,793 records) and 46.4% (452,147,182 records). Its whole conversion rate was 94.5%.

#### Data Characteristics and Visualization

The ACHILLES estimated that total number of subject in the cohort was 1.13 million. Total of 560,640 (49.8%) subjects were female (Figure 2). The reported number of all subjects and annual included infants in the cohort are compared with the result from the ACHILLES (Table 2).

The number estimated by the ACHILLES was equal to the reported number in 2002, 2010, 2011, 2012 and 2013. The ACHILLES overestimated the number of subjects in the other years. The numbers of annual subjects estimated by the ACHILLES were compared with the previous reported numbers. The numbers of infants match each other except 2009. The difference in the number of infants was only four in 2009.

The ACHILLES calculates and visualizes the statistics for the population-level data from Korean nationwide cohort. Since the
ACHILLES visualizes statistics for diagnosis, drug, procedures and hospital visits by calculating prevalence and frequency per person by using the size and color of the boxes in the tree maps. Users easily assess the statistics for population-level data from Korean nationwide cohort.

Graphs from the ACHILLES about visiting emergency room (ER) and use of cimetidine were depicted in figure 3 and figure 4, respectively. The total number of people visiting ER during whole cohort period was 188,954 with a rising trend. One of the most commonly used drug was cimetidine. Number of subjects using cimetidine was increased from 2002 to 2007, and then decreased. The most commonly used population was women in their 60s and 70s.

Results from ACHILLES Heel

The ACHILLES Heel issued 13 errors and 15 warnings from converted the NHIS-NSC OMOP-CDM data. Most of errors and warnings were resulted from discordance between range of observation period and real date of medical claims

Discussion

We demonstrate successful conversion process of the NHIS-NSC, Korean nationwide cohort database, to the OMOP-CDM version 5.0 in this paper. To date, this has been the first attempt to convert nationwide cohort database to universal standardized OMOP-CDM format in Asian countries. Although the randomized clinical trial (RCT) undoubtedly remains as a gold standard for developing medical evidence, applicability of evidenced produced by RCTs can be restricted because of gaps between environments in RCTs and real world routine practice [7]. Geographic and racial variations in the risks for disease or the results of treatment also exist. However, these differences have been often neglected in multinational RCTs [8]. Incorporation of Korean longitudinal nationwide large cohort data into the OHDSI network will be the the first milestone to generate global high-quality medical evidence, which is applicable to Asian population and real-world practice.

Figure 2– Dashboard of ACHILLES describes the total number of subjects in cohorts according to their gender, race, and year of birth.

Figure 3– Visit tab of ACHILLES depicts the trend in emergency room visits of subjects in the cohort according to their gender and age.

Figure 4– Drug exposure tab of ACHILLES shows the trend in usage of cimetidine in the cohort according to their gender and age.

Some limitations still exist in the process and the result of our data conversion. Despite regular process in code mapping as previously described [9], information loss was inevitable in the process of code mapping and ETLs owing to unapproved drugs or procedures in US and Korean traditional medical diagnosis and drug. Some tables in the OMOP-CDM, especially regarding to medical cost, were left for the conversion because we planned to construct data set for drug safety monitoring first. Errors issued from the ACHILLES Heel have not fully
investigated. However, the number of error was lower than the median number of 19, which revealed by multi-site evaluation of data quality by using the ACHILLES Heel [5].

Conclusions

We report the successful transformation of the Korean nationwide cohort database, the National Health Insurance Service -National Sample Cohort (NHIS-NSC), into the OMOP-CDM model with acceptable loss of information. Converting additional information including cost data and further verification of OMOP-CDM by replicating previous research are now under way. The OMOP-CDM version of the NHIS-NSC can be a valuable resource for multiple aspects of medical research by incorporation into the OHDSI research network.

³ New South Wales Health Pathology, Sydney, New South Wales, Australia

Abstract
In Australia, New South Wales Health Pathology’s implementation of managed Point-of-Care Testing (PoCT) services across rural and remote emergency departments (EDs) has the potential to significantly improve access to results for certain types of pathology laboratory tests and help to deliver timely patient care. The aim of this study was to assess the quality of the datasets, including the integration of PoCT results into clinical systems, as a precursor to the application of an evaluation framework for monitoring the delivery of PoCT services and their impact on patient care. Three datasets, including laboratory, ED presentations and hospital admissions data were extracted from the relevant clinical information systems. Each dataset was assessed on six dimensions: completeness, uniqueness, timeline, validity, accuracy, and consistency. Data incompleteness was the largest problem. Assessing the PoCT data integration and data quality is a precondition for the evaluation of PoCT and for monitoring and improving service delivery.

Keywords:
Point-of-Care Testing; Data Accuracy; Australia

Introduction
Point-of-Care Testing (PoCT) refers to pathology laboratory tests performed near patients and outside a traditional laboratory [1]. PoCT can be conducted in a variety of contexts within the community by patients themselves (typically in their own homes), or in medical environments (hospital bed side, general practice or pharmacies) by clinical personnel who are not necessarily trained in laboratory sciences [1]. The types of tests available range from a consumer-friendly dip stick or prick tests (e.g. home pregnancy tests or glucose meters) to moderately complex (often cartridge based) devices used by trained clinical personnel, to highly sophisticated instruments that can only analyse specifically prepared specimens [2].

Existing evidence shows that the key advantages of a PoCT service are greater access to laboratory testing, especially in underserved rural communities [1; 11; 12]. Traditionally, hospitals in rural and remote areas suffer from the ‘tyranny of distance’ and without on-site laboratory support face extended wait times for laboratory results alongside difficulties in specimen collection and transport [11; 12]. The introduction of PoCT in rural community based health services and hospitals has led to almost immediate access to results, enhanced clinical decision making, faster treatment onset, and disposition to dedicated wards reducing mortality rates and achieving optimal health outcomes [4; 11-13]. These benefits and the potential for improved outcomes rely on careful planning, readily defined roles of stakeholders and a model of clinical care that has been adapted to cater for successful integration of PoCT services [12].

Australia is the third least densely populated country in the world (less than 2.9 people/km²). With approximately one-third of the population living outside major cities, it has one of the lowest population densities outside its major cities [14]. NSW is the most populous state (6.9m) in Australia with more than 800,000 km² land [15]. NSW Health Pathology (NSWH) is implementing PoCT services across rural and remote EDs, including to areas with extremely limited access to health care services [1; 4; 11]. By the end of 2015, almost 400 PoCT devices had been delivered to 175 EDs in non-metropolitan areas of NSW. To our knowledge this is one of the world’s largest managed PoCT services [4; 16]. The rollout of this PoCT service offers the scope for a systematic investigation of the impact of PoCT implementation in rural and remote EDs to explore the operational impacts, evaluate patient outcomes and cost benefits and to develop an evaluation framework to aid PoCT expansion into additional health services such as ambulances and home care.

NSWHP’s commitment to the evaluation of PoCT services stems from the need to monitor and enhance the design, implementation and sustainability of the service and ensure the achievement of value for money, the delivery of improved efficiency, effectiveness and optimal patient outcomes. Undertaking an evaluation of PoCT services across rural and remote EDs in NSW involves the examination of data availability and quality. The Royal College of Pathologists of Australasia’s (RCPA) PoCT Quality Framework in 2014...
recommended that an information management system must be
developed to manage information generated by, entered into
and transmitted from the PoCT devices to the Laboratory
Information System (LIS) and then electronic Medical Records
(eMR) systems [17]. It is also one of the key objectives of
NSWHP’s implementation. The aim of this study is to assess
the quality of the datasets, including the integration of PoCT
results into clinical systems, as a precursor to develop and apply
a robust PoCT services evaluation framework.

Methods

Study design and setting
This was a retrospective before and after cohort study using
laboratory and emergency department (ED) data. The study
period was from January 2012 to the April 2015. The post
implementation period started from January 2014. The
evaluation was conducted across EDs in three Local Health
Districts (LHDs) in NSW; Far West, Murrumbidgee and
Western NSW LHDs (Figure 1). A total of 68 EDs were
included in this study (seven in Far West, 26 in Murrumbidgee
and 35 in Western NSW).

Laboratory services are provided by Pathology West NSW to
hospitals and EDs in these LHDs. The PoCT implementation
included the delivery of devices to many EDs that do not have
support of a 24/7 laboratory onsite, based on a test profile of 1)
Electrolytes, 2) Urea and Creatinine (EUC), 3) Blood gases +
lactate + haemoglobin, 4) Troponin and 5) International
Normalized Ratio (INR)/ Prothrombin Time (PT).

Figure 1: Local health districts, New South Wales, Australia
[18]

PoCT data reconciliation and integration
The PoCT management system ‘AQURE’ stores data relating
to every PoCT test ordered at the study EDs. PoCT tests in
AQURE can be included in the LIS data but only if the patient
demographic data entered into the PoCT device at the time of
testing can be matched to an individual patient by the AQURE
middleware which receives this information directly from the
Hospital Patient Administration System (HPAS). This process
is referred to as data reconciliation for this project. If
reconciled, the PoCT results will be integrated into the LIS
(Figure 2) and then into the patient’s eMR. The AQURE data
in the LIS was available from the 1st January 2014 after the
PoCT implementation.

Data sources and linkage
Three datasets were extracted from clinical information
systems. Laboratory data, including the reconciled PoCT data
from AQURE, were extracted from the LIS, while ED and
inpatient data were extracted from two information systems:
Emergency Department Information System (EDIS) and
HPAS. Three datasets were linked using a unique and non-
identifiable patient Medical Record Number (MRN), as well as
their gender and age. This process is depicted in Figure 2. The
shaded area shows the ED presentations with laboratory testing
including PoCT.

Figure 2: PoCT data integration and data linkage

Data quality assessment
Each dataset was assessed across six dimensions: completeness,
uniqueness, timeliness, validity, accuracy, and consistency (Table 1). Consistency was assessed in the linked
data across three data sources. The issue of completeness was
also examined for the rate of reconciliation for PoCT tests from
AQURE that were verified through a match with an individual
ED presentation and uploaded to LIS.

Ethics approval
Ethical approval for this study was granted by the Greater
Western Area Health Service Human Research Ethics
Committee (LNR/15/GWAHS/26). Site Specific Assessment
approval to conduct research within each of the LHDs was
provided by the Far West LHD (LNRSSA/15/GWAHS/48),
Murrumbidgee LHD (LNRSSA/15/MLHD/8) and Western
NSW LHD (LNRSSA/15/GWAHS/49).
Results
During the study period, there were 570,538 ED presentations, 262,806 inpatient admissions, and 727,168 laboratory tests, including PoCT tests, across three LHDs.

Completeness
Laboratory data including PoCT data integration
In Far West LHD, only one of the seven EDs had PoCT results reconciled and integrated into the LIS and eMR. In Murrumbidgee, data were provided for all 26 EDs. In Western NSW LHD, limited PoCT results were reconciled and integrated into the LIS and eMR at five EDs.
When comparing the LIS dataset with information from AQUIRE it was found that the LIS data contained fewer patients having PoCTs. Out of 68 EDs, 13 did not have compliant systems resulting in a proportion of PoCT tests that were unable to be reconciled. The average reconciliation rate across 55 EDs over the period encompassing the two to 13 months post the implementation of PoCT was 28.6%, increasing from 20.2% in the second month post the implementation of PoCT to 48.6% in the 13th month post PoCT.

ED data
For Far West LHD, the extract only included one ED, with no data for the other six EDs in this LHD. Due to a lack of systems compliant with HIE, ED data for Western NSW LHD were limited to 11 EDs with complete data available from December 2014 onwards.
Murrumbidgee was the only LHD which confirmed the availability of all ED data (Figure 4). However, the number of patient presentations per month in 2012 (range from 1968 to 2597) was much lower than those after January 2013 (range from 4647 to 6293). The median length of stay per month in 2012 (range from 85 to 114 minutes) was much higher than that afterwards (range from 70 to 85 minutes). In terms of the completeness of the data fields, Murrumbidgee was the only LHD that provided a variable distinguishing between ‘planned’ and ‘unplanned’ ED presentations.

Inpatient data
The inpatient data extracted from HPAS was confirmed as containing information relating to all inpatient stays in Murrumbidgee. In Far West LHD, the inpatient data were again limited to one site. In Western NSW LHD inpatient data were available for 33 out of 35 sites in this LHD.

Uniqueness
No duplications were identified in the datasets.

Timeliness
Laboratory data related to laboratory tests up to May 2015, while ED and inpatient data related to presentations/episodes of care up to April 2015. Analysis was performed between September and December 2015. Therefore, the data were regarded as adequate.

Validity
Construct validity is the extent to which data measure what they claim to be measuring. It was found that overlapping data in the ED and Laboratory data, such as patient MRN, gender, date of birth and patient location were in agreement. No overlap between data that was not supposed to relate to each other was found.

Accuracy
To determine the accuracy of the data, the contents of all fields were analyzed and suspect entries identified. Such entries were further analyzed by the research team and, after liaison with Pathology West and the LHDs, data deemed to be inaccurate were removed from the dataset.

Consistency
Consistency is particularly pertinent to this analysis, as a high level of consistency is required to enable triangulation of data from different sources through data linkage (Figure 2). It was found that after the accuracy of the data had been established matching data fields in the ED and Pathology data, such as patient MRN, gender, date of birth and patient location were in agreement. Therefore, the data were regarded as consistent.

Discussion
High quality data are required for accurately evaluating the impact of health interventions. Through data quality assessment, limitations and deficiency of datasets can be identified. Evaluation of data quality revealed a number of limitations related to the completeness of available data. Murrumbidgee was the only LHD that was able to supply all ED presentations for the period January 2013 to April 2015. The Western NSW LHD was only able to provide ED data from 10 of 35 sites. However, the completeness of these data could not be verified by the LHD. In Far West LHD data from only one hospital, only one ED was confirmed as containing all ED presentations over the entire study duration. Murrumbidgee
LHD was the only data source which allowed the distinction between ‘planned’ (arranged in advance) and ‘unplanned’ (emergency) ED presentations. This distinction can have an important effect on data analyses and interpretation.

Data linkage provides numerous opportunities to extend our understanding of health care phenomena. Nevertheless, as the challenges of integrating PoCT into hospital networks attest, linked data needs to be carefully assessed for quality. Ensuring the quality of linked data should therefore incorporate data profiling techniques to examine the quality of each dataset separately [20; 21]. This could involve the application of algorithms that identify missing data, duplicates, data formatting and compliance with logic rules (e.g. patient was admitted before they were discharged). It should also incorporate an interrogation of key variables using descriptive statistics to examine the range of findings, percentiles and outliers for consistency and validity [22].

The process of data linkage using hospital, patient and laboratory data involves key ethical, privacy and confidentiality issues involving data governance processes and approval from the appropriate Human Research Ethics Committees (HREC). It also involves controls to protect the integrity of the data and ensure that no identifiable data is publicly available.

Assessing data integration and data quality provided the basis for targeted recommendations for improvement. First, data incompleteness is the largest problem in these rural and remote LHDs. This problem is universal across three clinical information systems: the LIS, EDIS and HPAS. LIS data completeness is also dependent upon the reconciliation of data from HPAS with patient information entered on the PoCT device at the time of testing. Secondly, the reconciliation rate of available PoCT data were only 28.9% although it has been increased from 20.2% in the second month post the implementation of PoCT to 48.6% in the 13th month post PoCT. One of the key recommendation from Royal College of Pathologists of Australasia for quality use of PoCT include the capacity for seamless and automated transfer of results to patients’ electronic medical records [17]. Lack of electronic medical record systems in these rural and remote EDs could be one of main reasons for the low reconciliation rate, in addition to 1) incorrect entry of patient identifications into PoCT devices and 2) lack of resources to ensure that MRNs are available for new patients or that the patient visit is updated in HPAS at time of PoCT.

Conclusion

The NSWHP implemented one of the world’s largest PoCT services across rural and remote EDs. It has the potential to significantly improve access to on-the-spot results for certain types of laboratory tests as a means to deliver timely patient care. Assessing PoCT data integration and data quality is a key precondition for evaluating the implementation of PoCT services and for further monitoring and improving the services into the future. Although our study was based on Australian rural and remote sites, the data integration and quality issue is not unique to these Australian sites, but of relevance to researchers and implementation teams globally.

This study not only provided a rigorous assessment methodology but also highlighted the value of linking routinely collected datasets from different clinical information systems in data quality assessment and subsequently in evaluation of the PoCT implementation.

Acknowledgements

This study was commissioned by NSW Health Pathology and was conducted as part of a project to evaluate the implementation of PoCT service across NSW rural and remote EDs. AS and JI are employed at NSW Health Pathology. They contributed to the study design and revisions of the manuscript, but were not involved in the data assessment and interpretation. We acknowledge the contribution of Jill Reymert, Dominic Dwyer, Roger Wilson, Keira Robinson, Michael Whiley and Sue Carter to this project.

Abstract

Acute myocardial infarction is a major cause of hospitalization and mortality in China, where ST-elevation myocardial infarction (STEMI) is more severe and has a higher mortality rate. Accurate and interpretable prediction of in-hospital mortality is critical for STEMI patient clinical decision making. In this study, we used interpretable machine learning approaches to build in-hospital mortality prediction models for STEMI patients from Chinese Acute Myocardial Infarction (CAMI) registry data. We first performed cohort construction and feature engineering on CAMI data to generate an available dataset and identify potential predictors. Then several supervised learning methods with good interpretability, including generalized linear models, decision tree models, and Bayes models, were applied to build prediction models. The experimental results show that our models achieve higher prediction performance (AUC = 0.80–0.85) than the previous in-hospital mortality prediction STEMI models and are also easily interpretable for clinical decision support.

Keywords:

Myocardial Infarction; Hospital Mortality; Machine Learning

Introduction

Acute myocardial infarction (AMI) is a major cause of hospitalization and mortality in China, where the in-hospital mortality rate for ST-elevation myocardial infarction (STEMI) is even higher than that for non-ST-elevation myocardial infarction (NSTEMI) [1,2]. Because there is considerable variability in mortality risk among patients with STEMI, it is critical to accurately predict the risks of in-hospital mortality for STEMI patients at the time of hospital presentation, in order to decide on the allocation of clinical resources and the choice of interventional and medical therapies [3,4].

Current in-hospital mortality risk models for STEMI, such as TIMI score [3] and GRACE score [4], use predictors that are grounded in previous known evidence, including age, heart rate, systolic blood pressure (SBP), Killip levels, weight, history of hypertension, diabetes and angina, anterior STEMI, time to treatment, serum creatinine, and cardiac arrest. These risk scores were derived from logistic regression models, which are well understood and easy to apply in clinical practice. However, the performance of in-hospital mortality prediction for STEMI still has room for improvement. Besides the predictors used in the existing models, there are other potential predictors that are highly related to STEMI in-hospital mortality, which can also be used in risk prediction to improve the performance. Besides, some other machine learning models may achieve better prediction performance or interpretability than regression analysis models like logistic regression.

Therefore, this study investigated the modeling of in-hospital mortality prediction models in STEMI that have good prediction ability and interpretability using machine learning methods. The study was based on the Chinese Acute Myocardial Infarction (CAMI) [2] data, which collected the patients’ demographics, symptoms, medical history, results of physical examination and laboratory test, details of in-hospital treatments, and clinical events including mortality. Because the dataset is heterogeneous and redundant, dimensionality reduction methods and model learning algorithms that can handle redundant feature sets should be used for predictive modeling. Moreover, the objective of this study was to build human understandable and applicable risk prediction models. Though many previous works used feature engineering and supervised learning methods to build high accuracy risk prediction models for cardiovascular diseases and diabetes [5–10], the learning methods in which resulting models are difficult to interpret (e.g., principle component analysis, support vector machine, and deep neural network) are not preferable in building clinically interpretable risk models.

In this study, we integrated interpretable machine learning approaches to build in-hospital mortality risk prediction models for STEMI patients from CAMI data. Feature engineering methods, including feature construction, missing data imputation and filter-based feature selection, were used to generate available dataset, identify potential predictors and reduce redundancy. Then we applied different categories of supervised learning methods that have good interpretability, including generalized linear models, decision trees, and Bayes models, to build risk prediction models that are suitable for different clinical scenarios. The experimental results show that our models can achieve higher prediction performance than the previous risk prediction models for STEMI, and are also easily interpretable for clinical decision support.

Therefore, this study investigated the modeling of in-hospital mortality prediction models in STEMI that have good prediction ability and interpretability using machine learning methods.
Methods

Figure 1 shows our pipeline of building in-hospital mortality risk prediction models for STEMI patients. We first constructed the cohort of interest, and applied feature engineering to identify potential predictors. Then we trained prediction models using supervised learning algorithms, and evaluated their prediction performance and model interpretability.

Cohort Construction

The dataset used in this study were collected in the CAMI registry project [2]. The project started in 2013 and 26,103 patients with AMI were registered until 2014. From the CAMI data, we identified 18,744 patients who were hospitalized due to STEMI in 2013 and 2014, where 1,263 patients were cases who died in hospital (the in-hospital mortality rate is 6.74%), and the others were control instances who survived in hospital. The features used in this study were those collected at the time of hospital presentation (i.e., before any in-hospital treatment). In the CAMI data, 132 original features meet this criteria, including demographics, medical and treatment histories, life styles, onset symptoms, initial in-hospital vital signs, laboratory test results, etc.

In this study, we used the data of patients hospitalized in 2014 as the training set (9,619 patients, whose mortality rate is 6.78%) to develop the risk prediction models and the data of patients hospitalized in 2013 as the testing set (9,125 patients, whose mortality rate is 6.70%) to validate the prediction performance of the models.

Feature Engineering

In the raw CAMI data, some original features are not appropriate to be directly used in predictive modeling (e.g., birth year), and a large proportion of original features (more than 95%) have missing values. Moreover, not all original features are highly related to in-hospital mortality of STEMI. Therefore, we performed feature engineering to construct and select the potential predictors for risk prediction. We first transformed the original features to features that are easy to analyze by feature construction. For example, the “birth year” of each patient was transformed to “age”. Then, we employed data imputation to fill-in missing values and applied filter-based feature selection algorithms to identify potential predictors from the imputed features.

The raw CAMI data has significant omissions due to the questionnaire structure; unknown values or errors in data collection. Therefore, we performed missing data imputation before predictive analysis. Firstly, the features with too many missing entries (more than 20%) were discarded, because their distributions are difficult to estimate. For the remaining features, every missing value of a numeric feature (e.g., SBP) was replaced with the mean of the feature’s observed values, every missing value of an ordinal feature (e.g., Killip level) was replaced with the median of its observed values, and every missing value of an unordered nominal feature (e.g., history of diabetes) was replaced with the mode of its observed values. In this study, after feature construction and missing data imputation, 93 available candidate features were produced to the following feature selection step.

In machine learning, feature selection methods automatically test and select predictive features from a large number of candidate features. There are three main supervised feature selection strategies: filter, wrapper, and embedded models [11]. The filter models separate feature selection from model learning, and the wrapper and embedded models integrate feature selection in learning process. In the step of feature engineering, we performed filter models to remove the features that do not provide useful information and select the features that have high relevancy against the outcome. Concretely, the close-to-constant features, in which 99% of the instances have identical values, were first removed. Then we employed and compared two feature filtering models.

- **Univariate filter.** A univariate filter method calculates a score to represent the relevancy of a feature against the outcome, and filter the feature based on the score independently. In this study, we used the p-value from two standard statistical tests, the Chi-square test for categorical features and the ANOVA F test for numeric features, as the relevancy scores and selected the features whose p-value < 0.05.

- **Multivariate filter.** Different from the univariate filter method, a multivariate filter method evaluates the input features as a batch producing a subset of features that have the highest overall score. In this study, we used the correlation-based feature subset selection (CFS) method [12] to obtain the subset of features highly correlated with the outcome while having low intercorrelation between the features.

In this study, we also combined the features that were automatically selected by the filter-based feature selection algorithm with features that are well-known risk factors from prior knowledge [3,4], but were not automatically selected (e.g., anterior STEMI, time to treatment) as the predictors to build risk prediction models.

Predictive Modeling

In this study, we applied and compared different categories of machine learning models that have good interpretability, including generalized linear models (GLM), decision tree models, and Bayes models, to develop in-hospital mortality prediction models for STEMI patients. Besides, built-in feature selection strategies, including wrapper and embedded selection, were employed in some modeling processes.

- **Generalized linear model.** GLM generalizes ordinary linear regression by allowing the linear model to be related to the response variable via a link function, which is widely used in both medical statistics and machine learning due to its good prediction performance and interpretability. In this study, we applied logistic regression (LR), which is a GLM with a logit link function and a binomial distribution, and Cox proportional hazards model [13], which is a semiparametric GLM that takes into account the time of censoring. We also employed forward stepwise feature selection, which is a wrapper selection model, to evaluate the performance and statistical significance of the LR and Cox models under different selection of features.

- **Decision tree model.** Decision trees are very easy to interpret and therefore have been successfully applied in healthcare. Decision tree learning algorithms usually embed feature selection into the learning process of a model when splitting the source data set into subsets. In this study, we employed the Chi-squared automatic interaction detector (CHAID) [14] method to build tree-based prediction model. CHAID is an efficient statistical technique that uses significance of Chi-squared test as a criterion for tree growing. We also employed random forest [15], which constructs multiple random decision trees and integrate the outputs of the trees for prediction. Compared to single decision tree models like CHAID, random forest reduces the problem of over-fitting, but has worse interpretability.

- **Bayes model.** Bayes models can learn probabilistic relationships among features and an outcome; computing
the probabilities of the outcome given the features. The Bayes models are also interpretable based on Bayes theorem. In this study, we employed naive Bayes [16], which is a Bayes model with strong independence assumptions between the input features and therefore can be trained very efficiently. We also applied Bayes network [17], which is a probabilistic graphical model that represents features and their conditional dependencies via a directed acyclic graph, where both the dependencies between outcome and input features and the interdependencies among input features can be modeled.

Results

We evaluated the performance of our approaches in building in-hospital mortality risk prediction models for STEMI patients from the CAMI dataset. The area under the receiver operating characteristic curve (AUC) were used to evaluate the prediction performance of models. We performed feature engineering and model learning on the training set, applied the learned models on the testing set, and evaluated the AUC on both datasets.

We first generated four different feature sets by feature engineering:

1. None of the feature filtering methods were applied, all original 93 features were kept.
2. Univariate filter selection was performed to select 51 features
3. CFS, which is a multivariate filter algorithm, selected 19 features
4. A combination of features from CFS and prior knowledge [3,4].

Then we built different learning models described above using different feature sets and evaluated their prediction performance. The results are shown in Table 1, where the models with less features and higher AUC on the testing set are highlighted. Random forest and the Bayes network achieved the best performance when applied on all candidate features, but their performance cannot be increased by filter-based feature selection. In comparison, after performing filter-based feature selection, the performance of GLM methods (LR and Cox) increased. Moreover, the combination of auto-selected features by CFS and prior knowledge based features improved the prediction performance for the majority of learning models.

We also compared the performance of our approaches to the state-of-the-arts risk models: TIMI score [3] and GRACE score [4]. We applied both previous models and our trained models on the same testing set and computed the AUC. As shown in Figure 4, the prediction performance of most of our models outweighed the TIMI and GRACE models.

Figure 2 – AUC of different models, evaluated on the same testing set.

Figure 3 – CHAID tree model on CFS feature set.
Since the objective of this work was to develop in-hospital mortality prediction models that can be used in real world clinical practices, the interpretability of the models was as important as the prediction performance. Table 2 shows the stepwise LR model built on the Combination feature set (AUC: 0.842, 95% confidence interval (CI):0.826-0.859). As a traditional regression analysis model, the contribution of each selected feature can be represented by the odds ratio (OR), and its statistical significance can be evaluated using 95% CI and p-value. For example, in the LR model of Table 2, for every 10-year increase in age the odds of in-hospital mortality multiplies by 1.654. The cox regression models are similar for interpretation, where the contribution of each feature can be represented by the hazard ratio.

Though the AUC of the CHAID tree models are not as good as our other models, the CHAID model has the very clear interpretation. As shown in Figure 3, in the CHAID model built on the CFS feature set, the whole dataset can be split into four subgroup with very different mortality rates by Killip level. Also, the patient group with Killip = 1 can be further divided into four smaller subgroups by age. Therefore, each patient belong to a leaf node in the tree that can be uniquely defined using a set of rules, and the mortality rate of this node (subgroup) is explicitly used to predict the patient’s risk. In contrast, though random forest achieved the best prediction performance on every feature set of this study, each random forest model has many different decision trees (100 trees in our setting) and is not easy to interpret.

A Bayes model can represent the conditional dependencies between input features and outcome, and also has good interpretability. Because the interdependencies between features are complex in the Bayes network models built in previous experiments, for demonstration purpose we show the Bayes network model developed on the 12 well-known predictors using our training dataset in Figure 4. Both the dependencies between the outcome and the predictors (e.g., the death outcome has strong direct dependencies on creatinine, Killip level, heart rate, SBP and hypertension) as well as the interdependencies between the predictors (e.g., dependency between heart rate and Killip level, dependency between SBP and hypertension, etc.) are clearly represented in the Bayes network model.

**Discussion**

In this study, we compared the prediction of several feature selection and supervised learning methods in building in-hospital mortality prediction models for STEMI patients. For GLM models (LR and Cox), appropriate feature selection can not only reduce the model complexity, but also improves the prediction performance. This is probably because GLM makes the assumption of no multicollinearity between the features, but the whole feature set is redundant, which negatively affects prediction performance. The feature selection methods, including CFS, which minimizes the intercorrelation and stepwise selection that optimizes the performance and statistical significance, can reduce the redundancy of features and therefore increase prediction performance. In contrast, the random forest and Bayes network methods can handle the redundant and intercorrelated features and therefore achieved the best prediction performance on the whole feature set. Moreover, the known predictors from prior knowledge [3,4] were grounded in previous evidence. Adding them to the auto-selected features from our dataset essentially includes the information outside the dataset, and therefore improved the prediction performance.

We also compared the interpretability of different machine learning models for risk prediction. As there is a trade-off between prediction performance and model interpretability, the choice of machine learning models may vary depending on the real-world clinical scenario.

5. Clinicians need to quickly estimate a patient’s risk without any decision support tool requiring a human-memorable risk prediction model. Though the prediction performance of a single decision tree model (e.g., the CHAID model, Figure 3) is usually not as good as other machine learning models, it is human understandable and memorable, and is very suitable for this scenario.

6. Clinicians can predict a patient’s risk with an independent risk prediction tool, such as a risk calculator, but still needs to manually input the predictor values. For these cases, a model that is
developed by combining feature selection and GLM (e.g., the stepwise LR model in Table 2) can provide decent prediction performance while keeping the input workload acceptable.

7. Clinicians can directly load a patient’s data from the health information system (HIS) to perform risk prediction. For these cases, the complex risk prediction models with higher prediction performance (e.g., Bayes network and random forest models built on the whole feature set) can be used in clinical decision support.

For the purpose of interpretability, we did not apply more complex machine learning models such as deep neural network (DNN). However, there already have been attempts to make traditionally uninterpretable models interpretable. For example, Che et al. [18] developed a mimic learning approach, which can derive interpretable decision tree models from DNN models and maintain DNN’s strong prediction performance. For future work, we would follow this direction in order to develop interpretable risk prediction models with higher prediction performance.

Another limitation of this work is that we only used a standard data imputation method based on column mean, median, and mode to remedy missing values. Some more advanced statistical imputation methods like multiple imputation, as well as the machine learning based imputation methods such as k-nearest neighbors imputation and neural network imputation, could be tried in the future, to make a more accurate estimation for missing values.

Conclusions

ST-elevation myocardial infarction (STEMI) is a major cause of hospitalization and has high in-hospital mortality rate. Accurate and interpretable prediction of in-hospital mortality is critical for clinical decision making to STEMI patients. In this study, we used integrated machine learning approaches, including the feature engineering and supervised learning methods that have good interpretability, to build in-hospital mortality prediction models for STEMI patients from CAMI data. The experimental results show that our models achieve higher prediction performance than previous models, and are also easily interpretable for clinical decision support.

Abstract

Eligibility criteria among hundreds of National Health Insurance Research Database (NHIRD) research papers have similar constituent elements, such as demographic characteristics or diagnostic codes. The study results of the same disease could vary among different research due to the variation of the criteria statements, therefore the narrative patterns analysis tool would be helpful for summarizing the knowledge implicitly contained in the eligibility criteria. In this study, we developed a series of R-based text processing methods to extract the narrative eligibility criteria in NHIRD papers by simplifying the article titles and content paragraphs, identifying medical concepts and abbreviations, then detecting basic demographic characteristics and ICD-9-CM diagnosis codes. Although there is still room for improvement on study type identifying, the high performance in classifying the study type, detecting age restrictions and extracting ICD-9-CM codes still shows the system usefulness for the analysis of eligibility criteria.

Keywords:
Database; Natural Language Processing

Introduction

The de-identified and sampled claim dataset called the National Health Insurance Research Database (NHIRD) has been accessible by researchers purely for research purposes since 2000. This anonymous database contains comprehensive information on insured people, such as demographic data, ambulatory and inpatient medical claims, disease diagnoses, and prescription records. The diagnostic codes used were based on the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM). There are nearly 3,000 NHIRD studies published in international journals, and the number of articles has increased year by year.

Most of NHIRD papers aim to figure out the relationship among disease, medication, and procedure by analyzing the medical records in insurance claim data rather than the development of practical clinical trials. In these NHIRD studies, researchers must define a set of suitable eligibility criteria (also known as “case definition”) of study samples. Just like the clinical trial protocol, the eligibility criteria of NHIRD studies can be roughly divided into inclusion and exclusion criteria [1]. Inclusion criteria are the general description of the target population, while exclusion criteria are further fine-tuned in order to exclude patients that have some characteristics (e.g. medical history, not the age of onset of the disease) which might interfere with the study results. For example, the narrative of inclusion criteria of chronic kidney disease (CKD) might be “The claims-based diagnosis of CKD was defined by the presence of 1 inpatient or outpatient ICD-9-CM code 585 in the claims and without catastrophic illness registration cards for ESRD” [2], and an exclusion criteria of polycystic ovary syndrome (PCOS) like “Women with PCOS diagnosed at < 15 or > 45 years of age were excluded” [3]. However, there are still differences in the writing patterns. For example, when considering the accuracy of diagnosis, NHIRD researchers emphasize that they use the diagnosis records from specific data files and fields, or the minimum limit of medical visits, rather than physiological values and vital signs which are commonly used in the clinical protocols.

Several research that focus on eligibility criteria have suggested that study results (e.g. prevalence, hazard ratio) of the same disease would vary with a different setting of eligibility criteria. For instance, the incidence rate of Kawasaki disease defined by ICD-9-CM code (446.1) with ATC code (J06B02) was much lower than defined by ICD-9-CM code (446.1) only [4]; the estimated prevalences of cerebral palsy would differ from 6 kinds of criteria setting [5]; in the study of the risk of epithelial ovarian cancer (EOC) in patients with endometriosis (EM) [6], the authors compared 13 different criteria of EM, the loosest criterion just have 1 outpatient or hospitalization medical record with ICD-9-CM code 617.0-9 while the strictest must be confirmed by code for surgery (65.1X, 65.2X), and it is indicated that the looser the criterion used, the higher the prevalence of EM and the lower the incidence of subsequent EOC would be estimated. It goes to show that stricter eligibility criteria can improve the homogeneity of sample and research accuracy [1], but the number of samples would decrease at the same time [7]. On the contrary, if criteria were too loose, they might lead to overestimation or underestimation of the disease prevalence or even the correlation between disease and its risk factors [6], which would make the study results not representative.

Researchers have to search the ICD-9-CM code or other characteristics of target diseases from previous papers when designing their eligibility criteria. In addition, finding suitable references and then understanding the narrative is a time-consuming labor because researchers tend to use different vocabulary and narratives to avoid the doubts about plagiarism. In nearly 3,000 NHIRD articles, one criterion of the same disease might have dozens of varied statements, causing great obstacles in summarizing the knowledge in eligibility criteria.
If there is a processing mechanism of converting the eligibility criteria into structured form and further summarizing as a retrieval system, it would be useful for a researcher to refer to the existing criteria and facilitate their own study design. In addition, eligibility criteria can further be used as study material, for comparing the results from varied criteria and clarifying the suitable criteria for a specific disease in epidemiological research. There are studies that use natural language processing technologies in criteria text processing that focus on the documents of the clinical trial protocol [8-10] or descriptive clinical text [11; 12] in electronic medical record (EMR), while the criteria of NHIRD articles were written in a much simpler way, thus could be processed by pattern recognition tools without complicated NLP techniques.

In this study, we built a series of text processing tools to extract the narrative eligibility criteria in NHIRD articles. In the following sections, we will describe the methods of retrieving the criteria section in articles, detecting the medical concept, age and gender limitation of subjects, extracting the ICD-9-CM codes, detecting the restriction of specialist, and present the result of system performance.

Methods

Materials

All of our input data arrived from the NHIRD related articles of PLOS ONE journal which provided the open access XML format files (n=280). In the following description, we will introduce the article titled “Increased Risk of Primary Sjögren's Syndrome in Female Patients with Thyroid Disorders: A Longitudinal Population-Based Study in Taiwan” [13] as an example, and using the section titled within curly brackets (e.g. {Abstract}, {Introduction}, {Materials and Methods}) to represent the section of NHIRD articles.

Defining study events

In this study, we only focus on the issues of the diseases. We used the word “event” to represent the medical disease concept in the NHIRD researches. There is a temporal relationship between events in the same article, the order of occurrence event in the example paper is (1) thyroid disorders (2) primary Sjögren's syndrome.

Text processing

Our text processing framework is depicted in Figure 1. The processing works are all developed under R software (v.3.3.0).

![Figure 1 - Text processing methods overview](image)

Preprocessing of the article title

To simplify the article title, the segment sentences unrelated to study event such like “A Longitudinal Population-Based Study in Taiwan” and the words “patient”, “people”, “subject”, “adult” and “child” would be removed in this step, for avoiding the interference in later event identifying step.

In addition, some special diseases would be written in non-English vocabulary (e.g. “Sjögren” was a Swedish word), that could not be processed by the UMLS mapping tool MetaMap (2014 Linux version) [14], so we converted the Latin alphabets into English alphabets in this step. As the above processing, the title of the example article would be simplified to “Increased Risk of Primary Sjogren's Syndrome in Thyroid Disorders”.

Identifying the study type

In this study, we excluded the articles exploring the issues of disease mortality, socioeconomic factors, cost-effectiveness or utilization of the medical resource. The titles of remaining papers would be filtered with 6 regular expressions (Table 1) to find those that belong to the study type “Increased or decreased (Event 2) risk after (Event 1)”.

Identifying the study events

The phrases of “any words” captured from the last step would be mapped to UMLS Metathesaurus by MetaMap. The R code for extraction of MetaMap output was referred from Shah et al [15]. When the semantic types of the concepts in the MetaMap output are “Disease or Syndrome”, “Therapeutic or Preventive Procedure”, “Pharmacologic Substance” or other disease, procedure or medication related semantic types (priority were shown in Table 2), the concepts would be identified as study events. If there are more than two phrases matching to the specific semantic types above, the system would choose the first item of the output as the true study event.

 Detecting the abbreviations

The NHIRD papers often use abbreviations instead of the long medical term. For example, some papers use “HZ” to refer to herpes zoster, while UMLS does not include this abbreviation, thus “HZ” would be considered the abbreviation of “Hertz” by MetaMap. Therefore, we replaced abbreviations with corresponding full descriptions to prevent these systematic errors. Although there were some biomedical abbreviation identified algorithms [16], we built a simple method to detect the abbreviations. We defined the abbreviations as “only one word (contain at least one capital letter) within the parentheses”. The detection range included {Abstract}, {Introduction} and {Materials and Methods} sections. In the sentence “... and primary Sjogren’s syndrome (pSS). However ......” of the example articles, “pSS” was identified as an abbreviation. The system would then capture the words from the phrase before the abbreviation to each word with the same initial as the abbreviation (“p”), therefore the phrase “primary Sjogren’s syndrome” would be regarded as a candidate full description of “pSS”.

If there are more than one candidate full descriptions, like “prior primary Sjogren’s syndrome” and “primary Sjogren’s syndrome”, the system would create candidate abbreviations that consist of each initial of the candidates, then compute the string similarity between candidate abbreviations and original abbreviations by the function ‘strmp’ in R package ‘RecordLinkage’. The candidate full description with the most similar abbreviation would be regarded as the correct phrase.

In addition, diabetes mellitus is one of the most common study events of NHIRD research, while the possible abbreviations of type 2 diabetes mellitus might be “T2DM”, “Type 2 DM”, “Type II DM” etc., which could not be detected because of more than one word in the parentheses. We will process the abbreviations of diabetes mellitus specially in the next step.

 Preprocessing of the eligibility criteria paragraph

The eligibility criteria are often written in the {Materials and Methods} section, thus before further analysis, the abbreviations in this section will be replaced with the corresponding full description, and the full width rules will be replaced with halfwidth symbols. Other replacement rules are listed in Table 3. For the ease of analysis, we excluded the sentences which contain the phrases like “National Health Insurance Research Database” or “Data Availability”, and removed the descriptions of statistic analysis. The remain sentences would be regarded as eligibility criteria.

 Detecting the age and gender restriction criteria

Each sentence of eligibility criteria would be matched with 5 regular expressions (Table 4) for age restriction detection. In the example article, the sentence “We excluded patients under the age of 20 years and those with a catastrophic illness certificate for autoimmune diseases other than Sjogren’s syndrome” corresponded to the expression formula “(Comparing words) + the age of + (Value)” with the “excluded” concept, thus the age restriction is 20 years old for lower bound with no upper bound.

To detect the gender restriction, the article titles, and each criteria sentence were first filtered with 6 keywords (“males”, “men”, “boys”, “females”, “women”, “girl”) and detected the inclusion or exclusion concept. There was “female” in the title of example article, therefore the gender restriction was “female included only”.

 Extracting the ICD-9-CM codes

Each criteria sentence would be filtered with the keywords “ICD” and “code”, then the diagnosis code would be extracted with the regular expressions for ICD-9-CM code (Table 5). If the codes were written as a continuous code interval (e.g. “thyroid gland (240-242, 244-246)”), the start and end point would be annotated. The UMLS concept name and CUI of each code would be extracted by the R package ‘rUMLS’ (Table 6).

 Detecting the specialist restriction

Some papers would restrict the diagnosis records of study subjects made by specific specialists, in order to increase the accuracy and credibility. If there is the word “diagnosis” in the criteria sentence, the whole sentence will be further mapped to UMLS Metathesaurus by MetaMap. The words with the semantic type “Professional or Occupational Group” would be considered the restriction of specialists.
Results

Identifying the study type

In 280 papers, 99 belonged to the target study type “Increased or decreased (Event 2) risk after (Event 1)”. The 5-fold cross-validation results are depicted in Table 7. Papers like “Premotor Symptoms as Predictors of Outcome in Parkinson’s Disease: A Case-Control Study” [17] and “Irritable Bowel Caused by Irritable Bowel? A Nationwide Analysis for Irritable Bowel Syndrome and Risk of Bipolar Disorder” [18] were misclassified due to matching to the exclusion regular expression.

Table 7 - System performance on study type identifying

<table>

<td>0.794</td>
</tr>
<tr>
<td>Testing</td>
<td>0.778</td>
<td>0.818</td>
<td>0.789</td>
</tr>
</tbody>
</table>

Identifying the study events

In the 81 papers correctly classified as the target study type, the study events of 70 papers were correctly identified. Six other papers were identified with only event 1 or event 2, and 5 papers failed. The event 1 of the article titled “A Longitudinal Study on Early Hospitalized Airway Infections and Subsequent Childhood Asthma” [19] was airway infections. However, it could not match to the UMLS Metathesaurus directly, thus it would be separated into “airway” and “infection” by MetaMap. Following the priority of event semantic type, the system would consider “infection” as event 1. After reviewing abstract, we found the real event 1 was acute bronchiolitis, that is to say, airway infections were a general description of their event 1.

There were 8 papers titled as “...... associated with ......”. However, the word “associate” did not imply temporal relationship between event 1 and event 2. For example, the order of events occurrence of “Rheumatoid Arthritis Risk Associated with Periodontitis Exposure: A Nationwide, Population-Based Cohort Study” [20] was (1) periodontitis (2) rheumatoid arthritis, while the order of “Hyperlipidemia Is Associated with Chronic Urticaria: A Population-Based Study” [21] was (1) hyperlipidemia (2) chronic urticaria. It goes to show that the temporal relationship between events should not be identified by article title only.

Furthermore, some phrases could not correctly map to UMLS Metathesaurus, leading to an error in events identifying. As shown in Table 8, the CUI of “Organophosphates Poisoning” was C0700359, however it would be separated into “Organophosphates” and “Poisoning”; “Urinary Stone Disease” would map to “Urologic Diseases”, “Calculi”, “Urinary Calculi” and “Disease”, although “Urinary Calculi” was closer to the real study event, “Urinary Calculi” was chosen because of its semantic type “Disease or Syndrome”.

</table>

Detecting the age and gender restriction criteria

The 5-fold cross-validation results of age restriction detection of the 99 target papers are shown in Table 9. The most common criteria was “≥ 20 years old” (n = 23), and the second was “≥ 18 years old” (n = 18). We used the keywords “match” and “urbanization” to avoid detecting to the case matching description like “...... matched by the age (<20, 20-29, 30-39, 40-49, 50-59, 60-69, 70-79, >80 years) ......” or with the criteria of level of urbanization like “percentage of residents >65 years old”. In addition, one paper with criteria “younger than 36 months” was wrongly identified due to the system not converting the time unit in the preprocessing step.

In the development phase, the system detected the keywords of gender in eligibility criteria paragraph (Table 10). There were only 16 papers having the gender restriction, thus the false negative results would decrease the recall drastically. In addition, there were three papers titled with keywords about male or female reproductive system diseases thus the authors did not emphasize the gender restrictions and the system did not detect the restrictions in the paragraph.

<td>0.593</td>
</tr>
</tbody>
</table>

Extracting the ICD-9-CM codes

In the 99 target papers, there were 1575 ICD-9-CM diagnosis codes. 1438 of them were correctly extracted, the 144 lost were most due to (1) lack of “ICD” and “code” in the sentences , (2) written in ways like “401-5.x” which did not
meet our regular expression of ICD-9-CM codes, (3) the codes were written in tables rather than text content, (4) the continuous code were extracted but their start and endpoint were incorrect thus been considered as single codes. In addition, 67 items were mistaken for ICD-9-CM codes while they were actually the number of subjects.

**Detecting the specialist restriction**

The 5-fold cross-validation results of specialist restriction detection are shown in Table 11. The terms like “attending physician” were incorrectly considered as restrictions, thus decreased the precision.

**Conclusions**

In this study, we focused on developing a pattern recognition-based method to extract the narrative eligibility criteria in NHIRD papers as simple as possible, which could identify the study type, medical concept, abbreviations, basic demographic characteristics and ICD-9-CM code restrictions in titles and contents of NHIRD articles. In this preliminary stage, we only used the articles from PLOS ONE for the ease of processing with XML files. The training and testing data were all from PLOS ONE at present. Moreover, we only dealt with the study type “increased or decreased (Event 2) risk after (Event 1)” because the system could not identify the event relationship within article titles which include more than two events. In future work, we will include the 3,000 NHIRD papers across several journals as study materials, and establish the function of observation period and temporal relationship identifying, then convert the narrative text of scientific research articles into structured documents.

Assessing the Representation of Occupation Information in Free-Text Clinical Documents Across Multiple Sources

*Department of Surgery, University of Minnesota, Minneapolis, MN, USA,

Abstract

There has been increasing recognition of the key role of social determinants like occupation on health. Given the relatively poor understanding of occupation information in electronic health records (EHRs), we sought to characterize occupation information within free-text clinical document sources. From six distinct clinical sources, 868 total occupation-related sentences were identified for the study corpus. Building off approaches from previous studies, refined annotation guidelines were created using the National Institute for Occupational Safety and Health Occupational Data for Health data model with elements added to increase granularity. Our corpus generated 2,005 total annotations representing 39 of 41 entity types from the enhanced data model. Highest frequency entities were: Occupation Description (17.7%); Employment Status – Not Specified (12.5%); Employer Name (11.0%); Subject (9.8%); Industry Description (6.2%). Our findings support the value of standardizing entry of EHR occupation information to improve data quality for improved patient care and secondary uses of this information.

Keywords:
Occupations; Social Determinants of Health; Electronic Health Records.

Introduction

The need to accurately capture occupation and other social history information is central for the use of this information in the provision of direct clinical care and for secondary uses like research and risk stratification of patients [1]. As electronic health record (EHR) system use increases within healthcare organizations, there is an opportunity for improved capture of this information at the point of care. Within the United States, the National Academy of Medicine (NAM) in their 2011 report “Incorporating Occupational Information in Electronic Health Records” advocates for inclusion of social factors in EHR systems, due to the important impact of social factors on health status and outcomes [2]. Similarly, Phases 1 and 2 of their 2014 reports “Capturing Social and Behavioral Domains and Measures in Electronic Health Records” [3, 4] further emphasize the importance of these factors. The National Institute for Occupational Safety and Health (NIOSH), a leader in efforts to qualify occupation information in the United States, has done extensive work to promote documentation of occupation information in a standard manner by creating the Occupational Data for Health (ODH) data model [5].

Prior work has been done to broadly analyze how social history information is captured in EHR systems [6, 7], public health datasets [8], and how occupation-related information appears within standards and within social history in the EHR [9, 11]. More specifically, using a top-down approach, Rajamani et al. examined reports, standards, surveys, and research measures to analyze the ODH model’s ability to provide coverage for occupation-related information [9], including the Health Level Seven Clinical Document Architecture content module of the Integrating the Healthcare Enterprise Patient Care Coordination Technical Framework, which incorporates the ODH model [10]. Aldekhyyel et al. examined the content and quality of entries within the free-text occupation field of the Fairview Health Services enterprise EHR social history module [11]. The results of these studies provided a comprehensive overview of the current state of representation and standardization of occupation information. Collectively, they highlight that the ODH model is robust in coverage of occupation-related information and that the content and quality of occupation information within the EHR can be inconsistent and variable.

The main objective of this study was to build upon prior efforts of this group of authors by looking at a range of free clinical sources to further inform occupation representation leveraging the NIOSH ODH model. In performing our analysis, we anticipate additional refinements thus enabling future standardization and additional insights into language around occupation. These will ultimately aid in standards refinement and future natural language processing (NLP) efforts around occupation information.

Methods

Data Sources

This study utilized six clinical document sources comprised of a mix of both publicly available and local sources to analyze free-text mentions of occupation and related information within notes. Information was unstructured, yielding a large variety of occupation-related information. The public domain note sources used came from 491 “Consult – History and Physical” notes from MT Samples (MTS) [12] and 200 de-identified “H&P” (History and Physical Examination) notes from the University of Pittsburgh Medical Center (UPMC) [13] obtained via a data use agreement. Four document types were analyzed from the University of Minnesota (UMN)-affiliated Fairview Health Services Epic EHR: (1) Social History Documentation, (2) So-
sional Work notes, (3) Physical Therapy notes, and (4) Occupational Therapy notes available through the University of Minnesota Clinical Data Repository (CDR) from 2013.

Analysis of Clinical Text

Clinical text analysis consisted of three main parts: (1) text de-identification, (2) schema creation, and (3) text annotation. Sentences from Fairview Health Services were anonymized prior to annotation using the Safe Harbor method [14]. Codes for anonymizing data came from previous work [15]. Further obfuscation was used where necessary to avoid personally identifiable data, and descriptors were created to provide specificity regarding employer type. These included descriptors for level of government employers, hospitality industry employers, healthcare employers, education employers, and Fortune 500 employers. Fortune 500 companies were determined using the Fortune 500 yearly ranking for 2016 [16]. Any remaining companies that did not fit into more specific descriptors were anonymized to “company.”

Annotations were made using the brat rapid annotation tool (BRAT) [17]. Annotation schema and guidelines were derived from the NIOSH ODH model categories and elements, providing the parent entities Occupational History, Usual Occupation, Employment Status, Occupational Injury, and Occupational Exposure and associated child entities. The Systemized Nomenclature of Medicine-Clinical Terms (SNOMED CT) [18] was examined, but it was determined that the ODH model was more relevant for our corpora, given its usage in previous work by this group of authors [9]. An initial set of 25 sentences was annotated with a group of annotators, and 50 overlapping sentences were individually annotated to evaluate the annotation schema and guidelines (Figure 1) by three annotators (EL, SR, NM). Additional entities were created to increase coverage, including Subject, Negation, Temporal, Occupational Conditions, and Occupation Status. The final schema had 9 parent entities and 32 child entities, for a total of 41 elements (Table 1).

Annotators were instructed to annotate at the most specific level of detail. For example, in the sentence, “She is a registered nurse,” the text “registered nurse” is annotated as the child entity Occupation Description, rather than the parent entity Occupational History. Parent entities were used as general annotation categories when a child entity could not be specified. In another example, “Prior to retirement, pt worked as a civil engine,” the sentence contains annotations relating to both clauses (i.e., “Prior to” is Temporal – Time Frame; “retirement” is Employment Status – Retired; “worked” is Employment Status – Not Specified; “civil engineer” is Occupational Description). Relationships were created to describe how entities are connected to each other. An overlapping set of 10% of sentences was annotated to calculate inter-rater reliability between three annotators (achieving a Cohen’s kappa of 0.76 and proportion agreement of 0.95). When inter-rater reliability was ascertained, the remaining sentences were annotated using the most expanded version of the schema. Following annotation process, annotations were extracted by element, generating a list of values for each element. These values were grouped by similar meaning for highest frequency elements. For example, for Occupation Description, the group ‘Legal Occupations’ represents annotations ‘paralegal,’ ‘attorney,’ and ‘tax attorney.’

Results

A total of 868 sentences from the six sources of clinical documents were annotated, yielding 2,005 annotations, which were mapped to 41 entities. The most frequent entities were: Occupation Description (17.7%), Employment Status – Not Specified (12.5%), Employer Name (11.0%), Subject (9.8%), and Industry Description (6.2%). Table 1 summarizes the representation of entities across source type. The Fairview Social History Documentation sentences have the greatest variety of occupation information, containing 39 (95%) of 41 possible entities. The sentences from the Fairview Physical Therapy Notes have the least diversity in occupation-related information, containing annotations for 13 (32%) of the 41 possible entities. No annotations were made for the entities Volunteer and Usual Occupation.

Table 1 – Distribution of occupation entities across sources. (f# of sentences per source); *n=number of annotations; SH=Social History; SW=Social Work; OT=Occupational Therapy; PT=Physical Therapy

indicating work status, including “released to regular work” and “has been on light duty.

Table 4 summarizes the value sets for the entity Employer Name. All values from Fairview Health Services Epic EHR in this set were anonymized prior to annotation and are grouped accordingly. Educational Services was the most frequently occurring group with 83 entries (37.6%). Student status is a contributing factor to this result, as schools were annotated as Employer Name. Military employment is least commonly seen with 1 entry (0.5%). Five entries (2.3%) did not provide enough information in order to group by employer type.

Table 5 summarizes the value sets for the entity Subject. This entity was added to the annotation schema after initial evaluation when a need for granularity was discovered. Parent group entries are most frequent with 137 total entries (74.5%) and 13 unique entries. Names of individuals and references to spouses were also common — de-identified prior to annotation as “Name” – 15.2% and 7.1% respectively.

Discussion

This study’s findings demonstrate the wide variety and range of occupation-related information within EHR clinical texts. A total of 2,005 annotations were made for occupation-related information in 868 sentences from six clinical document sources. This pervasiveness of occupation-related information within free-text notes points to the need for standardized entry within the EHR. In large part, the NIOSH ODH model proves appropriate for representing most of the occupation information, but several additions to the schema were necessary for comprehensive representation in our clinical text corpus. Specifically, the Subject entity is one of the most frequently occurring entities (9.8%) and was added during initial schema evaluation when need was assessed. Within this element, parent group entries are highly used, demonstrating a clinical interest in parental occupation and a prevalence of pediatric patients in this dataset. This correlation could also point to the relevance of a parent’s occupation on a child’s health outcomes. Similarly, the prevalence and interest in spousal occupations within this dataset points to the relevance of a spouse’s occupation to an individual’s health outcomes.

The Fairview Social History Documentation notes represent the largest portion of the dataset, with 553 sentences and 1,295 annotations. This source also presents the greatest coverage of occupation-related elements, with 39 of 41 possible elements across the dataset. Volunteer and Usual Occupation (parent entity) are the two elements not represented in the dataset; these elements were also not seen in any other source. The Fairview Physical Therapy Notes present the least coverage of elements with 13 of 41 possible elements. The Fairview Occupational Therapy Notes and Fairview Social Work Notes also present a more focused coverage of elements with 17 and 23 elements, respectively. This could be due to the specialty nature of these notes and more focused reasons for obtaining occupation information. The MTS sentences presented the greatest coverage of elements per sentence annotated with 35 elements represented in 171 sentences.

The addition of the element Occupational Conditions was useful in describing daily stressors of an individual’s job that have noted long-term effects on health outcomes, but do not necessarily constitute injury or exposure. Among these are items such as “Pt describes standing 12 hour days on concrete for his job,” “Patient works at a computer and on the phone all day,” and “He is employed in sales, which requires quite a bit of walking, but he is not doing any lifting.” While Occupational Conditions annotations comprise only 1.1% of total annotations, there were zero duplicate entries, indicating the scope of conditions — both physical and mental demands — individuals face in their occupations.

Occupation Description is the most frequent element seen in this dataset with 354 total values in 868 sentences. Among these values, 267 were unique and all but one were categorized into 22 of 23 SOC major groups. The ability to classify a large number of unique entries into 22 groups proves that occupation descriptions could benefit from standardized entry of this information within the EHR. While value sets are wide reaching, many occupations fall into a smaller set of groups. Employer Name was also pervasive in the dataset with 221 total values. These were categorized into 7 groups based on anonymized codes.

We also observed that ambiguity was common within the Occupation Status related entities, such as Self-Employed and Homemaker/Housewife. For example, some individuals may hold more than one type of employment status (i.e., both a full-time position and a part-time position). Some individuals may have overlapping employment status (i.e., the term “stay at home mom” implies both a caretaker and homemaker role). Self-employment also presents ambiguity, as this could refer to either full-time or part-time employment status in addition to self-employment.
The fifth most frequent element within the dataset was *Industry Description* (6.2%). This value set was not grouped by any classification set because a large majority of entries were unique and presented varying degrees of information presented. The issue of discrepancies in information is best represented by *Industry Description* but was prevalent throughout the dataset. This underscores the lack of standardization currently in place in documenting occupation information within the EHR and the need for further work to characterize the wealth and variety of occupation information that has potential impacts on health status and outcomes.

This work builds off of previous work [8, 9] to identify how occupation information is represented across the literature and various aspects of the EHR. Work could be done involving comparisons against occupation information in EHR systems from other vendors. Future work will focus on dissemination of this research on the Brown Digital Repository [20], creating granularity within the current model, and lead to better NLP techniques to analyze occupation information. This will contribute towards standardized entry of occupation information within the EHR, promoting data quality, and ultimately improving patient care and secondary use of occupation information.

**Conclusion**

As EHR system use becomes more widespread it will become imperative to have standardized entry of factors that influence health status and outcomes. Several respected groups have recognized occupation as a factor of health status. With this recognition comes the need to understand and standardize how occupation-related information is being captured within the EHR. This study analyzed free-text clinical notes from a variety of sources in order to characterize the state of occupation-related information within the EHR. The NIOSH ODH data model proved robust in characterizing information content, and additions were made to the annotation schema to provide additional granularity. This work has potential to lead to more detailed and knowledgeable standards and provides a basis for creating a standardized entry system within the EHR and improved NLP techniques.

Precision Cohort Finding with Outcome-Driven Similarity Analytics:
A Case Study of Patients with Atrial Fibrillation

Abstract

Dividing patients into similar groups plays a significant role in implementing personalized care. Clinicians and researchers have been applying patient grouping techniques in disease phenotyping, risk stratification, and personalized medicine. However, the current approaches are either based on pure domain knowledge where the underlying patient similarity cannot be precisely quantified, or based on unsupervised clustering techniques which completely ignore the clinical context of measuring patient similarity. In the study, we propose an outcome-driven approach to identify clinically similar patients which are grouped together as a precision cohort. The approach quantitatively measures the similarity between patients in terms of a particular clinical outcome of interest, thus patients who have a similar clinical outcome tend to be grouped into the same group. We demonstrate the effectiveness of the approach in a real-world case study: from an atrial fibrillation patient cohort that is usually considered to be at high risk for ischemic stroke (IS), according to current clinical guidelines. Our approach successfully identified a precision cohort of patients with truly low risk of IS.

Keywords:
Cluster Analysis; Machine Learning; Precision Medicine

Introduction

In order to understand complex disease conditions and to provide personalized care, it is crucial for clinicians to divide patients into subgroups such that patients in one group are similar to each other. Successful patient grouping is particularly beneficial for the tasks of disease phenotyping, risk stratification and personalized medicine. In current clinical research and/or practice, patient grouping is generally conducted based on some scoring schemes recommended by clinical guidelines, which stratify patients into groups with different levels of risk. The patients with the same level of risk are considered to be similar. This mechanism may lead to some problems: 1) a general clinical guideline may not fit for the local clinical practice or population; 2) the similarity between patients with the same risk level are not quantified because the scoring scheme is generated for a population and the detailed patient conditions are not differentiated in the same level.

In recent years, unsupervised clustering has been applied to identify groups of patients with different phenotypes and implement personalized medicine [1,2] in clinical research. Although the method can be adapted to local clinical practice and quantify the similarity between patients using distances between vectors of patient features, it ignores the fact that patient similarities are usually context-based, i.e., the similarity degree between two patients’ conditions may vary in terms of particular clinical outcomes of interest. For example, for three patients A, B and C with atrial fibrillation (AF), clinicians would regard that A and B are more similar in terms of stroke-occurrence risk, and A and C are more similar to each other when considering myocardial infarction (MI) risk. This is because the impacts of risk factors on these two outcomes are totally different (e.g., smoking and body mass index play important roles in the risk of MI while their impacts on stroke are relatively smaller).

This study aims to demonstrate how an outcome-driven similarity analytics method can be utilized to address the issues above. With the given clinical outcome of interest, the key idea is to cluster patients into groups based on a learned similarity (distance) metric from patients’ clinical records where patients with the same clinical outcome are considered to be similar. One related work [3] has been reported using a learned distance metric to retrieve the K most similar patients and providing the prognosis insight based on the physiological time-series data of similar patients. Another work [4] is to learn the similarity metric from physicians’ feedbacks and use patient similarity for decision support. Our work differs from them in using the learned distance metric to divide the patients into groups, followed by identifying the characteristics of similar patients in each group. To further understand the resultant groups, we also discover the discriminating rules between groups. The discovered rules can guide clinicians to easily assign new patients into their similar patient group, and we call such a patient group a precision cohort. Personalized care can then be recommended to the patients based on the insights discovered from this precision cohort. An alternative approach to divide patients into subgroups without similarity metric learning and clustering is to directly build a decision tree to split the patients against the outcome [5]. However, it suffers from two limitations: 1) similar patients could be dispersed in different branches, thereby requiring manual regrouping after the tree is built; 2) there is no distance metric for measuring the exact similarity between two patients.

We validate our approach in a real-world case study where we stratify a population of AF patients with high risk of ischemic stroke (IS) into a few groups and identify a particular group of patients with truly low risk. With the demonstrated effectiveness, we believe that other diseases and scenarios of finding precision cohorts could generally benefit from the proposed approach.
Methods

As precise patient similarity is context-dependent, and varies along the patient conditions, outcomes of interest, and particular clinical scenarios, we first define patient similarity context as follows. A patient similarity context consists of:

- A target patient population of study, e.g., the patients with diagnosis of diabetes type 2 but without any other complications,
- A clinical outcome of interest, e.g., mortality in two years, re-hospitalization in six months, and so on. The assumption is that two patients with the same outcome are considered to be similar, and
- A clinical scenario when the similarity analytics need to be done, e.g., when patients are first diagnosed with type 2 diabetes, when patients are hospitalized, or when patients are registered into a particular study.

Figure 1 illustrates the overall methodology of how we find precision cohorts by outcome-driven patient similarity analytics. With a given clinical data set and a patient similarity context, we adopt a machine learning approach. First, we determine the set of features used to compute the similarity between patients, and determine the exact similarity metric based on the selected features where the outcome of each patient is considered. Then, we segment the patients into groups based on their similarities and characterize the groups with their unique characteristics. Downstream analytics can be performed on each group to discover insights for personalized care, e.g., local risk analysis and treatment efficacy analysis, which are beyond the focus of this paper. We describe the pipeline analytics in detail as follows.

Patient Similarity Determination

Observation Window  
Follow-up Window

Index Date  
Outcome  
T

Figure 2 - Alignment of patient data with a specific similarity context

Patient Data Context Alignment

Given a clinical data set and a patient similarity context, we prepare the patient data as illustrated in Figure 2. For each patient, we identify an index date as the time when a clinical scenario is setting, e.g., when the diagnosis of type 2 diabetes is initially made, and use the records before the index date (observation window) to conduct the similarity analysis (those records after the index date and before the outcome date are ignored). The patient is then represented with a vector of features summarized from these clinical records. These features could incorporate the patient’s information involving demographics, diagnosis, lab test, medication, and so on. In addition, we label the patient as positive or negative in terms of the outcome of interest (we now focus on the binary outcome only).

Similarity Feature Determination

Not all features are relevant to determine contextual patient similarities, and there are two typical ways to filter the relevant features from the candidates obtained from the previous step: 1) based on established domain knowledge (e.g. clinical guidelines), we identify the set of relevant features known as risk factors regarding the specific outcome; 2) we apply supervised feature selection methods [6] to automatically select the features relevant to the outcome. The analysis scenario determines which method to apply.

Similarity Metric Determination

Since the distance metric can be regarded as a measure of dissimilarity, similarity learning is closely related to metric learning. A few alternatives exist to measure the clinically similarity between two patients represented by vectors of the selected similarity features:

- Using the Euclidean distance between them or between their corresponding vectors with reduced dimensions by PCA (Principal Component Analysis) if there are too many similarity features.
- Using the distance between their predicted risk scores regarding the outcome of interest where we first develop a risk prediction model based on the selected features, and then applying the model to compute the risk score for each patient regarding the outcome. Patients with similar risk scores are considered similar.
- Using a learned Mahalanobis distance between them, which can automatically adjust the importance of each feature against the given outcome of interest. Formally, we represent a patient as a N-dimensional feature vector \( x \) where \( N \) is the number of identified relevant features. Let \( S \) be the set of equivalence constraints denoted by \( S = \{(x_0, x_i) | x_0, x_i \) belong to the same outcome class\} and \( D \) be the set of inequivalence constraints denoted by \( D = \{(x_0, x_i) | x_0, x_i \) belong to the different outcome classes\}. Our goal is to learn a generalized Mahalanobis distance between patient \( x_i \) and patient \( x_j \) defined as:

\[
d^2(x_i, x_j) = (x_i - x_j)^T A (x_i - x_j)
\]

Where \( A \) is positive semi-definite matrix and is designed by solving the optimization problem:

\[
\min_{A} \sum_{x_i, x_j \in S} d^2(x_i, x_j) + \lambda \sum_{x_i, x_j \in D} d^2(x_i, x_j) \geq 1
\]

As a result of metric learning, we expect to keep pairwise vectors in \( S \) close and those in \( D \) separated away. 

While a few algorithms [7] have been proposed to learn a Mahalanobis distance metric, in this study we have implemented three popular ones including linear discriminant analysis (LDA) [8], which projects the original feature vectors into a subspace that preserves the variance between class labels; large margin nearest neighbor (LMNN) [9], which learns a linear transformation of the input space where \( k \) nearest neighbor should have matching labels; and information-
theoretic metric learning (ITML) [10], which maximizes the
differential entropy of a multivariate Gaussian subject to
constraints on the associated Mahalanobis distance.

To determine which metric to use for computing patient
similarities, we evaluate them using a nearest-neighbor based
method. That is, for a specific metric, we compute the
classification performance against the given target outcome
using a KNN (K Nearest Neighbor) classifier that is built upon the
metric. We consider a metric a better fit if it achieves the
best classification performance.

**Precision Cohort Finding**

**Patient Clustering**

We apply agglomerative hierarchical clustering to group
patients so that the patients within a group are contextually
similar. The method starts with singleton clusters and proceeds
by successively merging the two “closest” clusters at each stage.
We customize the method by using the previously determined
distance metric to determine the distances between clusters rather than using the conventional unsupervised
distance metrics. With the learned distance metric, we expect
that there could be a substantial divergence in the result of the
targeted outcome (proportion of patients with a positive
outcome) between the resultant groups.

One advantage of hierarchical clustering is the flexibility of
determining the number of produced clusters based on the
results of one running. For our purpose, we determine the
number of reported clusters and evaluate the clustering
performance by: 1) an internal clustering performance metric:
the silhouette coefficient $SH$ [11] which is defined as $SH = \frac{(b - a)/max(a, b)}{a}$ where $a$ is the mean distance between a
patient and all other patients in the same group, and $b$ is the
mean distance between a patient and all other patients in the
next nearest group. A $SH$ near 1 indicates that the sample is far
away from the neighboring clusters, and a $SH$ greater than 0.2
is generally considered to be a fair clustering result; 2) An
external metric to measure the group outcome disparity (OD)
between the resultant groups which is defined as the difference
between the maximal and minimal positive outcome rates of the
groups. This metric reflects the effect of stratified risks among
the groups, and the grouping result with higher $OD$ is better for our
purposes.

**Patient Group Characterization**

After obtaining the patient groups with stratified outcome
results, our interest is to identify the characteristics of each
group and understand the differences between groups. We
address this by two means: 1) we compare the key feature
differences between groups using statistical tests (a Kruskal-
Wallis test for continuous features and Pearson chi-square test
for categorical features.); 2) in order to identify the unique
characteristics of groups, we build a decision tree that can
differentiate the resultant $M$ clusters where $M$ classes of
patients are labeled in accordance with their respective cluster
memberships. For easier applicability, we further derive the
explicit rules from the tree to interpret the group membership
of a patient. In this work, we use C5.0 [12] to build a decision
tree and convert it to rules.

**Results-Risk Stratification of AF Patients**

The CHA2DS2-VASc (CV) [13] score ranging from 0 to 9 has
been widely recommended and used to identify AF patients
with a high risk of IS (CV≥2) who need to be treated with oral
anticogulant (e.g. Warfarin) or radiofrequency ablation (RFA).
However, it is still arguable that the CV score may not
precisely capture the risk of particular AF patients from local
populations. For example, there is a subgroup of patients with
high CV but a low IS-occurrence rate for whom anticoagulation
may not be indicated. This is crucial because anticoagulants
may have severe side effects, such as warfarin-related bleeding,
and RFA incurs additional economic burden on patients. It
therefore might be unnecessary to treat those patients with truly
low risk. Thus, this study aims to apply our proposed approach
to identify such AF patient subgroups, who have truly low risk
but are misclassified as high-risk by high CV score.

**Data Set**

We use a data set from a cohort study for around 18,000 AF
patients across China [14]. The collected data includes patients’
structured baseline records (i.e. demographics, history,
medication history) and clinical records (i.e. interventions,
outcomes) during follow-up visits in a 3-year period. We are
interested in studying the risk of IS during one year of follow-
up by using the baseline features of patients, and also a selected
population of 2,907 patients from the population (with an IS-
ocurrence rate is 4.6%) with the criteria as follows: 1) complete
12-month follow-up records are available for the patient, or follow-up records until the occurrence of an IS event
within the 12-month follow-up period; 2) the patient either has
no intervention (warfarin or RFA) until the end of 12 months
of follow-up, or IS occurred before the intervention was started;
3) the patient’s CV was ≥2 (i.e. the patient is considered high-
risk). As the raw data has non-standard, missing and dirty
values, we apply the same approach as our previous study [14]
to automatically clean the data and impute the missing values.
In the end, we have a data set with 132 input features and a
binary feature for the outcome of having IS occurrence in 12
months of follow-up.

Furthermore, to validate the study results of analytics, we split
the data into a derivation patient set (1,743 patients) and a
validation patient set (1,164 patients) (60% and 40% of the
population, respectively). The splitting strategy is to keep both
the IS-occurrence rates and the CV score distributions the same
between the two sets. We observe that the lowest IS-occurrence
rate for the patients with CV≥2 is approximately 2.5%, thus our
objective is to discover a subgroup of patient with truly low risk
of IS where the IS-occurrence rate should be lower than 2.5%.

**Selecting Similarity Features**

From the original data set with 132 input features, we first
remove those that are relevant to IS occurrence but have strong
correlation with known risk factors as defined by the CV score.
We then automatically select the other relevant features using a
filter-based method (SPSS modeler version 17). In other words,
we select the top significant continuous features based on the p-
value of using the $F$ statistic and categorical features based on
the p-value of using Pearson’s $\chi^2$ statistic ($p <= 0.05$). Besides
the four known CV features including prior CHF, prior IS, prior
vascular diseases, and age, Table 1 lists the other 10 features
selected as potential risk factors.

Determining the Similarity Metric:
With the derivation data set where each patient is represented by 14 features above, we develop a few distance metrics to measure patient similarity (using scikit-learn 0.17): 1) EUCL. The Euclidean distance between the patient vectors; 2) LR_Score. The distance between the predicted risk scores using a logistic regression (LR) model trained on the derivation set (AUC of the derived LR is 0.72). 3) LDA. The learned Mahalanobis distance using LDA. 4) LMNN. The learned Mahalanobis distance using LMNN 5) ITML. The learned Mahalanobis distance using ITML. Table 2 reported their KNN classification performance on the validation set with the averaged results when KNN classifiers were trained on the derivation set with K set to 1, 3, 5, 7, and 9 respectively. While the overall F1 score is low for all metrics (this is due to our highly imbalance data set), LDA outperforms the other metrics.

With all the considerations above, we decide to adopt the three clusters resultant from the clustering with LDA for downstream analysis. As summarized in Table 4, on the one hand, there is a stratified risk of IS among groups where group 1, 2 and 3 corresponds to low, medium, and high risk groups respectively. Particularly the lowest risk rate is 1.5% in group 1 which is even close to the patients with CV=1 (1.4% in our source data set). This implies a group of patients with truly low risk of IS. On the other hand, the IS-occurrence rates increase with the rising of the CV median values of groups. This to some extent verifies the rough validity of CHA2DS2-VASc in this local population.

Table 4 – Summary of the resultant patient groups

</tr>
</tbody>
</table>

Moreover, we validate the resultant clustering model against the validation set where each patient is assigned to one of three clusters based on his similarity with the center of each cluster. In this way, the patients are also divided into three groups as shown in Table 4. We observe that it approximately coincides with the result from the derivation set, and in particular, a precision cohort with truly low risk of IS at 1.6% is successfully identified too. Likewise, we also test the clustering model with LR_Score against the validation set where clustering with LR_score achieves a comparable result with using LDA on the derivation set. However, it fails to get a satisfactory result on the validation set where among the resultant three clusters, the lowest risk rate is 3.4% and there is an extreme small group with only 61 patients.

Group Characterization Results:
Table 5 summarizes the key baseline characteristics that are significantly different among the groups from the derivation set where a p value <= 0.05 is considered statistically significant using Pearson chi-square test. Group 1 patients are the youngest and tend to have the lowest rates of comorbidities while group 3 patients are the oldest and have the highest rates of all comorbidities. The conditions of group 2 patients are in between group 1 and group 3 in terms of either comorbidities or medication taken or examination results. These group differences coincide with their varied IS-occurrence rates.

</tbody>
</table>

To further interpret the group characteristics, we build a decision tree using C5.0 (with a classification accuracy of 77% using SPSS modeler version 17) to classify these patients according to their cluster membership and derive a few rules to explicitly differentiate them. The resultant rules capture the unique characteristics of patients in different groups, and are easier to understand. In particular, we are the most interested in the patients in group 1 because they have the lowest IS-occurrence rate, and Table 6 lists the resultant 5 rules to characterize group 1 with high confidences (all are above 85%). Due to the space limitation, we do not list the other grouping rules.

Table 6 - Rules to characterize the group 1 patients.

<tr>
<td>4 Statin not used, no prior CHF, no prior IS, and age &lt;= 65</td>
<td>86.4%</td>
</tr>
<tr>
<td>5 VRCD not used, no prior CHF, no prior IS</td>
<td>85.5%</td>
</tr>
</tbody>
</table>
We validate the developed decision tree by applying it to the validation set. As shown in Table 7, the resultant three groups have the same CV median values with those from the clustering. To our interest, group 1 patients still have a low rate of IS-occurrence at 2.4% which is even lower than the patients with CV=2 (2.5% in our source data set). The results above support validity and stability of our approach.

### Discussion

One issue for further investigation is if the group 1 patients that we identified with truly low risk are simply a subset of patient with the lowest CV score. To answer that, we compared the breakdown of CV distribution of group 1 patients between the validation set. As show in Table 7, the resultant three groups should include all CHA2DS2-VASc factors and the novel feature candidates as in Table 1.

The critical part of our proposed methodology lies in determining an appropriate similarity metric for a specific context. While the outcome-driven learned metrics (including LR Score and Mahalanobis distance metrics) generally outperform the unsupervised EUCL, it is still challenging to identify the most appropriate one from various outcome-driven metrics. The performance of these metrics may vary depending on the different data sets or different clinical scenarios. Furthermore, in order to cope with a large and sparse data set, we could adopt deep phenotyping [15] (which is not the focus of this study) to learn a set of latent features to compute patient similarity rather than use the selected raw features.

### Conclusions

In this study, we developed an outcome-driven approach to identify groups of similar patients in terms of a particular clinical outcome. We validated the effectiveness of the approach by grouping AF patients with high risk of IS into three subgroups using a real-world data set and then identifying a precise group of patients with low risk of IS and their unique characteristics. This may help to better inform IS risk stratification in clinical guidelines. Further research would be necessary to verify the utility of novel risk factors identified. Subdividing high-risk patient groups may better target personalized care recommendations and improve patient outcomes. For example, a clinician could prescribe a treatment to a patient based on a treatment effectiveness analysis and comparison of the patient’s characteristics against those of a precision cohort which includes similar patients. Our future work includes adopting two-stage clustering to handle a very large data set and incorporating temporal similarity features and other outcomes of interest.

Abstract

Biomedical informatics plays a key role in the development of precision medicine and other new technology-enabled health disciplines. In this context, the exposome (defined as the whole set of exposures on an individual) has become a relevant topic. Although most of the research work in the exposome area has been conducted around the physical and chemical world, we sustain that in an increasingly digitised world more attention should be paid to the digital component of the exposome derived from the interactions of individuals with the digital world. We define this “Digital Exposome” as ‘the whole set of tools and platforms that an individual use and the activities and processes that an individual engages with as part of his/her digital life. In addition we support that biomedical informatics can and should lead research in this area.

Keywords:

Biomedical Technology; Environmental Exposure; Medical Informatics

Introduction

Advancements in recent years across multiple technological and scientific disciplines (including biomedical informatics), have produced an unprecedented increase in biomedical knowledge. The availability of new analytical tools (e.g. ultra-fast DNA sequencing) have facilitated the development of new approaches such as personalized medicine or precision medicine assisting the use and interpretation of individual genetic information for medical purposes. More recently, the term precision medicine has been popularised, thanks initially to a) the announcement of the Precision Medicine Initiative (PMI) in the US (known now as All of Us Research Program) and further b) with the allocation of funding for its development [1].

Precision medicine is often considered as a continuation of the previous personalised/stratified medicine efforts, and it should also be associated with other elements such as participatory medicine, lifestyle, behavior and the individual exposure to environmental factors [2]. This very ambitious initiative explicitly acknowledges that an individual’s health status is the result of various complex interactions between their particular genetic make-up (genome) and their environment [3].

A key element in our current understanding of said individual environmental factors, is the concept of the exposome (coined by Wild in 2005). In his original definition, this author referred to the exposome as the whole set of exposures of an individual since conception to death [4]. This definition has been revisited several times since [5,6]. The concept of the exposome has received substantial support both in Europe, the USA and Japan and has been fully embraced nowadays by an array of scientists and research funding agencies within the context of precision medicine. However, growing interest in environmental factors is neither new, nor uniquely associated with precision medicine. It has a long trajectory in epidemiology. In spite of this, the primary difference between those approaches and current perspectives on the exposome is that in most cases, epidemiology adopts a population perspective [7], whereas the exposome is aimed at studying environmental health at the individual level.

The alternate perspective we wish to consider in this light is that concurrently, our society is immersed within a digital revolution, living in a pervasive landscape of information and communication technologies (ICT), which are penetrating an increasing number of facets of everyday life, including our health. Internet connectivity is becoming so ubiquitous, with individuals increasingly spending more time online, driven by different motivations [8].

Therefore, with this in mind, we ponder the notion that society and individuals alike are living increasingly immersed in a digital world. Hence, it is both prudent and paramount that the concept of the exposome be reinforced to include its digital component. This perspective provides a fuller approach for biomedical research and potential future clinical purposes.

Health outcomes derived from digital environments and digital stimuli

The precision medicine movement builds off the fundamental paradigm shift, suggesting not only that personalised treatment is important, but also that the patient becomes the centre of decision-making, empowered and engaged in health management options [9]. With the rising infiltration of self-quantification devices, social media and other digital tools, it has become a relevant topic for health research along the last few years[10].

Concepts such as ‘digital medicine’ and ‘digital health’ have become greatly popular and describe a whole set of tools and approaches to health based on the digital revolution [11-13]. These terms cover a broad range of elements. In this context, the concept of exposure to different stimuli and Internet factors is not new and it has been used for different purposes since the early days of Internet [14,15].

In reference to impacts of immersion in digital environments, literature continues to appear in growing prevalence,
indicating that health outcomes may be precipitated in relation to use of various digital technologies. For example, social media use and their impacts on health outcomes of people managing chronic illness [16]. Whilst health effects are reported both positively and negatively in this context [17], the theory we reiterate in this manuscript is that regardless of outcome, exposure to various digital environments is a key component of the exposome of individuals.

Examples exist all the way through from basic website exposure, through to video games and social media as will be discussed.

**Websites:**
At a preliminary level, literature has gone so far as to show that browsing content of certain websites can be associated with health effects. This can be seen in the realm of literature commenting on correlation between web-based content and eating disorders (i.e. anorexia nervosa) [18,19].

**Video Games:**
Another area worthy of attention and of great interest for the study of digital health effects is engagement with video games. Gaming has garnered increasing attention in health and biomedical informatics through the inception of concepts such as ‘gamification’, with several instances of video game use and health outcomes reported [20-22]. This application highlights the power of the digital environment (and digital stimuli) to impact some element of health outcomes.

More specific examples of video game immersion have shown that the stimuli associated to recreational use of videogames can in-turn precipitate various effects, some deleterious, [23, 24] including the death of a patient due to cardiac failure associated with the stressed induced from gaming [25].

**Social Media:**
Social media have become an increasingly important part of everyday life, with literature commenting on social media’s impact in health growing exponentially [26]. One area where it is clear that digital exposure can play a role in health related outcomes has been in the selection and use of different social media platforms as part of the management of chronic diseases [27]. A 2012 example indicated improved scores on stress, depression and anxiety scales after immersion in a virtual world anonymously using an avatar [28,35].

Further Exploring Digital Exposure – A Social Media Case Example

Here we focus on the topical area of social media, examining exposure of patients to different social media platforms based on previous works and experiences of the authors of this manuscript [13,14,24]. Using the case of social media, we present how different digital exposures may be associated with different health outcomes. Social media or, peer-to-peer networks represent a layer of the digital environment in which participatory citizens are immersing themselves digitally as part of their health management. Empowered individuals are turning to such tools (i.e. social network sites, blogs, microblogs, wikis and virtual worlds) to source information about their conditions, connect with others, chat and share resources about their health, symptoms and treatments [10,16].

The influence of exposure to social media environments on one’s health outcomes cannot be overlooked [29]. Previous research has successfully depicted the influence of online social networking on weight loss, smoking cessation, and depression, arguing that decisions to change health behaviours are not only intrinsically motivated but also influenced by the effects of the individuals’ online social network [29].

Based on our previous research, the same may be said for patient-reported health outcomes and the influence of social media based environments. Research by the authors of this manuscript [16,27] has qualified how social media use may impact health outcomes through the lens of what social media therapeutically afford the individual. This process has focussed on various health variables such as: cognitive health, social health, psychological health and physical health and the therapeutic affordances of self-presentation in the online world, connection to others, exploration of online information, narration of experiences with illness and through adapting online behaviour based on disease specific needs [16].

Underlying this process is the theoretical proposition that social media exposure impacts the individual. Our research suggests the following social media exposures and their postulated impact:

- **Time spent online (engagement):** Literature review suggested a positive correlation between the number of times online social networking features are accessed, length of time spent on social networking and participation/engagement in health interventions [16]. Furthermore, statistical correlation also suggested that more frequent use of social media was positively linked to greater reported improvements in both psychological and social health variables in chronic pain management [27].

- **Interaction with others (support):** People living with chronic diseases (i.e. arthritis, cancer, fibromyalgia, diabetes) have reported a strong sense of support received from social online environments. Exposure to online support through interaction with others has been noted to improve acceptance and validation of one’s condition in complex regional pain syndrome and adaptive coping in HIV/AIDS for example [16] [30-32]. Other reports have also indicated exposure to peer support leads to improvements in empowerment, as well as increased participation in positive behaviours and activities [33].

- **Information access:** Information seeking is arguably still the most observed use of social media platforms, despite ability to connect and converse on these platforms [27]. Sourcing and improving disease-specific knowledge is reported as an important factor in self-management [16; 34; 35] and social media use has been shown to correlate to improved cognitive health surrounding one’s condition [27].

- **Simulated interaction:** Virtual and augmented reality environments are becoming more apparent in social media and chronic disease literature. The virtual environment allows users to interact and navigate the virtual world anonymously using an avatar [28,35].

**The Digital Exposome**

In the recent years, interest in exposome-related research has increased enormously as it provides a framework to access and assess individual exposures relevant for health. In many cases, this access is being mediated by advances in the development, miniaturisation and integration of sensors, enabling the collection of individualised environmental data deemed to be important for individual health management. In this context a “Digital Phenotype” [36] has been previously described considering part of the digital footprint of an individual as a relevant element able to be related with
manifestations of disease. Simultaneously, individuals are becoming increasingly engaged with a digitalised environment which undoubtedly has an effect in every individual’s health. Therefore there is a growing need to realise the timely relevance and importance of the digital subset of the exposome, the “Digital Exposome”, as shown in Figure 1.

![Figure 1– Both “real”(physical) and “digital” world exposures contribute to different individual health outcomes](image)

In order to identify to what extent the concept of the digital component of the exposome has already been used in the literature, we carried out a Pubmed search using different relevant terms. Table 1.

After conducting this search, it was clear that despite the relevance of the digital component of the exposome for health purposes, it has not as yet been sufficiently considered as a distinct element in the exposome literature.

Whereas in the physical environment the characterisation of an individual’s exposome mostly relies on the use of surveys, sensors, geographical information systems, analytical tools and devices [37-40], the digital realm would require a completely different set of approaches reliant on the development of software able to identify those components of the digital exposome deemed relevant for health purposes. In clear contrast with the physical world exposome (where capturing exposure to the different elements quite often requires the development of individual devices), monitoring the digital exposome will require a novel approach. One in which software is developed to trace all digital activities that are relevant to the health of an individual. Some early examples of digital tracing already exist, such as in electronic commerce sites where personalised suggestions are made based on existing electronic information of previous use of these online platforms (e.g.: Amazon, Netflix). Other attempts showed that although accessing to the individual digital exposome is to some extent technically feasible [41], it presents massive ethical challenges (e.g. data privacy) that require further elaboration [42].

The quantified-self (QS) movement aims to monitor different aspects of our daily lives and makes extensive use of digital tools [43,44]. Unlike the QS movement, where elements come together to engage with the digital environment to store, analyse and occasionally share this personal information for health and wellbeing purposes, the idea of self-monitoring our Internet use and other digital exposures in an integrated manner has not yet been sufficiently developed.

**Biomedical Informatics and the Digital Exposome**

The concept of the Exposome plays a critical role in the development of precision medicine. At the same time, the exposome, as a relatively new and strongly interdisciplinary area, poses new challenges for biomedical informatics [45]. The need for formal and systematic approaches to information processing in this context justifies a leading role for Biomedical Informatics within this new research avenue.

Most exposome-related research has been focused around the characterization of the “real-world” exposome, associated with physical, chemical and biological exposures[46,47]. Similarly, in early Precision Medicine studies and applications, “omics” approaches have played the central role, and so too has been the support provided by translational bioinformatics to them.

However, as reported in this manuscript, in modern societies where individuals are spending increasing amounts of time online or digitally connected, our digital exposures are becoming increasingly relevant to our health and therefore should be integrated with and considered as a relevant element of an individual’s exposome within a Precision Medicine context. Notably, the role of biomedical informatics goes far beyond these initial approaches. As seen throughout this work, there exist many other areas where exposure information is derived from different online or digital experiences. In these cases biomedical informatics’ role expands from the well known aspects of data management and analysis, to becoming an essential player in the generation of individual environmental data, with a particular emphasis on collecting and aggregating individual digital exposome data.

Therefore, further research work will be needed to characterize the digital component of the exposome, which we define as ‘the whole set of tools and platforms that an individual use and the activities and processes that an individual engage with as part of his digital life’. In many ways, the digital component of the exposome can be considered alongside the digital footprint of an individual. This concept of the “Digital Exposome” comes to complement the previously described “Digital Phenotype” in an holistic view of how the phenotype of an individual, and her health status, is defined by the complex interactions between the “real” (physical) world its digital component and the genetic component at an individualised level. Figure 2.

It is our aim to raise awareness about the need to monitorise individual exposome data and take into greater consideration the digital exposome as well as to highlight the key leading role that biomedical informatics should play if we are to foster research in this area to improve health outcomes. This could also have consequences in the design and content of biomedical informatics education and training programs.

Enhanced LexSynonym Acquisition for Effective UMLS Concept Mapping

Chris J. Lu\textsuperscript{a,b}, Destinee Tormey\textsuperscript{a,b}, Lynn McCreedy\textsuperscript{a,b} and Allen C. Browne\textsuperscript{a}

Abstract

Concept mapping is important in natural language processing (NLP) for bioinformatics. The UMLS Metathesaurus provides a rich synonym thesaurus and is a popular resource for concept mapping. Query expansion using synonyms for subterm substitutions is an effective technique to increase recall for UMLS concept mapping. Synonyms used to substitute subterms are called element synonyms. The completeness and quality of both element synonyms and the UMLS synonym thesaurus is the key to success in such applications. The Lexical Systems Group (LSG) has developed a new system for element synonym acquisition based on new enhanced requirements and design for better performance. The results show: 1) A 36.71 times growth of synonyms in the Lexicon (lexSynonym) in the 2017 release; 2) Improvements of concept mapping for recall and F1 with similar precision using the lexSynonym, 2017 as element synonyms due to the broader coverage and better quality.

Keywords:
Natural Language Processing, Semantics, Unified Medical Language System

Introduction

Subterm substitution is a popular technique in query expansion. It is used to increase recall when no direct UMLS concept mapping is found through normalization. For example, no concept is found by direct mapping through normalization if the source vocabulary is “nasal deformity”. By substituting the subterm “nasal” for its synonym, “nose”, the UMLS concept [C0240547, Nose Deformity] is found, where “C0240547” is the concept unique identifier (CUI) and “[C0240547, Nose Deformity]” is the preferred term in the UMLS. In this example, “nasal” and “nose”, which are used for substitution, are called element synonyms, while “nasal deformity” and “nose deformity” are the input term and expanded term, as shown in Figure 1. The normalized form of expanded terms is then used for concept mapping from UMLS synonyms.

Element synonyms are semantically equivalent terms (e.g. “nasal” and “nose” in the example above) used to identify subterms in the source vocabulary for substitution in UMLS concept mapping. This method increases recall by finding concepts for terms whose concept cannot found by normalization or not even in the UMLS. For example, if “elderly” and “geriatric” are element synonyms, “elderly patients”, a term in the corpus (PubMed) but not in the UMLS, is mapped to the UMLS concept [C0199167, geriatric patients] by substituting “elderly” with its synonym, “geriatric”. The performance of this method relies on the quality and completeness of the element synonyms for a given UMLS thesaurus. The broader the coverage of the element synonyms, the higher the recall. Commutativity and transitivity are two needed properties for quality element synonyms to preserve precision.

![Figure 1 – Element Synonyms and Subterm Substitution in UMLS Concept Mapping](image)

In this paper, we present a systematic approach to acquire a set of high quality element synonyms from the SPECIALIST Lexicon and UMLS Metathesaurus. The results show an improvement on recall and F1 with similar precision using this new acquired element synonym set for concept mapping.

Background

The 2016AA UMLS Metathesaurus of the National Library of Medicine (NLM), containing more than 3.25 million concepts and nearly 13 million unique concept names from over 190 source vocabularies, is one of the richest thesauri in the biomedical domain. UMLS concept mapping is used for managing knowledge in NLP applications including information retrieval (IR), document retrieval (DR), text classification, data mining, and decision support systems. Normalization is used as the initial step for UMLS concept mapping. All UMLS terms are processed through the Norm program in the Lexical Tools to normalize lexical variants, syntactic representation, and character encoding between ASCII and Unicode [1-2]. For example, “Behcet disease”, “Behcet’s disease, nos”, and “disease, Behcet” are UMLS synonyms because they represent the same concept. They have the same normalized term “behcet disease”. All UMLS terms are normalized and stored in the UMLS (MRXNS5_ENG.RRF) with their associated concept(s). Terms having the same normalized form from input vocabulary (even if they are not in the UMLS Metathesaurus) can be mapped to UMLS concepts. For example, “disease, Behcet”, which is not a UMLS term, like other terms above, is mapped to [C0004943, Behcet Syndrome] through this normalization process.

Subterm substitution is used to find concepts for terms whose concept cannot be found through normalization. To increase...
recall, strategies may use lexical or semantic information, or a combination of both. First, subterms can be substituted by lexically related variants, such as derivations. Derivations allow users to find closely related terms that may differ by part of speech (POS) for better recall [3-4]. For example, no CUI is found by direct mapping through normalization if the source vocabulary is “perforated ear drum”. By substituting the subterm “perforated” for its derivational variant, “perforation,” the UMLS concept is found [C0206504, Tympanic Membrane Perforation]. Second, subterm substitution by semantically equivalent terms (synonyms) improves recall [5-6]. Synonyms used for subterm substitution are terms that have the same meaning (concept) and are called element synonyms (such as “nasal” and “nose” from the example above). In practice, synonyms of synonyms are retrieved recursively (recursive synonyms) in such applications to increase recall. Third, subterms can be substituted by a combination of both lexical variants and synonyms [7-9]. These applications usually pre-generate all expanded terms and use them in a pool for concept mapping. The broader the coverage of the expanded terms, the better the recall for such approaches. Several works have used this strategy to find terms that the UMLS missed and improve recall [10-11]. This method of subterm substitutions generates many mapped concepts, including irrelevant concepts, and results in higher recall and lower precision. Ranking and filters, such as keyword match, frequency (TF-IDF), semantic types, concept distance and the longest lead-terms or end-terms, are used to improve the precision [12-13].

Other research has focused on different query expansion strategies by using UMLS Tools [14-15], MeSH [16-17] or their application systems [18-19] for effective UMLS concept mapping and information retrieval. Some research has explored the role of semantic similarity and semantic relatedness to similar and related terms having different UMLS concepts [20-21]. Prior to our work, there has been very limited effort devoted to acquiring element synonyms. Synonyms in the UMLS and Lexicon are two of most commonly used sources for element synonyms. However, several issues are found as described below.

UMLS synonyms with some restrictions, such as source vocabulary (MeSH), term length, and size of grams (usually unigram), were used as element synonyms for UMLS concept mapping in previous research [7-11, 14-16]. Three issues have been found in such approaches. First, UMLS synonyms are over-generated for element synonyms. For example, “allergy drug” and “allergy medicine” are UMLS synonyms, [C0013182, Drug Allergy] and considered as expanded terms. The concepts of these expanded terms can be found if their subterm, “drug” and “medicine”, are in an element synonym set. Slow runtime performance and computer resources are other concerns in practice when using the expanded terms of UMLS synonyms as element synonyms in subterm substitution due to the large-scale size. Second, element synonyms must have properties of commutativity and transitivity for effective concept mapping. For example, “ago” is the abbreviation (ISO country code) for the country “Angola” and thus they are UMLS synonyms (with the same CUI, C0003023). However, “ago” is more often associated with another meaning, ‘earlier,’ and is not a synonym for “Angola” (lack of commutativity). In short, UMLS synonyms that represent broader or narrower concepts (such as “adenexa” and “uterine adnexa”), acronyms, abbreviations, POS ambiguity (e.g. “mushroom” is a synonym of “Agaricales” when its POS is a noun, but the meaning shifts when its POS changes to a verb), terms with multiple CUIs, or the combination of the above, should be excluded from element synonyms. Acronyms mentioned above, such as POS, inflections, acronyms, abbreviations, etc. First, a lexical entry must be a word (single word or multiword) with a special unit of meaning.

### Approaches

Synonyms can be categorized into two types: cognitive synonyms and near-synonyms. Cognitive synonyms have fewer meaning differences with greater interchangeability, while near-synonyms lack these. Cognitive synonyms match the characteristics of element synonyms well for effective performance (recall and precision) because they have two properties, commutativity and transitivity. Commutativity, \( (x = y) \iff (y = x) \), preserves the naturalness of bi-directional synonyms. For example, if “joy” is a cognitive synonym of “happy”, then “happy” is a cognitive synonym of “joy”. Transitivity, \( (x = y) \ implies \ (y = z) \), preserves the precision in recursive synonym applications. For example, if “happy” is a synonym of “joy”, and “joy” is a synonym of “enjoy”, then “happy” is a synonym of “enjoy”. These two properties are necessary conditions of quality element synonyms for subterm substitutions in concept mapping. However, they are missing in most synonym sets used in NLP. They are required for lexSynonym acquisition in our new system to ensure the effective UMLS concept mapping: lexSynonyms must be cognitive synonyms.

To acquire a thorough synonym set, UMLS synonyms are chosen as source candidates in this project. UMLS synonyms are UMLS strings (element terms and expanded terms) with the same concept (CUI). They are grouped and represented as a key-value collection in a synonym class (sClass). Namely, the key is the CUI while the value is the list of all terms with the same CUI in the UMLS Metathesaurus. This is the common way of retrieving UMLS synonyms. The derived UMLS sClass is further enhanced through the integration of the Lexicon. The Lexicon includes additional information needed for resolving the NLP issues mentioned above, such as POS, inflections, acronyms, abbreviations, etc.
in itself [22-23]. The Lexicon is used as the source vocabulary to filter element synonyms: terms in the sClass that are not in the Lexicon, such as non-word phrases, are removed. For example, expanded terms of UMLS synonyms “allergy drug” and “allergy medicine” are removed to resolve the issue of over-generation, while “herpes zoster infection” is removed to resolve the issue of n-grams because none of them are in the Lexicon (do not meet the requirements of LexMultiwords) [23]. As discussed before, recall of concept mapping will not decrease because, “drug” and “medicine”; “zona” and “herpes zoster”, are terms in the Lexicon and used as element synonyms. Second, the POS information from the Lexicon is added to the sClass to resolve the POS ambiguity issues. Third, terms having the POS of noun, verb and adjective with inflections of base in the Lexicon are retrieved. This step eliminates inflectional variants, illegal POSs, and non-word phrases from the UMLS synonyms. Fourth, terms that are acronyms or abbreviations in the Lexicon are removed to preserve precision. Fourth, synonyms in the sClass need to be verified by experts to ensure they meet the requirements of commutativity and transitivity. Finally, the verified sClass is further processed into sPairs and sRecords to compose the element synonym set. All synonymous terms from the Lexicon (lexSynonyms) are acquired using this approach.

Implementation

A standalone lexSynonym set is established by collecting all synonymous terms in the Lexicon based on the above requirements and approaches. LexSynonyms are acquired from three types of sources: the Lexicon, the UMLS, and NLP projects. They are described as follows.

Lexicon-Sourced Synonyms – Nominalizations with EUI

Nominalizations are cognitive synonyms with the adjectives and/or verbs from which they are derived. They are recorded in the Lexicon and can be retrieved automatically to generate lexSynonyms. Additional information, the entry unique identifier (EUI) of the lexical record, is added to the associated sPair for downstream NLP processing. For example, the sPair of “[abilitynounable][E0006490]” is generated from the lexical record (E0006490). As shown in Figure 2, the noun of “ability” is the nominalization of the adjective, “able”.

UMLS-Sourced Cognitive Synonyms with CUI

The Lexicon and UMLS Metathesaurus are used to retrieve more synonymous lexicon terms as follows. First, all English terms from the UMLS (MRCONSO.RRF) with the same EUI are retrieved. Second, concepts of chemicals and drugs are removed from those described above, then added into lexSynonyms. For example, “death”, “dead”, “deceased” and “die” are base forms with qualified POSs in the Lexicon, have the same CUI (C0011065), and are not chemicals, drugs, acronyms, or abbreviations. They are thus synonym candidates and are gathered in a candidate sClass as shown in Figure 3. Among the synonyms, “die” is related by nominalization to “death” (E0020918), and is thus removed. This is the candidate sClass sent to LSG linguists for validation. Cognitive synonyms are tagged as “Y” while near-synonyms are tagged as “N”. The nominalizations, “deceased” (E0020885) from “dead” (E0020877) and “die” from “death”, are added back into the sClass automatically. The final sClass is composed of 5 synonyms, generating 10 (bidirectional) sPairs, and results in 20 synonym records (sRecords) in the lexSynonym set, as shown in Figures 4 and 5 respectively.

NLP Project-Sourced Cognitive Synonyms

Syonyms from NLP projects can be processed by similar steps to those described above, then added into lexSynonyms. For the 2017 release, we processed synonyms from Lexical Variants Generation (LVG). Duplicated synonyms of the previous two sources are removed from the candidate list without further process. Others are converted to sPair candidates computationally, reviewed by LSG linguists, and added to the lexSynonym set with POS if they are cognitive sPairs and in the Lexicon. “NLP XXX” is used as the source information for the NLP project “XXX”. For example, “NLP_LVG” is marked as the source for synonyms from the LVG. The NLP project-
sourced synonyms provide two important features of extendibility and compatibility. First, users are able to extend the synonym set by adding domain/project specific synonyms. Second, it preserves the same result for the specific NLP project (LVG) users when forward compatibility is required.

Results, Tests, Discussions and Applications

As a result, 22,779 sClasses and 58,134 synonym candidates are retrieved from the UMLS source type (2016 AA UMLS Metathesaurus and 2016 Lexicon). Cognitive synonyms from this candidate list are used to generate 118,468 sRecords. In addition, 67,584 sRecords from Lexicon nominalizations and 4,792 sRecords from NLP_LVG are generated, respectively. All sRecords from these resources are combined into the lexSynonym set and distributed in the 2017 release of the Lexicon. The results show a growth of 36.71 times from 2016 to 2017 release through this new approach (Table 1).

A model is established to measure the performance of using the lexSynonym.2017 for UMLS concept mapping through the Sub-Term Mapping Tools (STMT). STMT applies a real-time subterm substitution algorithm for UMLS concept mapping with the configurable options of choosing element synonyms and UMLS release. The UMLS-CORE project assigned CUI(s) to terms (13,076) that are within the top 95% usage and improvement. The default STMT element synonym set is comprised of high quality synonyms for subterm substitution algorithm for UMLS concept mapping. The STMT for comparison. The five normalized element synonym sets are configured in STMT to improve recall (25%). They are validated cognitive synonyms from sources of British English, Greco-Latin, acronyms, abbreviations, Emergency Care Research Institute (ECRI), etc. [6]. Results are shown in Table 2: 1) recall is increased over 10% from lexSynonym 2016 to 2017 due to broader coverage (from 5K to 150K). Also, the precision is increased due to better quality. 2) recall and F1 are further improved about 5% and 0.05 while precision is about the same (<0.03%) by adding 2017 lexSynonyms to the STMT synonym set. The set of lexSynonym.2017 contains 5,872 (~75%) normalized synonyms in the STMT synonym set. Adding the previous lexSynonyms (2016) to STMT offers no improvement.

*LS: LexSynonym Set, “N.”: Size of Normalized Synonym Set

Due to limited resources, about 1/3 of synonym candidates (20,566 out of 58,134) have so far been tagged. The properties of commutativity and transitivity of lexSynonyms are ensured by nominalization (Lexicon-sourced) or by linguists’ tags. 92.20% of synonym candidates are tagged as “Y”. The size of the UMLS-sourced lexSynonym is about 0.64% of the size of the UMLS synonyms in English. Accordingly, the size of lexSynonyms will be about 2% of the UMLS synonyms when the tagging process is completed. LexSynonyms thus yield a much smaller, more manageable set to be used as element synonyms. In addition, synonyms from other NLP projects, such as UMLS-CORE and STMT, can be further processed and added to the lexSynonyms. Recall is expected to be further improved as the size of element synonyms grows while the precision is preserved by the properties of cognitive synonyms.

We utilized lexSynonyms as element synonyms in NLP applications (Lexical Tools) to retrieve synonyms. Synonyms, POS, and source information are provided in the outputs of synonym features of Lexical Tools. A sophisticated algorithm is implemented as follows in the recursive synonym flow component to preserve precision. First, only synonyms with the same CUI are retrieved recursively if the source type is CUI. Second, all synonyms are retrieved recursively if the source type is EUI. Third, synonyms from the same NLP projects are retrieved recursively if the source type is NLP. In addition, the synonym source option (-ks) is implemented to allow users to restrict the results by source type (CUI, EUI, NLP), or any combination of the above. These new features provide needed information to preserve precision for downstream NLP processing. For example, the five synonyms of “die” are retrieved from the synonym feature (-f:y) in Lexical Tools. The source information is also included. As shown in Figure 6, “dead”, “deadness”, “death”, and “deceased” are from the source of UMLS with CUI of [C0011065], while “expire” is from source of NLP (project LVG). The POS information is included in the outputs of the Lexical Tools. “Terminate”, a synonym of “expire” from the resource of NLP_LVG, is retrieved when the recursive synonym feature (-f:r) is used in the Lexical Tools, as shown in Figure 7. The last two fields of the last line in Figure 7 show the source type (NLP_LVG) and the recursive history (y, means synonym of synonym). Thus, project specific non-cognitive sPairs, “dead” and “terminate”, can be distinguished by the different types of sources (CUI vs NLP) to preserve the precision in recursive synonyms.

Conclusion

We have demonstrated the usefulness of the general concept of element synonyms as well as the Lexicon-specific type of element synonyms, lexSynonyms, in concept mapping. A systematic and maintainable approach is used to acquire higher quality lexSynonyms through the use of the Lexicon. Issues of over-generation and n-grams are resolved by restricting UMLS synonyms that are base forms with noun, verb, and adjective POS in the Lexicon, and removing chemicals and drugs. Terms that are acronyms or abbreviations are removed to avoid a drop in precision. Synonym candidates in the sClass that do not match the properties of commutativity and transitivity are tagged by the linguists as invalid to resolve near-synonym issues. POS is added to sPairs automatically through a Lexical records lookup by using EUIs in the sClass during the generation process. The information of source with unique identifier (CUI, EUI, and NLP) is also included. This
information is vital for downstream NLP applications to preserve precision especially when recursive synonyms are used. As a result, a thorough set of element synonyms is generated. LexSynonyms are expected to grow with the Lexicon and UMLS Metathesaurus for better coverage through this system. This approach is generic for element synonym acquisition and can be applied to other corpora, vocabularies, or synonym thesauri. The generated lexSynonyms are used in the Lexical Tools with enhanced recursive algorithms to provide better usage of the synonym related features for NLP applications. We believe the impact of better quality and broader coverage for lexSynonym acquisition in the Lexicon for effective UMLS concept mapping will improve the precision, recall, and naturalness of NLP applications. The set of lexSynonyms is distributed in the 2017 release of SPECIALIST Lexicon with UMLS by NLM via an Open Source License agreement.

A Validated Risk Model for 30-Day Readmission for Heart Failure

Satish M. Mahajan, Prabir Burman, Ana Newton, Paul A. Heidenreich

Abstract

One of the goals of the Precision Medicine Initiative launched in the United States in 2016 is to use innovative tools and sources in data science. We realized this goal by implementing a use case that identified patients with heart failure at Veterans Health Administration using data from the Electronic Health Records from multiple health domains between 2005 and 2013. We applied a regularized logistic regression model and predicted 30-day readmission risk for 1210 unique patients. Our validation cohort resulted in a C-statistic of 0.84. Our top predictors of readmission were prior diagnosis of heart failure, vascular and renal diseases, and malnutrition as comorbidities, compliance with outpatient follow-up, and low socioeconomic status. This validated risk prediction scheme delivered better performance than the published models so far (C-Statistics: 0.69). It can be used to stratify patients for readmission and to aid clinicians in delivering precise health interventions.

Keywords:
Patient Readmission; Models, Theoretical; Heart Failure

Introduction

Based on the Precision Medicine Initiative (PMI) launched in the United States in 2016, the director of the National Institutes of Health (NIH) convened a working group that defined Precision Medicine as “an approach to disease treatment and prevention that seeks to maximize effectiveness by taking into account variability in genes, environment, and lifestyle” [1]. The group also identified development of quantitative estimates of risk for a range of diseases. The initiative further established that the need for pioneering efforts to merge, integrate, and analyze data from various resources including Electronic Health Records (EHR) [1]. Therefore, we sought to develop a use case for the goals established by the PMI by considering 30-day hospital readmissions for patients with Heart Failure (HF).

According to Fida and Pina, HF is the most expensive Diagnosis Related Groups (DRG) diagnosis for hospitalizations and the most frequent diagnosis for 30-day readmissions [2]. As a part of the American Heart Association’s Policy Statement on forecasting the future of cardiovascular diseases in the United States, Heidenreich et al. provide projections for the 2010 to 2030 timeframe for HF that forecast increases of 215% and 80% in direct and indirect costs respectively, and a corresponding increase in HF prevalence by 25% [3]. Thus, reducing the readmission rate, especially for HF, is important to quality-conscious and fiscally responsible hospitals in delivering precise health interventions.

A data-driven risk assessment approach would facilitate identification of patients at potentially high risk for HF readmissions [4]. Towards this goal, many researchers have proposed predictive models for worsening symptoms, mortality, and/or readmissions. However, there is no consistency across the models in terms of their use of readmission timeframe, data sources, algorithms, and demonstration of predictive power. Some models used either registry- or trial-based clinical data [4-8], while others used hospital-based or Medicare claims-based administrative data [9-12]. Recently, researchers suggested examining data surrounding patients’ overall health [13-15] to elicit better predictivity from such models. We propose a systematic combination of structured data from clinical, administrative, and psychosocial domains to understand the predictivity of each group on the 30-day readmission. We hypothesize that a model with the incremental inclusion of each domain would have a better prediction for the 30-day readmission rate than domain-specific models under sensitivity analysis.

Methods

Patient Population

We used data from the EHR at the Veterans Affairs Palo Alto Health Care System, Palo Alto, California (VistA) to derive and validate the predictive models for this observational retrospective cohort study. The data between October 1, 2005 and September 30, 2013 was used to build the cohort identified by using International Classification of Diseases version 9 – Clinical Modification (ICD-9-CM) codes for heart failure as a principal discharge diagnosis: 402.01, 402.11, 402.91, 404.01, 404.03, 404.11, 404.13, 404.91, 404.93, 428.0, 428.1, 428.20, 428.21, 428.22, 428.23, 428.30, 428.31, 428.32, 428.33, 428.40, 428.41, 428.42, 428.43, 428.9 [9; 13].

Primary Outcome

We adhered to the literature definition of 30-day readmission that indicates an all- or any-cause readmission within 30 days of discharge from the index hospitalization for the comparison of our results with the other published result. We excluded hospitalizations with a length of stay less than one day and elective hospitalizations from the readmission episode. If the patient had multiple episodes of 30-day readmissions, only the last episode of such readmissions was considered. We thus
produced a statistically independent and mutually exclusive sample of patients across the two classes of the cohort.

**Predictors**

Predictor variables were collected from the EHR with the understanding that they were routinely recorded and available across the timeframe under consideration. We considered significant variables from the prior models. Lastly, we applied clinical judgment from experts and prior experience with the similar studies to finalize the predictor dataset [16]. We further divided the set into clinical, administrative, and psychosocial domain variables to test the predictivity of individual and combined domains. Our clinical dataset consisted of vital signs and certain laboratory values. The administrative dataset consisted of comorbidities and demographic variables that were captured routinely during hospitalization. The psychosocial dataset mainly consisted of psychiatric comorbidities including substance abuse and other variables indicating patient’s behavioral and social situation. We gathered the data values for the variables that were closest to the date of discharge for the given episode. For the comorbidities, we individually tracked ICD-9-CM codes for the diseases and procedures that were suggested from the prior literature [4; 9; 12; 14]. The predictor dataset for each domain are shown in Tables 1, 2, and 3.

**Statistical Analysis**

The extraction of data from the EHR system yielded a sample size of 1210 admissions with 59 predictor variables after applying the exclusion criteria. We did not have any missing values for the dependent variable; a few independent variables such as BNP and blood glucose had up to 5% missing values. The missingness for the variables was tested and found to be missing at random. We used multiple imputation by chained equations resampled over five imputed datasets for the missing values [17]. We created separate dummy variables for missing values with higher rate of missingness for the categorical variables [13; 14]. This strategy allowed us to use all the available records in the analysis. Continuous variables were also examined for nonlinear effects and transformations were carried wherever necessary. We used the elastic net algorithm with combined least angle and ridge regression regularization for solving the logistic regression problem. The algorithm internally uses the shrinkage method for variable selection in a cross-validation scheme iterated with coordinate descent method [18]. The main advantage of this method is its usefulness in handling sparse data matrix with many variables. Thus, it allowed us to keep all the variables in our dataset. A 10-fold cross-validation scheme was used to derive and validate the models for the datasets in clinical, administrative, and psychosocial domains. All the results were reported for the validation dataset. All confidence intervals were calculated at 95% level using non-parameterized bootstrap adjustment. A bootstrapping process with 2000 iterations was used on the derivation cohort and the coefficients were averaged over this process. The discrimination using C-Statistics and predictive ability from lowest to highest deciles in the derivation and validation cohorts were calculated. We used R version 3.0.2 (The R Foundation for Statistical Computing Platform) for all analyses. The Veterans Affairs Palo Alto Health Care System’s Institutional Review Board approved the research protocol.

**Results**

White race (when documented) and male gender with an average age of 76.8 years predominantly characterized our cohort. The dataset represented 1210 patient admissions; 263 of which were readmitted indicating 21.74% (28.54% for repeated readmissions averaged over the study time) of 30-day readmission rate.

The lowest C-Statistics or Area Under Curve (AUC) (0.50, CI: [0.49, 0.51]) was obtained using predictors only from the psychosocial domain and the highest discrimination (0.84, CI: [0.83, 0.85]) was observed in the model with predictors combined from all the domains. Incremental increase in AUC was observed as (0.65, CI: [0.64, 0.66]), (0.71, CI: [0.69, 0.72]), and (0.77, CI: [0.75, 0.78]) for clinical, administrative,
and combined clinical and administrative predictors respectively. A graphical representation of AUC using Receiver Operating Curve (ROC) for various models for the validation cohort is shown in Figure 1. In our dataset, patients who got readmitted were more likely to have prior HF diagnosis, more vascular and renal comorbidities, more discharges to skilled nursing facilities and had less outpatient visits than those who were not readmitted.

The final model stratified by predicted risk for 30-day readmission rate was calculated. Its plot shown in Figure 2 confirmed that the risk predictions were highly concordant across both the derivation and validation cohorts and thus confirmed absence of overfitting.

Discussion

This paper explores 30-day readmission risk model based on the already established idea from the PMI that a few diseases drive facility readmission rate and stratified risk assessment of patients would benefit from precise set of intervention guidelines for each stratum. Many models have been suggested on the basis of available data in patient records [9; 14] – this situation is made possible by the implementation of the Health Information Technology for Economic and Clinical Health (HITECH) act of 2009 in the United States that required EHR applications to incorporate many patient-centric data items—such as demographics, clinical data, and other psychosocial determinants of health—into the record.

Our results have also verified the claims of the other researchers who have combined claims data with clinical data that more predictors from different domains are preferable to consideration of fewer [14]. We confirmed the findings from the previously published studies [9; 11; 13-15] (AUCs: 0.69; NA; 0.60; 0.61 respectively) by incrementally adding predictors from multiple domains and comparing the observed readmission rate and C-Statistics of our model to them.

Our work indicates that predictors combined from various domains have a strong influence on the prediction of 30-day readmission risk; at the other end of the spectrum, it also shows that predictors from a single domain tend to have limited impact on the risk prediction. These results also support the empirical observation that providers working in a multidisciplinary team in a patient-centered environment tend to reduce the risk of HF readmissions.

Our study has some limitations. First, we were limited by the demographics of our cohort. Second, our study was carried out at one health system although all the previously published model results were also single center studies. As the efforts of building large-scale clinical research data networks with...
multi-facility collaborations come to fruition in near future, we will be able to collectively overcome this limitation. Third, only structured predictors were considered in our study and future studies might benefit by exploring valuable information available in other components—such as imaging reports and clinical notes—of the EHR system. Lastly, 30-day readmissions that might have happened in other facilities were not considered in our analysis, although the proportion of such readmissions in the overall cohort was deemed small based on empirical observations.

![Figure 2 – Final Model Validation Cohort Performance](image)

**Figure 2 – Final Model Validation Cohort Performance**

## Conclusion

Risk of frequent readmissions in HF population is an important issue for patients, clinicians, and hospital administrators. Our study has shown that the use of information from multiple domains in the hospital EHR system helps to build a risk model for precise interventions for HF readmission, is effective, and applies novel statistical techniques to this domain. Additional risk factors using unstructured data could be incorporated into our model in the future to strengthen the foundation of a PMI effort started here.

CrowdMapping: A Crowdsourcing-Based Terminology Mapping Method for Medical Data Standardization

Huajian Mao, Chenyang Chi, Boyu Huang, Haibin Meng, Jinghui Yu, Dongsheng Zhao

Institute of Health Service and Medical Informatics, Academy of Military Medical Sciences of Chinese PLA, Beijing, China

Abstract

Standardized terminology is the prerequisite of data exchange in analysis of clinical processes. However, data from different electronic health record systems are based on idiosyncratic terminology systems, especially when the data is from different hospitals and healthcare organizations. Terminology standardization is necessary for the medical data analysis. We propose a crowdsourcing-based terminology mapping method, CrowdMapping, to standardize the terminology in medical data. CrowdMapping uses a confidential model to determine how terminologies are mapped to a standard system, like ICD-10. The model uses mappings from different health care organizations and evaluates the diversity of the mapping to determine a more sophisticated mapping rule. Further, the CrowdMapping model enables users to rate the mapping results and interact with the model evaluation. CrowdMapping is a work-in-progress system, we present initial results mapping terminologies.

Keywords:
Crowdsourcing; Medical Informatics; Vocabulary, Controlled

Introduction

Analyzing clinical data across medical centers requires mapping local and idiosyncratic information into standardized terminologies. Without this step, clinical data cannot be exchanged, shared, integrated or used in a meaningful way. There are lots of standard terminology systems for representing clinical data, including Logical Observation Identifiers Names and Codes (LOINC) [1], Systematized Nomenclature of Medicine - Clinical Terms (SNOMED CT) [2] and others, which are now used as international standards. However, in lots of the healthcare organizations, they still use local and idiosyncratic dictionaries, which always reduces the ability to integrate data from multiple organizations. Therefore, in order to understand generated medical information in digital systems, healthcare organizations must often translate the local data into standardized terminologies. The process of translating the local data into standardized terminologies is called mapping. A mapping represents a set of terminology mediation strategies used by clinical and public health organizations to enable health information exchange (HIE) within and among health enterprises [3].

At the Institution of Health Service and Medical Informatics of Academy of Military Medical Sciences (AMMS), we are undertaking this mapping process because our medical data center is involved in the creation of a nation-wide health information exchange that requires sharing clinical data across more than 200 first-class hospitals at Grade 3 in China. In the hospital information systems of these 200 hospitals, they use hundreds of dictionaries (e.g., diagnosis, operation, and other terminology dictionaries). Meanwhile, a large part of the terminologies’ dictionaries contain a huge amount of entities. How to standardize the terminologies from these 200 hospitals are the most challenging work when integrating their data.

Although there are deviations in terminology standards for different hospitals, there are a number of terms that are generally accepted. In this way, although different local terminology systems are used in different hospitals, a large part of the terminologies are the same. There would be a lot of duplicate work on terminology mapping if each of these 200 hospitals respectively standardizes its terminology system into a specified one. Besides, if the mapping work is done separately by each of the hospitals, it would probably generate different mappings for some selected terminology. For example, hospital A might map $U_v$ to $S_{T_1}$ terminology in the standard and hospital B might maps $L_{V_a}$ to a different $S_{T_2}$ terminology. How to eliminate the error mapping for the 200 hospitals and ensure that the local vocabularies in the different hospitals are correctly mapped to the same standard terminologies is challenging work. It would significantly improve the precision of mapping if we had some mechanism to verify the mapping and revise the error mapped ones.

Meanwhile, as there are a huge number of terminology entities in the mappings, it would be also a huge task to map all of them to standard terminologies. However, in practice, only a small part of the local items would be used in the actual healthcare systems. It would improve the efficiency if we considered mapping the terminologies based on their usage frequency.

In this paper, we propose a crowdsourcing based terminology mapping method, CrowdMapping, to help healthcare providers map their local and idiosyncratic data to standard terminologies. This would provide a better use of available medical data for analysis, integration and so on. First, CrowdMapping allows users from different organizations to specify mapping candidates in a standard terminology system like ICD-10. The model uses the mappings from the users and evaluates the diversity of the mapping to determine a most-selected, final best mapping rule if the diversity is less than a threshold value. Otherwise, if the diversity is too large, then some new mappings for the local terminology are generated from some more sophisticated experts. Further, the CrowdMapping model also enables users to give negative ratings to the final selected mapping rule if that mapping would be likely be wrong. CrowdMapping will recalculate the score for that terminology by subtracting a value which is related to the user’s reputation. Then, the final best mapping rule is recalculated. CrowdMapping is a work-in-progress system. It will be made public when the system is stable enough for usage.
Methods

Traditionally, standardizing local vocabularies is done by assigning the most likely terminology in the standard system by users. For example, as shown in Figure 1, a user can map \(LV_1\) in the local vocabulary to \(ST_1\) in the standard terminology, same with \(LV_2\) and \(LV_3\). However, mapping the local vocabulary to a standard terminology is not a trivial work. For example, different users might map some local vocabulary (\(LV_1\) in the figure) to different standard terminologies (for example, mapping \(LV_1\) to \(ST_1\), \(ST_2\), \(ST_3\), ... \(ST_n\) and so on). How to select the most likely candidate as the standard terminology for \(LV_1\) would become a problem in this scenario. CrowdMapping proposes a crowdsourcing based solution to solve this problem.

Overview

The target of CrowdMapping is to provide healthcare providers with a platform to map their local vocabularies, stored in dictionaries, to standard terminologies with high accuracy while keeping the mapping process simple and maintaining high efficiency. There are two basic design ideas in CrowdMapping.

1. CrowdMapping allows different experts to map a local vocabulary to several different candidates. It then uses a rating model to calculate a diversity value for the candidates. If the diversity value is less than a given threshold, a top-rated candidate will be automatically selected as the final terminology for the local vocabulary.

2. The volume of local data to be mapped is always very large, but fortunately, not all of the vocabularies in the local vocabulary systems are used; the usage of the local vocabularies are always biased. Mapping a small part of the local vocabularies would likely standardize most of the local data. With this evidence, CrowdMapping determines the next mapping vocabulary with terminology usage frequency in the local dataset.

Figure 1 shows the design of CrowdMapping. CrowdMapping system consists of three major parts, which are local vocabularies and standard terminology system repositories; a user reputation based priority scoring model; and a final mapping rule repository. The local vocabulary repository contains all the vocabularies which are local and are going to be mapped, while the standard terminology repository is the target to map the local ones to. The standard terminology systems are usually standard terminology systems like ICD-10, SNOMED and so on.

The users map the local vocabulary to standard terminology with their effort to make their decision of finding the most likely one in their opinion for the local one. CrowdMapping then records the user decisions (the raw mapping rule with the tag of which user made the mapping rule in the figure), and passes the raw user mapping rules to a reputation based priority scoring model with the user reputation values. The scoring model will calculate a candidate diversity score for each of local vocabularies (like \(LV_1\)). Besides, an ordered candidates queue, the priority scores are calculated by the scoring model. After the calculation, if the diversity is smaller than a given threshold a top-priority standard terminology will be selected as the final mapping value for the local vocabulary. For example, as shown in the figure, if the diversity is small, and \(ST_1\) has the highest score, then \(ST_1\) will be selected as the mapping value of \(LV_1\). However, when the diversity value is larger than the given threshold, the decisions from different users are not convergent signifying different opinions for the mapping of that local vocabulary. So more raw mapping rules are needed to make the final mapping decision. CrowdMapping will recalculate the diversity and priority scores when a new mapping rule is made for that local vocabulary until the diversity is small enough. After this progress, CrowdMapping will generate a final mapping rules repository for user.

Reputation Based Priority Scoring

In order to describe the reputation based priority scoring model, we would like to define several terms.

User Reputation

User reputation is a value describing the expert level of a user on mapping the vocabularies. If a user always maps local vocabularies to correct standard terminologies, then he will get a higher reputation. Suppose user A has worked on the CrowdMapping platform for some time, and he/she has mapped a set of local terminologies to the standard terminologies. Let’s suppose the mapping history of user A is:

\[
\text{val mappings} = \text{Set}{m_1, m_2, \ldots, m_n}\]

In which, user A has mapped \(k\) local vocabularies to standard terminologies correctly, and \(n - k\) to error ones. Besides, as we will discuss in the Mapping Rule Revision section, the mapping rules can be ‘+1’ or ‘-1’. Let’s suppose the support number of mapping \(m_i\) is \(p_i\), and the negative support number of mapping \(m_i\) is \(n_i\). Then, if the mapping \(m_i\) is selected as a correct mapping, all the \(p_i\) users who have ‘+1’ed this mapping will be processed as having mapped correctly one more time, while the \(n_i\) error mapped mapping number of the ‘-1’ed users for the mapping \(m_i\) will be increased.
Now let’s suppose that user A has mapped $k$ local vocabularies correctly, and $n - k$ wrong, and has $r + 1'ed$ per correctly, and $pw$ wrong, and has $r - 1'ed$ per correctly and $w$ wrong. Then we define the reputation $r_i$ of user A as:

$$r_i = \alpha \frac{k}{k + n - k} + \beta \frac{pc}{pc + pw} + (1 - \alpha - \beta) \frac{nc}{nc + nw}$$

where $\alpha$ and $\beta$ are two parameters which are configured by the CrowdMapping system.

**Mapping Set Diversity**

Mapping set diversity describes a status of the current mappings for a specific vocabulary. If there are many different mappings for a local vocabulary, that means users having different opinions on the mappings for that local vocabulary will have a high diversity. Otherwise, if all the mappings from different users are the same, then the diversity of the mapping set is 0. Diversity has been used in various areas [4-6]. In the system implementation, Simpson’s Diversity Index (SDI) [4] is used to calculate the diversity of the mapping set.

Suppose that the local vocabulary $LV_i$ is mapped to $k$ potential standard terminologies which are $\{ST_1^{i'}, ST_2^{i'}, ..., ST_k^{i'}\}$, and have $n_1^i$ users mapping $LV_i$ to $ST_1^{i'}$, $n_2^i$ users mapping $LV_i$ to $ST_2^{i'}$, and $n_k^i$ users mapping $LV_i$ to $ST_k^{i'}$. Then according to the algorithm of Simpson’s Diversity Index, we get

$$D_i = 1 - \frac{n_1^2(n_1 - 1) + n_2^2(n_2 - 1) + ... + n_k^2(n_k - 1)}{N(N - 1)}$$

where $N = n_1^2 + n_2^2 + ... + n_k^2$.

With this algorithm, the diversity value of the mapping set for $LV_i$ is mapped into a range of $[0, 1]$. For example, if all the users map the $LV_i$ to $ST_1^{i'}$, then $N = n_1^2$, so $D_i = 1 - \frac{n_1^2(n_1 - 1)}{N(N - 1)} = 0$.

Or, if all the users map the $LV_i$ to different standard terminologies, then all the $n_i$’s equals to 1, which will lead to

$$D_i = 1 - \frac{n(1 - 1)}{N(N - 1)} = 1 - 0 = 1.$$  

**Mapping Confidence**

Mapping confidence defines the level of how much of the mapping can be trusted. Mapping confidence is always calculated on the selected final mapping rule which has the highest score. It is affected by the mapping count, user revision score, and the mapping diversity. A higher mapping confidence means a higher probability that the mapping can be trusted.

Let’s continue with the example used in Mapping Set Diversity. Suppose the mapping $M_i^j$ from $LV_i$ to $ST_i^{j'}$ is the mapping which has the highest score. Suppose that the count of the users who map $LV_i$ to $ST_i^{j'}$ is $c_i^j$, and the diversity of $LV_i$ is $D_i$, and $pc_i^j$ users ’$+1'ed$ the mapping $M_i^j$, and $nc_i^j$ users ’$-1'ed$ the mapping $M_i^j$. The confidence of the mapping $M_i^j$ can be calculated as:

$$C_i^j = \frac{pc_i^j}{pc_i^j + nc_i^j} \cdot D_i \cdot \frac{\text{count}_i^j}{\text{count}_{\text{MIN}}}$$

Only the mapping with a high confidence larger than a threshold $C_{MIN}$ will be selected as a final mapping for the local vocabulary and be put into the mapping rule repository.

**Score Calculation**

Based on the definitions above, suppose that $n$ users ($U_1$, $U_2$, $...$, $U_n$) are working on mapping the local vocabularies $LV_i$ to standard terminologies. Let’s annotate the reputation of $U_i$ as $r_i$. The user-generated $k$ mappings for $LV_i$, $\{ST_1^{i'}, ST_2^{i'}, ..., ST_k^{i'}\}$ (where $k \leq n$), Suppose that those who have mapped the $LV_i$ to $ST_i^{j'}$ are the users ($U_a$, $U_b$, $...$, $U_z$). Then we will calculate a temporal reputation summary of the mapping $M_i^j$ from $LV_i$ to $ST_i^{j'}$:

$$\text{Reput}_j = \sum_{i=1}^{x} r_i$$

and then the score for the mapping $M_i^j$ is calculated as:

$$\text{Score}_j = \frac{\text{Reput}_j}{\sum_{i=1}^{x} \text{Reput}_i}$$

The reputation based priority scoring model will calculate all the mappings and their scores and generate an scored terminology map as $\{ST_1^{i'}, \text{Score}_1, ST_2^{i'}, \text{Score}_2, ..., ST_k^{i'}, \text{Score}_k\}$.

After the scores are computed, the CrowdMapping method will calculate the mapping confidence value for the mapping with the highest score. CrowdMapping will compare it with a given threshold value, if the diversity score is less than the threshold, CrowdMapping will select the standard terminology $ST_i^{j'}$ with the highest score (for example, $\text{Score}_k$) as the mapping terminology for the local vocabulary (for example, $LV_i$ in the figure). CrowdMapping will also update the user reputation table according to the last mapping decisions. In this way, the users who have mapped $LV_i$ to $ST_i^{j'}$ will get a higher reputation value, while the users mapped $LV_i$ to other standard terminology will be reduced on their reputation. However, if the confidence value of the mapping is too small, suggesting that the users do not have a consistent decision on how to map $LV_i$ to the standard terminology, CrowdMapping will not do the following steps as described above. It will wait for more user raw mapping rules.

Algorithm 1 shows the process of reputation based priority scoring method of finding the most likely mapping $M_i^j$ for $LV_i$. The CrowdMapping system will use this algorithm to process the mappings for all the local vocabularies.

With these processes, a final mapping decision will be made based on all the user mapping decisions, as shown in the Mapping Rules in the figure.

**Algorithm 1:** reputation based score algorithm for $LV_i$ mappings ← all the mappings of $LV_i$ with user info

1. $Di ←$ calculate diversity of the mappings
2. If $Di > D_{\text{threshold}}$, then
   1. users ← get users of the mappings
   2. For each user in users, do
      1. $ri ←$ calculate user reputation for each user
   End
   3. scoredMap ← init scored terminology mappings
   4. For each mapping in mappings, do
      1. $\text{Score}_i ←$ calculate Score of mapping
      2. $Ci ←$ calculate confidence of mapping
      3. If $Ci > C_{\text{MIN}}$, then
         1. Add $\{ST_i^{j'}, \text{Score}_i\}$ to scoredMap
   End
   5. orderedScoredMap ← sort scoredMap by score
3. Return top of orderedScoredMap
   Else
   1. Return NULL
Frequency Based Local Vocabulary Candidate

Local vocabularies are always having a large volume of entries. In practice, only a limited part of the local vocabularies are used in the healthcare systems. So different entries in the vocabularies have different significance for health care systems. It would significantly improve the work efficiency if the most ‘important’ entries in the local vocabulary are mapped first. So CrowdMapping defines a usage frequency based priority value for local entry candidate selection. If an entry in the vocabulary is used quite frequently in a health care setting it will have a higher priority for mapping.

However, the frequency is calculated from online health care systems. In some case, users might not be able to get the frequency. In these situations CrowdMapping will use a similar frequency statistic from another health care organization. If no organization has the frequency information, then equal priority will be assigned to the local vocabulary entries. In this way, the next local vocabulary entry to be processed is selected randomly.

Mapping Rule Revision

After the steps described above are performed a usable mapping rules repository will be generated. And users from different healthcare organizations can use these mapping rules to automatically standardize their local vocabularies. However, CrowdMapping is a machine-based automation tool, so there might exist erroneous mappings in the system-generated rules. An official selected mapping may also have expired and/or become invalid. For these reasons, CrowdMapping has a mapping rule revision module. In this module, the users can ‘+1’ a mapping rule or ‘-1’ it. And these actions will trigger the mapping confidence computation. If there are too many users ‘+1’ ing that mapping rule, the mapping confidence will decrease. When the confidence is lower than a threshold, the mapping rule will be removed from the final mapping rule repository to the raw mapping rule repository to await more user mapping decision.

Results

As CrowdMapping is still a work-in-progress project, we have not performed large scale testing. However, with using the key design idea in a demo platform, we found that CrowdMapping combines the mapping decisions from multiple users and selects the most likely rule for the local vocabularies which makes the rule mapping decision more precise.

When the platform is ready, we will evaluate CrowdMapping with the traditional mapping method on mapping precision and the processing time. Also, we will make CrowdMapping as a public web application. All the users from healthcare organizations can use our service together with the effort from the experts all over the world.

Discussion

Terminology mapping is important work for the medical informatics community. There is already a large body of work describing various aspects of mapping local codes to standard terminology systems from both academic and industry researchers.

Several studies [7-11] have evaluated different automated tools to assist with mapping local vocabularies to other terminology systems. Yet, even with the best available automated tools, expert human review is still needed to resolve computer generated candidate mappings. Also, because local and standard vocabularies evolve, the burden of maintaining the mappings is significant, ongoing, and easily underestimated. Therefore, all healthcare organizations whether data senders, receivers, or both, require people, processes, and tools to support mapping activities.

It is a complex and resource intensive job to map local terms to standard terminology systems. Even a sophisticated person with a good understanding of the corresponding terminology system, he/she might lack the specific knowledge required to correctly map all of their local terminologies [3,12,13]. How to efficiently combine the effort from the experts of the institutions to improve the mapping precision is a necessary work. Crowdsourcing has been used in many fields to improve the work efficiency. In the terminology mapping, several work [3,12,13] have been done to make mapping more efficient and effective with crowdsourcing. However, they are strongly integrated with special standardized terminologies, for example, LOINC.

CrowdMapping allows users from different organizations to specify mapping candidates in standard terminology systems like ICD-10. CrowdMapping uses the mappings from the users and evaluates the diversity of the mapping to determine a most-frequently selected final best mapping rule. This strategy would likely improve the accuracy of the mapping. Mapping set diversity and the mapping confidence model are used in CrowdMapping to automatically divide the ‘hard’ mapping tasks from the ‘easy’ ones (a local entry with a high mapping diversity is always a ‘hard’ mapping task). CrowdMapping can let the ‘right’ person to do the ‘right’ thing; the ‘hard’ mapping tasks are assigned to sophisticated experts to make the mapping more precise.

Conclusion

In this paper, we propose CrowdMapping, a platform for generating terminology mapping rules that leverages the crowd effort. CrowdMapping uses an algorithm which considers both the user reputation and crowd selection, which likely leads to a more confident mapping result. Using the demo program, we found that CrowdMapping reduces the mapping time and increases precision. Terminology mapping is a very common step for medical data analysis, we will deploy an online service for public use as soon as the platform is more stable.

Case Report Form Reporter: A Key Component for the Integration of Electronic Medical Records and the Electronic Data Capture System

*Medical Informatics, Osaka University Graduate School of Medicine, Osaka, Japan
#MKS Ltd, Osaka, Japan
Division of Medical Informatics, Osaka University Hospital, Osaka, Japan

Abstract
To improve the efficiency of clinical research, we developed a system to integrate electronic medical records (EMRs) and the electronic data capture system (EDC). EDC is divided into case report form (CRF) reporter and CDMS with CRF receiver with data communication using the operational data model (ODM). The CRF reporter is incorporated into the EMR to share data with the EMR. In the data transcription type, doctors enter data using a progress note template, which are transmitted to the reporter template. It then generates the ODM. In the direct record type, reporter templates open from the progress note and generate narrative text to make record in the progress note. The configuration files for a study are delivered from the contents server to minimize the setup. This system has been used for 15 clinical studies including 3 clinical trials. This system can save labor and financial costs in clinical research.

Keywords:
Electronic Health Records; Clinical Study; Data Systems

Introduction
We need a method for transcribing the data recorded in a patient’s medical record to a predetermined form for submission to a party outside of the hospital. In the era of managing medical records via a paper medical chart, the data written in the record needed to be transcribed by hand to another piece of paper; however, in the era of electronic medical records (EMRs), we now need a way to fill out forms without redundant data input. This function is particularly important in clinical research and would also be useful when sending a report to external organizations when for example following up a patient in collaboration with other medical facilities.

In clinical research, such as clinical trials, observational studies and registries, data for pre-determined items are systematically collected for patients who meet the entry criteria. In clinical trials, source data verification (SDV) by a monitor is required to confirm the consistency of the data in the case report form (CRF) with those in the medical record. This increases the costs associated with a study. In observational studies and registries, data are often entered without the support of clinical research coordinators (CRCs); as such, redundant entry in the medical record and electronic data capture system (EDC) is a major obstacle to promoting these studies. As registries become more popular, we may encounter instances where one case needs to be submitted to multiple registries, which results in redundant data input.

Interoperability between medical care and clinical research would be advantage, but has not been achieved in a wide scale [1]. The Clinical Data Interchange Standard Consortium (CDISC) Electronic Source Data Interchange Group identified issues that may inhibit adoption, explored the values and benefits of implementing standards for data acquisition, exchange and archive of eSource [2]. We developed and already reported on a system to achieve these issues [3]. In our model, the EDC is divided into a CRF reporter, which functions as a data input and transmission unit, and a clinical data management system (CDMS) with CRF receiver, which functions as a data reception and storage unit. Data communication between the CRF reporter and the CRF receiver is achieved via an operational data model (ODM) developed by CDISC [4]. The CRF reporter is incorporated into an EMR system that can automatically retrieve the data recorded in the EMR and output narrative text generated from the data included in the CRF reporter to the medical record. In order to automate setup, a template master, an ODM and a study configuration file are distributed via a network from a content server to the hospitals participating in the study (Figure 1). Since the previous report, we have added several functions and refined the system further. In this paper, we describe our system, with focus on the CRF reporter, which is a key component for integration of EMRs and EDC.

Methods

System Overview
There are two types of CRF reporters: a data transcription type, and a direct record type. The functions of each are outlined below.
Data Transcription Type

When recording progress notes, the data used for clinical research are input using a template. The CRF reporter is an application independent of the EMR. In the CRF reporter, after selecting a study and a subject, an event list is displayed. One event consists of several forms. When a form is selected, the corresponding template is displayed, along with a data retrieval button. By clicking this button, the data entered by the template for the progress note or data (e.g. laboratory test data) stored in the EMR database are retrieved and used to populate the items in the template. When the input of the template set corresponding to a study event is completed, the input data are mapped to the ODM, which is sent to the data center (Figure 2).

Direct Record Type

The start button of the CRF reporter is placed in the progress note. Clicking this button brings up a list of studies in which the patient and the user are participating. After selecting a study, a list of events with forms is opened. Selecting a form displays the corresponding template. After data input is completed, the narrative text is generated and added to a frame in the progress note. The subsequent process is the same as that of the data transcription type (Figure 3).

Input Template Function

The input template is a key module for this system. We developed “dynamic template” to acquire medical records in structured form [5]. If any abnormalities are noted in the observation items, a detailed description of the abnormality is required; this allows the medical description to be presented in a hierarchical tree structure. Therefore a template where the next input item changes according to the selected value is suitable for medical description.

Data & contents center

![Figure 2 – Configuration of Data Transcription Type.](image)

Data Retrieval Interface

In the EMR database, data such as patient characteristics (height, weight, etc.) and laboratory test results are stored. These data frequently need to be collected into templates. When retrieving laboratory test results or similar, an assigned test item code is required in order to obtain the value for a designated test item. However, the test item code differs among hospitals. Therefore, a conversion table (correspondence table between a universal keyword and the local code) is created at each hospital. This table also has a multiplied number to convert the value in local units to standard units and has a correspondence table to convert local enumerated values to standard ones.

In the template master, the parameters for data retrieval, such as the test item code, search period, and selection method, are described. In the template master, the test item code is described in the notation generally conforming to the CDISC-controlled terminology. The template engine obtains the local code for the test item and the information for converting the value into the standard form from the conversion table. Then it passes the parameters including the local code, search period, and selection method to the interface module. The selection methods are for example selecting one latest value, one oldest value or user’s selection. If there are several corresponding data in a given search period, the data picker module presents them all to the user for selection.

The template can also retrieve values entered in other templates in the past by designating the element code with the template code of the source template or the concept code if it is written to the corresponding element.
Data Mapping to the eCRF

In our system, the ODM was used as the eCRF form outputted from the CRF reporter. After the completion of input, the template engine generates a dataset in a tree structure, where each leaf corresponds to a value and each node corresponds to an item. The value of a node is the narrative text generated from the data under the node. For each ItemData of the ODM, the corresponding value of the leaf or node can be mapped. For example, when a value of “the date of occurrence” is entered by selecting the year and month from a combo box on the template, the leaf value is year = 2010, month = 10, and the node value is “October 2010”. Thus, if the ItemData value corresponding to “the date of occurrence” is requested in a string, “October 2010” can be mapped to it.

ODM Transmission

First, we must enter subjects who meet the inclusion and exclusion criteria. At this point, the subject key is determined on the hospital side or issued on the server side; in our system, both are possible. The CRF reporter performs ODM transmission to the CDMS/EDC in the data center. To check the contents of the ODM, a readable case report form is also generated. After checking the contents, the ODM is transmitted to the center server.

Originally, the CRF reporter sent the ODM to one CDMS; however, it must now be able to send the ODM to any CDMS/EDC equipped with an ODM import function in datacenters, depending on the study. Because the communication procedures of ODMs differ, CRF reporters need to be able to switch transmission modules according to the destination center server.

User Management

The CRF reporter needs to manage local users as well as center server users linked to local users. When logging into the CRF reporter, a local user table is checked, but when creating and sending the ODM, the center server user is used instead. The user ID for the center server is recorded in the AdminData element in the ODM. When connecting to the center server, authentication is performed using the center server user.

Setup Automation

Occasionally in clinical trials, there are cases where several subjects are handled at a given hospital. Requiring a system engineer to set up this system at each hospital can be costly, resulting in the operation using our system becoming more expensive than that with a regular EDC. Therefore, we developed a function to automate setup using a template master, an ODM and a study configuration file, all of which are distributed via a network from a content server to the hospitals participating in the study. The only operation required by each hospital is user management and the maintenance of the correspondence table between the universal keyword and the local code. Before starting a study, the operation staff on the hospital side need only to confirm that the ODM is correctly created using test subjects.

User Operation

Data Transcription Type

The CRF reporter is a system independent of the EMR. After logging into the system, it shows the studies for which the user has been given operation authority. When a study is selected, the subjects participating in the study are displayed. When a new subject is entered, patient identification information such as the patient ID, name, gender, date of birth, etc., are acquired from the EMR database added to a correspondence table between the subject key and the patient ID. The patient identification information is then displayed in the subject list to help the user select the correct subject. These data, however, are not sent to the data center.

When a subject is selected, the event list for the subject is displayed. Each event includes several forms. After selecting a form, the corresponding template is displayed. By clicking on the data retrieval button in this template, the fields of the template can be populated by the data if they have already been entered by the progress note templates.

After entering all of the required items for an event, the status of the event changes to “completed”, and ODM creation becomes possible. The user checks the contents of the ODM. If no amendment is needed, they click the send button and transmit the ODM to the center server in the data center. When the center server receives the ODM correctly, the data reception status is returned to the CRF reporter.

Direct Record Type

The direct record type is currently under development and set to start operation from April 2017. The functions scheduled to be included are shown in Figure 4.

When a patient is selected in the EMR, the patient’s medical record screen is opened. On opening the progress note input screen from this point, an activation button for the CRF reporter is displayed. If the patient is a subject or a subject candidate and the user has been given operation authority, this button flashes. Clicking on this button displays the event list for the study. When a form for an event is selected, the corresponding template is displayed. The user then enters data in accordance with the items on the template. For items such as laboratory test results, the corresponding data are automatically retrieved and populated. By clicking the send button, the ODM is created and sent to the center server in the data center.

![Figure 4 - Operation of Doctors when using Data Record Type](image)

1. Open the event list of the study for the patient by clicking activation button for the CRF reporter
2. Select a form to open the corresponding template
3. Output the narrative text to record in progress note
4. Create the ODM and send it to the center server

Results

Dynamic templates have been incorporated into the EMR system developed by NEC since 2000. Thus far, more than one hundred hospitals have employed this system, and more than seventy thousand templates have been created and used in these hospitals. For example, at Osaka University Hospital, 2182 template masters have been registered, and 123,191 templates per month are used, resulting in 1,195,831 data items per month being entered.

At present, only the data transcription type CRF reporter is being used. Three hospitals have implemented this CRF
reporter in their EMR systems; however, at other hospitals, the CRF reporter is installed on a single PC for use. While the CRF reporter cannot cooperate with the EMR system in such cases, it can still be used as a terminal for usual EDCs. The ability to create CRFs offline makes this approach convenient compared with normal EDCs. Using this system, we have carried out 12 observational studies and 3 clinical trials so far. Six of these studies consisted of more than 10 events. These clinical studies have successfully collected data, and six of them have already been completed. The maximum number of the entry subjects were 1119.

Discussion

This system is a special type of EDC comprising a CRF reporter and a CDMS with a CRF receiver. The CRF reporter is built into the EMR. This model is similar to the Retrieve Form for Data Capture (RFD) model proposed by Integrating the Healthcare Enterprise (IHE) [6]. The RFD model consists of a Form Manager, Form Filler, Form Archiver, and Form Receiver. Our model consists of a content management system corresponding to a Form Manager, templates in the CRF reporter corresponding to Form Filler, a local server of the CRF reporter corresponding to a Form Archiver, and a CDMS with a CRF receiver corresponding to a Form Receiver. However, our model is not completely RFD-compliant, as we used a unique template module instead of XForms for the form filler and REST communication instead of SOAP for communication between Form Filler and Form Receiver. However, several challenges to the EDC and EHR interoperable systems have been reported, and a completed system based on the RFD model has not yet been developed.

Regarding the integration of EHRs and EDCs, one report described a system that retrieves the data elements of patinet care-centric template in use in the EHR to pre-populate the CRFs, but only 13.4% of the data elements in the CRFs were able to be retrieved [7]. In our model, even with the data transcription type of CRF reporter, a template used for patient care is purposefully created to allow users to enter data for a given study; as such, almost all data collected in the study can be retrieved. In addition, since narrative expression-style text generated from the data are entered as a record of the progress note and doctors can freely add supplementary text to the progress note, the note can be treated as a medical record as well.

For registries, various patient data such as the symptoms, findings, laboratory test results, image examination reports, and treatments, are entered. In the data transcription type, a template for the progress note can be created freely at each hospital. When registering a single case in multiple registries, if a template with unified items in the case report forms for multiple registries would be created, with the initially entered data then retrieved by the templates for the respective CRFs and the completed CRFs sent to the corresponding data centers. For clinical and prospective observational studies, certain forms must be input for each visit, and some forms are used across several visits. If such studies use data transcription type CRF reporters, the template corresponding to each visit is not shown and data input cannot be guided. Another problem is that retrieving the data for the same form from different visits using the corresponding CRF reporter form is complicated. In contrast, when using the direct record type of CRF reporter, the events and forms to be entered are displayed and their statuses shown, guiding doctors to input data into the proper template for each visit. The preparation of the CRF reporter for the direct record type is easier than that for the data transcription type. As such, for prospective clinical studies, the direct record type is more suitable.

This system saves labor through the simultaneous entry of the medical record and the CRF as well as the automatic retrieval of the data recorded in the EMR. The former is an essential function of this system, but the latter depends on the interface function between the template and EMR. The more easily various data can be retrieved from the EMR database, the more efficient clinical research becomes. Details of this function of our system were reported in MIE in 2016 [8].

When integrating EDCs and EHRs, locus of responsibility should be clear [9]. With this system configuration, the CRF reporter is a investigator side system. Therefore, we believe that the validation for clinical research is required within the scope of using a CRF reporter. For data transcription type CRF reporters, since the system automatically retrieves the data and applies it to the template of the CRF reporter, the mechanism of correct retrieval must be validated. For the direct record type as well, we must also validate the automatic retrieval function for laboratory test data and similar values; however, the data retrieval range is narrow compared to the data transcription type. For the direct data record type, since data is output to the medical chart, we must validate whether or not this output is correctly recorded in the EMR. From the viewpoint of the locus of responsibility, the investigator side should be responsible for the CRF reporter and for directly transferring data between the CRF reporter and EMR, regardless of data transcription type or direct record type.

For the data transcription type, the doctor may describe the record in free text in the progress note, and the CRC manually transcribes the data to the template of the CRF reporter. Even when doctors input data using the template in the progress note, after theCRC transcribes the data into the CRF, the doctor may change the data using the template, which may result in inconsistencies between the CRF and EMR record. Therefore, interaction with the data transcription type CRF reporter requires an SDV, as in ordinary EDCs. In contrast, in the direct record type, the contents entered by the CRF reporter are forcibly added to the medical record, so it matches the contents of the medical record. Also, when revising, since the template of the CRF reporter is opened and modified, inconsistency does not occur. Therefore, an SDV is unnecessary when the direct record type CRF reporter is used. This further underscores the suitability of the direct record type over the data transcription type for clinical trials.

The integration of EDCs and EHRs relies heavily on the unification of terms. However, using the direct record type of reporter essentially creates a system closed to the EDC, so there is no need to match the term code of ItemData with the EMR side. In contrast, when using the data transcription type of reporter, the item code of the template in the progress note must be designated in the field of the template of the CRF reporter in order to retrieve data. We assume that a template for the progress note is additionally created for clinical research, and doctors purposely select that template if a patient is participating in a given study. It is therefore not absolutely necessary to unify item codes of both templates. However, if the CRF reporter would be set independently from the creation of the templates in the progress note, a universal keyword must be wrote as a concept code of a given element of the template in the progress note.

It has often been said that a unified vocabulary for medical care and clinical research is prerequisite for the interoperability of EHRs and EDCs [10;11]. However, compiling a complete dictionary of terms in both medical care and clinical research is an endless task. Thus, if the creation of this dictionary was premised, the integration of EHRs and EDCs would be
realizable. In our system, while establishing a list of unified keywords would be useful, it is not necessary. We feel that this element makes our system practical for clinical research support.

Because the CRF reporter is an independent component of the EMR, it can be incorporated in any EMR system. We have so far incorporated it in the EMR developed by NEC and another by IBM. With accordance of the communication procedure between CRF reporters and the receiver, a different type of CRF reporter comes into effect. Fujitsu is trying to develop another type of CRF reporter which can communicate with the same center server. By incorporating the CRF reporters in the EMRs in the hospitals, we are creating a hospital cluster for networked clinical research, which will consist of more than 16 hospitals in Osaka in the following years.

Conclusion

We developed a CRF reporter to integrate EHRs and EDCs. The CRF reporter incorporated in an EMR system can retrieve data recorded in the EMR, generate an ODM, and transmit the ODM to the CDMS. With the data transcription type of CRF reporter, doctors enter data using a template for the progress note, and the data are then transmitted to the template for the CRF reporter. In the direct record type of reporter, templates of the CRF reporter open from the progress note, generating narrative text to make a record in the progress note. This system can save both labor and financial costs in clinical research.

Scholarly Information Extraction Is Going to Make a Quantum Leap with PubMed Central (PMC) — But Moving from Abstracts to Full Texts Seems Harder than Expected

Franz Matthies and Udo Hahn

Jena University Language & Information Engineering (JULIE) Lab
Friedrich-Schiller-Universität Jena, Jena 07743, Germany

Abstract

With the increasing availability of complete full texts (journal articles), rather than their surrogates (titles, abstracts), as resources for text analytics, entirely new opportunities arise for information extraction and text mining from scholarly publications. Yet, we gathered evidence that a range of problems are encountered for full-text processing when biomedical text analytics simply reuse existing NLP pipelines which were developed on the basis of abstracts (rather than full texts). We conducted experiments with four different relation extraction engines all of which were top performers in previous BioNLP Event Extraction Challenges. We found that abstract-trained engines loose up to 6.6% F-score points when run on full-text data. Hence, the reuse of existing abstract-based NLP software in a full-text scenario is considered harmful because of heavy performance losses. Given the current lack of annotated full-text resources to train on, our study quantifies the price paid for this short cut.

Keywords:
Natural Language Processing; Information Storage and Retrieval; Information Extraction

Introduction

While abstracts contain only the major results of the corresponding journal article in a highly condensed manner, the full-text body of scholarly publications makes accessible all single pieces of information from scientific studies. Since the demand for this maximum level of information is also high in the life sciences, the NLM launched a full-text collection for a subset of PUBMED abstracts, PUBMED CENTRAL (PMC),1 which currently (April 2017) archives 4.3 million articles and is growing at high speed. Given such a bulky resource, unlimited access to the information contained in scholarly full texts seems both a realistic and rewarding goal, since a great deal of relevant biomedical information is only contained in the full-text portions of scientific articles and is not mentioned at all in the corresponding abstracts of the full texts [1–3] – so the information gain from processing full texts can be enormous.

Tanabe and Wilbur [4] were the first to hint at technical problems of dealing with special non-ASCII characters, tables and figures embedded in full texts. Going beyond low-level technicalities, within the BioCREATIVE Gene Normalization Challenge, for the first time, evidence was gathered that performance dropped significantly when tested on full texts [5] instead of abstracts [6].

Cohen et al. [7] substantiated these warnings that the processing of full texts will be more than challenging by investigating their intrinsic properties. They conducted an empirical study in which they investigated different structural and linguistic properties of abstracts and their corresponding full texts. They found longer sentences in the full texts than in the abstracts and much heavier use of parenthesized material (e.g., abbreviations, citations, data values, figure/table pointers, etc.) in the full texts than in the abstracts. Both phenomena make full texts much harder to parse than abstracts. Syntax-wise they also gathered evidence that the incidence of conjunctions, passives, pronominal anaphora, as well as sentence complexity/readability were markedly different from full texts to abstracts. However, syntactic parsing using the Stanford Lexicalized Parser yielded no statistically relevant difference between both genres (taking ParsEval’s metrics for bracket recall and tag accuracy). Yet, POS tagging was more accurate in abstracts than in full texts. Analysis errors caused by the increased syntactic complexity of full text articles (compared with abstracts) were also recognized by Tudor et al. [8]. McIntosh and Curran [9] further point out that coreference relations (anaphora) between sentences play an important role in full texts. Semantics-wise, Cohen et al. found that the distribution of named entities such as genes/proteins, mutations, drugs, etc. differed between the two text genres as well.

Most important for our own work, Cohen et al. also investigated the impact these differences had on the performance of information extraction tools. They found that three common gene mention recognition systems (BANNER, ABNER and LINGPIPE) performed much worse on full texts than they did on abstracts – F-measures were generally about 10 points higher on the abstracts than on the full text portions. Consequently, the authors advocated retraining models on full texts.

If this suggestion is taken seriously, annotated full-text corpora have to be supplied. Given the large volume of utterances contained in full texts, this is an enormously resource-consumptive task. Cohen et al.’s study is based on their self-developed CRAFT full text corpus [10] which reflects the findings for full text phenomena from [7]. It consists of 97 (67 publically released) full texts, plus corresponding abstracts (comprising nearly 31k sentences or 800k text tokens), dealing with mouse genomics. This corpus was annotated for part-of-speech (POS) and syntactic parsing data, as well as proteins/genes as named entities [11].

1 https://www.ncbi.nlm.nih.gov/pmc/
The authors carefully discuss the large variance in testing conditions, e.g., the types of named entity tags (BANNER, ABNER and LINGPIPE), the types of models being considered (trained on the abstract-based BIOCREATIVE II, NLPBA and GENIA and the full-text-based CRAFT corpora where, in addition, the full set is distinguished from a development set), different definitions of the named entity type 'protein' and different matching criteria for gene mentions). Still, the CRAFT study reveals inconsistent results for the 'gene' named entity recognition problem. For the LINGPIPE system, gains for retraining on the full-text corpus amount to 0.18 F-score points, but ABNER’s performance drops after retraining (increased precision comes at the cost of substantial recall losses). BANNER’s results are already competitive with the out-of-the-box model so that no retraining on CRAFT-style full text corpora is required. The authors summarize their results that “retraining the gene mention recognition systems unfortunately did not show much improvement” [10, p. 21] but anticipate a significant improvement if the learning problem will be rephrased (see also [10, p. 21]). Note that CRAFT is not annotated for any relational information so that no empirical data could be collected for this task from this resource. The CRAFT study also measured the impact of sentence splitting, tokenization, POS tagging and syntactic parsing relative to the two text genres—abstracts and full texts. For parsing, e.g., substantial improvements of CRAFT-trained models over standard (non-biomedical) English models were found.

Another full-text corpus, ID, remedies the lack of biomedical relation annotations. It was supplied for the series of BioNLP Event Extraction Challenges starting in 2009, with the second round in 2011 [12]. ID contains 30 full texts (more than 5k sentences, 150k text tokens) annotated for biomolecular mechanisms of infectious diseases that involve associations between multiple types of molecular entities, disease-causing microorganisms and other organisms undergoing the diseases. With more than 13k named entities and 4,15k events the entity count is comparable to the 2009 Challenge; whereas the event count is only approximately one third of the Shared Task 2009 data. On this data, the top-performing systems scored at almost the same level as in 2009 (where abstracts were analyzed), with the winner system (FAUST) peaking on 50% F-score (trained and evaluated on sections of ID full texts).

Since the biomedical NLP community has developed a battery of well-engineered analytic engines—starting from domain-adapted tokenizers, POS taggers and parsers to domain-specific named entity tags and relation extractors—one is tempted to simply reuse these tools and composite pipelines on full texts in order to unlock the vast amount of still hidden information. The fact that almost all of them were developed and fine-tuned on abstracts as textual training data does not seem to be an issue here. Instead, we claim that moving from the abstract to the full-text level of analysis is by no means a free lunch. We rather stipulate that classifiers trained on abstracts (irrespective of whether they deal with named entities or relations between them) will drop significantly in performance when run on corresponding full texts due to the increased level of linguistic, structural and conceptual complexity in the latter. Thus, the potential cheap benefit of making full texts available, instead of (informationally much poorer) abstracts, is likely to disappear. —But at what rate? And, is this rate, when quantified, tolerable or not?

In this paper, we deal with the problem of trading off abstract vs. full-text processing for the life sciences domain, with focus on relation extraction. We thus study the effects of text genres on system performance by switching between abstract and full-text documents. We substantiate our claims by running four prominent relation extraction systems, which were top-performers in the most recent BioNLP 2013 Event Extraction Challenge [13]. This selection of systems should guarantee that despite the small 'sample size' of the four classifiers the results we achieve might cautiously be generalized for a much larger class of relation tags in the biomedical domain.

**Methods**

In this section, we describe the experimental set-up of our work. First, we introduce the systems we used for relation extraction. Then, we describe the full-text resources for our experiments. From a methodological perspective, a general observation can be made. The best-performing BioNLP systems (cf. the top performers in challenge competitions such as BIOCREATIVE [15-17], BIONLP Shared Task [18,19], I2B2 [20,21], or DDI [22,23]) either exclusively rely on some (semi-)supervised form of machine learning (ML) techniques, or combine ML with rule- or dictionary-based approaches in terms of hybrid systems. The ML systems (or ML portions of hybrid systems) being used are thus highly dependent on their textual input for training, i.e., subsets of PUBMED (MEDLINE) abstracts annotated by humans, since they constitute the gold standards both for training and evaluating these classifiers. Unsupervised ML systems are rare and, if running against competitor systems, are usually outperformed by supervised approaches in the challenges.

**Relation Extractors**

For our experiments, we used four systems that performed exceptionally well in previous BioNLP Event Extraction Challenges. Another criterion of choice was technical in nature—(the code of) the systems should be easily accessible and processable without much effort in our computing environment. The latter is important because technical portability of systems is an indicator for the extramural reproducibility of results. In the following, we briefly summarize each system and point out main differences among them and their approaches to relation extraction. For a more in-depth description, we kindly refer to the respective papers cited in Table 1.

**TEES**

The TEES system [24] was successful in all three BioNLP Shared Tasks, achieving the first rank in 2009 and the first rank in half of the subtasks in 2011 and 2013, respectively. Since the team has also provided the code as an open source project7 to the scientific community, it was clearly the first choice for our experiments.

TEES approaches the task of relation extraction in a linear fashion, by first detecting potential triggers in a text and, in

---

7 [https://github.com/jbjorne/TEES](https://github.com/jbjorne/TEES)
the next step, defining valid edge candidates between entities: triggers or arguments. At this point, overlapping events are possible—that is, they share the same trigger node. This ‘merged event graph’ is unmerged in the next step. A Support Vector Machine (SVM) sequentially and independently solves all these steps with a linear kernel handling them as multi-class classification problems.

### BioSEM

The BioSEM system\(^3\) [26] stands out from the other three systems we consider here because of two interesting facts. Firstly, in the training phase, it learns rules for relation representations by means of a semantic and syntactic feature list and, secondly, it refrains from deep syntactic parsing, but rather builds its structured representation of the text from the output of a shallow parse (i.e., chunks) only. Among other decisions, this leads to an outstanding computational efficiency, paving the way to relation extraction on a larger scale. The authors estimate their system to be around 170–230 times faster for completely extracting an event from a sentence compared to state-of-the-art ML-based systems. (see [26] “Computational Performance”). The usage of rules also yields a superior precision (between 60-70% depending on the set-up) compared to the other systems we consider here.

### HDS4NLP

In the official results for the GENIA task, HDS4NLP [28] only achieved rank 6 (with 43.03 F-score). However, its developers identified a serious bug after disclosure of the test results, and, after fixing it, their system reportedly achieved an F-score of 51.15, outperforming the top ranked competitor EVEX (50.97 F-score).\(^4\) Since they trained the model for producing the results for the 2013 Shared Task on all documents from both the development and the training sets of the BioNLP 2011 and 2013 GE tasks, the numbers we present here differ from the ones they reported, as we only use 2013 GE task documents. However, we still achieve a much higher F-score (47.81) than the official figures, putting them among the top five performers of the challenge. Also, HDS4NLP outperforms the other three systems when evaluated on terms of the BioNLP 2009 Shared Task with 54.37 F-score by at least 2.3 points.

In comparison to the other systems used for our experiments, HDS4NLP tackles relation extraction by training a model that directly extracts pairwise structured events (and the event type they belong to) of the form \((\text{trigger}, \text{argument})\) rather than relying on a sequential technique (i.e., extracting triggers first and then looking for applicable arguments). A point the authors make why this might be beneficial is that the usual approach of detecting triggers in isolation could lead to contextual information loss. Running an SVM (as implemented through PYTHON’S scikit-learn environment)\(^5\) on the sentence level addresses the problem of classifying candidate-argument pairs [26]—taken from the cross product of the sets of possible trigger tokens and arguments—in a one-vs.-all set-up. We will elaborate on this point in the Results Section.

### JReX

The JReX system, developed in our lab, participated only in the BioNLP 2009 GE task [14] where it ranked on 2nd place among 24 teams. Since then it has undergone almost no updates. This stagnation is clearly reflected in the performance figures compared to the other three systems used in our experiments which are/were under active development. JReX incorporates manually curated dictionaries and ML methodologies (SVM, MAXENT) to sort out associated event triggers and arguments on trimmed dependency graph structures, the latter being simplified dependency structures from which representational ‘noise’ has been eliminated (cf. [14, 29]).

### Text Corpora

The textual resources we exploited were taken from the text repository of the 2013 Event Extraction Challenge for the full texts and the 2011 repository for the abstracts (cf. Table 2 for a quantitative breakdown). For the former to get a reasonable amount of material, we used training and development set, whereas for the latter we only used the train set for training as to keep the size approximately on a par with that of the full text collection.

</table>

This set-up results in performance figures for the systems that differ from those reported in the 2009 Shared Task, since they used both development and training sets as input for training. Differences in the results when replicating the Shared Task 2013 set-up (compared to the original scores) can be accredited to the fact that all the systems used 2011 (abstracts, as well) and 2013 resources for training.

### Events

In order to give an idea of the quantitative scope of the text collections we used, in Table 3, we distinguish the Abstract and Full Text corpus, with counts of all

- simple unary relations which refer to all events constituted only of an event trigger (a sequence of tokens indicating an event mention) and an argument, a protein or gene,
- the binary Binding relation which can have two arguments (both a gene or a protein),
- Regulation relations, which—besides proteins or genes—can also have other events as arguments.

### Results

In this section, we present the results the four systems achieved for all possible combinations of training and evaluation data, i.e., the cross-product of the abstract (AB) and full text (FT) material. Hence, we:

- trained models on the Abstract corpus and evaluated them on Abstracts (AB on AB),

Discussion

There are some caveats that need to be made explicitly for the experimental set-up we have defined:

- **Text Genre Mix-up.** The collection we here referred to as "Full Text" does include the abstracts. We could not change this mix-up because we, obviously, do not have any access to the test set. We could have done this separation for the training phase, but this would have led to the elimination of roughly about 400 relations.
- **Training Set Imbalance.** The textual material used for training the Full Text models is lower in size than that for training the Abstract models (approximately 6,000 vs. 8,600 events, respectively). This could be seen as a problem for comparability of the results. Yet, we still have the strong figures where Abstract models were tested on both AB and FT, and we did further experiments on both JREX and BioSEM where these systems were subsequently tested with more and more training material for both AB and FT on both AB and FT (data not shown).

To provide a thorough error analysis, we would need to deal with 16 cases (all four systems with all four combinations of AB and FT for training and evaluation). We leave this discussion for a companion paper.

The outlier results for the HDS4NLP scores also deserve several remarks: The system

- achieves the highest F-Scores when trained and evaluated on abstracts—54.37; see Table 4 (AB on AB),
- yet has the lowest difference when these AB models are evaluated on full texts instead (Δ = 4.07); see Table 5, column 2,
- drops the highest (Δ = –8.59) when FT-trained instead of AB-trained models are used for evaluation on the AB test sets; see Table 5, column 3
- and further drops the highest when comparing AB-AB vs. FT-FT (Δ = –6.56); see Table 5, column 1.

We tend to explain this special role of the HDS4NLP system as a result of taking an entirely different methodological approach than the other three systems—HDS4NLP directly extracts pairwise structured events (and the event type they belong to) of the form (trigger, argument) instead of using a linear technique (i.e., extracting triggers first and then looking for applicable arguments). From the three competitive systems, HDS4NLP performs the worst in a solely FT on FT set-up so that these preliminary analyses could lead to the cautious conclusion that the HDS4NLP system is best (and better) suited to utilize abstracts as training material.

The exceptions coming from the JREX system (see its inconsistent increase in performance when Full Text models are evaluated on Abstract data, Table 5, column 4) are completely overshadowed by a substantial performance penalty in comparison with all other systems. This is clearly an effect of lacking maintenance over the past five years.
Conclusions

We focused in this paper on the implications of running established tooling and pipelines, developed on scientific abstracts as training data, on scholarly full text data from the life sciences. Our experiments reveal that F-score losses up until 6.6 F-Score points have to be anticipated. Abstracting away from the specific system particularities, there is a consistent trend for performance degradation when abstract-trained models are transferred without changes to full texts.

The apparent solution—providing annotated full-text corpora—is costly and resource-intensive. Currently, only one corpus (ID) provides relation encodings for full texts, whereas another one contains only highly specific named entity encodings (CRAFT). Given the resource-density in the life sciences field, distant supervision (via database contents) might be a reasonable alternative [30], while moving to unsupervised relation extraction is likely to be accompanied away from the specific system particularities, there is a trained models are transferred without changes to full texts.

Abstract

This ‘vision’ paper refers to sonification – a novel method to represent data by sounds. A short theoretical background comprises the main features to attach sound to a set of data – here to map the correspondence between the sound parameters (pitch, duration) and the initial set of data. The classification of sonification methods is followed by a description of sound display tools – temposlenses and artifacts (saccadic display or loudness variations). The Results section comprises examples of sonification performed by our team: heart rate (HR), ECG signals, HR variations during exercise, including warning procedures. The procedure to evaluate the discriminant power of various sonification algorithms is then described. As a ‘vision’ paper, the most important part is not represented by the results, but the potential future developments, presented in the Discussion section, which starts with a critical view of the present state and presents future potential applications of sonification in medicine.

Keywords:
Sound; Heart Rate; Electrocardiography

Introduction

There are several intuitive means for data representation in science, developed for a better understanding of various phenomena, mostly based on performances of visual perception. Indeed, all visualization procedures have proved their capacity to give us a deeper insight of the processes and even reveal interesting features. But, the auditory system is also feeding our brains with different kinds of information, a way still insufficiently explored. Yet, some attempts have been made to develop such procedures, yielding a new method for data representation – sonification. It is defined as "the use of non-speech audio to transform data into an acoustic signal". Sonification is the core element of the "auditory display", which comprises "any technical solution for gathering, processing, and computing necessary to obtain sound in response to data" [1]. A comparison between visualization and sonification [2] can partially excultate the much lower use of sonification for scientific purposes as compared to visualization. Nevertheless, the present technical advent and the permanent increase of expectations to extend the ways we interact with the environment open the doors for new developments in this direction.

This paper aims to present an overview of the potential approaches for various applications, to describe authors’ experience and explore in more detail the potential future applications for medical data representation.

Methods

The good survey of the sonification domain, until 2011, was done by Hermann et al [1] to which one can add the news from the site of the International Community of Auditory Display [3].

There is a large variety of methods, but almost all start from the same basic principle: to associate the major physical parameter of a sound — frequency (pitch) — with a (major) property of the data to be represented. Other properties of the data set can be linked to other properties of the sound sequence — duration or intensity or even raising the complexity of representation by introducing timbre, rhythm, harmony (multiple sound channels), etc.

We will present here our approach [4], which has multiple similarities with the one in [1], starting with temporal sequences.

Formalization Levels

We will first refer to two major parameters of sound — frequency (pitch) and duration.

Frequency

From a physical point of view, there are two distinct levels, corresponding to the sonic output: continuous or discrete frequency spectrum. However, for the purpose of potential applications we will prefer to define three levels:

1. Acoustic level — with a continuous spectrum,
2. Sonic level (S) — with a discrete spectrum, having values belonging to the musical scale, and
3. Musical level (M) — a complex level, with multiple channels, rhythm, and harmony.

As the original set of data can have values expressed by numbers in any region, they are usually normalized (y\textsubscript{i}), to fit an interval — the simplest [0, 1] interval. A reference frequency (f\textsubscript{0}) is also needed to yield results within the audible interval. Some practical values would be 440 Hz (A4 on musical scale) or 262 Hz (C4). Since the natural sound scale is exponential, for the acoustic level the sound will have the frequency:

\[ f = f_0 \times 2^{y_i} \]  

(1)

For the S level, the fi value will be rounded to one of the values from the scale.

Duration

One can choose to display sound for data originating from time series with a duration equal to the real duration of the corresponding event. However, most of the times the data are discrete; even continuous processes are sampled. Hence, we need a conventional rule for the transition between two consecutive sounds. There are two major possible transitions:
1. Continuous transition (also called sublevel A), when for two consecutive points, at \( t_i \) and \( t_{i+1} \), the frequency will vary continuously from \( f_i \) to \( f_{i+1} \); and

2. Discrete representation, when frequency \( f_i \) will be displayed for the interval \( dt = (t_i, t_{i+1}) \), followed then by \( f_{i+1} \). Usually the intervals \( dt \) are very short and this sub-level is called “quasicontinuous” (Q).

We have used the subdivision into A and Q sublevels only for the acoustic level, using the S level long durations, to be perceived as separate sounds.

There are several cases when the structure of the input data can suggest various corresponding relations between data characteristics and sound characteristics (often called ‘natural’ correspondence). Some such examples will be given in the section on potential medical applications.

**Sound display**

The large diversity of mapping data over sound parameters is still increased when thinking about the possibilities to display the results.

**Tempolenses**

For the cases when the duration of the analysed phenomenon is either too long or very short, and the duration of the sonic display is different from the recording, we can use compression or dilation procedures, also called “tempolenses” [5]. The main parameter of a tempolens (TL) would be the “magnification”, defined as the ratio between the sound display duration (t-repr) and the corresponding real process duration (t-real):

\[ m = \frac{(t\text{-repr})}{(t\text{-real})} \tag{2} \]

When \( m > 1 \) the TL dilates the signal, good for detecting details (especially for very short events); when \( m < 1 \), it compresses the signal – good for exploring long recordings in a short time.

An interesting case is represented by TLs with variable magnification (TL-v). Unlike the TL with fix magnification (I), for TL-v, the magnification is \( m > 1 \) in certain regions and \( m < 1 \) in other regions – a version recommended for detailed representation of fast process, without an overall sacrifice of the total displaying time; for instance, for the ECG sonification, the QRS complex is a fast event and can be dilated, while the T–P interval does rarely contain relevant events and can be compressed. A tempolens with a variable magnification is like a “distortion” tool, with potential applications.

**Sound artifacts**

Depending on the potential use, the conventionality degree can be increased by introducing various artifacts, with specific significance. This would be especially useful in monitoring systems associated with warnings. Two such artifacts are described here.

- **Saccadic display**
  
  The auditory system contains phasic receptors, hence it has an efficient adaptation (decrease of the response at a constant value of stimulus intensity), hence an interrupted sound would be better perceived than a continuous sound. Thus, instead of a single sound, we can introduce a “saccad” of two or three sounds as a warning. Moreover, some patterns can be used for different situations; these patterns can easily be learned (when not too many of them).

- **Intensity (loudness)**
  
  For different levels of warning, the intensity of the sound can also be varied, especially when reaching “alert” regions of the followed parameter (for example, heart rate during exercise).

**Differential display**

One of the potential future developments might rely on the capacity of the ear to distinguish close frequencies. We can compute an average normalized period for periodic signals, then display it repeatedly on one channel while the real signal is displayed on a second channel so that even small deviations will be perceived very easily.

**Non temporal sequences**

A relation similar to (1) for frequencies can be used for non temporal sequences such as the primary structure of nucleic acids or proteins, but the \((y_i)\) array is not an ordered array. One can introduce an “order relation” into the original data starting from some properties which might be relevant such as molecular weight, hydrophobicity index, or percent abundance in a certain structure. The correspondence map does not have to follow the ordered musical scale, it might also be linked by some other properties such as probabilities to find a certain note in a musical composition. One can imagine the tremendous variety of mapping systems and it is difficult to qualify/score them.

**Transforming digital images into sounds**

A serial transmission of an image is actually a signal which can be sonified by any of the procedures described above, and therefore, indeed, such transformations might be useful.

**Results**

As this paper is submitted as a “vision” paper, this section does not present only our own results [6], but also other applications, all are regarded as examples to be discussed. All examples refer only to applications in medicine and life sciences.

**Sonification of cardiac signals**

Cardiac signals, especially the electrocardiogram (ECG) are periodic signals, often used for diagnosis in cardiovascular diseases.

**Heart rate analysis**

Cardiac heart rate (HR) is one of the simplest signals to record, either from pulse oxymeter devices or from ECG. It was one of the first attempts to sonify a physiological signal done by Ballora [7] in which he tried to raise the complexity up to the musical level. Instead, we tried to keep closer to the original signal [4], using a couple of different sets of sonification parameters and compared the results. Thus, we realized the sound produced by the acoustic level A would not be attractive (sounds like whistling), the same for Q sublevel with very short durations. Sublevel Q with larger durations or level S seem appropriate for detecting deviations from normal (sinus) rhythm. For recorded signals (we have used RRIs and ECGs from Physiobank [8]), a compressed sonic display \((m=1:6 \text{ to } 1:4)\) seemed to be most appropriate.

**ECG analysis**

We had bigger expectations to get better results from ECG analysis. Indeed, interpreting the classical recording was not an easy task, some modifications were very small, it was important to analyse both amplitudes and intervals, one had to look over the recordings in several leads. What would be the most convenient sonification procedure to reveal all these aspects?

- **Integrated display**
  
  We tried to apply several sonification parameter sets for the same signals [6, 9], including various types of tempo-lenses [5], and compare them (Figure 1) using an integrated display – both visual and sonic; a library of various signals and their sonification was created [10].
An important issue in our project was to test the discriminant power of various sonic representations i.e. the capacity of listeners to distinguish details and recognize various types when the same signal is represented in different ways [11]. An example is presented in Figure 1: a 10 sec ECG signal was displayed in eight different forms (A or Q mode, for v display, TL 1× or 4×). For Q mode we had dt = 0.4 sec. The sounds were presented in two groups, one of physicians (residents) and one of music students. We present here some relevant conclusions from this study:

- Representation in A mode was less preferred by both groups (it sounds like a whistle); however it had a higher discriminant power in sleep apnea, during the obstructive episodes;
- Tempolenses with variable magnification did not bring the expected increase in resolution of the QRS complex;
- Short durations (less than 0.2 sec) in Q mode sound like A;
- The distinction between Q and S modes was much clearer for the group of musicians; small differences for other cases.

Our studies showed that there were clear distinctions between the sonic display of different signals (normal sinus rhythm, arrhythmia, and atrial fibrillation), such a simple “additional sound” did not prove to be very attractive to physicians, since their classical procedures did fully satisfy their needs.

### Cardiac parameters variation during exercise

We found an interesting application, with a higher user acceptance for monitoring cardiac parameters rate during exercise. Professional equipment can trace various parameters important for the exercise tests on cardiac patients, like the heart rate HR or depression of the ST segment in ECG recordings, with warnings when some parameters exceed thresholds. But this information is mostly visually displayed and the patient is usually kept passive.

We have developed an application to add sounds for various thresholds of HR [12] or ST segment [13]. The threshold warnings for HR have been established using Kevonen relations [14], separating four exercise levels: quasi-rest/start threshold/aerobic mild exercise/attention threshold/hard exercise anaerobic zone/alert threshold/risk zone with HR > HRmax. Each level (zone) has a specific intensity, from very low to loud, and saccadic display (no saccades/1/2/3 saccades). The original record is trimmed, keeping the regions comprising transitions between zones.

An example is given in Figure 2 and the sonic displays can be downloaded from [10]. Three types of sonic displays have been tested: with various patterns of pitch/saccades/intensity. The preferences were oriented towards a warning display using four distinct patterns: no sound or low intensity continuous sound for normal (safe) domain, and increasing the number of saccades, the frequency and the intensity for each higher level. The patients as well as the physicians monitoring the exercise tests appreciated the warning system.

An extension of the application for the self monitoring of the HR during daily individual exercise (jogging) has also been tested.

### Molecular sequences

One of the most prolific areas of sonification was inspired by the similarity between musical sequences and biomolecular structures, especially DNA or proteins. Among early attempts we can cite Susumu Ohno’s mapping of DNA [15], associating the nucleotides with notes of the musical scale (C cytosine to ‘do/C’, A adenine to ‘re/D or mi/E’, G guanine to ‘fa/F or sol/G’ and T thymine to ‘la/A or si/B’) and applying some rules for durations linked to the repetitions in sequences. Several other algorithms have been developed: ‘gene-2-music’ project at UCLA (R Takahashi, JH Miller and F Pettit) [16], ‘Algorithmic Arts’ for protein sequences, by John Dunn [17], ‘genetic-musicproject’ by Greg Lukianoff [18].

We have also tried an algorithm based on the relations between physico-chemical properties of amino acids (hydrophobicity, polarity, size, and abundance) and the musical scale [10].

Ohno and Midori [15] have also tried the reverse correspondence – to transpose a musical piece (Chopin’s Nocturne op.55) into a DNA sequence and compare the simulated molecular structure with real molecules, obtaining a certain resemblance with the structure of an enzyme (mouse DNA polymerase II).

There are now several sites (such as [17, 18]) allowing you to upload a sequence (real or imaginary), which generates a musical sequence. The results are attractive, but, despite the attempt to build algorithms based on ‘natural’ maps, often using statistical data processing or even more sophisticated procedures, the
impact on scientific community remains modest. This might be, at least partially, attributed to the low degree of usability.

**Sonification of other types of data**

Our experience include also other applications (not detailed here), like pulse wave signals in experiments on mice, cellular kinetics (especially protein-protein interaction for p53-mdm2 system), and molecular sequences (work in progress now).

We should mention here that there are several teams working in this field and we can cite several papers from the literature. A comprehensive site is the one of ICAD [3]. There are two other interesting applications in the biomedical domain:

1. Analysis of fetal heart rate, Paracelsus Clinic, Austria [19], and
2. Bio-rhythm analysis [20].

**Discussion**

The results presented above as well as a full list of references would rather give the impression, at a first glance, of a well set domain, with well defined tracks to be developed in the future. However, a thorough and fair analysis would reveal several weaknesses and inconsistencies that actually brought such a limited applicability in the bio-medical domain.

**Analysis of the present state**

We can point to the following as among the potential reasons to account for the reduced use of sonification:

- The technological support was not fully available for handling sounds. This point is no longer an issue.
- Most authors had tendency/ambition to reach the musical level. It seems attractive, indeed, but it introduces a high degree of arbitrary/conventional rules, moving us farther from the real signal. Not all real data carry harmony! Moreover, quite often the algorithms generated ‘atonal’ values that have been rounded to make them musical.
- A new tool would be accepted only if it brings something new, which is not easily achieved by present methods. Currently, visualization, complemented by the well-developed technical support, meets expert expectations in bio-medical practice.
- Even when a new method brings more information, the ones in use have several objective and subjective barriers.
- The limited usability is, perhaps, the most relevant factor; most of the work done in the sonification area started as an ‘interesting’ approach, almost as a curiosity, and not as a real need to solve a practical problem in a better (or cheaper or more convenient) way than by other methods.

Some such potential applications will be presented below.

**Let’s learn from visualization**

A comparison between the two methods might help us in finding better ways to strengthen the usefulness and use of sonification as a method for data representation.

**Table 1 – Comparison between Visualization and Sonification**

<table>
<thead>
<tr>
<th>Property</th>
<th>Visualization</th>
<th>Sonification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Best representation</td>
<td>spatial</td>
<td>temporal</td>
</tr>
<tr>
<td>Prevalent elements</td>
<td>static</td>
<td>dynamic</td>
</tr>
<tr>
<td>Type of attention</td>
<td>focused</td>
<td>distributed</td>
</tr>
</tbody>
</table>

A deeper insight into this table will let us propose a set of properties of a sonic display, similar to that defined by Tuft for graphical/visual displays [21]; some requirements are valid for both types of displays (marked with *).

Thus, we can consider that a ‘sonic display’ should:

- (*) represent the data
- (*) avoid distorting what they do represent
- (*) make large data sets coherent
- (*) serve a clear purpose: description, exploration
- Preserve the initial sequence
- Bring out information that is inaccessible (regardless the reason) or unavailable by other means
- Be integrated with other informative displays, when possible.

The list above can (should) be refined for a more comprehensive and clearer meaning.

**Potential bio-medical applications of sonification**

The experience accumulated during the research—both positive and negative—would let us find the directions to be followed for future successful applications in the bio-medical domain.

One category of applications refers to the cases when the visual system is engaged in other activities, such as providing information during driving or jogging.

A second category would refer to all kinds of warnings, based on the property that sonic/acoustic warnings do not need a focused attention. It might become a useful tool in the context of the rapid development of wearable devices for monitoring various physiological parameters. We think this direction might turn into a prolific domain.

There are still less explored directions for applications to categories of people with attention disorders, like elderly people or children with ADHD.

Yet, one can also consider the potential exploration of large databases to find small differences between patterns or to detect mutations in molecular structures.

Last, but not least, we can also include several applications for visually impaired people—another direction which has not been explored enough.

This list is, of course, incomplete, and will have hopefully new items in the future.

**Conclusion**

Sonification is a method with several potential applications in medicine, yet it is not explored enough. The large palette of sonification methods, without well-defined procedures or standards and the quasi-random examples have unwittingly limited its application, generating a low user acceptance.

The discussion section, based on the present data and the previous work of the authors, tried to analyze the present state of the domain and anticipate future directions of work.

Constructing a Gene-Drug-Adverse Reactions Network and Inferring Potential Gene-Adverse Reactions Associations Using a Text Mining Approach

Sui MingShuang, Cui Lei

School of Medical Informatics, China Medical University, Shenyang, Liaoning, China

Abstract

Our objective was to identify and extract gene-drug and drug-adverse drug reaction (ADR) relationships from different biomedical literature collections, and to predict the possible association between gene and ADR. The drug, ADR and gene entities were recognized by a CRF model with multiple features. Logistic regression models were constructed for each drug-ADR and drug-gene pair based on its frequency, Mesh Rule association and similarity with known association etc. Using predicted score to generate drug-ADR matrix and drug-gene matrix, and then calculating for gene-ADR matrix. Network and clustering analysis were applied to verify and interpret the relationship between them. A total of 78014 potential gene-ADR associations were predicted. Part of the predicted results can be explained by the network-clustering-pathway analysis, and verified in the literature. The gene-drug-ADR network constructed in this study can provide a reference for the possible association between the gene and ADR.

Keywords: Drug-Related Side Effects and Adverse Reactions; Data Mining; Algorithms

Introduction

Adverse Drug Reactions (ADR) is a major burden on public health systems in the world, the complex mechanism of drug action and clinical trial makes pharmacovigilance long way to go. The onset of ADR is closely related to drug’s interaction with its transporter, metabolizing enzyme and its targets, whose deletion and other changes can cause the corresponding genetic variation of expression products, further affected drug efficacy, or even serious ADR such as CYP2C9 and VKORC1 gene variants and warfarin caused bleeding [1]. Therefore, Detecting the relationship between drug related genes and ADRs can help to determine the specific response of individual gene to drugs, so as to improve drug safety and provide evidence for precision medicine.

Recently, a large number of text mining-based biomedical knowledge discovery researches have shown that text mining can be successfully applied to detect the relation between gene, protein, diseases and other biomedical entities [2, 3]. Measuring similarity between entities through structural pathway properties, intrinsic properties, and taxonomies can help to predict drug adverse reactions and targets[4, 5, 6]. For example, Yamanishi constructed a high-dimensional matrix based on drug chemical structure, in which each drug was encoded according to whether specific drug features and the targets extracted from Pubchem was observed, and then predicted ADR using machine learning algorithms [7]. Liu applied chemical properties (substructures and fingerprints), biological properties (protein targets and pathways), phenotypic properties (indications and ADR) to predict potential ADR [8]. These studies, although different in approach, are confined to a single topic study sample. Professor Swanson (1985) proposed a knowledge discovery approach to discover valuable knowledge hidden in the medical literature based on non-related topics literature collection, which provides an insight into the predicting potential link between gene and adverse drug reactions in the literature[9].

This paper aims to recognize and extract gene-drug (D-G) and drug-ADR (D-ADR) associations from biomedical literature collections, and then infer potential association between genes and ADR by network and cluster results.

Methods

Overview

First, we integrated data from multiple databases, including literature collections, vocabularies and prior knowledge. After naming entity recognition, we extracted the D-ADR and D-G relationship by Logistic Regression (LR) model, thus forming hypothesis about G-ADR relationship. Ultimately we interpreted these inferred relationship by combining network analysis, clustering analysis and related literature information (see Figure 1).

Data Sets

Drug vocabulary was obtained from Mesh and Drugbank [10], and ADR vocabulary was from Mesh and MedDRA (Medical Dictionary for Regulatory Activities), and gene vocabulary was from NCBI Gene database.

Prior knowledge was gained from CTD (Comparative Toxicogenomics Database) [11] for D-G associations, SIDER (Side Effect Resource) [12] for D-ADR associations, and Drugbank database for drug-target associations. We mapped these associations to which identified by Mesh ID and NCBI Gene ID.

**Name Entity Recognition and Relationship Extraction**

After splitting abstracts into sentences, we applied a CRF-based model for Drug and ADR Name entity recognition in our previous work [14]. Gene recognition was generated from GNormPlus [15] and gene dictionary matching results.

We extracted the co-occurring D-ADR and D-G entities in a sentence as candidate pairs. To determine whether there is association between D-G (ADR) for each pair, we applied a knowledge-driven algorithm [16] to construct two LR models based on existing D-G (ADR) knowledge.

The covariates used in LR models are of two main types. Baseline covariates include D-G (ADR) co-occurrence frequency ($F_c$), key verbs frequency ($F_v$), Mesh Rule association (MR) (only for D-ADR), co-occurrence with prior knowledge in SIDER ($F_s$), and minimum distance (MINd). Taking a candidate D-ADR pair as an example, the key verbs refer to verbs that appeared between the drug and the ADR in a sentence, indicating that they have clear semantic relations, such as “cause”, “induce” etc [17]. In order to reduce the false positive rate (such as drug-treat-disease), we introduced MR covariate, it refers to semantic association in Mesh terms. For each pair of D-ADR, we checked out whether “drug/adverse effect” and “ADR/chemical induced” co-occurred in a article (Supplemental concept record would be mapped to the corresponding Mesh term according to “heading mapped to”). The MINd measured the minimum distance between the drug and the ADR in the sentence with key verbs betweenthem.

The second covariate type was Network covariates, it depend on the structure of the prior D-ADR(G) network [18]. We constructed a bipartite network to represent the drugs, ADRs, and their associations in SIDER. In this network, nodes denote drugs or ADRs and edges denote known D-ADR associations.

These covariates aimed to capture the structural similarity between drug pairs and ADR pairs. Denoting variable i as a drug, variable j as an ADR, and $A_D$ denotes the set of neighbors of node $D_i$, and $A_D$ denotes the set of neighbors of node $A_D$.

1. **JSDM (Jaccard-sider-drug-max)**: For each $(D_i, A_Dj)$, we introduced JSDM covariate to measure the max similarity between the $D_i$ with $A_Dj$’s neighbor nodes $D_i$.

   It was computed as follow,

   $$ JSDM(i,j) = \max_{k \in \text{Min}(j,k)} \{ J(j,k) \} $$

   $J(j,k) = \frac{A_{DRj} \cap A_{DR(k)}}{A_{DRj} \cup A_{DR(k)}}$

2. **JSAM (Jaccard-sider-adr-max)**: For each $(D_i, A_Dj)$, we measured the max similarity between the $A_Dj$ with $D_i$’s neighbor nodes $A_D$.

3. **JDDM (Jaccard-drugbank-drug-max)**: Studies have shown that drugs with a common target tend to lead to same or similar ADR [19]. Therefore, we constructed a drug-targets bipartite network based on drug-target information in Drugbank, and defined Target ($i$) as the neighbor nodes of the node $D_i$. For each pair of $D_i$-ADR, the maximum similarity of the ADRj’s neighbor node set $D_i$ of was calculated.

4. **JCDM (Jaccard-ctd-drug-max)**: In order to support the hypothesis that the genes interacting with the same drug may affect its ADR, we constructed a bipartite network using the D-G association in CTD, and defined Di’s neighbor node set $D_i$ of in calculating.

Similarly, for D-G, we calculated drug similarity based on SIDER (Jaccard-sider-drug-max, JSDM), drug similarity based on Drugbank (Jaccard-drugbank-drug-max, JDDM), drug similarity based on CTD (Jaccard-ctd-drug-max, JCDM), gene similarity based on CTD (Jaccard-ctd-gene-max, JCGM).

After the multicollinearity diagnosis, the variables were imported into the LR model, and the optimal parameters was set according to the model results. The D-G matrix and the D-ADR matrix were generated. The G-ADR matrix was obtained by multiplying the above two matrices [20] as the potential basis for G-ADR prediction.
Network and clustering analysis

Network analysis can help us to understand the resulting matrix and association, we constructed three types network according to D-G matrix, D-ADR matrix with Cytoscape [21] (for the global network) and Gephi [22] (for local network). Additional, we carried out systematic clustering analysis on the G-ADR matrices. The cluster results were expressed according to the principle of TF-IDF [23].

Results

The corpus used in study contained 59,660 and 64,499 abstracts from MEDLINE for D-G and D-ADR literature collection, corresponding to 63,259 and 114,919 co-occurrence pairs respectively.

Relationship Extraction Results

LR analysis showed that $F_c$, MR, MINd, Fs, JSDM, JSAM, JDDM, JCDM covariates were included in D-ADR model, and $F_c$, $F_{cud}$ (co-occurrence frequency with CTD), MINd, JSDM, JCAM and JDDM in D-G model, with AUROC 0.986 and 0.952 respectively.

The two LR models both contain the interactive network covariate JCDM and JSDM, which indicated that gene (ADR)-based similarity is meaningful variables for predicting D-ADR (G), which provided an indirect explanation for our study. Based on predictive scores (cutoff 0.5), a D-ADR matrix (854 * 717), a D-G matrix (764 * 2,153) and then a G-ADR matrix (1,488 * 665) was generated.

Network analysis

We constructed D-ADR and D-G networks by Cytoscape and Gephi. The sub-network structure was shown in Figure 2, the left orange node represents the gene, the middle green node represents the drug, and the right purple node represents the ADR. The two color edges indicate the D-G and D-ADR relationships (using predicted scores as weight). It can be seen that 17 kinds of genes and 29 kinds of ADRs were linked by tamoxifen, corresponding to 442 potential G-ADR associations. For the G-ADR association, the more drug nodes connected to each G-ADR pair may indicate a more potential association between these drugs, which can be inferred that the gene may be associated with ADR of certain drugs. Compared with the results of G-ADR matrix, network analysis can provide information on the drug medications.

We selected Drug Hypersensitivity Reactions as a case study. Drug Hypersensitivity Reactions is a serious systemic drug response, mainly characterized by acute extensive lesions, with fever, lymphadenopathy, multiple organ involvement (hepatitis, nephritis, pneumonia), eosinophilia and mononuclear cells and other hematologic abnormalities, including Eurasian disease, Drug Eruptions, Hand-Foot Syndrome, Erythema Nodosum, Acute Generalized Exanthematous Pustulosis, Stevens-Johnson Syndrome and other ADR. Network analysis showed that these ADRs could be associated with 857 genes through 179 drugs. A total of 1,713 gene-ADR pathways are related via different drugs. Among them, some associations have been confirmed in the relevant studies, such as hypersensitivity can be associated with and Human Leukocyte Antigen (HLA) [24] through Carbamazepine as shown in Figure 3. In addition to HLA, the network can also infer unc-13 homolog B, microsomal epoxide hydrolase, uchl1, monoamine oxidase B, voltage-gated sodium channel a subunit type I, dopamine receptor D2, tachykinin 3 and amphiregulin may be related to the onset of hypersensitivity induced by drug.

Network clustering analysis results

Clustering analysis can help better understand for ADR and gene mechanism with drug and allow us to grasp the potential association from the perspective of the overall cluster. For the integrated ADR-D-G network, we use the Cytoscape plug-in Auto Annotate community detection algorithm to obtain the corresponding clusters and interpret them with the cluster topic. As shown in Figure 4, the green, blue and yellow nodes represent drugs, ADRs and genes respectively. These nodes can be divided into 10 clusters and several subgroups. There are also associations between clusters.
Matrix clustering analysis

We carried out clustering analysis for the G-ADR matrix and obtained representative ADR that can explain the content for each cluster. In order to facilitate understanding, we selected several serious ADR to explain the three associations combined with REACTOME pathway information, the G-ADR clustering results are shown in Table 1.

CLUSTER 1: The results of clustering analysis combined pathway information showed that these genes mainly involved in retinoic acid pathway, signal transduction pathway, immune metabolism pathway, and have potential association with skin lesions related ADRs represented by pruritus, rash, pigmentation. Signal transduction genes, such as retinol-binding proteins, are vitamin A transporters. Vitamin A plays an important role in maintaining normal physiological function of epithelial cells and promote the synthesis of immunoglobulin. More than normal values will lead to dry skin, scaling and hair loss and other symptoms, can also cause pseudo-brain tumor; Victoria A acid as the metabolic intermediates of vitamin A, can regulate the melanin produced by melanoma cells, pigmentation may be due to drug-effected Victoria A acid pathway. Other gene such as solute carrier family 40 member 1 is directly involved in the pathogenesis of hemochromatosis. Combined with the local network, these genes and ADR is the main mediator of tretinoin.

<td>Pancreatitis, Rhabdomyolysis, Muscular Diseases, Flushing, Myalgia</td>
<td><img src="image" alt="Table 1- Results for G-ADR Clustering analysis" /></td>
</tr>
</tbody>
</table>

CLUSTER 2: It was showed that genes involved vitamin K metabolic pathways, hemostatic pathway and platelet-associated pathways may be involved in the development of thrombocytopenia. Immune-related pathways may be responsible for pneumonia, rash, neutropenia and other ADR. The mechanism of hypokalemia is associated with cisplatin and diazoxide, which
may affect the potassium ion-gated channel. Network analysis showed that integrin subunit alpha 2b was associated with thrombocytopenia via aspirin, decitabine and so on. Decitabine mediates the association of thrombocytopenia, pneumonia, febrile neutropenia and numerous genes such as interferon beta 1, thrombomodulin and so on.

CLUSTER 3: Topic of this cluster is clear and representative ADR was pancreatitis. Pathway analysis revealed that the major difference between the cluster and others was zinc finger protein and metal ion transport pathway related gene. Network analysis showed that pancreatitis was linked to these genes through Zinc, hydrochlorothiazide and other drugs, most of which related to metabolic pathway with zinc, such as zinc finger protein. In addition, potassium voltage-gated channel subfamily J member 11 is involved in energy metabolism and muscle formation, which may be helpful to explain the ADR of rhabdomyolysis.

Discussion

Here, we proposed a pattern for generating hypothesis for G-ADR relationship by integrating D-G and D-ADR association extracted from two different literature collections. Petric I had applied similar method for identification of relations between biomedical concepts in disconnected sets of articles [25]. Finally, we constructed a G-D-ADR network by integrating knowledge of databases, and detected the potential association between gene with ADR. Our study proved the possibility of knowledge discovery from large data for basic and clinically relevant research and will lay the foundation for this field.

The limitations of this study are mainly three aspects, the first was many variables built for relationship extraction in this study based on SIDER/CTD knowledge, which was confirmed good predictive performance for the new D-ADR/G relationship [18], but this method was disadvantageous for drugs not in database (Because they are not included in the prior knowledge network); Secondly, there should be greater efforts to filter G-ADR association we inferred by weakening genes/proteins weights that are related to most drugs, such as p-glycoprotein, those unspecific gene may lead to a higher false positive rate. Lastly, the goal of our study was to demonstrate the utility of the integrated network, not to develop an optimal model which is a broader objective.

Our D-G associations allows multiple further analysis, such as clustering analysis and pathway analysis. By clustering analysis, we observed that some ADRs-Genes association could be partly explained by pathways such as Stevens-Johnson and HLA-B [24].In addition, a lot of new G-ADR associations have been found through the calculation of network link prediction, and some of them are currently unexplainable. These associations may be false-positive or may not yet be found. It is also possible that the gene and drug ADR interact through a cascade of reactions, not just through a gene or protein. We recommend that more attention should be devoted to severe ADR.

Conclusion

Our proposed approach for integrating D-G and D-ADR association is intended as a complementary hypothesis generation tool to identify potential G-ADR relationships. Further research directions will focus on defining the relationship between drug and gene types, and integrate more complex biological pathway information to provide more accurate evidence for D-G prediction.

Establishment of New National Rare Disease (Nambyo) Registry and Registry Guidelines in Japan

Hiroshi Mizushima, Mai Tanabe, Yasutaka Sugamori, Yoko Sato, Hiromitsu Ogata

National Institute of Public Health, Saitama, JAPAN

Abstract

A new legal structure for rare disease (nambyo) has been established in Japan this year after 42 years of measures of nambyo. We have been accumulating registry for nambyo from 2003, however, as it was based on paper registration, quality was not enough.

Our new registry system will be based under ISO13606 which is a new medical international standard. Authorized doctors can put in data On Line by the new system, which has data cleaning filter for accurate data entry. Patients will be supported their medical expense by authorization by this system, so the registry will be efficient.

Keywords:
Rare Diseases; Registries; Demography

Introduction

In 1972, the Ministry of Health and Welfare enacted the “General Outlines for taking Measures to deal with Intractable Disease [NAMBYO]” which was the first one ever established in the world. The extent of Nambyo was proposed as: a) Unknown etiology b) Un-established therapy c) Frequent after-effects d) Chronic course e) Heavy burdens in terms of economical, psychological and physical issues.

At this stage, there was no concept of rareness in the extent of Nambyo. More than 25 years was needed until rareness was added to the extent.

A revised definition of Nambyo in 1995 was: a) Etiology is unknown. b) Frequency is low (less than 50,000). c) Therapy is not established. d) Economical, psychological and physical burdens. e) Diagnostic criteria should be established.

Frequency in Japan (< 4/10,000; below 50K) is similar to that in EU(< 5/10,000) or in US(< 7/10,000; below 200K)

Selection of Nambyo

One hundred and thirty diseases were selected as Nambyo for special research. Two hundred and fourteen diseases were further selected as candidates of the second group of Nambyo for research support. Of 130 diseases, 56 diseases were targets for being treated with special favor in terms of medical expenses (see Table 1).

Budgets for researches (for 364 diseases) are 10 billion yen, and budgets for medical expenses (for 56 diseases) are 35 billion yen. Number of recipients of medical expenses are approximately 700,000 patients and increased by 30,000/year.

Nambyo was reviewed and a new legal structure was established in June 2014. This included: medical system, subsidized health care costs, promotion of research, consultation and support, human services, work and employment support, international cooperation, and awareness.

At this time, supporting diseases were expanded from 56 to about 300, which will be defined by the committee and authorized by the government. This will double the patient numbers. New law will be effective from January 1, 2015. There are 330 from April 2017.

However, the most important issue to date is that the current registry system is done in paper form and not well organized.

As a result, we established a new registration system, which doctors input the data themselves which is then sent to an online national database. This will be the first national online database for rare disease, and will support the patient care and research for rare diseases.

Methods

Systematic design of the registration system was done by analyzing the current paper-based registry system. Research in international standardization of terminology and modeling architecture was also completed. Prototype system was constructed with Mitsubishi Space Software, NISplus, and R102 company.

Results

Problems of Nambyo

Comprehensive measures for Nambyo are important, however demographics of the 56 diseases are changing. As shown in Figure 1, some diseases, such as Ulcerative Colitis, Parkinson’s Disease and SLE were included from the beginning, but they already exceed the the patient size (50,000).

Also, as this registry is based on the application for the medical expense reimbursement, doctors tend to write more severe notes for better approval by the government.

New Registry System

A diagram for new registry system is shown in Figure 2. Any doctor can complete the form in the current system, however, only certified doctors for Nambyo can write (input) the form. This will make the report more accurate. Data will be inputted in to the system, and checking will filter inaccurate data entries.

At this point, the doctors can be notified when they have the patient data (in current system, it required long time as government staff asks the doctor after the application). Also, it was prefectural government’s task to input the paper allocation to the database system, and not required for the patient reimbursement. As a result, some prefecture did not get imputed in to the national registry. Doctor’s data entry is...
nessary to make the application for the prefectural government, to ensure all patient information should be in the system comprehensively.

**International Standardization**

International collaboration is very important in rare diseases, as the patient size is limited for each disease. There are many standard coding systems, however each one varies per country. We have searched for many registries and many international discussions about which terminology to use, and which clinical modeling should be used.

As rare diseases are premature in clinical research, many diseases are not well described in the terminology. Even in ICD-10, most of the rare diseases in Orphanet (http://orpha.net/), the most well known rare disease directory) are not coded. This is also the case for Japanese standard nomenclature, SNOMED, and HL7.

We are still waiting for this international standardization, but currently following Orphanet as disease names, CIMI for clinical information Modeling, and ISO13606 for archetype.

As for the minimum dataset for the registry, we have compared it with Global Rare Disease Registry (GRDR http://rarediseases.info.nih.gov/) at NIH/NCATS, and EUCERD/Epirare (http://eucured.eu).

**Grouping Datasets as Modules**

Current registry form is defined by each disease, and no there was no concept of systematic cross disease analysis. There were difference in units or abbreviations between diseases. As we are designing a new registry system, we wanted to standardize the data set, and also wanted to be systematic as we have to add about 250 new diseases.

Figure 3 currently shows 14 Neurological Nambyo grouped into 4 groups and extracts common data sets for each groups. From this analysis, we were able to define a dataset as set module so we can design a new registry by just combining the modules.

We also made the dataset module management software, to make the registry for new diseases a systematic process.

**Web-Based Entry System**

Our new registry looks like Figure 4. Sections are categorized by tabs which have a) Basic information Diagnosis; b) Onset and Prognosis; c) Clinical evidence; d) Laboratory findings; e) Severity; f) Differential diagnosis; and g) Therapy and care.

There are filters and mandatory defined datasets. Tabs will be red if mandatory data is not sufficient or data is out of range.

**Offline Registration Tool**

There are some hospitals where internet access is restricted. Some local governments also have restrictions in internet use. To support data entry in these conditions, offline data entry application were developed. Data entry is similar with the online system however, data will be stored locally with encryption, and will be uploaded with other methods. Printing application forms for local government can be performed using this application.

This will also enhance the security issue using internet, as data upload is much more safer than online data entry.

**Discussion**

We are planning to perform a pilot study using this system at some hospitals along with local government installation.

Total numbers of registry entries will be about 1,500,000 every year. This will be one of the largest registry for rare disease in patient numbers.

This will be the first National Registry System by remote data entry with standardized coding. We are hoping to include other registries in the near future.

**Conclusion**

A New legal structure for rare disease (Nambyo) has been established in Japan this year, after 42 years of measures of Nambyo. We have been accumulating registry for Nambyo since 2003, however, as it was based on paper registration, quality was not strong enough.

Our new registry system will be based under ISO13606, which is a new medical international standard. Authorized doctors can input data online by the new system, which has a data cleaning filter for accurate data entry. From the discussion about integrating the data from registry for each diseases, we established a guideline in Japan. This guideline is now in the process of finalization and authorization.

Unsupervised Abbreviation Expansion in Clinical Narratives

Michel Oleynik\textsuperscript{a}, Markus Kreuzthaler\textsuperscript{a,b}, Stefan Schulz\textsuperscript{a}

\textsuperscript{a} Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Austria
\textsuperscript{b} CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria

Abstract

Clinical narratives are typically produced under time pressure, which incites the use of abbreviations and acronyms. To expand such short forms in a correct way eases text comprehension and further semantic processing. We propose a completely unsupervised and data-driven algorithm for the resolution of non-lexicalised and potentially ambiguous abbreviations. Based on the lookup of word bigrams and unigrams extracted from a corpus of 30,000 pseudonymised cardiology reports in German, our method achieved an F\textsubscript{1} score of 0.91, evaluated with a test set of 200 text excerpts. The results are statistically significantly better (p < 0.001) than a baseline approach and show that a simple and domain-independent strategy may be enough to resolve abbreviations when a large corpus of similar texts is available. Further work is needed to combine this strategy with sentence and abbreviation detection modules, to adapt it to acronym resolution and to evaluate it with different datasets.

Introduction

Clinical narratives are typically produced under time pressure. Besides incomplete sentences and typing errors, a typical manifestation of this is the tendency towards short forms like acronyms and abbreviations [1–3]. Their widespread use complicates further semantic processing and makes text understanding difficult, not only by laypersons, but also by clinicians from different disciplines or professional groups. In the context of large-scale concept mapping of medical texts for secondary use [4], the first processing steps are commonly devoted to text cleansing. This involves the correction of misspellings, the identification of sentence delimiters, and the expansion of short forms.

The use of abbreviations is especially pronounced in agglutinative languages such as German, in which single words are often formed by composition of morphemes, normally stems and affixes. The longer such a word grows, the more easily its completion can be guessed. Typing under time pressure therefore tends to stop close to the ending and an abbreviation marker is set. Thus, so-called ad-hoc abbreviations are created. Interestingly, the trailing period, required by German grammar to mark abbreviations, is mostly set, even in non-standard clinical narratives. It is also important to note that German requires capitalisation of all nouns, not only proper names, a rule commonly followed in clinical notes.

In combination, these characteristics lead to several NLP challenges related to the ambiguity of the period mark, which can be: (a) the trailing character of an abbreviation; (b) a sentence delimiter; or (c) both. Sentence delimitation, tokenization, and abbreviation resolution are, therefore, hardly separable tasks.

Regarding abbreviation resolution, three specific tasks are commonly listed: abbreviation detection, sense detection, and sense disambiguation. While the first is related to the disambiguation of the period character, the second and third relates to the sense expansion and its disambiguation, respectively.

Our recent work has focused on the first task, viz. abbreviation detection, first with a supervised approach based on support vector machines [5] and then with an unsupervised strategy that combined co-occurrence information with a large abbreviation-free domain dictionary [6]. The current paper will focus on the expansion (second task) and disambiguation (third task) of so-called period abbreviations, i.e. tokens that include a period as their rightmost character. The proposed approach is completely unsupervised.

Period abbreviations are clearly distinguished from acronyms, which consist mostly of upper case letters, never end with a period, and often represent multiword terms (e.g. “MI” for “myocardial infarction”). They are also distinct from other abbreviations that do not end with a period (e.g. “Ca”, which stands both for “Cancer” and “Calcium”).

Period abbreviations have, therefore, the following characteristics: (i) they abbreviate mostly single words; (ii) their first character always coincides with the first character of the word they abbreviate; (iii) in most cases, the string left of the period equals a string of characters from the left side of the abbreviated word. Moreover, we distinguish between lexicalized period abbreviations and ad-hoc period abbreviations. Whereas the left sub-string rule can normally be taken for granted for the latter ones, lexicalized period abbreviations can be easily expanded via a lexicon. We also distinguish between unambiguous and ambiguous period abbreviations. General and domain specific dictionaries often list more than one sense for an abbreviation, especially for very short ones. Longer, ad-hoc period abbreviations are normally unambiguous. Conversely, single letter abbreviations like “E.” in “E. coli” for “Escherichia coli” are almost always ambiguous.

The following work is limited to period abbreviations that cannot be unambiguously resolved by lookup in a general or medical domain lexicon. We also do not consider the special case where two period abbreviations are glued together thus forming one token, e.g. “St.p.” = “St. p.” = “Status post” (Latin for “history of”). It furthermore ignores the resolution of ordinal number expressions, for which in German the use of the period character is mandatory, such as “2.” for “2.°”. Consequently, the focus of our investigation is only on non-lexicalised, supposedly ad-hoc abbreviations.

Our hypothesis is that a high efficiency of abbreviation expansion can be obtained in a fully unsupervised fashion, i.e. without the (often considerable) effort of producing manually annotated training data. We thus hypothesize that if a clinical collection is sufficiently large, all knowledge needed is present therein.
Materials and Methods

Cardiology corpus

We tested our approach on a corpus of 30,000 pseudonymised discharge summaries from the cardiology department of the Graz University Hospital, the second largest hospital in Austria. The documents were written by German-speaking physicians. Figure 1 shows a typical sample from our corpus.

We first split the corpus into 90% for training and 10% for testing. Two hundred random substrings (100 characters) centred around a period character (followed by a single space) were extracted from the training corpus as source for building a validation set, in which 147 (73.5%) valid abbreviations were manually expanded by the third author, a physician. The period marks in the remaining substrings were considered out of scope for this work (see Introduction for our scope definition). Successful experiments were performed with this set. For the final evaluation, a set of 301 text snippets from the test set was used, of which 200 (66.4%) were considered valid abbreviations. The surrounding context, together with the original text corpus, allowed for unambiguous manual expansions in all cases. We report results from both sets.

N-gram lookup lists

Two frequency tables were created out of the tokenised training corpus, viz. a unigram list $U$ and a bigram list $B$. The tokenization process ignored period characters, so that they are included in the tokens. Also, as capitalization is an important feature in German and properly used in our corpus, the n-grams were not normalised. The lists were arranged in decreasing order of frequency. Corpus frequencies were calculated for all 155,801 token types and all 803,243 bigram types.

Abbreviation and expansion assumptions

An expansion $E$ is a valid expansion of an abbreviation $A$ (with its abbreviation mark, i.e. the final "." character, stripped) if:

- $E$ does not end with an abbreviation mark (".");
- $E$ is at least one character longer than $A$;
- $E$ has only alphabetic characters.

Additionally, we define the relative gain $G(A,E)$ as the ratio of the length difference to the abbreviation length, as seen in Equation 1. The intuition behind this restriction comes from the observation that longer words are rarely abbreviated by overly short strings, as this may lead to ambiguity. Nonetheless, they are seldom abbreviated by very long forms either, because the "economy" of using an abbreviation mark would be minimal.

$$G(A,E) = \frac{\text{Length}(E) - \text{Length}(A)}{\text{Length}(A)} \quad (1)$$

Thus, we add extra assumptions regarding relative gains:

- $G(A,E)$ is greater than 0.01;
- $G(A,E)$ is lower than 6.

Finally, two matching types are distinguished, one of which must be true:

- Strict matching: $A$ is a left-sided substring of $E$;
- Relaxed matching: all characters of $A$ are contained in $E$ in the same order. The first character of the abbreviation equals the first character of the full form.

While the strict matching accounts for the general case (e.g. "maximal" abbreviated as "max."), its relaxed version allows the correct matching of "Tbl." to its expanded form "Tablette".

Resolution strategy

Our resolution strategy is based on the co-occurrence of adjacent tokens where one of the tokens appears both in shortened and expanded forms in the corpus. As an example, "A. subclavia" can be correctly resolved to "Arteria subclavia", as the latter is the most common expanded form that matches the abbreviation prefix (see Figure 2). To this end, the bigram frequency list is used. Only when the right or left context does not provide any valid expansions, the unigram frequency list is looked up.

1 For example, Pathology would preferably be abbreviated as Path., as Pat. would be ambiguous with Patient.
In the special case where any of the contexts \( L \) or \( R \) is also an abbreviation itself (e.g. “St. p.”), hereafter denominated pairwise abbreviations, two extra initial lookups are performed:

- Lookup in \( B \) for the first bigram \( E_i E_j \) or \( E_i E_k \) where \( E_i \) is a valid expansion of \( i \) with strict matching;
- Lookup in \( B \) for the first bigram \( E_i E_j \) or \( E_i E_k \) where \( E_i \) is a valid expansion of \( i \) with relaxed matching.

**Similarity index**

To overcome mismatches due to adjective inflection endings, which is typical for German, we consider guessed expansions \( E \) with similarity \( S(A,E) \) to the abbreviation \( A \) greater than 70% as a correct match, as seen on Equation 2. The threshold was empirically found in a conservative way.

\[
S(A,E) = 1 - \frac{\text{Levenshtein}(A,E)}{\text{Max}(\text{Length}(A),\text{Length}(E))}
\]

**Evaluation**

We report precision, recall and \( F_1 \) score of our algorithm. Precision is defined as the ratio of correctly expanded tokens to all resolved abbreviations. Recall is defined as the ratio of correctly expanded tokens to all abbreviations [7]. To overcome high precision rates expected when the method gives only expansions with high confidence, \( F_1 \) score is defined as the harmonic mean between precision and recall, with equal weights.

Additionally, we define unigram lookup with relaxed matching as a baseline strategy, with which other strategies are compared. We perform a Chi-square test (Fisher’s exact test) to verify if the differences are statistically significant and not by chance, with \( \alpha = 0.05 \).

**Source code**

The source code was made available under Version 2 of the Apache License at [https://github.com/michelole/abbrev](https://github.com/michelole/abbrev).

**Results**

We report results for every lookup considered separately and in the combined approach in Table 1. Bigram strategies, as well as pairwise with strict matching, showed the highest precision rates, but low to moderate recall. When combined with the lower precision unigram approach, we boosted recall to 0.91, thereby achieving an \( F_1 \) score of 0.91 in the combined approach (measured in the test set). The combined approach is statistically significant better (\( p < 0.001 \)) than the baseline approach (unigram with relaxed matching). Bigram with relaxed matching is statistically significant better (\( p < 0.05 \)) than the baseline. Any pairwise approach is statistically significant worse (\( p < 0.001 \)) than the baseline approach. Other approaches showed no statistically significant differences to the baseline.

Investigation of errors shows two main patterns: (i) abbreviations preceded or followed by a number (e.g. “52 jähr. Patientin”, which should expand to “52 jährige Patientin”, German for “52 years old patient”); and (ii) abbreviation pairs (e.g. “Z. n.”, which should expand to “Zustand nach”, German for “state after”, i.e. “clinical history of”). We relate the former problem to the lack of any value normalisation (e.g. the conversion of “52” to “00”), which distributes frequencies in the bigram list over every number possibility. Even though we specifically addressed the latter problem in our pairwise resolution strategy, some abbreviation pairs are still ambiguous (“Z. n.” could also be expanded to “Zeit normal”, German for “normal time”) and a larger context window might be needed.

**Discussion**

**Related work**

Several works have been published on the problem of clinical abbreviation detection, expansion, and disambiguation, with different approaches, languages and types of data. Pakhomov [8] used a semi-supervised Maximum Entropy model for disambiguation of different short forms in a given context. The system was evaluated exploiting a dataset of about 10,000 rheumatology notes from the Mayo Clinic. Extended context information as well as different models trained on disambiguating one specific acronym yielded about the same accuracy of 0.89 for acronym and abbreviation normalization compared to using one model for the normalization task. The hypothesis that similar context information of abbreviations and acronyms compared to their resolved form supports correct normalization in context could be exploited and confirmed in this work.

Joshi et al. [9] compared three different supervised machine learning approaches for acronym expansion: Naïve Bayes Classifier, Decision Trees and Support Vector Machines. All three models achieved an accuracy of over 0.90. The feature set consisted of part-of-speech tags, unigrams, bigrams and a combination of all of them. A flexible window chosen to catch a certain level of occurrence information of lexical features had a significant impact on the overall evaluation efficiency.

Suominen et al. [10] provided an overview of the ShARe/CLEF eHealth Evaluation Lab 2013, in which Task 2 was focused on normalization of abbreviations and acronyms to UMLS concept unique identifiers (CUIs). The challenge used data from the US intensive care publicly available in the MIMIC-II dataset, originally annotated to build the ShARe corpus. The corpus was further enhanced with annotations regarding abbreviations and acronyms text spans and mappings to UMLS codes. The best team obtained an accuracy of 0.72.

Later, Mowery et al. [11] compared the efficiency of participating systems to a majority baseline and with variable majority sense distribution. They observed that a majority approach performed second best (accuracy of 0.69), given that an estimate of around 81% of short forms have no ambiguity (one unique sense) or low ambiguity (two or more senses, with one incidence over 80%). The only winning system showed a slight improvement (accuracy of 0.72) with a hybrid technique that exploits the same differences in abbreviation frequency and ambiguity.

Siklósi et al. [12] addressed the abbreviation resolution problem in Hungarian ophthalmological notes, a language with less linguistic resources available. They specifically dealt with long series of abbreviations commonly found in their documents. The impact of an external lexicon (built out of 3,329 ICD descriptors), a handmade lexicon (with a size of 44 entries) and the corpus itself in the abbreviation expansion phase was evaluated. Additionally, the influence of the context window (from zero to three tokens) and corpus size (with a total of 2,008 documents) in the final expansion efficiency was measured. The expansion strategy leveraged regular expressions built out of the abbreviations and matched (i) again the corpus and (ii) against the lexicons. In the disambiguation phase, their system used a weighted ranking score based on features such as the size of the longest and shortest span covered. We calculated an \( F_1 \) score of 0.85 from the reported precision (0.93) and recall.

(0.78) metrics. Moreover, their experiments showed that “considering the tokens without any context always performs worst” and “a context larger than one token […] has a positive effect only if the manually created lexicon is not used”.

Wu et al. [13] applied three different neural word embedding models, viz. SBE (surrounding based embedding feature), LR_SBE and MAX_SBE as additional features for a support vector machine to disambiguate abbreviations in context. The investigation used annotated abbreviation datasets from Vanderbilt University Hospital’s admission notes and narratives from the University of Minnesota-affiliated Fairview Health Services. The MIMIC-II corpus was used to initialise the word embeddings using the algorithm proposed by Collobert et al. [14]. About 42,000 sentences with resolved abbreviations were used for evaluation, achieving a maximum accuracy of 0.96.

Wu et al. [15] developed an open-source framework for clinical abbreviation recognition and disambiguation and evaluated it with a corpus from the Vanderbilt University Medical Center (VUMC) and in the ShARe/CLEF 2013 challenge corpus. They applied semi-supervised clustering methods for sense expansion and profile-based word sense disambiguation. While the former depends on manual review of around 20 sense clusters for each abbreviation to create a sense inventory, the latter builds upon feature vectors representing different senses in a vector space model. Their system achieved an F₁ score of 0.76 in the VUMC corpus, and a 0.29 F₁ score in the ShARe/CLEF dataset.

Our method differs from most of the works being totally unsupervised. Compared to Siklósi et al. [12], the main difference lies in the fact that our disambiguation strategy is also fully data driven and relies only on the frequencies of words and bigrams in a closely related corpus. Although we agree that a weighted ranking of features (e.g. combining the n-gram frequency to its type and relative gain) could improve the disambiguation process, it would need additional annotations to optimize the weight coefficients, thereby transforming our strategy into a supervised approach. Additionally, we did not observe the same incidence of abbreviation series in our corpus, which could explain our better results. Finally, we hypothesize that our much larger corpus (30,000 versus 2,008 documents) might have overcome the need of any lexicon.

Limitations

Our data-driven strategy might show suboptimal results in languages and subdomains with fewer data. It is also sensitive to spelling errors (e.g. “bdx”), German abbreviation for “both sides”, is at least once incorrectly written as “bdx” in the corpus

— note that the “I” character is found near the “.” character in most keyboards. Although a minimum frequency could be enforced, preliminary experiments showed no improvement over training data.

Furthermore, we propose some basic writing guidelines that could further improve the automated processing of clinical notes. Considering the abbreviation expansion and disambiguation problem alone, guidelines should stress the importance of (a) correct capitalization (e.g. “Patient” instead of “patient”); (b) avoiding typos (e.g. “hdst” instead of “hds”); (c) marking abbreviations with a period consistently (e.g. “Tbd” instead of “Tbd”); (d) standardizing double abbreviations, preferably with a space character (e.g. “St. p.” instead of “St.p.”); (e) separating numbers from their units (e.g. “10 mg.” instead of “10mg.”). These simple measures would ease data-driven approaches like ours by increasing the signal-to-noise rate.

Future work

Future work could start exploring the impact of value normalization (i.e. the transformation of all numbers to a standard value) in the results. At least in the training set, this was noted as a common error pattern.

Explorative work also suggests that our algorithm could be useful for the expansion of abbreviations without the period mark, as well as for expanding non-lexicalized and ambiguous acronyms. When uppercased and stripped of their abbreviation mark, abbreviations are similar to acronyms considering the relaxed matching strategy. However, many acronyms are rarely ever expanded, so that the clinical corpus might lack enough full forms. Therefore, other corpora may be necessary, thus complicating the disambiguation task. Our decision to focus on period abbreviations also makes it difficult to compare the results to other works that considered all kinds of short forms.

The proposed strategy should also be evaluated in the broader context of a natural language processing pipeline, in which sentence detection, tokenization, and abbreviation detection are performed together. The special case of glued (without a space mark) pairwise abbreviations (e.g. “St.p.”) might be better addressed with the correct output of a tokenizer. Nonetheless, correct abbreviation detection might be fundamental to distinguish between sentence delimiters and real abbreviations, thereby avoiding false positives.

Apart from evaluation, the application of our method over a full sentence should be considered in the context of a Hidden Markov Model. Hence, the best sentence outcome might be obtained via a dynamic programming algorithm such as the Viterbi algorithm. Larger windows, e.g. trigrams, could be then

² The inclusion of the relaxed pairwise strategy did not improve results in the combined approach and is therefore excluded from it.
exploited to assure maximal context. Suavisation (e.g. Good-Turing) might be needed for cases unseen in the training set. Finally, we would like to evaluate our strategy in other subdomains, other languages (e.g. English and Portuguese), and with different corpora sizes, both in publicly available and other restricted corpora. However, our approach would be difficult to run in challenge datasets, like ShARe/CLEF 2013, because it needs a large related corpus as a key resource. For its practical use in clinical language processing this should not be a problem because electronic health record systems do not lack large amounts of text and the choice of domain specific corpora (e.g. cardiology, intensive medicine, nursing, radiology) can be done with attached metadata.

Conclusions

We presented a completely unsupervised approach to the problem of abbreviation expansion. We focused on non-lexicalised and ambiguous abbreviations, commonly created ad-hoc and therefore abundant in clinical narratives. Our strategy is based on bigram and unigram lookup and yielded a 0.91 F1 score when evaluated with a German cardiology corpus. The result is statistically significant better (p < 0.001) than a baseline approach. Our hypothesis that high efficiency rates can be obtained in an unsupervised fashion was therefore not rejected. Hence, our work provides a successful and reusable method for abbreviation expansion. It improves text comprehension by non-experts and is supposed to improve processing of clinical abbreviation expansion. It improves text comprehension by non-experts and is supposed to improve processing of clinical narratives, such as concept mapping and semantic analysis.

Abstract
The shift to electronic health records has created a plethora of information ready to be examined and acted upon by those in the medical and computational fields. While this allows for novel research on a scale unthinkable in the past, all discoveries still rely on some initial insight leading to a hypothesis. As the size and variety of data grows so do the number of potential findings, making it necessary to optimize hypothesis generation to increase the rate and importance of discoveries produced from the data. By using distributed Association Rule Mining and Contrast Mining in a big data ecosystem, it is possible to discover discrepancies within large, complex populations which are inaccessible using traditional methods. These discrepancies, when used as hypotheses, can help improve patient care through decision support, population health analytics, and other areas of healthcare.

Data Mining; Electronic Health Records; Population Health.

Introduction
Within the past two decades health records have moved from the paper realm to the digital [1]. As the amount of digitized health data has grown, data mining has been used to make sense of it all. Knowledge that took a lifetime of observation to gain is now obtainable in an instant, given enough data, helping hospitals and researchers to improve their quality of care [2]. For example, the areas of decision support and intervention have both benefited greatly from the application of data mining [3]. Knowledge can now be learned directly from electronic health records using algorithms such as decision trees, association rule mining (ARM), or other pattern recognition techniques then acted on by care givers, doctors, and researchers [4]. While this has been a boon to healthcare both at the individual and institutional levels, it has caused a shift in medical research from hypothesis driven to data driven, often removing the hypothesis of "why" from the equation [5]. This "why" is important, however, as treating the symptoms does not always treat the root issue, and so using this knowledge to form hypotheses becomes an important task.

As the volume and variety of healthcare data grows, so does the computational power required to perform analysis. Though a small single-provider practice may be able to run data mining against their data on a single machine, large hospitals or government databases hold too much data for a single machine. ARM, for example, increases exponentially with the number of attributes available. Given n attributes, there are 2^n-1 unique combinations of those attributes [6]. Distributed computing techniques allow us to address this exponential scaling factor.

Contrast Mining for Pattern Discovery and Descriptive Analytics to Tailor Sub-Groups of Patients Using Big Data Solutions

Cluster computing enables distributed analysis of data and storage of large datasets by utilizing an array of machines. Performance can be improved by adding more machines [7]. Through distributed computing in a big data ecosystem it is possible to utilize ARM on datasets on which it would not be possible otherwise. There are several reasons to apply ARM, a special case of Pattern Mining [8], in healthcare applications. Pattern Mining algorithms work by finding groups of items/events/attributes that appear together at higher than expected frequencies. This differs from more traditional statistical and machine learning techniques that may not scale well or have limited explanatory power and intuitively understandable action plans in medicine. While traditional techniques often evaluate a large number of conceivable combinations of attributes, Pattern Mining continuously filters its patterns so that only those which are significant (user defined) are ever evaluated [6]. Using these approaches on health data can still generate millions of rules, many of which can be too general or specific for the research at hand.

While studying each rule on its own may be preferable, it is untenable due to the exponential number of co-occurrence of comorbidities and demographic information. It is necessary to define a way to filter these hypotheses based on their importance and impact. To solve this issue, human-directed hypothesis generation can once again come into play through a process known as Contrast Set Mining (CSM). CSM is the process of using Pattern Mining across a partitioned population in order to find differences in their pattern distributions [9]. Used in its most basic sense, it can be a tool for classification and prediction. In the last decade, CSM has been applied to many data-rich areas, such as genome wide association studies, or disparities in preventative healthcare [10]. Although the ability to use CSM for classification is powerful, patterns alone do not explain why those differences exist or why and how they are important. This, combined with the number of patterns which must be compared, creates four challenging research problems: removing redundant or insignificant patterns, determining the comparative importance of the patterns, doing both at a large scale, and determining why these patterns exist.

One of the primary advantages of using ARM and CSM is the explainability of results. The patterns detected are clearly understandable action plans in medicine. While traditional algorithms often evaluate a large number of conceivable combinations of attributes, Pattern Mining continuously filters its patterns so that only those which are significant (user defined) are ever evaluated [6]. Using these approaches on health data can still generate millions of rules, many of which can be too general or specific for the research at hand.

It is necessary to define a way to filter these hypotheses based on their importance and impact. To solve this issue, human-directed hypothesis generation can once again come into play through a process known as Contrast Set Mining (CSM). CSM is the process of using Pattern Mining across a partitioned population in order to find differences in their pattern distributions [9]. Used in its most basic sense, it can be a tool for classification and prediction. In the last decade, CSM has been applied to many data-rich areas, such as genome wide association studies, or disparities in preventative healthcare [10]. Although the ability to use CSM for classification is powerful, patterns alone do not explain why those differences exist or why and how they are important. This, combined with the number of patterns which must be compared, creates four challenging research problems: removing redundant or insignificant patterns, determining the comparative importance of the patterns, doing both at a large scale, and determining why these patterns exist.

One of the primary advantages of using ARM and CSM is the explainability of results. The patterns detected are clearly understandable action plans in medicine. While traditional algorithms often evaluate a large number of conceivable combinations of attributes, Pattern Mining continuously filters its patterns so that only those which are significant (user defined) are ever evaluated [6]. Using these approaches on health data can still generate millions of rules, many of which can be too general or specific for the research at hand.
combinations of features at once.

Methods

Pattern mining, at its most basic, can be thought of as applied counting. It is used to find a collection of attributes that occur together above a user-defined frequency. The data, \( D \), can be described as a list of transactions, \( T \). In this research, a patient is considered as a transaction. Each transaction contains a set of items, \( i \), each of which exists in the set of all possible items, \( I \). Patients’ demographic information, diagnosis-related groups, and risk levels are potential items for a transaction. Any arbitrary collections of items, \( \{i\} \), is considered an itemset. Itemsets with a support above the user-defined minimum are considered frequent, with support calculated as \( \text{sup}(x) = \frac{\text{count}(x)}{|D|} \). While the Apriori approach [6] works well for finding common patterns, it quickly exhausts the resources of a normal machine when rare patterns are sought. Common patterns may be found even with a high support; however, rare patterns require a very low support threshold, allowing for near exponential intermediate pattern generation and requiring either numerous reads or very large amounts of memory.

In addition to the volume challenge, the variety of data generates a large amount of intermediate data. During the exploratory analysis, the number of potential itemsets for our data collection reached hundreds of millions, requiring terabytes of memory to index. In order to generate as many patterns as possible, we utilized a Big Data environment to handle large datasets and distributed approaches, which are necessary to tackle scaling challenges. To handle intermediate data of this magnitude, we developed a suite of distributed Apriori tools built on Apache Spark as well as the Apache Hadoop Distributed File System (HDFS) to store the initial, intermediate, and final data. We utilized several low-cost commodity machines equivalent to a system with 18 cores and 144 GB of RAM. For this study, the computing environment consisted of a cluster of 9 Intel NUC machines, each equipped with 16 GB of RAM, an Intel i3 processor, and 1.5 TB hard drive. We were able to perform the computations by distributing the data across all nodes and performing each step of pattern mining on the data. Most computations could be done in parallel, such as candidate generation and filtering for minimum support, while counting was done by aggregating across the cluster (Figure 1).

In association rule mining, the next process would be to generate rules based on confidence. Rules are generally of the form \( \{a, b\} \rightarrow \{c\} \), with the confidence calculated as

\[
\text{confidence}(\{a, b\} \rightarrow \{c\}) = \frac{\text{sup}(\{a, b, c\})}{\text{sup}((a, b))}
\]

Rule mining can be over-generative when used for classification between groups, with most rules either lacking the class label or with the class in the antecedent. In cases such as these Contrast Set Mining (CSM) can be used instead, a special case of ARM in which the class is always the consequent [9]. CSM is normally applied during ARM in order to only produce patterns which strongly indicate a class. Patterns that have a measurable difference in support are ranked to find those of highest importance. Many different techniques exist for filtering and prioritizing contrast sets, each with its own strengths and weaknesses. All rely on some measure of difference in support. This lends itself well to a distributed approach, as the millions of contrast sets can be grouped, measured, and filtered, allowing even large datasets to be instantly processed and analyzed in parallel for quick data discovery as depicted in Figure 1.

A key goal was reporting mining results that were statistical significant or worthy of conducting further research for vulnerable populations. Patterns rejecting the null hypothesis \( H_0: \text{support}(X, \text{Population}_1) = \text{support}(X, \text{Population}_2) \) using the Z-Test with high contrasts were selected. Some patterns included minority populations with sample sizes too small to produce an acceptable \( p \) values (\(<0.05\)) were also selected, to retain visibility into these vulnerable populations.

In our implementation, we designed the system to flexibly apply various filters for different goals after removing non-significant patterns. By setting a target class we could focus on those patterns that had a stronger support in one class than the other. This filtering mechanism allowed us to focus on patterns that were more common in patients that experienced drastic declines in health. It is important to choose the correct measures of significance and importance based on the types of patterns sought. For this we used three significance measures: growth rate, largeness (support difference), and confidence. Though these measures could be calculated in parallel, sorting could not. This final step was done on a single node as shown in Figure 1.

*Growth rate* is represented as the ratio between supports. This measure is preferred for rare itemsets. The growth rate represents the idea that as more items are added to a pattern, the supports get smaller, and thus differences which may have been imperceptible with smaller, common itemsets become more pronounced as they grow [14].
Any pattern with a support difference greater than a user-defined value $\delta$ is known as large. As mentioned previously, patterns with statistically different ($p < 0.05$) or existent supports are known as significant. Those patterns which are both significant and large are known as deviant [15]. As largeness works with high valued supports, the patterns generated may have a relatively small growth rate.

Confidence is the conditional probability of a Class, given a certain pattern. That is to say, how strong is pattern $X$ at predicting Class. The following equation defines the confidence metric, freq counts the occurrences of an itemset, and the denominator sums to the total frequency count of pattern $X$ in both classes.

$$\text{conf}(X \rightarrow \text{Class}) = \frac{\text{freq}(X, \text{Class})}{\text{freq}(X, \text{Class}) + \text{freq}(X, \neg \text{Class})}$$

Once these measures had been calculated, a post-processing step was run so that only closed patterns remained, a pattern being closed if there is no super-pattern with the same support [16]. This works because it is impossible to increase support by adding items, as the maximum support of the new pattern is the minimum support of all subsets.

$$\text{closed}(X): \forall Z \supseteq X \text{ sup}(X) > \text{ sup}(Z)$$

Finally, we obtained three different top-ranked lists, sorted by growth rate for rare contrast sets, or support difference for common, and confidence for both. These three ranked lists of contrast sets provided a broad range of hypotheses to study and act on for healthcare improvement. In order to ensure due diligence, all results generated using these methods were systematically validated against the raw data, ensuring all rules were accurately portrayed.

**Experiment Design**

The population this data comes from is the LIGHT² (Leveraging Information Technology to Guide Hi-Tech and Hi-Touch Care) project, with goals of improving patient health through risk detection, utilization prediction, prevention, and intervention. Patients in the population were primary care patients in the University of Missouri Health System as well as enrolled in Medicare or Medicaid. Patients were enrolled between February and July of 2013, with 9,581 patients still enrolled by the time the first risk tier evaluation was given on October 1, 2013. All data on the patients’ diagnoses, outpatient visits, and hospital visits were based on the University of Missouri Health System electronic medical record, as maintained by clinicians between 2012 and 2014.

For this case study, the attributes used were age (under 65, over 65), sex, marital status, ethnicity, race, language, and 42 diagnosis-related group (DRG) codes applied to the patient over the previous year. This gave a minimum possible itemset size of seven for every patient, as each patient had at least one chronic condition. This resulted in $2^7 > 280$ (Trillion) possible attribute combinations for exploratory analyses.

### Table 1 - Tier definitions for the LIGHT² project, based on hospital utilization and number of chronic conditions

<table>
<thead>
<tr>
<th>Tier</th>
<th>Definition (based on past 12 months)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Healthy</td>
<td>Chronic conditions defined by the Centers for Medicare &amp; Medicaid Services (CMS) = 0</td>
</tr>
<tr>
<td>Chronic</td>
<td>Chronic conditions $\geq 1$ AND (hospitalizations = 0 AND outpatient visits $&lt; 5$)</td>
</tr>
<tr>
<td>Stable</td>
<td>Chronic conditions $\geq 1$ AND (hospitalizations = 1 AND outpatient visits from 5 to 12)</td>
</tr>
<tr>
<td>Unstable</td>
<td>Chronic conditions $\geq 1$ AND (hospitalizations $&gt; 1$ AND outpatient visits $&gt; 12$)</td>
</tr>
<tr>
<td>Complex</td>
<td>Chronic conditions $\geq 1$ AND (hospitalizations $&gt; 1$ AND outpatient visits $&gt; 12$)</td>
</tr>
</tbody>
</table>

In order to generate potentially actionable data, we chose to focus on those patients who started in Tier 2, “Stable” patients suffering from chronic disease who are otherwise healthy. From here, we compared patients who never left Tier 2 with those who left Tier 2 and entered Tier 4 within a 30 day period, indicating a catastrophic worsening of health (Figure 2). A 30-day window was chosen because it indicated multiple hospitalizations or a large number of outpatient visits in an abnormally short period of time. A two-week buffer was added between the end of data collection and the tier movement due to tier recalculations happening every two weeks. Observations from this period included attributes responsible for tier movement, and thus were not actionable.

### Figure 2 - Population creation criteria used for case study.

Those patients who started in Tier 2 and moved to Tier 4 within a 1-month window were chosen as a contrast to patients who started and remained in Tier 2.

Due to the patient privacy regulations of the Health Insurance Portability and Accountability Act (HIPAA), detailed statistics regarding this population were not available. However, general statistics about size and complexity of the different populations were available (Table 2). One thing that was surprising when compiling these statistics was that, overall, the population that
stayed in Tier 2 seems to suffer from a higher number of comorbidities. This can be explained by the data collection process, however: while patients who moved from Tier 2 to Tier 4 only had 12 months of data used for analysis, we include data spanning the lifetime of LIGHT 2 when analyzing those who stayed in Tier 2. Those patients had a longer period to accumulate DRG codes from visits. Table 3 provides example DRG and demographic codes.

Table 3 - DRG code mappings. This list contains only those codes that appear in the contrast sets in Results

Results

The top ten itemsets that were strongest indicators of being in the high risk patient group, moving from Tier 2 to Tier 4 in a 30 day period, are shown in Table 4. The stable group comprised 94.4% of patients, while the at-risk group was 5.6%. After extracting the strongest contrast patterns based on the growth rate, we used logistic regression to test how well these patterns correlated with the tier movement. The test statistic was a distributed chi-squared with degrees of freedom equal to the differences in degrees of freedom between the current and the null model (i.e., the number of predictor variables in the model). Considering a p value less than 0.05 as a significant model, 8 of the 10 highest growth patterns were significantly correlated with tier movement.

The highest growth rate reported in the first three rows of the table means that the support of the three contrast patterns was 9.593 times greater in the at-risk population. In addition, the highest confidence level was also reported for these three patterns. This confidence 36.4% means that given a contrast pattern, the conditional probability that a patient would move from Tier 2 to Tier 4 in 30 days. This may seem low; however, since the baseline probability for transitioning to Tier 4 was 5.6%, it showed that a patient that exhibits this pattern was over 6 times more likely to transition to Tier 4 than an average patient. The largeness measures were all over 2% which means the percentage of each pattern in Tier movement group was 2% greater than in the stable group.

Another interesting aspect of the results was the size of itemsets; the smallest contrast pattern reported consisted of four items. Within the top 10 contrast patterns there were 12 unique items. In addition to the DRG Codes given in Table 3, we have: over65, 65orLess, Male (M), Female (F), Married, Divorced. Of the 12 attributes, 5 were chronic conditions, 2 were sex, 2 were age, and 1 was race. While chronic conditions were included in every contrast pattern, marital status occurred in 7, sex in 6, age in 5, and race in 2. The highest support among the contrast sets reported was 2.9% and the lowest support was 2.4%. This suggests the high-risk and stable populations were composed of many subpopulations. Identified contrasts were defined by these small populations.

All reported contrast patterns were indicative of increased risk of hospitalization. The lowest confidence reported was 25%. Although this was a low probability, since the base probability of transitioning to Tier 4 is 5%, it suggests a 5-fold minimum increase risk of transitioning to Tier 4. The support difference was relatively equal between all of the contrast patterns reported in Table 4, around 2%. When all support values are low, the support difference was not as useful.

Discussion

Using these results, it is possible to identify patients who are at risk of having their health deteriorate quickly. Contrast sets formed a strong set of interpretable rules, which can be used by population health managers and clinicians when choosing which patients to spend more time with, and they provide a great starting point for future research questions.

One of the primary advantages of using ARM and CSM is that the results are understandable in a clinical setting, where accountability and transparency are paramount. For example, the top frequent patterns in Table 4 show that married males with chronic kidney disease and ischemic heart disease were significantly more prevalent in the high-risk population. A patient fitting this description is highly likely to have increased hospitalization within 30 days compared to others with stable chronic condition. The third row of Table 4 shows that an African American female over 65 years old with stable diabetes and a history of perinatal conditions also had a high risk of imminent worsening health and hospitalization. Each of these attributes is a well-known risk factor for poor health outcomes; however, these methods identify combinations of risk factors, which lead to particularly high risk of imminent hospitalization. Patients that fit these easily understood profiles could be flagged for additional care management by population health managers and preventive care by clinicians.

One of the main limitations of ARM and CSM is the combinatorial nature of patterns. The methods can create a large amount of data. By utilizing a big data environment, we can extend the limits of this sort of data mining analysis.

Conclusions

With these findings, we have shown how contrast mining on a big data scale can be used on complex datasets for both immediate health care improvement and directing future research in clinical settings. Our findings for the LIGHT² dataset will be used as a guide for patient prioritization by
population health managers, as well as helping project members find new directions to pursue. The combinations of attributes that indicate risk should be provided to population health managers. While this is being done, clinical researchers can formulate more detailed explanations as to why certain individuals are prone to experience severe health complications. By identifying at-risk individuals earlier, the overall quality of care patients receive may be improved.

There are many other large, complex, and new healthcare related areas where this method can be applied. This method can be applied in areas of disparity, adherence, genetic health, and impact of comorbidities. The scalability of distributed computing gives researchers the ability to study larger, more complex datasets than in the past, while this approach to Contrast Set Mining allows for quick exploratory analysis of data as a post-processing technique. The combination of these attributes removes the complexity involved in multivariate analysis and allows for rapid discovery with the need for reprocessing, making distributed Contrast Set Mining an important tool for clinical and translational research.

The next phase of this work is to construct a contrast set classifier for improved prediction of at-risk patients. This data set is particularly challenging due to the skewness between stable and high-risk populations and complex patterns within the high-risk group. Our preliminary results with a direct matching on frequent patterns for the high-risk population are promising and showing advantages over generic machine learning algorithms. Our contrast set classifier was able to achieve a balance between sensitivity and specificity (72% and 32%), while decision tree J48 (0%, 0.1%), random tree (5.2%, 0.1%) struggled for the high-risk group. Our preliminary results with a direct matching on frequent patterns for the high-risk populations due to the complex patterns shared by subgroups of high-risk patients; as we have shown in this paper, the predictive power lies in the combination of key attributes. Our ongoing effort to correctly classify the stable group (patients who stayed in Tier 2) focuses on constructing an aggregate metric to assess which population has the strongest indications of membership in the group. This metric would likely be a combination of growth rate, support difference, confidence, or other contrast metrics.

Abstract

With the rapid development of medical information systems in Chinese hospitals over the last two decades, many of these organizations have accumulated astronomical amounts of structured and unstructured clinical data, including patient diagnostic data, treatment data, lab test data, etc. Secondary use of these data for research, such as Real World Evidence (RWE) studies, has the potential to improve medical quality and safety in daily clinical practice. In this study, we describe CaseBase, a Clinical Data Warehouse (CDW) that extracts structured clinical symptoms or findings and related temporal information from narrative clinical documents and integrates medication information from the CPOE system. An Adverse Drug Event (ADE) signals detection platform has also been developed based on CaseBase to analyze and visualize drug-symptom relations in clinical data. A prototype of this platform has been evaluated in a 2,000-bed hospital and some initial results are reported here.

Keywords:
Information Storage and Retrieval; Drug-Related Side Effects and Adverse Reactions

Introduction

Secondary use of Real-Word Data (RWD) from clinical information systems has been studied for many years, as it has been proven to be beneficial to both medical research and the quality of clinical practice [1]. Particularly, it could help to strengthen our current understanding of healthcare delivery and patient outcomes, as well as increase the potential for generating new knowledge [2, 3]. Furthermore, RWD could provide evidence for clinicians to guide their practice [4, 5]. Despite the above benefits, due to the distributed and heterogeneous nature of RWD, they are difficult to use directly. As a result, most clinical RWD remains underutilized by hospitals. This is a great waste of clinical information resources.

To fully use clinical RWD, it generally requires a prior integration and structural optimization process in a unified clinical database, also called a Clinical Data Warehouse (CDW). Generally, a CDW is used to support medical education or research, or to satisfy demands for management information and clinical information in the medical field [6].

In addition to using RWD to improve care and organizational processes, there are also potential applications in drug safety, which can vary from controlled trial findings when used widely in practice. Each year, ADEs cause a great threat to human life and health worldwide [7, 8], and place a huge economic burden on the world [9-11]. Most of the ADEs are known and have been labeled with the drug specification, but there are still a small number of potentially unknown ADEs. By identifying these unknown ADEs, ADE signal detection [12] can be used to help reduce the incidence of potentially serious ADEs.

In this study, we describe CaseBase, a secondary use oriented CDW based on RWD from the Computerized Physician Order Entry (CPOE) system and Electronic Medical Record (EMR) in a Chinese hospital. Additionally, we will describe our application of the statistical frequency based Disproportional Analysis (DPA) [13] method to develop an ADE signal detection platform based on this CDW.

Methods

CaseBase Database Design

Given the sparse and dynamic characteristics of the raw clinical data involved in this study, the Entity-Attribute-Value (EAV) modeling methodology is used for the CaseBase database design [14-16]. In this study, one patient visit is seen as one case in the CaseBase, and one case could contain many data items or facts. For example, data items like a symptom, a laboratory test result, or a drug order all could be seen as facts.

Therefore, the CaseBase database is composed of one FACT table and two other related tables, named the CASE table and CONCEPT table respectively, as shown in Figure 1. These three tables form a star structure, and combined, they describe one fact. Specifically, the FACT table in the center is used to store the detailed core data content of one fact, such as the result of a laboratory test, the name of a drug, the symptom of a patient, etc. The CASE table is designed to store the relevant patient case information about the fact and also can be used to assist in retrieving fact data. To protect the privacy of patients, names, phone numbers, and family addresses are not contained in the CaseBase. Finally, the CONCEPT table is used to store...
the detailed description items for a specific fact, such as the name and type of fact. In brief, the CASE and CONCEPT tables are used to support the FACT table.

The ETL Process

The Extract, Transfer, Load (ETL) process will extract the required structured patient fact data from distributed and heterogeneous medical information systems and load them into the CDW. The process includes three steps: Extracting clinical data stored in various information systems, Transforming the extracted data’s structure and meaning, and Loading the transformed data into the CaseBase.

In this study, patient medication lists from the CPOE system and relevant progress notes from the EMRs are processed and loaded into CaseBase. All this information can be accessed through an Integration Engine deployed in the hospital. A platform-independent Web service application called BuildCase was developed to interoperate with the Integration Engine and the CaseBase. For instance, when a patient is discharged from the hospital, the Integration Engine will call the BuildCase service with a parameter containing the patient’s VisitsId (one patient’s unique identifier in one visit to this hospital), then the BuildCase would access the information systems and get the required data.

In the second step, the extracted raw clinical data is transformed into the required format, which involves two aspects of transformation, the data structure and the data meaning. For the former, it needs the BuildCase service to restructure the data extracted from the heterogeneous information systems according to the demands of the CaseBase data model. Most of the data coming from the CPOE system require this step. For the latter, it is more complex relative to the data structure transformation, for example, transforming the patient’s birth date to age. To get the patient symptom data, a dictionary-based Chinese Named Entity Recognition (NER) technology, a kind of Natural Language Processing (NLP) technology, is applied to transform the free text, unstructured progress notes from the EMR system to the form of symptom terms needed for the timeline. As shown in Figure 2, a patient’s progress note was recorded regularly day by day. The progress note was first segmented into multiple parts by time using regular expressions. Then, each part was processed into several temporal symptom relationships using a Chinese NER technology based on a home-grown medical terminology dictionary described in our previous work [17].

In the last step, the transformed data need to be loaded into the CaseBase CDW, and the whole ETL process is finished. In addition, all the ETL process related services are called in asynchronous mode, and thus will not change the data in the original system and reduce the running speed of the source system.

Mining of the DEC and the DPA method

To mine the potential Drug-Effect Combinations (DECs), some pre-processing and data cleaning steps are carried out ahead of the whole process. Specifically, the facts data unrelated to drugs or ADEs are filtered out first; then the facts that belong to solution type (e.g., glucose solution) are filtered out. Next, the long-term doctor’s orders are divided into single orders with the day as the unit; lastly, the symptoms that occurred within 12 hours after admission are filtered out, because most of the symptoms that happen in the first 12 hours were not treatment-related.

After the completion of pre-processing, a DEC screening process is applied as illustrated in Figure 3. In the figure, the horizontal axis represents time; the circle point represents that a drug has been used, and the triangle represents a symptom. In order to include only the symptoms occurring after drug use, rather than before drug use, a shielding set A, a candidate set B and a target set Δ were defined, and their detailed definitions are represented by mathematical expressions as follows:

- \[ A = \{x | \text{time} \geq \text{d.time} - t1 \text{ and } \text{time} < \text{d.time} + t2\} \]
- \[ B = \{x | \text{time} \geq \text{d.time} + t3 \text{ and } \text{time} < \text{d.time} + t4\} \]
- \[ \Delta = \{x | x \in B \text{ and } x \notin A\} \]

Thus, according to the above conditions, the DEC could be defined as the two tuples formed by the drug \( d \) and the symptom in the \( \Delta \) set decided by drug \( d \). For example, as shown in Figure 3, the shielding set A contains symptoms a2 and a3, the candidate set B contains symptoms a1, a2, and a4, and as a consequence, the target set \( \Delta \) contains a1 and a4. So, the DECs selected are \( d - a1 \) and \( d - a4 \), two pairs in total. In addition, the four parameters \( t1, t2, t3, \) and \( t4 \) can be adjusted for different study purposes, generating different results.

On the basis of the DECs produced above, the DPA method, one of the most commonly used ADE signal detection methods, is applied to this study to mine the potential ADEs. In this method, the frequencies of presence or absence of the drug and adverse effects are recorded based on the cross table method illustrated in Figure 4. As shown in the figure, there are four frequency parameters (A, B, C, and D) defined to count the statistical frequency for each of the DECs of interest. The letter A represents frequencies for when the drug of interest and the adverse effect of interest are present together. The letter B...
represents frequencies for the drug being present and the adverse effect being absent. The letter C represents the frequencies for when drug is absent and the adverse effect is absent. The letter D represents the frequencies for when both the drug and the adverse effect are absent. Based on these four statistical frequency parameters, four highly correlated assessment factors can be calculated. They are Relative Reporting (RR), Proportional Reporting Rate Ratio (PRR), Reporting Odds Ratio (ROR), and Information Component (IC) respectively, and their calculating formulas are listed as follows.

1. \[ RR = \frac{A(B+C+D)}{(A+C)(A+B)} \]
2. \[ PRR = \frac{A(C+D)}{C(A+B)} \]
3. \[ ROR = \frac{AD}{CB} \]
4. \[ IC = \log_{2} RR \]

**Results**

In this study, a total of 23,898 cases from a 2,000-bed hospital were collected in the CaseBase, from which 8,320 cases were included for ADE signal detection. Particularly, there were 250,865 facts of symptoms and 414,500 facts of orders in these cases. Usually, the finding and recording time of an effect or a symptom of a patient by a physician would be later than the creation time of the drug order; therefore, \([24h-72h]\) was selected as the effective time window, meaning the parameter t3 equals 24 hours and t4 equals 72 hours. Finally, a total of 150,623 DECs of 71,980 different kinds were selected for inclusion. Further analysis found the frequency of most DECs to be no more than 2, and the kinds of DECs reduced rapidly with increasing DEC frequency. Moreover, the average IC value of all frequencies showed no obvious difference. According to these analyses, the DECs that have a relatively high frequency and a larger IC value should be more likely to be the ADE signals. Therefore, the DECs in which frequencies are no less than 3 and IC values are above 20 were selected (shown in Table 1). From the table, first, it can be seen that the four factors PRR, ROR, RR, and IC have a high correlation, and second, the 20 DECs could be divided into four categories as listed in the last column.

The “confirmed” category means the side effects have already been discovered in clinical trials or studies, the “indication” category means the DEC is a kind of indication symptom of the drug, the “error” DECs are caused by wrongly extracted symptoms, and the “suspected” DECs are possible new drug-ADE pairs that need to be further analyzed and researched. As can be seen through preliminary analysis, in the 20 DECs, the “suspected” DECs make up about half, and the “indication” and “confirmed” DECs each account for a quarter.

The detailed mining result was visualized using Microsoft Silverlight technology for a project involving our organization’s clinical pharmacist. A sample of the visualization results are shown in Figure 5. The drugs and symptoms are represented as bubbles with different colors. The size of the bubble shows the number of cases in which the drug was used or the number of times a symptom was observed in the data set. The distance between symptom and drug bubbles represents the confidence level measured by the IC assessment factor. Drug and symptom pairs with larger IC values will have a shorter distance. The width of the arrow between drug and symptom bubbles shows the frequency of the drug-symptom pair occurring under this profile. The color of the arrow was used to distinguish whether the relationship is a known side effect of the drug in our knowledgebase, indicated below by a golden arrow.

Table 1 – IC Top 20 DECs
Furthermore, clicking on any drug or symptom bubble will navigate to a new scenario. For example, clicking the MOSAPRIDE TABLETS in Figure 5B will navigate to the MOSAPRIDE TABLETS centered view as shown in Figure 5A. So users can evaluate both the potential adverse effect of a drug and the potential drugs causing an adverse effect in a user-friendly way.

**Figure - 5 Sample of the visualization result for drug-symptom relationships: A. Drug-centered view. B. Symptom-centered view.**

**Discussion**

This is the first prototype of an ADE signal detection platform using Chinese EMRs that has been reported. Although only a small dataset was used in this study, it definitely showed its feasibility for RWE studies in clinical information systems in
China. Considering the increasingly serious drug-safety issues in China, we believe this prototype will inspire more investigations in this field.

The most challenging part of this study was to automatically extract symptoms from progress notes, as there are still limited Chinese symptom terminology resources available. To evaluate symptom extraction methods, 100 progress notes were randomly selected from the EMR system and manually annotated by two independent annotators. These two annotated results were combined to create a gold standard for the evaluation. A total 666 symptoms were manually annotated as positive symptoms observed in the 100 progress notes. The NLP methods used in this study extracted 399 symptoms from the test progress notes, of which 388 symptoms met the gold standard. Thus, the recall rate of the NLP methods did not perform very well in the evaluation, although the 97.2% precision rate is high enough to provide a good foundation for further analysis. It is hard for a home-grown medical terminology dictionary to cover all symptoms, thus a comprehensive Chinese symptom terminology dictionary or other machine learning based NER method is needed for future study.

Timestamps of the progress notes were assumed in this study to be the time when symptoms were observed, though we found this is not always the case in certain conditions. To improve the temporal accuracy of extracted symptom facts, a temporal information extraction and relationship extraction study will be conducted in the future.

In the future, if this ADE signal detection platform is deployed in a real-time clinical setting, the facts database will be up-to-date, and analysis results and reports will be generated every day, week, and month to present the potential ADE signals for our organization’s clinical pharmacist. This project holds promise to help our clinical pharmacist to detect ADE signals earlier or work as an efficient support platform for our current spontaneous ADE reporting system.

Conclusions

In this study, making use of the clinical data from a 2,000-bed Chinese hospital and the ETL process, a CDW called CaseBase has been constructed to facilitate the secondary use of clinical RWD for the purpose of providing RWE for clinical studies or projects. Additionally, an ADE signal detection platform prototype based on the constructed CDW was developed and some initial results were obtained. These results preliminarily demonstrated how this work is feasible to facilitate the secondary use of clinical RWD.

Abstract
The aim of this work is to share our experience in relevant data extraction from a hospital information system in preparation for a research study using process mining techniques. The steps performed were: research definition, mapping the normative processes, identification of tables and fields names of the database, and extraction of data. We then offer lessons learned during data extraction phase. Any errors made in the extraction phase will propagate and have implications on subsequent analyses. Thus, it is essential to take the time needed and devote sufficient attention to detail to perform all activities with the goal of ensuring high quality of the extracted data. We hope this work will be informative for other researchers to plan and execute extraction of data for process mining research studies.

Keywords:
Hospital Information Systems; Process Mining; Database Management System

Introduction
Process mining consists of a set of techniques that enable the analysis of business processes using system data. Specialized algorithms treat the data identifying patterns and trends. The use of process mining algorithms allows to discover process models (process discovery), identify deviations in a process (conformance checking), identify bottlenecks and performance indicators (performance checking), and identify how information flows between resources using social networks [1,2].

The event log is the raw material for running process mining algorithms. It contains all events used to construct a journey map and has as main attributes a case ID that represent one instance of the process (in healthcare field it could be the patient or hospitalization identification), the activity performed (e.g. “Perform triage”, “Discharge of patient”), and the date and time the activity was performed [1,3].

Several research studies have applied process mining techniques for healthcare and they are present in many medical fields such as cardiology, oncology, diabetes and clinical images [4][5]. For example, Forsberg et al. [6] performed a study to identify the reading chest radiograph process in a Picture Archiving and Communication System (PACS). Rattanavayakorn and Premchaiswadi [7] applied the “working together metric” of social miner techniques to understand the behavior of healthcare professionals when treating patients in a hospital in Bangkok. Mans et al. [8] applied the heuristics miner algorithm to discover and compare the stroke treatment process in four Italian hospitals. Also, they applied performance checking algorithms to discover the bottlenecks and performance indicators for the pre-hospital process. Huang et al. [9] presented a technique that creates a summary of the structure of clinical pathways. They applied the approach for four different diseases (bronchial lung cancer, colon cancer, gastric cancer, and cerebral infarction) discovering essential medical behaviors with specific execution order. Another study analyzed the control flow, organizational and performance perspectives of a gynecological oncology process in a Dutch hospital to obtain insights in the care flow [10].

We are performing a research study using process mining techniques to identify deviations and bottlenecks in a sepsis treatment process in a Brazilian hospital. We expect to identify actions (changes in the process) that can improve the sepsis treatment process. Our first step was the extraction of data from a Hospital Information System (HIS).

The aim of this work is to present the steps we followed to extract data from the HIS to perform the process mining work. The main purpose of this work is to share our experience regarding the data extraction and all the preparation work associated with this task. We hope that our experience can help other researchers to plan and execute the extraction of data for process mining research studies.

Methods
Below we present all steps we followed to extract the data from the HIS database.

Research definition
First, we defined the research questions we want to answer in our work:

1. Which is the AS-IS (current process) sepsis treatment process of the hospital? How does the hospital staff treat septic patients?
2. Which are the deviations in the process? Do professionals perform activities in a different order than defined in the normative sepsis treatment process?
3. Which are the bottlenecks in the process? Are there activities in the process that are taking more time than expected?
4. What is the workload of each professional in the hospital? Could a heavy workload cause delays in the process?
5. Which actions can improve the process? For example, we would like to identify changes in processes that might reduce the time it takes to administer initial antibiotic therapy.
The research questions were crucial to understanding which type of information we should extract from the database. For example, if we want to know the AS-IS process, we need to create an event log with the case identification (in our case it is the hospitalization identification), the activity type ("Registry of patient," "Triage," "Medical evaluation") and the completion date and time. If we want to analyze the workload of healthcare professionals then in the event log we need to add the health professional identification and extract information about all hospitalizations (not only of sepsis) to get a complete overview of health professionals tasks.

Mapping the process

In a first visit to the hospital, we analyzed the process the hospital applies for treating sepsis patients. We studied the hospital documents (sepsis guidelines and sepsis screening form), performed interviews with health professionals (2 physicians, 2 nurses, 2 nurse technicians, 1 quality analyst, 1 receptionist) and performed shadowing. The number of interviewers was four.

With all the information collected, we designed two models using the Business Process Model and Notation (BPMN). One model represents the sepsis treatment in the Emergency Department and the second the sepsis treatment in the Intensive Care Unit. The models represent the way health professionals should work when treating sepsis patients (normative models). Both models were updated and validated by the staff (4 physicians, 3 nurses, 2 nurse technicians, 1 quality analyst, 1 laboratory technician, 2 pharmacists) in a second visit to the hospital. The number of interviewers was five.

Figure 1 presents a simple model of a treatment process based in the Emergency Department model. We created it to help the reader to understand the extraction process. We linked the process activities to the next steps of the extraction. The process models and all the information collected from the hospital visits were very important to guide us in the selection of the attributes to collect from an immense amount of attributes presented in the database. For example, in the “1. Register Patient” activity we needed to know the time and date this event happened, and who performed the registration.

Identification of tables and fields of the database

When we started this research, we had no knowledge about the HIS database structure. We did not know from which tables and fields we should extract the data we needed to perform our research.

We asked the HIS development team to give us guidelines of which tables and fields we should collect all the information needed for our research. For this task, we created a spreadsheet containing all attributes that we needed to extract from the database based on the research questions and process models. We sent this spreadsheet together with the process models to the HIS development team and asked them to complete it.

We created two versions of the spreadsheet. The first one presented just one tab with the attributes needed by each step (activity) of the treatment processes. We denominate this tab as “Process Oriented”. Since it was difficult and confusing for the development team to fill it, we created a second version of the spreadsheet that contained a new tab, denominated “HIS Modules Oriented”, presenting the same attributes needed grouped by functionality of the system. We believe this module oriented view would help them to more easily associate the correct tables and fields of the database, since this is closer to their way of thinking (they do not necessarily know the clinical process that is followed, but they do know the modules used by the users). The main difference between the process and module tabs is the way that the attributes needed are organized. The “Process Oriented” tab presents the attributes grouped by each activity of the process, and the “HIS Modules Oriented” tab presents the same attributes grouped by each module of the HIS. To convert an item from the “Process Oriented” tab to the “HIS Modules Oriented” tab we identified the HIS module used by the clinical user to register the information (attribute) associated with the process activity.

Below we present both tab structures of the spreadsheet.

**Process oriented tab**

Table 1 presents a small sample of the first tab. It contains the following columns:

- Step name (A): name of the activity from the BPMN model. E.g., “1. Register Patient”, “2. Perform Triage” from Figure 1;

![Figure 1 - Simple BPMN model representing a treatment process in the emergency department (Note: this model was created as an elucidative example. It does not represent the exact and complete process as followed by the hospital)](image)
### Table 1 - Sample of process oriented tab of the spreadsheet (Note: all content data presented is fictitious. The idea is to present the structure of the table. The table presents a subset of the activities from Figure 1)

<table>

<td>blood_pressure</td>
<td>start_date</td>
</tr>
<tr>
<td>Electronic Health Record</td>
<td>Clinical Notes</td>
<td>GJV</td>
<td>NOTES</td>
<td>clinical_notes</td>
<td>exec_date</td>
</tr>
</tbody>
</table>

- **Attribute (B):** name of the attribute that we need from the process activity. E.g., from the triage step (2. Perform Triage) we need to extract the “temperature”, “blood pressure”, and “clinical notes”. One step name can have many attributes;
- **Responsible (C):** contact information of the responsible from the HIS development team who filled the spreadsheet line. This is important in case we had doubts about an attribute and thus we could contact directly the professional;
- **Table (D):** name of the table from the database where the field is located;
- **Table field (E):** name of the field from the database which contains the attribute information to be extracted;
- **Execution - date and time (F):** field from the database that contains the date and time that the action was performed in practice. E.g. “What was the time that the administration of the medication was performed for patient John?”;
- **Execution - role of user (G):** field from the database that contains the role of the professional who performed the action. E.g. “Nurse”, “Physician”;
- **Registry - date and time (H):** field from the database that contains the date and time that the attribute was entered in the system. E.g. “What was the time that the administration of the medication for patient John was entered in the HIS?”;
- **Registry - Role of user (I):** field from the database that contains the role of the professional who entered the attribute in the system. It is important to also retrieve this information as the person documenting the activity may not be the same as the one executing it (e.g. a doctor may perform an action and ask a nurse to document it in the HIS).

Columns from C to I should be filled by a professional from the HIS development team.

**HIS modules oriented tab**

Table 2 presents a small sample of the second tab. Columns B to I are the same from Table 1. The column “Step Name” (A) was replaced with “Module”. This new column presents the module name from the HIS that the information requested can be collected. E.g. “Patient registry”, “Electronic Health Record”, “Computerized Physician Order Entry”, “Imaging”, “Transfer of Patient”. Columns from C to I should be filled by a professional from the HIS development team.

Table 1 and Table 2 present the same content in different views.

**Filling the spreadsheet by the HIS development team**

We had one main contact person who was in charge to make the communication bridge with the development team. We sent him the spreadsheet and the BPMN process models with clear instructions on how to fill the spreadsheet. This procedure was performed with both versions of the spreadsheet. For the second version, we made it clear that the developers could choose any of the two tabs to fill. During the “filling of the spreadsheet” step, we kept direct contact with the development team to solve their doubts. When receiving a newly filled part of the spreadsheet, we immediately reviewed it to check if there was any white cell (cell not filled) and to check if the cells were with a coherent value (e.g. we asked for “prescription of medication” and we received “prescription Procedure” in the table name – this seems clearly to be not right). In the case of any problem identified, we contacted them to discuss and update the information.
Extraction of data

Based upon the fields identified in the previous step, SQL queries were written to extract the relevant fields from the HIS. For the extraction, we had to anonymize patient and hospitalization data to guarantee that no-one outside the hospital could identify a patient or link the extracted data with the hospital database. In this stage, to anonymize the data:

1. We encrypted any identification code like patient and health professional codes, chart number, hospitalization number, and prescription and administration ids;
2. Rather than storing the date of birth, we calculated the age of patients according to the admission hospitalization date. Patients older than 90 years old have a higher probability of being identified, thus all of these cases (> 90y) were classified as 90 years old;
3. Patients with a weight greater than 130kg also have a greater probability of identification, thus all of them (> 130kg) were classified as 130kg;
4. All extracted dates were shifted to a given time interval to further remove context which could lead to identification of patient data;
5. For text fields (like clinical notes and discharge summaries) we anonymized names of patients and professionals, specific numbers like chart, hospitalization, telephone, bed numbers.

Results

Regarding the “mapping the process” step (item 2 of the Methods section), several iterations were required to ensure we understood health professionals correctly and vice versa. For us it was a challenge to identify the commonalities and differences in treatment of different patient groups, as defined per severity, age, or list of comorbidities.

The “identification of tables and fields of the database” (item 3) was performed by 10 developers. All of them filled the module oriented tab. Only one developer filled both tabs. At the end we could successfully fill all cells of the spreadsheet. For this step, it was fundamental to have a single contact point to orchestrate the work.

Regarding the “extraction of data” step (item 4), we extracted 4,516 sepsis hospital encounters for a period of two years. We also extracted all (not only sepsis) 61,260 hospital encounters for a period of 2 months, to collect information regarding the workload of professionals (to answer our fourth research question). All the information is present in 57 tables and more than 600 fields.

Discussion

Mapping the sepsis processes was not an easy task, mainly because the communication between two different teams (health and information technology) is very challenging. The use of activity cards (cards filled by the hospital staff containing questions regarding each activity of the process; e.g. step description, notification process, tools used) helped us to understand better the processes. In addition, when validating the processes, the hospital staff could easily understand the BPMN notation (after an explanation of its elements). Thus, the BPMN models were important tools in the communication process between our team and the hospital staff.

Regarding the “identification of tables and fields of the database” step (item 3), all developers filled the module oriented tab. In our understanding, the process oriented tab was difficult for the development team to work with, since they had to search in all spreadsheet for the fields that they were responsible for. Indeed, for one step a clinical user may have to work in multiple modules, meaning that the attributes would be distributed over the system; and the development team is organized in such a way that sub-teams are responsible for individual modules. We believe that the module oriented tab helped them to easily identify the required fields.

It is important to mention that it was only possible to convert the process oriented view to the module oriented view since we had access to the hospital information system and we had shadowed clinical users during their use of the system. In addition, some of our researchers had previous experience in HIS architecture.

Columns F, G, H and I from the spreadsheet are used to collect the name of the fields regarding the time and user role that executed and registered an action. Professionals that execute actions are not necessarily the professionals who document them. These columns are very important for process mining research and they could lead to interesting insights when it is performed analyses using performance checking or social networks techniques. The executed time and user role might not always be available, and then the best alternative for process mining is to use the information of the registration of data, however taking into account the assumption made in subsequent analyses.

The extraction of non-structured fields is very important for process mining research. These fields may have some information that can be converted to process activities or they can help to find answers for some questions. For example, when a deviation is discovered in a treatment process it is important to understand why certain cases took this unexpected path. Some answers can be found studying clinical notes discovering for example, that patients that followed this deviation were in a critical stage of the disease. Friedrich et al. [11] discussed that it is estimated that 85% of the information of companies is stored in non-structure format and this source of information can be important for creating models. Most of process mining techniques need a very structured event log as input, and the use of natural language processing (NLP) techniques takes an important role for process mining research since it allows to convert unstructured data to concrete events.

Performing this work we could understand that to extract data from a HIS system is not an easy task: a lot of pre-work, knowledge about the treatment process but also about the HIS and its use, and collaboration with multi-disciplinary teams are needed. In general, the complete extraction process took us more time than we expected. Below we present the main reasons:

1. The HIS was not originally designed with the sepsis management pathway, and therefore it was a challenge for us to collect all the information that is relevant for the pathway and to identify where it was located in the system;
2. Limited time availability of the development team to support this initiative;
3. We had to deal with challenges to understanding the data structure of the system;
4. We had to guarantee that all patient and hospitalization information was properly anonymized by our scripts (especially in the non-structured fields);
5. We had limited time to run the scripts to not compromise the use of the system by the hospital.
Our initial attempts of process mining analyses encompassed the evaluation of conformance of a simple sepsis process [12]. It took us great effort to check the quality of the data and to create a simple event log, however this opened up subsequent analyses. Later we started a more complete analysis and we could identify the AS-IS sepsis treatment process in the emergency department, identify deviations, and identify bottlenecks. During this investigation, we had to deal with many challenges (e.g. creating specific events, filtering the right cases, dealing with missing timestamps) and it was very important to have the close participation of health professionals. The results of the research study are very promising. The next step is to validate the results with the hospital staff.

The investigation of healthcare processes is far from a trivial task. Healthcare processes tend to be very flexible and complex. Healthcare professionals play an important role providing health information, analyzing and interpreting results, getting insights and guiding to new analyses. Data scientists know methods and tools to organize and consolidate data in a proper way, and they can propose solutions to optimize resources and improve processes. To reconstruct, analyze and improve healthcare processes it is important to use smart approaches combining informatics/engineering techniques with healthcare knowledge. That means that data scientists and health professionals should work always together in all stages of a research to provide meaningful results. This approach should also be applied in the extraction phase.

We believe that the extraction steps we presented in this work (applying specific adjustments) could be applicable to other healthcare fields of research that uses, for example, data mining, simulation and neural networks techniques.

The extraction phase requires a lot of attention, active and clear communication with external teams, to guarantee that the extracted data will have quality and will allow to perform the research correctly. Getting the wrong data will result in wrong results for the entire research (“garbage in, garbage out” as they say).

Conclusions

With this work, we share our experience in extracting data from a hospital information system to perform process mining research. Any errors made in the extraction phase will have implications on subsequent analyses, thus it is essential to devote a great deal of attention in this phase, even if it is time-and resource-intensive to perform all activities, with the goal of ensuring high quality of the extracted data.

Acknowledgements

The authors thank all professionals from the hospital and the HIS development team for supporting us in the extraction phase.

The authors thank CAPES and Philips Research for funding the development of this work.

Development of a Deep Learning Algorithm for Automatic Diagnosis of Diabetic Retinopathy

Manoj Raju, Venkatesh Pagidimarri, Ryan Barreto, Amrit Kadam, Vamsichandra Kasivajjala, Arun Aswath

Enlightiks Business Solutions Private Limited – a Practo Company, Bangalore, Karnataka, India

Abstract

This paper mainly focuses on the deep learning application in classifying the stage of diabetic retinopathy and detecting the laterality of the eye using funduscopy images. Diabetic retinopathy is a chronic, progressive, sight-threatening disease of the retinal blood vessels. Ophthalmologists diagnose diabetic retinopathy through early funduscopy screening. Normally, there is a time delay in reporting and intervention, apart from the financial cost and risk of blindness associated with it. Using a convolutional neural network based approach for automatic diagnosis of diabetic retinopathy, we trained the prediction network on the publicly available Kaggle dataset. Approximately 35,000 images were used to train the network, which observed a sensitivity of 80.28% and a specificity of 92.29% on the validation dataset of ~53,000 images. Using 8,816 images, the network was trained for detecting the laterality of the eye and observed an accuracy of 93.28% on the validation set of 8,816 images.

Keywords:
Neural Networks (Computer); Diabetic Retinopathy; Artificial Intelligence.

Introduction

Diabetic Retinopathy (DR) is one of the avoidable causes of blindness. Approximately 33% of people in the USA living with diabetes develop some stage of DR, out of which 10% evolve to a vision-threatening form of the disease [1]. Detecting DR is a time-consuming procedure that requires a trained clinician to evaluate digital funduscopy retinal images. Hence, early and quick diagnosis is a critical aspect in treatment of DR.

Computer Vision (CV) works around building Artificial Intelligence (AI) systems by interpreting information from digital images. Deep learning algorithms have the potential to produce such systems, since they do not revolve around handcrafted features. Convolutional Neural Networks (CNNs), a branch of Deep Learning, is the state of the art algorithm for image classification [7, 9]. From the 1970s and onwards, neural network based approaches were built for pattern recognition. They did not gain prominence due to their ineffectiveness to handle images of a high resolution.

CNN architecture is designed to take advantage of the 2D structure of an input image. It uses two main concepts, namely, local receptive fields and pooling. In CNN, the connections are localized to small regions called local receptive fields, and each input pixel, in turn, is not connected to all the hidden neurons. CNNs also contain pooling layers which help generate translation of invariant features and simplifies the information from the convolutional layer.

Despite having many attractive features, CNNs are still expensive to apply in high-resolution colored images. Current Graphical Processing Units (GPUs), paired with the highly-optimized implementation of 2D convolution are powerful enough to train large datasets of high-resolution images [5].

The hypothesis that CNNs have the potential to improve the efficiency and speed of DR screening, and thereby help prevent visual loss and blindness from this destructive disease, is the basis of this work. The other interesting work is the building of a second convolutional net which detects the laterality of the eye. We were unable to locate any other paper which identifies the laterality of the eye using fundus images along with the detection of the DR stage. Hence, our system is complete in a way that, when multiple images of a patient are uploaded, the system:

- Detects the laterality of the eye (Left vs Right)
- Detects the stage of DR for each eye
- Provides a diagnosis report for each eye

Few research projects have been conducted on the automatic detection of DR, but most of them were carried out with Support Vector Machines (SVMs) or fully connected neural networks. Gardner et al [2] used a neural network to detect diabetic features in fundus images. A fully connected neural network was trained on 147 diabetic and 32 normal fundus eye images. The blood vessels, exudates and hemorrhages were detected with an accuracy of 91.7%, 93.1% and 73.8% respectively.

Usher et al [3] in their work built a system using macula centered color retinal images from 1,273 patients, out of which 500, were used for training the model. Image preprocessing, identification of normal structures and candidate lesions, extraction of candidate lesion features were performed to identify if a patient was normal/abnormal. The trained system was evaluated using the remaining images and observed a sensitivity of 95.1% and a specificity of 46.3%.

Pratt et al [4] in their work managed to use a CNN based approach for automatic detection of DR on the Kaggle dataset (www.kaggle.com) comprising 80,000 fundus eye images. They observed a sensitivity of 30%, specificity of 95% and a 75% accuracy. This is claimed as one of the first papers on classifying DR into five stages.

Google (Gulshan et al [6]), in its vision of deep learning augmented healthcare, has trained a CNN indetecting referable DR using 128,175 training images which were labelled by 54 licensed ophthalmologists and trainees in a massive exercise organized for annotating the dataset. They achieved an average sensitivity of 92.72% and specificity of 95.97%. While the numbers achieved are better here, it requires massive datasets and considerable investments.
This paper provides an overview of the dataset, hardware and software configuration used, architecture of the CNN, the way the model was trained and the observed results with a note on future possibilities.

Methods

DR progresses through four stages, namely: mild, moderate, severe nonproliferative DR (NPDR) and the advanced stages of proliferative DR (PDR). During mild NPDR, small areas of balloon-like swelling in the blood vessels of the retina called microaneurysms occur. As the disease progresses, multiple microaneurysms, hemorrhages, venous beading and cotton wool spots (CWS) occur which make the patients lose their ability to transport blood to the retina, termed as moderate NPDR. The diagnosis is severe NPDR when the abnormalities intensify and are seen on multiple quadrants of the eye and the patient has either of the following: diffuse intra-retinal hemorrhages and microaneurysms in 4 quadrants, venous beading in ≥2 quadrants, or intraretinal microvascular abnormalities (IRMA) in ≥1 quadrant. As the disease progresses, new blood vessels grow and this stage is termed PDR. The new blood vessels are fragile and are prone to bleeding and cause retinal destruction.

Dataset, Hardware and Software

EyePacs, a telemedicine platform which helps prevent vision impairment from DR (http://www.eyepacs.com/), provided the datasets used for training and model validation. Eyepacs uses telemedicine to build sustainable DR screening programs in community clinics. It links primary care providers with ophthalmologists, helping early detection of sight-threatening cases of DR. The data was accessible via the Kaggle website.

The distribution of each type of image used for training from the dataset is shown in Table 1. A few of the eye images can be seen in Figure 1.

Due to the challenges faced during the CNN model training, namely, long training duration and the daunting hyper-parameter tuning, only 35,126 out of 88,702 images are used. The images were of different resolution, cameras, angles, lighting, noise and artifact levels (Figure 2). The biggest challenge the algorithm had to encounter was to generalize all these cases and avoid overfitting.

The images range up to 4500 x 3500 pixels having 3 channels (R, G, B). Processing such huge images on a CNN required a high-end GPU. Two machines were used to train our model.

- NVIDIA GTX980Ti GPU containing 2,816 cores with a video memory of 6GB. The CPU contains an intel core i7 processor with 16GB memory and an Ubuntu OS.
- Amazon EC2 instance containing NVIDIA GPU with 1,536 cores, a video memory of 4GB and an Intel Xeon E5-2670 processor with 15GB memory.

The software used were, Python, NumPy and Theano (www.deeplearning.net/software/theano/), in combination with the cuDNN library. For convenience, we used Lasagne (www.lasagne.readthedocs.io/), a library built on top of Theano to build and train CNN. Preprocessing of the images was done using the Python Imaging Library (PIL) and the scikit-image was used for the augmentation process.

Diabetic Retinopathy Prediction

Data Preprocessing

The images were captured using different variants of fundus cameras, each having their unique recording method, due to which the exposure and lighting varied. In addition, images were also too large to be trained with CNN directly. The following pre-processing steps were followed:

- Cropping the image – The images were cropped by distinguishing the foreground from background.
- Resizing the image – The images were resized to 128x128, 256x256, 512x512, 768x768 and 1024x1024 pixels.
• Normalizing the channels – ZMU (Zero Mean Unit Variance) was performed on each channel.

Data Augmentation

Data augmentation was performed randomly on every image over all epochs. The data augmentation steps performed were:

- Rotation – Images randomly rotated between 0 and 360 degrees
- Translation – Randomly shifted between -40 and 40 pixels
- Zoom – Randomly stretched between (1/1.2, 1.2)
- Flip – Randomly flipping of images
- Image centering

The output size after data augmentation were 112x112, 224x224, 448x448, 672x672, 896x896 pixels for 128x128, 256x256, 512x512, 768x768 and 1024x1024 pixel images respectively.

Network Training

Deep learning is the process of training a neural network to perform a given task [6]. The deep learning algorithm (CNN) computes DR severity by analyzing the pixel intensities over each channel separately. Although the algorithm does not detect the lesions in the eye images explicitly, it learns to recognize them using the filter weights.

The training set comprised of 35,126 images for which the labels were provided by the Kaggle team. The problem was treated as a regression problem (with network output threshold at 0.5, 1.5, 2.5, 3.5) to calculate the accuracy, sensitivity and specificity. The network architecture for DR prediction is shown in Table 2. The network used in this work is inspired by Oxfordnet [7].

</table>

Input - holds the raw pixel values of the image. Here, an image having the width of 448, height of 448, and three color channels R, G, B (depth = 3).

Convolution – computes a dot product between the filter weights and a small region they are connected to in the input volume.

Maxpool – performs a down sampling operation along the width and height. A maxpool of 3x3 will obtain the maximum of the local region of size 3x3.

RMSpool – also performs a down sampling operation. It calculates the root mean square (RMS) value of the local region.

Dropout – used to prevent overfitting. Nodes were randomly dropped with a probability, p = 0.5.

Fully connected – each neuron in this layer will be connected to all the inputs from the previous layer.

Feature pool – It is an activation function which is the max of the inputs. In our case, we use a pool size of 2.

There are about 12 million learning parameters for the network. The parameters are randomly initialized using orthogonal weight initialization. The mean squared error objective between the known label values and the network output for each image was calculated and in turn used to modify the weighting parameters during a back propagation step to reduce the training loss. This process was repeated for every image in a training set over 250 epochs with data augmentation at each step. The parameters calculated were general enough to work on new fundoscopic retinal images. The classes in the dataset were highly imbalanced (Table 1) due to which the CNN tends to bias towards the majority class. For training, a resampling of the images was done in a way that all classes were present in equal proportion. The weights of the rare classes were gradually reduced that left us with a final resampling of weights of 1, 2, 2, 2, 2 for normal, mild, moderate, severe NPDR and PDR respectively. The network training started with a batch size of 32, and a learning rate of 0.005. The learning rate was constantly decreased as the number of epochs grew and ended up with a learning rate of 0.00005. A leaky rectified linear unit (ReLU) of 0.01 was used after every convolutional and fully connected layer. An L2 regularization with a factor of 0.0005 was applied on every layer.

For spatial invariance, RMS pooling was used at the last pooling stage of the network. The output of the RMS pool layer was also used as features for the blending network (Table 3) which was trained to improve the prediction results. To increase the quality of the features, feature extraction was repeated up to 50 times with different augmentations per image, and the mean and standard deviation of each feature was used as input to the blending network.

Total Features after RMS pool layer = (Number of filters * Output size after RMS pool) * 2 = (512 * 4) * 2 = 4096

All features were normalized to have a zero mean and unit variance and were used to train a simple fully connected network. A ReLU of 0.01 was introduced after each fully connected layer and an L2 regularization with a factor of 0.005 was applied to every layer. The batch size used was 128 with a mean squared error objective.

**Laterality Detection**

**Data Preprocessing**

Laterality detection prediction used the same preprocessing techniques with uncropped images. The images in the dataset were at times inverted, which needed to be identified to detect the laterality (Figure 3). The inversion of the image is detected by the absence of a notch.

![Figure 3 – (a) Non-inverted image (b) Inverted image](image)

**Data Augmentation**

The same data augmentation process, described for DR prediction was performed, except that the images were not flipped.

**Network Training**

The training set comprised of 8,810 images for which the labels were provided by the Kaggle team. The laterality detection challenge was treated as a regression problem with a network output threshold at 0.5 to calculate the accuracy.

The network architecture for laterality detection is shown in Table 4. The number of learning parameters for this network are about 31 million.

The training process for the network remained similar to the DR prediction network in the weight initialization, loss function definition, regularization technique, data augmentation steps at each epoch and the number of epochs for training. The images used for training contain 50% for the left eye and 50% for the right eye and thus did not require resampling strategies.

A batch size of 32 was used to train the network. The training of the network was started with a learning rate of 0.003 (reduced as the number of epochs grew). Usage of ReLU remained the same as the DR prediction network.

RMS pooling was used for spatial invariance and feature extraction for the blending network (Table 3). The feature extraction was repeated up to 5 times with different augmentations per image and used the mean and standard deviation of each feature as input to our blending network.

The total number of features used for this network remained 4096.

**Application Overview**

An authenticated Java application was built, which accepts patient info (patient name and patient id) and multiple images of the patient and provides a downloadable diagnosis report. The report contains the laterality of the eye, the stage of DR for each image, the follow-up advice and provides an overall diagnosis for each eye.

**Results**

Image characteristics used for training the network for DR prediction have been summarized in Table 1. Out of the 35,126 images used for training, 9,316 images (26.52%) had DR. The validation set consisted of 53,126 images (Table 5), of which 13,593 images (25.59%) had DR and graded between 0 and 4 (0 – no DR, 1 – mild NPDR, 2 – moderate NPDR, 3 – severe NPDR, 4 – proliferative DR). To train the network, 4x4 filters were used, which observed a specificity of 92.29% and a sensitivity of 80.28%. The confusion matrix of the classification results can be seen in Table 6.

Table 6 – Confusion Matrix (DR Prediction)
From Table 6, we can see that there are 10 images which have been totally rejected by the system and classified as normal. Also, 23 images which were normal have been classified as proliferative DR. The main cause for these misclassifications are the noise in the images (Fig 4). These images skew the prediction results.

![Image](image.jpg)

**Figure 4 – Noisy Image Labeling**

The confusion matrix for laterality detection is shown in Table 7. A total of 8,810 images were used to train the model which contains 4,405 right eye and 4,405 left eye images. The laterality of the eye was detected with an accuracy rate of 93.3% in a validation set containing 4,408 right and 4,408 left laterality of the eye was detected with an accuracy rate of 93.3% in a validation set containing 4,408 right and 4,408 left images.

The exciting aspect of the network is its ability to classify thousands of images every minute which helps in providing a real-time diagnosis for DR.

**Discussion**

The network was trained using filters of size 3x3, 4x4, 5x5 and 7x7 for DR prediction and laterality detection. The best results were observed with 4x4 filters for DR prediction and 7x7 filters for laterality detection. The smaller filter size was better suited for DR prediction due to the lesions in the images which were of smaller size, such as, microaneurysms. In contrast, laterality detection requires identification of the direction of the blood vessels from the disk for which larger filter sizes suited better. Categorical cross entropy, the objective function used for classification, followed a diverging trend as the epochs progressed. Hence, regression was a better suited option for training the model. The features generated from multiple networks were ensemble but did not observe substantial change in the prediction results. Several image pre-processing strategies, such as edge enhancement, image smoothing, etc. were performed to see if learning could be improved, but neither of them provided better prediction results. Laterality detection was also observed to be inaccurate when the inverted images were mixed with non-inverted images. A dip in the laterality detection accuracy was also seen for images with no disk and macula.

The classification of Diabetic Macular Edema (DME) is an important addition required in the system. We have collaborated with ophthalmologists in getting DME annotated on the image. Deeper neural networks such as Residual Networks [8] or a variant of GoogLeNet [9] needs to be analyzed on the dataset.

**Conclusion**

We observed high sensitivity and specificity in the detection of DR staging, as well as laterality of the eye from funduscopic retinal images, using a CNN based algorithm. This demonstrates the potential of CNNs to automatically classify fundus images based on laterality and severity in real time. Further research is warranted on automatic classification of DME. Other parameters such as patient demographics, past history, family history etc. need to be analyzed to improve the prediction accuracy. Criteria need to be incorporated to filter out images with poor quality. Lesions on fundal images must be identified to help ophthalmologists with their diagnoses. With the incorporation of the improvement areas identified, detection of DR staging and laterality detection of the eye from funduscopic retinal images would be more robust.

We present a unified framework for envisioning PHI. We men and the elephant. interpreted, and applied by the researchers, policy makers and practitioners. In the following, we describe the framework, selective frameworks in the literature, some explicitly articulated and others implicitly incorporated. The framework is none in the literature now. It draws upon many simple and frameworks developed from other perspectives, although there recognize the possibility of other equally plausible article ‘the’ in characterizing the framework. In doing so, we emphasize the indefinite article ‘a’ instead of the definite taxonomies.

Abstract

We present a unified framework for envisioning precision healthcare informatics (PHI). The framework, presented as a high-level ontology, deconstructs PHI into six dimensions derived from the informatics and healthcare disciplines—the structure, function, and semiotics of informatics, and the stakeholders, care, and value of precision healthcare. Each dimension is articulated as a taxonomy of its constituent elements. Thus, the framework encapsulates the combinatorial complexity of PHI and can be used to describe its 37,800 potential components in natural English. The framework will help envision PHI systematically, systemically, and symmetrically in contrast to the often simplified, selective, and skewed approaches. The framework can be used to map the state-of-the-research, -practice, and -policy on PHI, discover the gaps within and between the states, and develop a roadmap for the future. It can be scaled and extended as PHI evolves by adding dimensions, and extending/ refining the taxonomies.

Keywords:
Precision Medicine; Medical Informatics

Introduction

Informatics will be key to realizing the full potential of precision medicine and solving the problems likely to emerge from it [1]. Many authors have highlighted the characteristics of informatics required for the purpose [2-7]. However, there is no unified framework to envision precision healthcare informatics (PHI). We need to make the PHI ‘elephant’ visible like the allegorical wise sage does in the story of the six blind men and the elephant.

We present a unified framework for envisioning PHI. We emphasize the indefinite article ‘a’ instead of the definite article ‘the’ in characterizing the framework. In doing so, we recognize the possibility of other equally plausible frameworks developed from other perspectives, although there is none in the literature now. It draws upon many simple and selective frameworks in the literature, some explicitly articulated and others implicitly incorporated. The framework is both systemic in its coverage and systematic in its development. Its outlook is symmetrically neutral with respect to the value of precision healthcare—recognizing that the value could be both positive and negative. It is presented using structured natural English and can be easily understood, interpreted, and applied by the researchers, policy makers and practitioners. In the following, we describe the framework, discuss its application, and conclude with a roadmap for future research on the topic.

Methods

PHI is a complex domain. The challenge of constructing a unified framework for designing, developing, and applying informatics to precision healthcare is to construct one which is logical, parsimonious, and complete. It must be logical in the deconstruction of the domain, and parsimonious yet complete in the representation of the domain. It must be a closed description of PHI in its entirety yet adaptable to the evolution of the domain. We represent the combinatorial complexity of PHI using an ontology.

The ontology represents our conceptualization of the PHI domain [8]. It is an “explicit specification of [our] conceptualization,” [9] and can be used to systematize the description of the complexity of PHI domain knowledge [10]. The ontology organizes the terminologies and taxonomies of the PHI domain. “Our acceptance of [the] ontology is… similar in principle to our acceptance of a scientific theory, say a system of physics; we adopt, at least insofar as we are reasonable, the simplest conceptual scheme into which the disordered fragments of raw experience can be fitted and arranged.” [11] It is a domain ontology that “helps identify the semantic categories that are involved in understanding discourse in that domain.” [12] Ontologies are used in computer science, medicine, and philosophy. Our ontology of PHI—unified framework—is less formal than computer scientists’, more parsimonious than medical terminologists’, and more pragmatic than philosophers’. It is designed to be actionable and practical, and not abstract and meta-physical. Its granularity matches that of the discourse in research, policy, and practice, and facilitates the mapping and translation of the domain-text to the framework and the framework to the domain-text. It is also adaptable. In the concluding section of the paper we will discuss how the framework can be scaled and zoomed (in and out) to adapt to changing requirements.

The framework is shown in Figure 1. Three illustrative components derived from the framework are shown below it with an example of each. The elements of the framework are defined in the glossary in Appendix A. In the following subsections, we describe the construction of the unified framework and argue about its validity. In the next section, we will articulate the application of the framework.
Informatics can be defined by its Structure, Function, and Semiotics—a commonly used deconstruction. Thus:

Informatics = Structure + Function + Semiotics

There are many ways of defining the Structure of an information system. The traditional taxonomy is: hardware, software, networks, people, policies, and procedures. We have modified the taxonomy for two reasons. First, the emergence of technologies like cloud computing and IoT (internet of things) [13] have blurred the lines between hardware, software, and networks. They constitute the Infrastructure of PHI. Second, there is likely to be multiple information systems competing and collaborating with each other in precision healthcare. They need an Architecture to work effectively. [Note: Elements of the framework in the text are capitalized.] The Systems includes the technical and social systems constituting PHI. The Services are those provided by PHI; the Policies and Processes govern the operation of PHI; and the People are the users and operators of PHI. Thus:

Structure ⊂ (Architecture, Infrastructure, Systems, Services, Policies, Processes, People)

The traditional Functions of an information system are to Acquire, Store, Retrieve, Process, and Distribute. To this taxonomy, we have added Delete—a hotly debated issue often discussed in relation to the “right to be forgotten” [14]. It is an issue which has become critical in the context of healthcare information privacy and security [15]. Usually these functions are sequential and iterative. Thus:

Function ⊂ (Acquire, Store, Retrieve, Process, Distribute, Delete)

Semiotics is the repetitive cycle of generation and application of knowledge. The taxonomy of the Semiotics dimension is commonly used [16]. They correspond roughly to morphologics (data), syntactics (information), semantics and pragmatics (knowledge) [16]. Sometimes Wisdom is included as a fourth element of the taxonomy. It is still an ephemeral construct and hence not included in the present taxonomy. They are generally sequential and iterative. Data is translated into Information and Knowledge in the generation phase, and from Knowledge to Data in the application phase.

Semiotics ⊂ (Data, Information, Knowledge)

Precision Healthcare

There is no universally accepted definition of precision healthcare. It is sometimes used synonymously with personalized healthcare. At the core of these two constructs is the recognition of individual differences in the manifestation of illness, wellness, care of illness, and continuation of wellness. Thus, precision healthcare is the personalization of care to an individual based on his or her characteristics, instead of on the basis of the person’s inherited population characteristics [17]. The reference population may be based on one or many enduring traits of an individual such as genes, age, gender, race, ethnicity, geographical region, and culture. They may also be based on transient states of an individual such as psychological, economic, physical, and social state. Thus, the characteristics considered for precisely targeting healthcare may be may be a person’s genetic, physical, psychological, cultural, economic, social, and other characteristics. Although the term is frequently used to describe the use of genetic characteristics for personalizing healthcare, its scope is far broader. At its core, it recognizes the importance of simultaneously considering a person’s similarity with a population and his/her differences with the population [17; 18].

Precision medicine is far more semiotics intensive than generalized medicine. Data, information, and knowledge have to be generated and applied at a far finer level of granularity. The structure and function of informatics have to be designed to support the scaling of requirements, qualitatively and quantitatively, by orders of magnitude. Even if the dominant focus is on genetic precision, the care’s life, psychological, economic, social, cultural, and ethical values will determine the efficacy of care. While approach to health and disease is based on population evidence, treatment is often at the individual level requiring a multitude of factors to consider in ensuring a favorable outcome [19].

Further, the precision care could be delivered at different stages of illness (or its absence). It could be to avoid, prevent, treat, cure, or eliminate the illness [20]. The value profile and the informatics requirement for each stage would be different.

There are many stakeholders in personalized healthcare—as in any healthcare. We can broadly classify them as recipients,
providers, payers, researchers, pharmaceuticals, governments, and regulators. The recipients could be further classified as individuals, families, communities, and societies. The stakeholders’ perspective on different type of care and their value can vary significantly. Consequently, their requirement of informatics too will vary significantly.

Thus, we can deconstruct precision healthcare as follows:

Precision Healthcare = Stakeholder + Care + Value

Stakeholder ∈ (Recipients, Providers, Payers, Researchers, Pharmaceuticals, Governments, Regulators)
Recipients ∈ (Individuals, Families, Communities, Societies)
Care ∈ (Avoidance, Treatment, Cure, Elimination)
Value ∈ (Life, Psychological, Economic, Social, Cultural, Ethical)

The dimensions of the framework are arranged left to right with adjacent words/connectors such that the concatenation of an element from each dimension with adjacent words/connectors creates a natural English sentence illustrating a potential component of PHI. The components and fragments (incomplete components) define the domain.

At the most detailed level, the framework encapsulates 37,800 (7*6*3*10*5*6) potential components of PHI. It encapsulates the ‘big picture’ of the domain and helps visualize the combinatorial complexity of PHI. Three illustrative components and examples are listed in Figure 1. A component may be instantiated in many ways in research, policy, and practice. It may also be instantiated fully or partially (as a fragment). Obversely, a research, policy, or practice may be mapped to a component, a fragment, multiple components, and/or multiple fragments.

The validity of the framework in Figure 1 will determine how well it captures and represents PHI. We draw upon the traditional constructs of validity commonly used in social sciences [21] to justify the face, content, semantic, and systemic validity of the framework of PHI similar to justifying the validity of mHealth ontological framework [22].

Discussion

The proposed framework is a lens to study the anatomy of PHI. For a complex domain like this, there may be other lenses to study the same and each can be encapsulated by a different framework. They will provide different perspectives. We will discuss the present one in detail.

We have discussed the individual dimensions (columns) and elements of the framework while describing the construction of the ontology. Multiple elements of a dimension may coexist independently but may also interact with each other. Thus, many values, types of care, and stakeholders may coexist and interact with each other. Knowing the independent and interacting elements is critical to understanding PHI. The framework can help systematically study and manage the elements’ interdependence and interactions. In the following, we discuss how the ontology can be used to systematically study the interaction of: (a) elements within a dimension, (b) elements across two dimensions, and (c) elements across multiple dimensions, to understand the anatomy of PHI at different levels of granularity and complexity.

Combinations Within a Dimension

All possible first-order interactions among the elements of a dimension can be mapped into a table of the dimension with itself. Such a mapping can reveal strong interactions (both constructive and obstructive), weak ones, absent ones, and unexpected ones among the elements. It can also highlight the direction of the interaction—one-way (a to b OR b to a), and two-way (a to b AND b to a). In the following, we will discuss some possible insights from such a mapping of each dimension.

Value

The value of life is central to healthcare and the physicians are sworn to preserve life by their Hippocratic oath. Yet, with medical advances that have led to precision healthcare, one is compelled to consider the other values. How does it affect the recipients’ psychological quality of life? Their economic wellbeing? How is it viewed in their social and cultural milieu especially, for example, in the context of terminal illnesses and views about death and dying. Last, the ethics of all of the above. Thus, although some of the values can be identified separately they interact with each other strongly. The informatics for precision healthcare should provide the data, health records, and knowledge to understand and manage the multiple values.

Care

The Care elements are quasi-sequential. One seeks to prevent a condition that cannot be avoided; to treat the one that cannot be prevented; to cure what is treated; and to eliminate what has been cured. Looked at differently, the precision healthcare strategy for a stage of care will depend on the strategies for the prior stages, and will affect those for the subsequent stages. However, sometimes a stage or two may be skipped. Thus, the management of semiotics (data, healthcare records, and knowledge) for care has to be cumulative and supported by the appropriate informatics structure and function.

Stakeholders

The stakeholders act independently and interactively. Their interaction may be cooperative and conflicting. An interaction matrix of the stakeholders will help map the dynamics which can affect the value of PHI. A frequent source of conflict among stakeholders may be the absence of a common base of data, information, and knowledge about precision healthcare. PHI can partially help reconcile the differences by developing a common repository on a universally accessible platform. Such a platform can make the semiotics transparent, even if it does on reconcile the differences.

Semiotics

Data, Information, and Knowledge are bi-directionally sequential. From Data to Knowledge during generation, and in the opposite direction during application. Precision healthcare will require repeated cycles of generation and application of knowledge. Errors in data can lead to errors in knowledge and subsequent errors in actions resulting from the application of that knowledge. The errors may be perpetuated and amplified in subsequent cycles unless they are identified and attenuated. Similarly, valid data can lead to valid knowledge and appropriate action. These too may be perpetuated and amplified in subsequent cycles unless they are overlooked and attenuated. A challenge in the design of PHI is to attenuate the dysfunctional cycles and amplify the functional ones.
Function

The Function elements are strictly sequential—Storage follows Acquisition, Retrieval follows Storage, and so on. They are also repetitive. Consequently, the impact of PHI choices will be propagated from Acquisition to Deletion. For example, inclusion of data on Communities as Recipients in the specification of the system can help acquire data about it and process the same. On the other hand, ignoring community data will result in the inability to personalize healthcare to the community based on information about and knowledge of variations in health in the community. The effects of inclusion/exclusion will be propagated to the subsequent cycles, unless corrected. The inclusion/exclusion of the right data is as likely to be propagated as the inclusion/exclusion of the wrong data.

Structure

The Structure elements are generally hierarchical. Architecture defines the Infrastructure, Infrastructure defines the Systems, and so on. As such the lower-level elements are likely to inherit their properties from the higher ones. Although possible, it is less likely that the properties of the lower elements will be propagated to the higher ones. Thus, elements of PHI which are part of the Architecture will likely permeate the Policies, Processes, and People. However, elements of PHI inserted at the lower levels in Policies, Processes, and People are less likely to be propagated into the Architecture and Infrastructure; in fact, such propagation is likely to be resisted.

Combinations between Dimensions

In addition to interactions among the elements of a dimension, all possible first-order interactions among the elements of a pair of dimensions can be mapped into a table. Such a mapping can reveal strong interactions (both constructive and obstructive), weak ones, absent ones, and unexpected ones between the elements of the two dimensions. It can also reveal the direction of the interaction—one-way (a to b OR b to a) and two-way (a to b AND b to a). With the six dimensions of the framework there are fifteen possible pairs. In the examples in the previous section we have some possible interactions between many of the dimensions.

Conclusion

The proposed framework fills an important gap in the literature on PHI. It defines the domain of PHI systematically, systemically, and symmetrically (by being effect-neutral and hence including both positive and negative effects of PHI). All researchers, policy makers, and practitioners may not universally agree with the framework even though a systematic attempt has been made to include all the key elements from the extant literature. The disagreements can be accommodated by extending the taxonomies by including overlooked elements, reducing them by eliminating redundant elements, coarsening them by combining elements, and refining them by dividing the elements.

The scope of the framework can be broadened by adding absent dimensions and narrowed by deleting present dimensions. For example, a Temporal dimension may be added with three elements—Short, Medium, and Long term as a dimension of Precision Healthcare. Inclusion of this dimension will compel consideration of the Care x Value combinations in each of the time horizons by the stakeholders, rather than in the aggregate. It would also require information system support with finer granularity, lead times, and response time. On the other hand, the Semiotics dimension may be eliminated if Data, Information, and Knowledge for PHI are aggregated and labeled Information. These properties of scalability (extensibility, reducibility), and zoomability (up and down) make the unified framework versatile to study the domain.

The framework of PHI presented in this paper makes visible the combinatorial complexity of an important and timely topic in healthcare informatics. The ontology is logically constructed but grounded in the theories prevalent in the domain and relevant disciplines. The dimensions are logically specified and not empirically generated. They are deduced from the definition of the domain. Thus, it helps us address the problem of PHI in its entirety rather than fragmentarily. A common tendency in research into a complex domain is to highlight the complexity of the whole domain and then to address selected parts of the domain, hoping that somehow the parts will fit together and enlighten the whole problem. Unfortunately, very often, even after an extensive body of research is accumulated the problem is not illuminated in its entirety. The proposed framework and the mapping of the literature will help obviate the problem.

The framework is a lens to study PHI. There may be other lenses to study the same. Each can be described by an ontology. Each ontology is constructed from the theory and practice of the domain. The logical construction of our ontology minimizes the errors of omission and commission. For example, inclusion of the Stakeholder dimension compels the researchers to explicitly consider different stakeholders. Without consideration for the Stakeholder dimension (error of omission), researchers will be unlikely to advance the field of PHI. By the same token, it may specify PHI (error of commission) stakeholders (for example, Societies) not relevant in a particular context and which should be removed.

Last, the framework is a multi-disciplinary lens. The Structure, Function, and Semiotics dimensions are drawn from the information systems and knowledge management literature; the Stakeholders, Care, and Value are from the healthcare management and related literature. The framework compels the user to analyze the issues surrounding PHI and synthesize solutions by drawing upon these disciplines. One may construct other frameworks/lenses and study the subject from a different perspective.

The framework of PHI can advance the state-of-the-research in the domain. It can be used to systematically identify the ‘bright’, ‘light’, and ‘blind/blank’ spots in the research on the topic. The state-of-the-research can be analyzed by mapping the corpus of research onto the framework. The mapping can be done by identifying categories within each dimension articles in the corpus fit into. An article may be mapped to one or more categories in one or more dimensions, or none. Such mapping will highlight the bright, light, and blind/blank spots in PHI research. The map will help researchers visualize the landscape of the PHI enabling them to set appropriate research direction. Similarly, the state-of-the-practice can be analyzed by mapping current practices onto the framework. The resultant mapping will identify the focus of and gaps in the inclusive practices. The comparison of the ontological maps of research and practice will bring to fore the alignment between the two states, or lack thereof. The gaps between the two states should inform researcher, practitioners, and policy makers alike the need for action to advance research and policy. In other words, the maps can be used as a roadmap for PHI research and practice. It can illuminate the ‘big picture’ of the domain.
The landscape of PHI will change over time with emerging technologies. The ontology-based road map can be amended to reflect the changing landscape. New categories and dimensions can be added, obsolete ones discarded, and existing ones modified. Changes can also be introduced by the shifting focus in the domain. The finer levels of dimensions and elements can be added to the framework to reflect the greater focus on certain dimensions or categories. On the other hand, sub-categories and -dimensions can be collapsed to echo their diminishing importance in the domain. The shifting focus and direction of research and development can be monitored by analyzing the snapshots of the ontological maps over time. The unified framework can help visualize the past and present of the domain, and envisage its future.

“Precision medicine has the potential to profoundly improve the practice of medicine. However, … fundamental changes are needed in the infrastructure and mechanisms for data collection, storage and sharing. This will create a continuously learning health-care system with seamless cycling between clinical care and research. … The building blocks for such a system are already forming and they will accelerate the adoption of precision medicine.” [23] The proposed unified framework for PHI will help envision the roadmap for achieving precision healthcare’s full potential.

A Virtual Earth Model of the Dementias in China

Hamish Robertsona, Nick Nicholasb, Jo Travagliaa, Andrew Hayenc, Andrew Georgioud

Abstract
This developmental project was undertaken to explore how applying spatial science analysis and visualisation methods might inform societies undergoing significant structural and demographic change. China is rapidly transitioning to an aged society. It already exceeds all other countries in its population aged 65 years and older. Dementia is closely correlated with ageing and intersects with a variety of physical and cognitive disabilities. Information dashboards are a growing part of health and social policy data environments. These visual data applications increasingly include mapping capabilities. In this paper, we explore the utility of a geographic modelling approach to exploring the complex nature of population ageing and the dementias in China.

Keywords:
Geographic Mapping; Ageing; Dementia

Introduction
China’s population is ageing rapidly. Current estimates indicate an increase in total population from 1.304 billion people in 2010 to 1.402 billion in 2020 (https://populationpyramid.net/china/). In 2015 China’s 65+ population overtook the entire population of Japan, which is still the most aged society on earth. And further to this, China’s ageing is expected to accelerate from around 2025 as both the overall 65+ group increase and the more dependent oldest old cohorts, aged 80 and over, grow faster still [1]. Average life expectancies increased from just under 72 years in 2000 to almost 76 in 2014 in what is a continuing upward trend (http://data.worldbank.org/). China may even exceed Japan as the most aged society by 2030. Figure 1 depicts the rapid expansion and changing composition of China’s ageing population. In particular, by 2050 almost one third of the 65+ population will be 80 years and over. This means that the ‘old-old’ will be a major feature of China’s population ageing, as they are in Japan and many European countries. This is a positive outcome for the population given that it reflects rising life expectancies for a huge group of people (120 million by 2050). However, this group is also much more likely to experience a dementia in association with a variety of other age-related health problems, meaning that the prevalence and incidence of sub-acute and acute will conditions rise proportionally.

Population ageing is generally associated with rising rates of chronic disease and disabling conditions – including both physical and cognitive disabilities. As a result, China can expect rapid expansion in the need for age-related care of all kinds. The dementias, in particular, are likely to prove very challenging because they impair cognitive capacities and intersect with other acute and chronic health problems in older people. In addition, China is a very large country with major structural and resource differences between urban and rural areas. In other words, the geography of ageing in China will be an important consideration in responding to these pressing demographic trends.

This project takes these issues as a starting point and examines them from a spatial health informatics perspective. Health informatics is a growing sector for research and investment globally in a process driven by demographic changes, urbanisation and systemic developments. One of the important roles of health informatics is in informing governments, funders and health providers about how such systems are performing as well as where, how and why variations emerge. In countries with very large populations, such as China, effective health informatics requires a spatial perspective in order to respond adequately and appropriately across distances and at different scales (e.g. provincial, municipal, county, village).

This paper explores one of the options for visualising the complexities of demographic change in equally complex geographic and systemic environments. The value in this approach lies in its capacity to inform a broad audience about growing complexities in an explicitly visual environment. The shift to data visualisation is already an important process in
other industries and we can see how health, aged care and disability – all complex social informatics domains – will benefit from the application of visualisation methods. This is one example of such an information strategy.

Methods

We used age and sex data for all Chinese counties (2872) from the 2010 Chinese census for our demographic modelling. The data were extracted in csv. file formats and manipulated in Microsoft Excel. The population data were sourced from the China Data Center online project at the University of Michigan (http://chinadatacenter.org/) through our institutional library subscription. We applied dementia rates to selected cohorts (aged 55+), by age and sex, of these data from the results of the study by Chan et al (2013) to this county population modelling. These rates only included the prevalence rates for the 85-89 age group as the top estimate. This was because the Chinese Census data was only available at the aggregate level for 85 years and above (see Limitations below). The results of this analysis were then mapped onto China’s county-level geography using standard geocoding methods to link the data to a latitude and longitude.

We initially mapped these results using a geographic information systems (GIS) package (MaptitudeTM). The results were then visualized in a secondary analysis stage using Google EarthTM to create a Keyhole Markup Language (KML) format file of the data. This is a method that many GIS packages support internally (i.e. export to KML or Google Earth format) or users can use a free software application like GEGraph (http://www.sgrillo.net/googleearth/geograph.htm). The growing development of three-dimensional mapping is seeing a much closer integration between traditional GIS, and mapping functionality, and these emerging data visualisation methods.

Virtual earth technologies are a growing area of application in China in addition to many other countries, and thus congruent with current research and planning applications [2]. This later stage produced a more dynamic visual information in a three-dimensional (3D) format with which users can engage. The focus here was on applying contemporary spatial methods to health-related information and its visualization. Another consideration was the use of non-proprietary software options to enhance potential accessibility of the results. We note that this is an area undergoing rapid developments and other industries and we can see how health, aged care and disability – all complex social informatics domains – will benefit from the application of visualisation methods. This is one example of such an information strategy.

Results

The first stage in the analysis developed a detailed estimation of dementia prevalence by age and sex cohorts in the 2010 population at the county level for the whole of China. This method produced a dementia-affected population of just over 10.2 million people, higher than the Chan et al [3] estimate (9.2 million people) but probably lower than actual numbers due to the cut-off estimation at 55 years and over, our inability to access detailed cohorts for the over 85 groups, and the use of a combined rate for males and females. These results are therefore indicative only and designed to illustrate the relationship between population ageing, geography and a progressive and innovative health information strategy for China – an area which requires further development. It is possible, for example, that prevalence and incidence rates may differ between urban and rural areas. Chan et al have suggested this is not a major differentiator in their meta-analysis but they also note the limitations of the studies they utilised and suggest more detailed research is warranted.

The chart above shows that the top ten counties in China with the largest dementia population estimates account for less than 250,000 patients (222,869). Of these, 134,917 are likely to have Alzheimer’s disease while the remainder have vascular or other dementias. This might seem an unusually low impact weighting for a top ten listing but there are another 2,862 counties, many with similar population sizes and demographic compositions. This also indicates that the geographic impact of the dementias in China is not restricted to specific regions but is a nation-wide phenomenon, even taking into account the massive rural to urban migrations of the past several decades [4].

China’s population is ageing and there is a distinct geographical pattern to this process. The illustrations below were generated using the data we modelled in conjunction with the GEGraph software package and Google EarthTM. The result is a Keyhole Markup Language (KML) file including dementia estimate data for all counties in China. The data range has been scaled down to reduce the differences between the highest and lowest county data. The image below is a JPEG image but the output is an active file that any user can engage with if they have Google EarthTM installed on a device – desktop, portable device or tablet.
regional density patterning of China’s ageing population. Each county’s data is illustrated in red for easier visibility and the actual KML file is fully accessible in Google Earth™ which greatly enhances its visual accessibility compared to this reduced detail JPEG image.

Figure 4: County Level Estimates of Alzheimer’s Disease in China 2010

In the second Google Earth™ image above, we have segmented out the data estimates for Alzheimer’s Disease (AD) specifically, and visualised these in green to avoid any confusion between the different images. As with a geographic information system (GIS) these KML files can be supplemented with files of other data, such as hospital locations or pharmacies, to illustrate and explore the relationships between a specific health condition and health services infrastructure. As health systems and health informatic progress globally, we suggest that these types of additions to the health informatician’s toolkit will greatly enhance the utility of health information datasets and health informatics modelling practices. All health and disease problems exhibit a spatial dimension and this type of visualisation can support understanding of these problems and our efforts to manage and resolve them.

In a third Google Earth™ image below, we have combined the AD prevalence estimates with a KML file of counties in China sourced from GDAM (http://gadm.org/). The resulting output shows the coloured polygons of the counties in association with their projected AD prevalence as vertical data columns. In addition we turned off the borders and labels for other countries in Google Earth so that the user can focus more directly on China and its data in preference to supporting contextual geographic data. This further illustrates the importance of careful methods selection and use in communicating complex health information, especially so when using a spatial health informatics environment. Too much information, if not absolutely essential, can be as confusing as too little.

Figure 5: Dual Layer Map of Counties and AD Prevalence Estimates for 2010

Finally, it is important to note that as more health systems develop and utilise ‘big data’ strategies, new tools and methods will be necessary to inform non-health audiences of the findings of such studies. In this context data visualisation is a relatively new but rapidly expanding field. Spatial data visualisation, as illustrated in these examples, is a key aspect of these emerging changes in the health informatics environment. The drive towards strategies such as tele-health and m-health, including methods such as the remote-monitoring of patients, will add to the necessity of having spatially-informed data that can be used to lobby for funding, resources, workforce and so forth.

Discussion

This project explores the likely impact of dementia and dementia sub-types in the People’s Republic of China which is now the largest ageing society in the world. China is already utilising spatial science and technology to address age-related problems from a planning and service delivery perspective (e.g. Cheng et al, 2012) [5]. In addition, Yang et al [6] state that health and medical geography research is growing rapidly in China, indicating that ageing research and spatial methods will continue to converge. Lastly, several studies, such as the China Health and Retirement Longitudinal Study (CHARLS), are researching the prevalence and progression of the dementias in China [7]. This project adds to that complex emerging picture by modeling and visualising, in a spatial form, the scale of the issues that rapid population ageing presents for China and where its effects will be felt most strongly.

The value in this first iteration of our research is to make the totality of population ageing and its clinical and social effects accessible to a wide audience including various levels of government, policy developers, service planners, service providers and the broader citizenry. The need for societal level responses to the complexities and challenges presented by population ageing need to be supported by new and innovative instruments for monitoring and understanding the implications of current and future interventions. One such area of support lies in the new geographic and allied data visualisation tools becoming available to governments, planners, service providers and insurers.

The scale and speed of population ageing in China is profound and of an order of magnitude unlikely to be seen anywhere else except perhaps India. The multi-dimensional capacities of spatial science and technology represent a key domain for supporting societal-level responses to population ageing that aim for humane and sustainable outcomes. Ageing is fundamentally linked to space and place including the
connections people have to spaces and places as they age [7]. The future of population ageing requires a spatially informed and enabled approach to health information if such outcomes are to be achieved.

While the data we present here is shown at the county level, other administrative geographies can be utilised, such as province or prefecture. This means that, within the one information environment, data can be visualised for multiple scales and at different administrative levels. In addition, maps with more than one variable can be produced to examine factors such as demography versus healthcare expenditure data, utilization of acute care services or the rates of other health conditions or events (cardiac, stroke, cancer etc.). Change is not only a feature of population ageing; it is a central feature of these spatial technologies. Their potential contribution to managing the complexity of health systems and health information management is on an upward developmental pathway. Which software to use and for what purposes will be highly contingent on the rate of change in this sector but the potential utility of such approaches remains clear and we can expect to see spatial methods added to other data visualisation environments.

**Limitations**

This is a point-in-time estimation of dementia prevalence and has the limitations of any similar modeling exercise. The aim of this model is not one of absolute accuracy, and we make no claims to that, but rather the application of spatial analysis and visualisation to a demographic trend with major implications for the Chinese government, healthcare systems, economy, and society. We have used the year 2010 as our reference year because of the production of the official Chinese census for that year, and recent revisions of dementia prevalence in China produced for the same year [8]. This makes the model reasonably accurate in a county-level approximation under those conditions, and a starting point for further investigation.

It is important to note, as indicated earlier, that research on dementia and their population-level effects is ongoing in China. Consequently, between this present work and the 2020 Chinese Census, we can expect to see a growing research information base come on stream. Simply put, because demography is so dynamic in China and researchers are working rapidly to build their understanding of population change and its effects, new data will almost certainly alter this picture and do so very soon. Its value lies in the visual dimension and in the technology’s flexibility for exploring complex phenomena at the national level and below (provinces, counties etc.), all within the one virtual environment.

**Conclusion**

This developmental paper supports the growing awareness of the challenges that population ageing presents to China’s health and social policy domains, as well as its rising number of elderly. The increasing survival of older people is a key achievement of China’s health and economic developments of the past few decades, but systemic change will be necessary to meet the challenges posed by these successes. One key concern will be addressing the geographic scope of the inevitable challenges presented by population ageing and the rise of dementia across the country. These will co-occur with many other chronic and acute health conditions, making for new levels of complexity in identifying and treating the health needs of an ageing population.

We have presented a spatial virtual earth approach that makes a link between population ageing and dementia, which supports planning and response activities, as well as research and interventional programs. While this is a pilot project, it seems clear that the complexities of China’s physical geography, its population dynamics, and governance structures (central, provincial, city, local etc.) would benefit from a spatial strategy in order to cope with health and social care implications of ageing and dementia. In addition, we suggest that a spatially informed health informatics strategy can support policy design and applied responses to the challenges presented by population ageing. The future of health information management and population ageing responses are, we suggest, highly spatial, if current and emerging challenges are to be effectively addressed.

Abstract
This study analyzed ascending branch slope (A_slope), dicrotic notch height (Hn), diastolic area (Ad) and systolic area (As) diastolic blood pressure (DBP), systolic blood pressure (SBP), pulse pressure (PP), subendocardial viability ratio (SEVR), waveform parameter (k), stroke volume (SV), cardiac output (CO), and peripheral resistance (RS) of central pulse wave invasively and non-invasively measured. Invasively measured parameters were compared with parameters measured from brachial pulse waves by regression model and transfer function model. Accuracy of parameters estimated by regression and transfer function model, was compared too. Findings showed that k value, central pulse wave and brachial pulse wave parameters invasively measured, correlated positively. Regression model parameters including A_slope, DBP, SEVR, and transfer function model parameters had good consistency with parameters invasively measured. They had same effect of consistency. SBP, PP, SV, and CO could be calculated through the regression model, but their accuracies were worse than that of transfer function model.

Keywords: Pulse wave analysis, Regression analysis, Data accuracy

Introduction
Pulse wave contains abundant physiological and pathological information, which can reflect early changes of cardiac function parameters [1-2]. Information extracted from pulse wave can be used for clinical detection and treatment. A large number of studies have indicated that central artery is more accurate than brachial artery in predicting cardiovascular events [3]. However, since central pulse wave study is invasive, the direct measurement of its parameters is quite limited clinically. As far as the peripheral is concerned, brachial artery reflects cardiovascular events more accurately than radial artery does [4]. Therefore, the parameters of brachial pulse wave often indirectly reflect cardiovascular events. In addition to DBP and SBP, PP, k, SV, SEVR, CO, and Rs are also important indicators of cardiovascular function. Their meanings and calculation formulas are shown in Table 1. From the shape of the waveform, characteristic value of A_slope, Hn, As, Ad can also reflect the changes of cardiovascular function, and their descriptions [5-6] are shown in Figure 1. The ascending branch slope is defined as [7]:

\[ A_{\text{slope}} = \frac{\text{Peak amplitude-Trough amplitude}}{\text{Time corresponding to peak-Time corresponding to trough}} \]

Borrow and Newburger [8] found that SBP and DBP of brachial artery and aorta were significantly related with a correlation coefficient equaling to 0.984 and 0.969. A linear correlation between brachial and aortic BP was reported, and it was used for the estimation of aortic BP by applying linear regression equations [8]. Then, similar significant correlation between aortic and brachial BP was proposed by Band et al [9]. However, in recent years, research on the regression relation of parameters is rarely reported. This paper presents the regression relationship between parameters of central pulse wave and brachial pulse wave, and makes a comparison with the transfer function model. The generalized transfer function (GTF) model is widely used to estimate the parameters of central pulse wave [10, 11]. However, the regression model has the following advantages over the transfer function model: simple structures, few parameters, less sample requirements, and strong capacity of generalization that shows adequate performance of popularization to the new samples.

This paper analyzed some parameters that can reflect cardiovascular events effectively. The accuracy of the parameters, which were obtained by the regression model and transfer function model, was compared to explore whether the parameters of brachial pulse wave can effectively reflect the corresponding parameters of central pulse wave by establishing a linear regression model. This study not only plays a role of clinical diagnosis and treatment in the prediction of cardiovascular events, but also helps to develop new medical devices.
Materials and methods

Research materials

Patients who underwent coronary angiography in the First Hospital of China Medical University were selected for the study. A total of 40 patients were included in the study, 21 males and 19 females, age (54.76 ± 13.8 years), and weight (67.53 ± 8.5kg). Invasive central pulse wave and brachial pulse wave were collected in interventional catheterization room. The pulse pressure waveforms of the aorta and brachial artery were collected synchronously with the pressure guide wires. Invalid waveform was excluded, and each volunteer provided a set of data for the study.

Instruments and data acquisition

Experimental instrument: St. Jude Medical Company’s RadiAnalyzer Xpress, with sampling frequency of 100Hz.

Data acquisition procedures: In this study, the pressure waveforms of the ascending aorta and brachial artery were invasively measured by arterial catheter. The right radial artery of subjects was punctured using Seldinger technique in the supine position. Two pressure guide wires were placed about 2 to 3 cm above the elbow to calibrate the pressure. After calibration, one of the pressure guide wires was placed into the ascending aortic root, and the position of the other wire was unchanged. The invasive central pulse wave and brachial pulse wave were recorded when the pressure curve tended to be stable. The relevant parameters were calculated according to the pressure waveform. The relevant parameters were calculated by continuous five high quality pulse waveforms. The average of the five values was taken as the individual parameter.

Statistical and research methods

Parameters were extracted and calculated with MATLAB. Data were analyzed with SPSS software and Bland-Altman diagram was drawn with MedCalc software. Measurement data were expressed in "±s". Pearson correlation method was used to analyze the correlation. Paired t test and Bland-Altman analysis were used to test differences and consistency respectively.

A linear regression model was obtained with brachial pulse wave parameters (cA) and central pulse wave parameters (cA – the "gold standard" [19]). Transfer function model was established with the waveform of the brachial pulse wave and the central pulse wave. New central pulse wave parameters (eA, gA) were obtained with the two models. The differences between cA and eA, cA and gA were tested with paired t test. The consistency between cA and eA, cA and gA was analyzed with Bland-Altman diagram. Finally, the results of the two models were compared. A p<0.05 indicates that the difference was statistically significant.

Results

Correlation analysis and regression equations

The parameters were extracted from central pulse wave and brachial pulse wave according to the formula of the parameters. The correlation of each parameter was analyzed with Pearson correlation analysis method. The results showed that k value of central pulse wave and brachial pulse wave were not correlated (p>0.05, r<0.3), Rs were moderately correlated (p<0.01, r>0.5), and other parameters were highly positively correlated (p<0.01, r>0.8).

The regression equations were established according to correlation in the SPSS software, and the following equations were significant according to the criteria of regression analysis (parameters of central pulse wave are expressed as Y’ and the corresponding parameters of brachial pulse wave are expressed as x). The regression equations are shown in Table 2.
Parameter calculation results

The gold standard was the feature parameters extracted from the invasive central pulse wave. Regression model parameters (cA) are a new set of parameters of central pulse wave, which were calculated by linear regression models and parameters of brachial pulse wave (pA). Transfer function model parameters (gA) were a new set of central arterial parameters, which were calculated by the transfer function model (the establishment of a transfer function model refers to the contribution of Chen et al. [10] and Paucia et al. [11]).

Difference analysis with paired t test

The parameters eA and cA, gA and eA were tested by paired t test (gA and cA have been proved highly correlated (p<0.01)), and the results are shown in Table 3. The results showed that there was no significant difference between eA and cA (A_slope, DBP, SBP, PP, SEVR, SV, CO, p>0.05), so the above parameters could be obtained by regression model. There was no significant difference in all parameters of gA and cA.

Consistency analysis with Bland-Altman analysis

The above two groups of parameters – cA and eA, cA and gA – do not have statistical difference. The two groups were analyzed by Bland-Altman analysis method. The scatter points of each parameter were in (X±1.96SD) range. The values of 95% limit of agreement are shown in Table 4. The Bland-Altman diagrams of A_slope, DBP and SEVR are shown in Figure 2, Figure 3, and Figure 4. In addition, cA and gA (A refers to Hn, Ad, As and Rs) also were analyzed. The Bland-Altman diagram of the five parameters showed that there were more than 95% scattered points distributed in range of X±1.96SD.

SBP (-9.3, 9.3) (-5.6, 5.6)
PP (-8.9, 8.9) (-5.4, 5.4)
SEVR (-13.5, 13.6) (-13.6, 13.6)
SV (-29.8, 32.6) (-16.5, 16.5)
CO (-2473.0, 2465.7) (-885.1, 889.4)

The results showed that the parameters of central pulse wave (A_slope, DBP, SBP, PP, SEVR, SV, CO) calculated by the regression model had good consistency with the gold standard. Similarly, the parameters of transfer function model had good consistency with the gold standard. The consistency of the parameters (SBP, PP, CO, SV) calculated by the transfer function model was better than that of the regression model. Both the regression model parameters, including A_slope, DBP, SEVR, and the transfer function model parameters had good consistency with the parameters invasively measured, and their consistency had the same effect. The Hn, Ad, As, k value and Rs calculated by the transfer function model had good consistency with the gold standard.

Discussion and Conclusions

In this study, the linear relationship of the parameters between brachial pulse wave and central pulse wave was discussed, and the regression model was established through the waveform of the invasive central artery and brachial artery. The transfer function model was established as a contrast of the regression model. The eA and gA were compared to determine the accuracy of the regression model. To discuss whether reliable parameters of central pulse wave can be obtained by regression models, the following conclusions were obtained:

1. Clinical parameters of central pulse wave and brachial pulse wave (A_slope, Hn, As, Ad, DBP, SBP, PP, SEVR, SV, CO) were highly correlated, Rs was moderately correlated and k values were not correlated.
2. eA and cA (A_slope, DBP, SBP, PP, SEVR, SV, CO) did not have statistical difference (p>0.05), and the consistency was good. Therefore, the above parameters could be obtained by regression model. However, Hn, As, Ad and Rs could not be estimated by regression model because of their statistical differences.
3. The consistency of A_slope, DBP and SEVR calculated by the two models was about the same, that was, eA could achieve the same effect as gA, and their regression equations were Y=0.509x+1.453, Y=0.932x+3.846, Y=0.946x+21.173.
4. The consistency of gA (SBP, PP, CO, SV) and eA was better than eA and cA. However, whether the accuracy of the regression model will be improved needs to be further studied, in the case of a large sample.
5. Hn, As, Ad could not be estimated by regression model. From the formation mechanism of pulse wave, dicrotic notch is caused by the overlap of reflected wave caused by impact on peripheral arterial by ventricle sinister ejection, and Dicrotic wave caused by flow of artery blood from telecentric end to proximal end, what is affected by factors like elasticity of vascular wall [20]. Another reason is that the influencing factors of blood vessels, such as vascular elasticity, have great individual differences. Therefore, Hn had a significant statistical differences and it could not be obtained by regression model. Similarly, the calculation of As and Ad were related to Hn.
6. k value is only affected by the shape of the pulse wave, which is irrelevant to blood pressure [14]. It will lead to the fact that two different waveforms probably have the same k value, which will be mistaken for same...
physiological conditions of the two pulse waves. Therefore, k value needs to be directly calculated by the waveform, which could not be directly derived from the regression equation.

Abstract

The LIGHT2 project managed the care of approximately 10,000 Medicare (primarily elderly) and Medicaid (low income) patients between 2013 and 2015. Risk tiers based on chronic disease diagnoses and recent healthcare utilization were strongly predictive of future healthcare utilization, and the authors expected that the members of an aging and well-insured population would gradually rise in risk of healthcare utilization over the course of three years. Various analytic techniques were used to characterize the members of higher risk tiers. However, retrospective cohort analysis and simple data visualization discovered the tendency of patients in lower initial risk tiers to remain healthy, and the tendency of patients in higher initial risk tiers to improve. In a time frame of three years, this return to stability was a more important influence on healthcare utilization than risk or aging.

Introduction

Managed Care and Risk Stratification

LIGHT2 (Leveraging Information Technology to Guide Hi-Tech and Hi-Touch Care) was a Health Care Innovation Award from the Centers for Medicare and Medicaid Services to examine the use of advanced health information technology and care coordination in a managed population. With over 10,000 patient cases to be managed by fewer than 25 advanced practice nurses, the LIGHT2 project needed clinical decision support to help focus preventive and longitudinal care on those patients who were at highest risk [1].

Definition and Validation of Risk Tiers

The LIGHT2 investigators defined four risk tiers as (1) Healthy, (2) Stable, (3) Unstable, and (4) Complex, on the basis of diagnoses that are included in the Chronic Conditions Data Warehouse (CCW) [2] and on healthcare utilization in the preceding year (see Table 1). These risk tiers, based on simple retrospective data, were useful predictors of the prospective risk of patient healthcare utilization [3]. The authors expected that the members of an aging and well-insured population would gradually rise in risk of healthcare utilization during the course of the study period.

Objective

The objective was to demonstrate and visualize the longitudinal changes in risk stratification within a population of well-insured primary care patients.

Methods

LIGHT2 Population and Setting

The University of Missouri Health System (UMHS) enrolled over 10,000 primary-care patients with Medicare or Medicaid coverage in the LIGHT2 study between early 2013 and early 2015.

Data Sources

Diagnoses and utilization histories for all LIGHT2 patients between 1 January 2012 and 31 December 2014 were collected retrospectively from the UMHS Health Analytics Library, an analytic data mart created for the LIGHT2 study to reflect the relevant contents of the UMHS electronic health records system.

Visualization of Movement between Risk Tiers

In order to visualize the longitudinal stability of the four risk tiers in the study population, cohorts were retrospectively identified by the risk tier of each patient at the beginning of the study period. The risk tiers were then retrospectively recalculated bi-weekly for each patient in the cohort over the following three years. The percentage of each cohort in each tier, as well as the percentages deceased or lost to follow up, were calculated and displayed as stacked bar charts.

Results

“Healthy” (Tier 1) patients had a large chance (56%) of staying in the same risk tier, and most of remainder (27%) moved only to the next higher tier (see Figure 1). “Stable” (Tier 2) patients had a very large chance (68%) of staying in the same risk tier, and half of remainder (13%) moved only to the next higher tier (see Figure 2). “Unstable” (Tier 3) patients had a large chance (48%) of moving to the next lower tier, and almost half of remainder (25%) moved to the next lower tier, leaving a fairly small chance (18%) of remaining in the same tier (see Figure 3). “Complex” (Tier 4) patients had a fairly large chance (37%) of moving to a much lower risk tier, and almost half of remainder (25%) moved to the next lower tier, leaving a fairly small chance (18%) of remaining in the same tier (see Figure 4).
The rate of death increased steadily in higher risk tiers, at 1%, 4%, 7%, and 9% respectively (see Figures 1-4). The rate of loss to follow up was fairly consistent across tiers, at 12%, 9%, 10%, and 11% respectively (see Figures 1-4).

Discussion

Contrary to the authors’ hypothesis, patients in lower risk tiers (“Healthy” and “Stable” patients) at the beginning of the study period were most likely to remain in lower risk tiers after three years, and those in higher initial risk tiers (“Unstable” and “Complex” patients) were most likely to move to lower risk tiers after three years.

The consistently higher death rate in higher risk tier cohorts provides an additional validation of the predictive utility of the risk tiers.

Because initial validation of the tiers showed that “Complex” (Tier 4) risk stratification was associated with significantly higher utilization [3], additional data science techniques were used to characterize the “Complex” patients, including contrast mining. For this analysis, patients were initially stratified by high cost and low cost, and those among the most expensive 5% were found to incur 50% of costs. Complex (Tier 4) patients were 4-5% of the total managed population at any given time, therefore roughly equivalent to the 5% high-cost patients. Association rule mining [4] was used to find all possible combinations of 19,014 sparse attributes. Those found frequently (Pr ≥ 0.2) in 479 high-cost patients but infrequently (Pr < 0.2) in equal numbers of low-cost patients were tested for statistical significance, revealing eleven associations that characterized the high-cost patients (see Table 2) [5].

Although contrast mining found distinct patterns of utilization within the “Complex” (Tier 4) patients, less than one fifth of that cohort remained in Tier 4 by the end of the three-year study period, with another fifth deceased or lost to follow up. The remaining three fifths of the cohort had returned to the lower “Stable” (Tier 2) and “Unstable” (Tier 3) risk tiers.

Limitations

Because the data were collected from a single healthcare system, some utilization of other providers may be missing. This could affect both the risk stratification of patients and the number of their utilization episodes after stratification. This data gap could be resolved by supplementing electronic medical records with insurance claims data for the same population over the same period.

Future Research

This study measured the net number of patients in each risk tier at each point in time, but did not distinguish how many individuals move in each direction made up this net result. To gain a greater insight into these movements, hidden Markov models could be used to track the tiers or “states” though which individual patients moved. Contrast mining, which has been applied successfully to the “Complex” (Tier 4) sub-population, should also be applied to patients in all risk tiers. These methods and sequence mining techniques are needed to find the characteristics of patients in each tier that move to lower or higher tiers, as well as those who remain in their initial tiers.

Conclusion

Despite the use of several sophisticated analytic techniques, including deeper understanding of high-risk patients using contrast mining, simple data visualization discovered a remarkable pattern in this study population: the tendency of patients at lower initial risk to remain healthy, and the tendency of patients at higher initial risk to improve. In the time frame of a few years, this return to stability was a more important influence on healthcare utilization than risk or aging. The expected gradual rise in risk tiers, which was not seen in these results, may be detectable with longer longitudinal data.

Phenotypic Analysis of Clinical Narratives Using Human Phenotype Ontology

Feichen Shen, Liwei Wang, Hongfang Liu

Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA

Abstract

Phenotypes are defined as observable characteristics and clinical traits of diseases and organisms. As connectors between medical experimental findings and clinical practices, phenotypes play vital roles in translational medicine. To facilitate the translation between genotype and phenotype, Human Phenotype Ontology (HPO) was developed as a semantically computable vocabulary to capture phenotypic abnormalities found in human diseases discovered through biomedical research. The use of HPO in annotating phenotypic information in clinical practice remains unexplored. In this study, we investigated the use of HPO to annotate phenotypic information in clinical domain by leveraging a corpus of 12.8 million clinical notes created from 2010 to 2015 for 729 thousand patients at Mayo Clinic Rochester campus and assessed the distributional information of HPO terms in the corpus. We also analyzed the distributional difference of HPO terms among demographic groups. We further demonstrated the potential application of the annotated corpus to support knowledge discovery in precision medicine through Wilson’s Disease.

Keywords:
Semantic Annotation; Human Phenotype Ontology; Phenotypic Analysis

Introduction

Phenotypes, defined as observable characteristics and clinical traits of diseases and organisms, have attracted increasing attention in the area of translational medicine by serving as the connectors between medical experimental findings and clinical practices. For example, in genomic medicine, phenotypes provide evidence to stratify and differentiate various groups of patients in order to discover specific hidden genotype-phenotype associations [1].

As a tool for annotating human phenotypic abnormalities, Human Phenotype Ontology (HPO) [2] has been developed as a controlled vocabulary for phenotypes by mining and integrating phenotype knowledge from medical literatures, Orphanet [3], Database of Chromosomal Imbalance and Phenotype in Humans Using Ensembl Resources (DECIPHER) [4], and Online Mendelian Inheritance in Man (OMIM) [5]. HPO also provides associations with other biomedical resources such as Gene Ontology [6]. Multiple studies have utilized HPO for data annotation. For example, Taboada [7] developed a semantic annotation system to automatically extract rare disease information from PubMed literature using HPO. In addition, Westbury and his colleagues [8] used a HPO-based clustering approach to identify group of heritable bleeding and platelet disorders (BPD) cases. Zhu and her colleagues [9] leveraged HPO to develop a genetic testing knowledge base.

Here, we used HPO to annotate a large collection of clinical narratives consisting of all clinical notes generated from 2010 to 2015 at Mayo Clinic Rochester campus and assessed the distributional information of HPO terms. A case study was performed to demonstrate the potential application of the annotated data.

In the following, we describe the methods used for generating the annotated corpus. Next, we present and discuss our results. We then analyze the distributional differences among demographic groups and detail the case study followed by the conclusion and potential future directions.

Background and Materials

Clinical Data Collection

We collected all clinical notes created between 2010 and 2015 at Mayo Clinic Rochester campus with research authorization. The resulting corpus contains 12.8 million clinical notes corresponding to 729 thousand patients. Specifically, we limited our annotation to the diagnosis section of clinical notes for better extracting phenotype related terms.

The Unified Medical Language System and MetaMap

The Unified Medical Language System (UMLS) [10] is an integrated database that contains all key medical terminologies and their related resources. Each term in the UMLS has a Concept Unique Identifier (CUI) and belongs to a specific semantic type. MetaMap [11] is a configurable application that is able to map biomedical terms to UMLS Metathesaurus. In this study, we applied MetaMap with the UMLS version 2015 on free-text clinical notes to extract related terms as a preprocessing step.

Human Phenotype Ontology

We used the latest version of Human Phenotype Ontology (HPO) released on September 2016. The HPO contains four sub-ontologies as shown in Table 1, and each sub-ontology has its different focus on annotating area.

HPO package contains an ontology file that records all HPO phenotype terms with their synonyms and resource references (e.g., the UMLS). As shown in Figure 1, in the ontology hierarchical structure, Menorrhagia (HP_0000132) belongs to sub-ontology Phenotypic Abnormality and is listed as a subclass of abnormal bleeding. Two synonyms abnormally heavy bleeding during menstruation and hypermenorrhea are connected to it through object property has_exact_synonym. Moreover, Menorrhagia relates to a UMLS CUI C0025323 through Web Ontology Language (OWL) axiom and object property annotatedTarget. The corresponding Resource Description Framework (RDF) representation in Figure 1 indi-
icates such triple relationships. Although HPO has link to the UMLS, the current version of HPO has not been fully incorporated into the UMLS version after 2013. Due to this limitation, the combination of both HPO and the UMLS is able to make a more comprehensive annotation than using only one of them.

In addition, there is another clinical annotation file wrapped in HPO package that captures around 119,000 phenotype-disease associations where a majority of them (115,000) correspond to hereditary conditions. Take Wilson’s Disease as an example, the HPO annotation file records 33 relevant phenotypes, e.g., Proteinuria, Dementia, and Coma etc.

Semantic Annotation Module

Our annotation focuses on the main HPO sub-ontology Phenotypic Abnormality (HP_0000118) and its descendants. It contains 11,721 phenotype terms and 19,358 related synonyms defined in HPO or inferred from the linked UMLS CUIs. Our mapping includes two steps: we map UMLS concepts derived from the NLP preprocessing module to HPO terms using exact match, in case of ambiguity, we select the one with the smallest CUI number; and for HPO terms that failed to be mapped to the UMLS, the module then conducts another round of string matching refinement. Specifically, it reviews tokenized original text to check if there exists any possible candidate missed by MetaMap.

Results

The proposed annotation system was developed with Eclipse Standard/SDK version Luna 4.4.0. The interface to access MetaMap, the UMLS, and HPO were coded in Java programming language. In addition, we deployed the whole system on the Open Grid Scheduler (OGS) framework running on 64 bit Linux CentOS 6.8 servers hosted by Mayo Clinic to improve processing speed on large amounts of clinical notes.

In the following, to protect patients’ privacy, any phenotypes with counts less than 11 were marked as <0.0015% or <11.

HPO Phenotype Coverage in Clinical Data

Overall, 3,241 out of 11,721 (27.7%) HPO phenotypes were extracted from 6,771,409 (52.8%) clinical notes. HPO has 23 abnormality categories. In our cohort, we counted the number of unique phenotypes and computed phenotype coverage for each category as shown in Figure 3. For example, Abnormality of the nervous system has the most phenotypes involved (599), e.g., Anomia, Anxiety, Bone pain and Dysesthesia while Abnormality of the thoracic cavity has no phenotype contained. Meanwhile, Abnormality of the voice holds a small group of phenotypes (11), including Dysphonia, High pitched voice, Hoarse cry, and Laryngeal dystonia etc. However, in terms of phenotype coverage, 78.6% (11 of 14) phenotypes under Abnormality of the voice were found. Abnormality of the breast also holds the second highest phenotype coverage as 55.6% (15 of 27). Since one phenotype can belong to more than one abnormality categories, in clinical notes, we found that 846 phenotypes are marked by 2 categories, 157 phenotypes dropped in 3 categories, 15 phenotypes are depicted by 4 categories, and only 1 phenotype is described by 5 categories.
Table 2 shows the top 10 frequent phenotypes as well as 10 phenotypes with relatively less frequent occurrences in clinical notes. We can see that many HPO common phenotype terms were found in cohort, such as Hypertension, Hyperlipidemia, Apnea, or Anxiety, etc.

We also noted our clinical notes contain phenotypes that related to rare diseases. For example, Alacrima is one of the features for Triple A syndrome. Hemifacial hypertrophy is a rare congenital disease. Episodic tachypnea often comes along with Joubert syndrome. Alobar holoprosencephaly is associated with Holoprosencephaly. Barrel-shaped chest is one of the symptoms of Dyggve Melchior Clausen (DMC) syndrome. Chemodectoma contributes to one of the signs caused by Abdominal Chemodectomas with Cutaneous Angiolipomas.

We retrieved patients' associated demographic information and assessed the phenotype distributional difference among demographic groups. We analyzed the distribution of HPO abnormality categories among different age groups. Basically, we grouped age 0-17, 18-35, 36-54 and >55 as children and teenagers, young adults, mid adults, and old adults age groups. As shown in Figure 4, Abnormality of the nervous system is popular in each age group. Abnormality of immune system occurs more frequently in children and teenagers. Abnormality of the digestive system often comes with young adult patients. While Abnormality of the cardiovascular, skeletal, metabolism/homeostasis and respiratory systems are common problems for mid adults but more common problems for old adults. In addition, Immune system disorder, Abnormality of genitourinary system, and Neoplasm have a high prevalence in old patients.

In total, there are 2,864 unique phenotypes found in male and 2,907 unique phenotypes detected in female. Based on patients' percentile for both genders, we found that Hypertension, Apnea, Hyperlipidemia, Back pain, and Obesity are 5 most frequently occurred common phenotypes. We also conducted two case-control studies on male and female respectively to discover dominant phenotypes for each gender. We ranked phenotypes by descending order of odds ratios and filtered out phenotypes that are only associated with one specific gender (e.g., Cryptorchidism for male and Amenorrhea for female). With the odds ratio of 13.6, Hypergonadotropic hypogonadism is the phenotype that closely related to male (Table 3). Meanwhile, Hirsutism shows the highest odds ratio of 94.3 with female (Table 4). In general, top phenotypes in female held a relative higher average odds ratio.

Demographic Phenotype Analysis

We retrieved patients' associated demographic information and assessed the phenotype distributional difference among demographic groups.

We analyzed the distribution of HPO abnormality categories among different age groups. Basically, we grouped age 0-17, 18-35, 36-54 and >55 as children and teenagers, young adults,
We also extracted 29 races from clinical notes and picked 2 with the most population (excluding other and unknown races), which are White (519,098) and Black or Africa (8,835). Based on phenotype frequencies, we found top 5 common phenotypes for both races are Hypertension, Apathy, Hyperlipidemia, Depression, and Back pain, which highly overlapped with top 5 common phenotypes for male and female except Depression. We also conducted two case-control studies on White and Black or Africa patients to acquire significant phenotypes for each race. Table 5 shows top 5 significant White-specific phenotypes based on odds ratio. Based on literature review, we validated that Basal cell carcinoma, Melanoma, and Macular degeneration are highly related to patients in white race [12–14]. Table 6 shows top 5 significant Black or Africa-specific phenotypes based on odds ratio with the number of affected patients greater than or equal to 3. We found that 4 out of 5 top Black or Africa-specific phenotypes are related to genetic and rare diseases. Scarring alopecia of scalp is a rare disorder that destroys hair follicle. Clitoral hypertrophy is a congenital malformation and a rare condition. Intellectual disability, profound is a severe asthma. Literature indicated that Scarring alopecia of scalp and Intellectual disability are related to Black or Africa patients [15–16]. For other 3 phenotypes, even they occur in few patients but it may be worth to explore more as little evidence has been found about the relationship between them and Black or Africa patients in literature.

A Case Study of Phenotypic Analysis

Wilson’s Disease (WD) is an autosomal recessive rare inherited disorder that makes copper accumulate in organs, and its diagnosis can be challenging as its signs and symptoms are often indistinguishable from those of other liver diseases, such as hepatitis. In this section, we conducted two case-control studies to demonstrate the potential of HPO-annotated data in supporting disease diagnosis. Among a total of 615,590 patients, we extracted 39 patients with confirmed diagnosis of WD and 63 patients suspected for WD but negative by genetic testing, leaving 615,488 patients with no clinical assertions or doubts for WD. Based on the three groups, two case-control studies were designed as follows: 1) To reveal significant phenotypes of WD, odds ratios of phenotypes were computed for 39 confirmed WD patients compared to 615,488 Non-WD patients; 2) To investigate the phenotypes significant for similar disease differentiation, odds ratios of phenotypes were computed for 39 confirmed WD patients compared to 63 patients suspected for WD.

Table 7 and 8 shows top 10 phenotypes ranked by odds ratio (with the number of affected patients greater than or equal to 3) representing significant clinical features of WD patients against the general population and the specific cohort with similar symptoms, respectively. Overall, odds ratio of phenotypes in the WD cohort against the general population were higher. Although the number of patients was relatively low, manual evaluation showed that all phenotypes are related to WD [17–19]. In contrast, odds ratio of phenotypes in the WD cohort against the similar cohort were relative lower, reflecting the reality that differential difficulties exist in the diagnosis of WD and WD similar diseases. However, according to [17], 7 phenotypes Hypoalbuminemia, Nevus, Osteopenia, Cognitive impairment, Cirrhosis, Renal insufficiency, and Fever are common symptoms of WD, of which only Osteopenia and Cirrhosis are covered by WD-related phenotypes recorded in HPO annotation file. The remaining are possible comorbidities highly occurring with WD. This analysis revealed the potential of these phenotypes in differentiating WD from similar diseases.

Discussion

Our study showed that almost half of the clinical notes contain no HPO terms. To investigate further, we extracted top 10 frequent phenotypes from those notes including Fatigue, Pharyngitis, Dyslipidemia, Dermatoheliosis, Insomnia, Diabetes, Fibromyalgia, Snoring, Chronic Obstructive Airway Disease, and Rash. In general, most of these phenotypes are not hereditary ones, and some of them are more generic than HPO terms (e.g., SNOMED CT terms [20]). For example, Fatigue...
covers HPO annotated phenotype *Exercise-induced muscle fatigue, Pharyngitis* gives a more general description of HPO annotated phenotype *Recurrent Pharyngitis*, and *Diabetes* is the super set of HPO annotated phenotype *Insulin-resistant diabetes mellitus*.

Note that in our case study, since *Wilson’s Disease* is a rare disease, we were not able to provide a large sample size, which results in relative low odds ratio and high p-value when compared confirmed patients to the general population and suspected patients. In addition, in this research, to reduce the confounding factor of comorbidity, we picked phenotypes at the same year with WD diagnosis. In the future, to further address this issue, a more specific timestamp can be added to put restriction on diagnosed period. Currently, HPO records 33 phenotypes specifically related to WD. Although HPO coverage for WD is not sufficient, phenotypes in HPO can help on extracting all symptoms of diseases, making it possible to reveal significant phenotypes of WD by conducting case-control analysis. Therefore, it is possible to combine clinical notes with HPO to provide empirical evidences to further help diagnose and differentiate WD from similar diseases.

The integration of genotypic and phenotypic knowledge is an essential step to facilitate knowledge discovery in translational medicine. HPO, as a tool with linkage to gene databases and statistics of patients’ percentile of phenotypes for each disease (e.g., 1% as very rare, 5% as rare), can be leveraged for this purpose. Especially for rare phenotypes, HPO makes it convenient for researchers to explore the potential genotype-phenotype associations.

**Conclusions and Future Work**

In this study, we used HPO to annotate phenotypes in clinical text for conducting phenotypic analysis. We demonstrated its potential in facilitating knowledge discovery.

In the future, we will try different ontologies and dictionaries to detect phenotypes from clinical notes and compare performances among them. Furthermore, a more specific diagnosis time range will be considered to largely reduce mischaracterization caused by complication and comorbidity. Moreover, we will use HPO with NLP and machine learning techniques to link various phenotypes with genes and drugs to perform knowledge discovery on gene disease and drug repositioning.

**Acknowledgements**

We would like to thank the support from our colleague Ravikumar Komandur Elayavilli for his valuable suggestions on this research. This work was made possible by internal funding from Center for Individualized Medicine of Mayo Clinic and NCATS Biomedical Translator Award, OT3TR00201901.

The Study of Pulse Condition of Traditional Chinese Medicine in Information Age

Cheng Shi, Yu Zhang, Qingyue Gong, Jinhai Zhou, Lisheng Xu

Abstract

Using the study of pulse condition in Traditional Chinese Medicine (TCM) as a case example, this paper discusses the characteristics of pulse information obtained by Chinese medicine practitioners, how to correctly understand the relationship between the human body and Chinese medicine in the information age, how to deal with pulse data, and how to study TCM pulse condition. Furthermore, we point out that the application of modern big data processing technology to the pulse of Chinese medicine offers new opportunities.

Keywords:
Traditional Chinese Medicine; Delivery of Health Care; Pulse condition

Introduction

In the information age, with the development of science and technology, our understanding of the human body is being gradually deepened. The observation of the human body has extended from human vision to the microscopic world of cells, proteins and genes. Medical equipment is being constantly developed, from the optical microscope to the computerized electron microscope, from the stethoscope to X-ray, CT, MRI and beyond. Surgical treatment has been expanded from operations by surgeons to remotely operated robots. Similarly, with the advent of the information age, Chinese medicine treatment and diagnostic technology is also being constantly developed, evolving from the traditional acupuncture using silver needle to electro-acupuncture, intermediate frequency treatment and laser acupuncture; from the observation of the tongue by naked eye to the acquisition and quantitative analysis on tongue images; from the fuzzy sense of pulse-taking by fingers to pulse condition acquisition and quantitative analysis; from handwritten medical records to electronic medical records.

Currently, some of the studies of traditional Chinese pulse diagnosis return to the anatomy of the cardiovascular system, such as using Wrist-type self-help sphygmomanometer device to evaluate the function of cardiovascular system. We cannot say that these results are not related to the clinical pulse image of Chinese medicine, but the relevance is not believed to be of a great degree. Pulse images within traditional Chinese medicine (TCM) should be associated with the 28 clinical pulse patterns of TCM. The fingertip’s feeling during clinic pulse-taking should be analyzed and the pulse condition information should be acquired and quantified using some kinds of sensors. Following this acquisition and quantification, the fuzzy boundary between these objective data and clinical pulse measurements can be determined by big data analysis. In addition to the dynamic feeling of pulse-taking, many properties can constitute a feeling sensation such as thickness, float, length, frequency, rhythm, hard and soft, etc. In clinic, different pulse patterns can appear in one pulse image. Even for the TCM doctor with many years of experience, it is difficult to accurately differentiate pulse patterns. Therefore, for the analysis of pulse condition by using big data, ambiguity is a big challenge.

In a word, TCM diagnosis and analysis technology is developing rapidly in the information age. However, compared to other diagnosis and treatment technologies, the development of TCM diagnosis and treatment technology is much slower. New diagnostic techniques based on TCM are not easily used in clinical practice, for example the electropulsograph and tongue image. The reason is related to the characteristics of clinical information obtained by Chinese medicine practitioners, their methods of clinical information processing and their means of treating diseases. Furthermore, one can argue that this generalization is related to the information characteristics of Chinese culture and the theory of TCM. The relationship between the human body and Chinese medicine needs to be correctly understood in the information age. Studying the pulse image as an example, this paper discusses the characteristics of pulse information obtained by Chinese medicine practitioners, how to deal with pulse data, and how to study pulse diagnosis in TCM [1].

The human body needs to be correctly recognized in information age

As we know, the human body is extremely complex. The system can use sensitive sensory organs at any time and any place to receive all kinds of information from the outside world such as visual observation, smelling, listening, and palpation. In order to maintain equilibrium, the human body ingests a variety of substances and energy through the digestive and respiratory systems, and eliminates waste by exhaling carbon dioxide, feces, urine, and sweat. In order to adapt to the changing natural and social environment, it needs to store energy, accumulate experience, learn knowledge, and update information constantly in the struggle for survival. As can be seen from modern science, the internal environment of the human body is extremely complex. The body system is composed of a number of interrelated and mutually cooperative subsystems such as the digestive system, respiratory system, cardiovascular circulatory system, and nervous system. These systems are composed of a variety of cells and intercellular substances, which are invisible to the naked eye. From in-depth study, the human body is a huge, open, adaptive, self-organizing, complex information system. It becomes more and more complex when one examines how micro-systems communicate, transfer information, and maintain the normal activities of the human body. As a complex system, the human body is not easy to investigate.

This system is observed to have the properties of automatic regulation and self-recovery, with a complete set of defenses, such as adaptation, immunity, compensation, self-organization. In the future, if the human body incurs disease, doctors should be able to mobilize the body’s own disease prevention and treatment system to the target, and it will be a big step forward in medicine [1].
TCM needs to be correctly recognized in the information age

The human body is an extremely complex information system. For human beings, the "human system" is still a "black box." In response to such a "black box," modern medicine attempts to gradually open the "black box" through our knowledge of nerves, body fluids, organs, tissues, cells, proteins, and genes. Although TCM does not clearly understand the internal structure of the human body, the collection of data still remains the basis of four diagnostic techniques: "observe, smell, ask, pulse-feeling and palpation". The data collected by these techniques reflect the disease state of the body. Using this information, treatments such as TCM tinctures and acupuncture can be performed to mobilize the body's defenses against diseases. This applies a black box control theory to the management of diseases. This method is the most practical method to solve complex problems. For thousands of years, the Chinese people have been using this principle to analyze and treat with human disease, and have created a wealth of information and methods to treat the complex system of the human body. This method of TCM which mobilizes the immune system to treat disease, is the direction of the development of modern medicine for diseases such as cancer. Therefore, the abundant clinical history of TCM is worthy of our exploration and promotion [2].

The Significance of Pulse Information of Traditional Chinese Medicine

Pulse information is a very important component of clinical information for TCM. Traditional pulse information is collected by the fingertips touching the radial artery resting against bone. This segment of the radial artery is located above the radial bone, and the tissue covering it is not thick, so it is easy to detect. Placement of the radial head also supports easy measurement of pulse. The position of the radial artery is between the aorta and the arterioles. Cardiac output produces a reflected wave of blood due to the narrowing in front of the vascular wall. These reflected waves and forward pulse waves are superimposed on the radial artery to form a pulse wave, carrying a wealth of information on the dynamic characteristics of the cardiovascular system including heart, internal organs, the end of blood vessels, etc. The circulatory system coordinates body tissue energy metabolism, oxygen and nutrients, and helps remove metabolic waste. Generally, modeling disease information from the circulatory system is very important, as it provides a basis for life. Therefore, the pulse diagnosis in TCM is a meaningful and important means of diagnosis of disease.

Chinese medicine is shrouded in mystery. However, as early as 1979, Professor Zhaorong Liu at Fudan University used numerical simulation to uncover the mystery behind slippery pulse. They simulated the slippery pulse of pregnant women by increasing the flow from the abdominal cavity; the results of this study are consistent with the clinical practice of traditional Chinese medicine, however, is based on the fuzzy logic of the human body. This segment of the radial artery is located above the abdominal cavity, which results in an independent variable for big data analysis. For example, Yin and Yang, inside and outside, cold and heat, the actual situation of the internal organs and so on. Therefore, the abundant clinical history of TCM is worthy of our exploration and promotion [2].

How to Study TCM Pulse in Information age

Perplexity in the study of TCM pulse condition

TCM pulse condition is a visualized expression which is related to the radial pulse and the state of the patient. It can be obtained by the clinical doctor using the sensation of touch. It is an important basis for clinical differentiation of TCM syndromes. Generally speaking, it can be classified according to the descriptive adjectives of Float, Sink, Slow, Fast, Thick, Thin, Strong, Weak, Fluent, Astringent and Rhythm.[4]

In the Jin Dynasty (266-420 BCE), Shuwe Wang subdivided the pulse into twenty-four kinds in the book "Maijing". In the Ming Dynasty (1368-1644 BCE), Shenzhen Li described pulse with up to twenty-seven kinds in the book "BinHu Sphygmology". This knowledge about the pulse is in the form of natural language to provide a vivid expression for pulse diagnosis in TCM. For example, in the description of the pulse image of TCM, slippery pulse (Hua Mai) which is fluent should refer to the smooth, such as beads moving on the disk. Floating pulse (Fu Mai) refers to that which beats easily, heavily presses down and is diminished but not empty. In the understanding of diseases, floating pulse is mainly for surface symptoms; however slippery pulse is mainly for phlegm and food stagnation. Slippery pulse is also common phenomenon when women have no disease and pregnancy. Clinically, TCM determines the pulse properties according to the comprehensive sensations from the doctors' fingertips, and combines the pulse information with patients' overall characteristics rather than understanding the pulse according to the position of modern radial artery in the cardiovascular system. For example, Yin and Yang, surface and inside, cold and heat, the actual situation of the internal organs and so on. That is, the pulse of traditional Chinese medicine is fuzzy and subjective data, and the rules of TCM treatments are abstract. These problems have caused a lot of confusion in Chinese medicine research [5].

How to Study TCM Pulse in Information age

Reviewing the history of study of the TCM concept of pulse, this study involves a lot of cross disciplinarity. In order to explore the mechanism of pulse generation, it is not only necessary to have knowledge of cardiovascular pathophysiology, but also knowledge of biomechanics, cardiovascular dynamics and blood rheology. In order to objectively reflect the information of doctors' fingers, not only reliable and sensitive sensors are needed, but further analysis is also needed as to the mechanical characteristics of the finger and the charactistics of the sensory cells of the finger surface when the doctor of traditional Chinese medicine is taking a pulse. Pulse information refers to a feeling of the doctor's finger surface, and is a doctor's subjective qualitative data. In addition, the study of pulse condition based on the application of pulse instrument in a previous study in China, has lead to doctors merely using the obtained information to analyze the cause of the disease instead of extending such information to the dynamic characteristics of the whole human body. Clinically, traditional Chinese medicine uses the information of pulse to judge overall dynamic trends of the human body such as Yin and Yang, inside and outside, cold and heat, asthma and phlegm and so on. In that case doctors can use the theory of Chinese medicine to treat patients with syndrome differentiation. All of the above adds great difficulty to research into TCM pulse.

In the era of big data, Google Flu Trends project has been developed to predict flu using search words from people on the Internet who were seeking to investigate their health problems. Google collects people's "cough", "fever", "pain" and other subjective data determine the direction of the spread of influenza with big data analysis. This shows that the subjective data are useful as long as the correct use of big data association rules. However, there is no intersection among the "cough", "fever", "pain" and other subjective data concepts mentioned above, which results in an independent variable for big data processing.

Chinese clinical medicine, however, is based on the fuzzy sense of doctors' fingers to obtain the pulse information, and the concept of pulse is a comprehensive qualitative conception, of which the most common is composite pulse. Composite pulse is assembled by a variety of pulse characteristics. From the same pulse condition, doctors' subjective judgments result in multiple diagnoses. There therefore are intersections between the pulse data, which result in data traps for big data processing. Therefore, in order to
avoid these data traps, the pulse data must be preprocessed. First of all, it is necessary to set up a pulse acquisition and analysis instrument that simulates the pulse diagnosis of TCM and acquires the pulse condition with floating, sinking, thick, thin, strong, weak, slippery, astringent, frequency and rhythm information [3]. At present, the three-inch-foot pulse instrument developed by Shanghai University of Traditional Chinese Medicine has been developed in line with these requirements. Then, we can combine the objective data recorded by the clinical pulse condition with the characteristics of the TCM pulse condition to establish a qualitative classification database meets the requirements for the method of big data processing. There are thousands of Chinese medicine hospitals in China, in which many hospitals have adopted the "electronic medical record system" to record clinical data. If these hospitals can be equipped with pulse acquisition and analysis devices, the amount of data could be amazing. Therefore, modern large-scale data processing technology has brought new opportunities to researching pulse condition within TCM [6].

Conclusions

In information age, with the high degree of scientific and technological development, the research on the human body has extended from the human visual sense to the microscopic range such as cell, protein, gene and etc. In clinical treatment, CT, MRI, ultrasound and other equipment have been applied to detect the internal state of the human body. Also people have used a fully automated instrument to detect blood and urine and obtain patients’ information. However, traditional Chinese medicine seems to have not yet entered the information age. TCM still uses sensory organs to subjectively collect clinical data and apply experience and traditional Chinese medicine theory to deal with data. This paper analyzes the causes of this confusion and believes that the pulse data which perceived by TCM fingers are consisted of a variety of physical quantities. The obtained information by doctors’ sensory organs is subjective and the boundary is fuzzy.

The clinical TCM pulse condition is composed of largely a composite pulse and doctors have different subjective judgments. There are intersections between the classification of Chinese pulse conditions, these intersections create barriers to the use of big data methods. To solve these problems, the authors suggest collecting the objective data about floating, sinking, fast, thick, thin, strong, weak, smooth, astringent, frequency, and rhythm by a pulse analysis system used for simulating the clinical Chinese medicine pulse diagnosis. Further studies on the function of Chinese medicine pulse condition within TCM analysis of diseases should be subjected to big data analysis to advance the theory of pulse condition. There are new breakthroughs in the field of Chinese pulse condition in the near future.

Automated Evaluation System for Human Pupillary Behavior

Cleyton Rafael Gomes Silva, Cristhiane Gonçalves, Eduardo N. R. Camilo, Fabio Boaretti dos Santos, Joyce Siqueira, Eduardo Simões de Albuquerque, Fabrizio Alphonsus Alves de Melo Nunes Soares, Leandro Luís Galdino de Oliveira, Ronaldo Martins da Costa

Abstract

Analyzing human pupillary behavior is a non-invasive method for evaluating neurological activity. This method contributes to the medical field because changes in pupillary behavior can be correlated with several health conditions such as Parkinson, Alzheimer, autism and diabetes. Analyzing human pupillary behavior is simple and low-cost, and may be used as a complementary diagnosis. Therefore, this work aims to develop an automated system to evaluate human pupillary behavior. The solution consists of a portable recording device, a pupillometer; integrated with a recording and evaluation software based on computer vision. The system is able to stimulate, record, measure and extract relevant features of human pupillary behavior. The results show that the proposed system is fast and accurate, and can be used as an assessment tool for real and extensive clinical practice and research.

Keywords:
Pupil; Computers

Introduction

Human pupillary behavior has been an increasingly important subject in scientific research, showing promising contributions to biometrics [1] and mostly to the medical field [2,3]. Controlled by the autonomic nervous system to provide more accurate vision and ensure retinal integrity [4], this behavior is considered a non-invasive and alternative method to assess neurological activity [3]. Abnormal pupillary behavior can indicate diseases and neurological disorders such as Parkinson [5], Alzheimer [6], autism [7] and diabetes [8].

This pupillary behavior is based on two reflexes, contraction and dilation, or miosis and mydriasis; both are involuntary reactions and are triggered to manage the amount of light entering the eyes [4]. Pupil size management depends on the illuminance level to which the eyes are exposed. Pupil size is inversely proportional to illuminance level. Contraction occurs as the illuminance level increases [9] while dilation occurs whenever illuminance level decreases [10].

As an important biosignal and potential indicator of health states, pupillary behavior is often evaluated by measuring pupil diameter over time under light stimuli, a process known as Pupillometry [11]. This method usually depends on modern technology composed by devices equipped with infrared cameras, which is able to record images even in low light conditions. Such devices, combined with software solutions based on computer vision, are responsible for image acquisition, processing and feature extraction, essential steps for research involving monitoring pupillary behavior.

In this scenario, automated pupillometry solutions can provide effective technology to extract reliable data for patient medical evaluation. Previous studies have shown advances, presenting recording devices in many formats, from robust and large equipment [12] to solutions made with regular materials, as a common eyeglass frame [13]. However, the proposals are not always viable or portable devices with fully integrated systems for real and extensive clinical and research practice.

Therefore, this work aims to develop a portable and comfortable recording device, a pupillometer; with an automated and integrated evaluation system based on computer vision to perform pupillometry procedures. These two components combined form an Automated Pupillometry System (APS), capable of stimulating, recording, measuring and extracting relevant human pupillary behavior features. Results demonstrate the system as a useful and efficient solution and tool for medical and research investigations.

Methods

The method is presented accordingly in the Automated Pupillometry System (APS) stages (Figure 1).

![Figure 1– Stages of the Automated Pupillometry System (APS): (A) Image Acquisition; (B) Segmentation; (C) Object Identification and (D) Pupillary Behavior.](image-url)
The first subsection, Image Acquisition, describes the pupilometer resources and operation, recording function of the software, participants description and the pupillometry protocol applied. The second subsection, Segmentation and Pupil Identification, presents the image processing to highlight the pupil in images and explains the measurement of pupillary diameter. The third subsection, Pupillary Behavior, shows the feature extraction.

**Imagem Acquisition**

**Pupillometer**

The recording device (Figure 2) was built by adapting a virtual reality glasses frame. Two infrared cameras were attached to two acrylic plates, and then on a printed circuit board with an eyeglass shape. The cameras are Point Grey’s mono firefly, FMVU-03MTM-CS model, CMOS sensor (global shutter) and have a USB 2.0 interface. The circuit board was configured to control five RGB LEDs and four infrared LEDs on each side. Infrared LEDs provide illumination for a low light condition whereas RGB LEDs are used for stimuli.

![Figure 2– (A) Pupillometer Off; (B) Pupillometer On.](image)

On each side, Infrared LEDs were arranged in a rhombus format, Figure 2 (B), from five RGB LEDs; four were arranged in a square form and the last one fixed below the acrylic plate. These plates have a circle drawn and become visible by turning the lower LEDs on. Used to guide the gaze, the orientation circle’s luminosity is adjusted so the patient can locate them without triggering pupillary reflexes. During the procedures, to avoid distraction, this circle is lit only in the non-stimulated side.

**Recording Interface**

The developed software was built in Matlab® R2016b platform, using the following toolboxes: image acquisition, image processing, parallel computing and Matlab GUI (graphical user interface). The first window is dedicated to the recording procedures (Figure 3) and has six operation modes, separated by a stimulated and a recorded side, as follows:

1. Stimulated Eye: Right; Recorded Eye: Right.
2. Stimulated Eye: Left; Recorded Eye: Right.
3. Stimulated Eye: Right; Recorded Eye: Both.
4. Stimulated Eye: Left; Recorded Eye: Left.
5. Stimulated Eye: Right; Recorded Eye: Left.
6. Stimulated Eye: Left; Recorded Eye: Both.

In addition to the direct reflection, which is the result of the behavior of the stimulated eye, options: 2, 3, 5 and 6 were created to evaluate consensual reflex, because both pupillary reflexes are expected to be symmetrical, regardless of which side is illuminated [4,14]. This particularity has a medical value as asymmetries are an indicator of optic nerve and retinal diseases [14], as well as brain trauma [4].

In this part of the system, fields and buttons allow users to: define the destination folder and the patient’s ID; display the camera feeds; initiate the timer for dark adaptation; and start or abort recording procedures. The videos are recorded at 30 fps with 640×480 pixels resolution (Figure 5 (A)) and exported in an uncompressed AVI file with the name formed by the patient’s ID plus the letter ‘R’ or ‘L’, depending on the recorded side.

**Participants**

All experimental procedures were reviewed and approved by the Research Ethics Committee in a project submitted to the Brazil platform, under CAAE number: 57179216.8.0000.0033. Forty volunteers were recruited and agreed to participate in this research by signing a free and informed consent term. The research aim and details were explained to all.

![Figure 3– APS Record Window.](image)

![Figure 4– The pupillometer being used by a volunteer: (A) Front View; (B) Side View.](image)
Pupillometry Protocol

The pupillometry protocol (Figure 5) was designed to satisfy three goals: a dark adaptation period of 10 minutes to reach maximum dilation [15], stimuli in colors used for medical [16,17] and biometrics [1] research, and lightless intervals between stimuli to allow the recovery of pupillary size. All these goals were combined in 14:05 minutes.

![Figure 5- Pupillometry Protocol.](image)

Procedures begin with pupillary adaptation in a room with lights off, <1 lux. After the pupillometer is put in position (Figure 4), the software starts the recording the first five seconds to register dilation and continues with a cycle of four stimuli with 1 second duration each, every 59 seconds, in red-blue-green-white order. All stimuli were set in scotopic condition (100 lux) and the intensities were checked by a TAS1-8721 light meter, with ±4% rdg ±10dgt (≤ 10,000 lux) of accuracy. Infrared LEDs were adjusted considering the limit for the eyes’ exposure [18] to 4:05 minutes of recording procedure.

Segmentation and Pupil Identification

Through segmentation, the pupillary region can be isolated and measured in the images. The end result is a signal of the pupillary diameter as a function of time, representing the patient pupillary behavior during the procedure. This signal gives rise to relevant features used to evaluate the pupil behavior. In this work the segmentation proposal consists of six steps (Figure 6).

Gaussian Filtering

The first step, Figure 6 (A), eliminates noise in images. Noise might cause interference in the subsequent processes. Noise is relatively common in the image acquisition process and to minimize the effects, smoothing techniques can be applied [19]. Thus, at this stage, the images are smoothed using a Gaussian filter with σ = 2 and window size = 9. These parameters, defined experimentally, allow most of the noise to not be highlighted in the binarization.

Binarization (Weighted Otsu)

Through the binarization, regions in the image can be highlighted in two different colors; black and white. For this division to be made, a threshold representing the intensity that divides such regions needs to be defined. Although the pupil represents a large and connected dark region in the image, finding the ideal threshold is not a trivial task. Position, color of adjacent areas, facial structure, color and intensity of stimuli, and proximity to the camera are examples of situations where image characteristics can change dramatically. In these cases the same threshold does not get a correct separation.

In this scenario it is important to adapt to these changes and to perform binarization using automatic thresholds. In this step, a segmentation similar to that used in [20] is applied, when using the Otsu’s method. This method seeks to minimize the sum of the object and background variance. For this, the technique performs iteration for all possible thresholds until it finds one that minimizes the sum of the object and background variances.

This method applied to an image that contains the eye structure tends to separate the sclera region, white region, from the pupil and iris, darker regions. However, in order to restrict the pupillary region of the iris region, a weighting factor of 2.5 is applied. This weighting of the otsu value (WO) is efficient and adaptive, as can be seen in the values and results shown in Figure 6 (B). The factor was defined by means of empirical tests on images with different illuminations, proximities and ocular structures.

Morphological Filtering

During the recording procedure and due to the stimuli and the infrared illumination, videos have moments with different levels of illumination. The main difficulty is the presence of reflexes produced by the cornea. For this reason part of the pupillary region is not captured or is extremely compromised (Figure 6 (A-2)). In order to overcome this problem, morphological operations of opening and closing in conjunction with a flood-fill process to close holes are applied in the image resulting from the binarization (Figure 6 (C)).

Numeric Shape Descriptor

Once the objects are isolated in the previous process, there is the possibility that other objects may be highlighted, such as: remaining noises, occluded pupil, pupil with a large part covered by the eyelid and/or eyelashes, as can be seen in Figure 6 (C- 2), or another large dark region. A numeric shape descriptor is used to recognize the pupil or detect moments in which measurement is not possible, such as blinking occasions.

![Figure 6- Segmentation: (A) Gaussian Filtering; (B) Binarization (Weighted Otsu); (C) Morphological Filtering; (D) Numeric Shape Descriptor; (E) Best Fit Circle and (F) Pupil Measurement, (1) Normal, (2) Blinking.](image)
To recognize the pupil or detect moments that there is no possibility of measurement, such as blinking moments, a numeric shape descriptor is used.

The descriptor, equation 1, allows the circularity of the objects in the image to be to calculated [19]. The value resulting from the calculation approaches 1 as the circularity increases, and the value 1 represents a perfect circle. Considering that the pupil does not represent a perfect circle and that in some moments there will be deformations resulting from reflexes, a threshold of 0.65 was experimentally defined and proved to be effective. This value allows to separate images eligible for measurement from those where there is absence of a sufficient pupillary region, as shown in Figure 6 (D-2).

\[ C = \frac{4\pi \cdot \text{Area}}{\text{Perimeter}^2} \]  

(1)

Best Fit Circle and Measurement

Images identified with circular objects pass through a last step before they have their diameter measured. To correctly measure the diameter, even in images whose pupil is partially segmented, a circular fitting process (Figure 6 (E)) calculates the circle that best fits the rectangular limits of the object. This procedure allows for a simple and fast operation to find the approximate pupil diameter (Figure 6 (F)). The diameter extracted through this process is a good approximation of the actual diameter even in images with partial pupils. For research that aims to use the iris boundaries, where it is important to isolate the original pupil shape, the method is also efficient. In these cases the fitting step should be ignored.

Pupillary Behavior

Feature Extraction

The points of interest in the data are those closest to the stimuli. For this, the signal is decomposed by the system in four parts, one for each region influenced. Representing five seconds prior and ten subsequent to a second of stimulus, each decomposed signal represents sixteen seconds of observation. Eight features are extracted from each signal. These features are relevant in order to understand changes in human pupillary behavior [11,21]. Such features are given in Figure 7.

\[ F1. \text{Maximum dilation:} \quad \text{maximum diameter registered in the signal, usually found in the period before the start of the stimulation.} \]

F2. Latency: time spent in seconds between the start of the stimulus and the beginning of the process of contraction, thus considered as a 10% change in diameter.

F3. Time to maximum contraction: time spent in seconds between the start of the stimulus and the maximum contraction registered.

F4. Relative amplitude: percentage value of the difference between the largest and smallest diameter.

F5. Absolute amplitude: absolute value of the difference between the pupillary diameter before the stimulus and the value of maximum contraction.

F6. Maximum contraction: smaller diameter contraction registered, usually found during stimulation.

F7. Post-Illumination response: time in seconds the pupillary diameter takes after the stimulus to achieve 85% of the previous value.

F8. 6 sec test: diameter registered 6 seconds after the end of the stimulus.

Results and Discussion

In this research, the experiment was accomplished with 40 volunteers. In all cases both eyes were recorded with the right side receiving stimuli. As each video was recorded at 30 frames per second, they are composed of 7,350 frames each. The procedure was able to extract the pupil behavior using the diameter and calculate the features successfully in all cases. A total of 588,000 frames were processed by the system. At the end of each processing a screen displays the results, as shown in Figure 8. All data are stored automatically in an Excel file, with the diameter values in pixels and percentage scales. The file also contains a comparison between the left and right side.

In order to measure the performance and effectiveness of the segmentation process, the images from each participant were separated into five categories, one for the moment without stimulation and one for each color used: red, blue, green and white. This is justified by the fact that each color of stimulus changes the features of the image differently. After this separation, two images for each period and participant were randomly selected, totaling 400 images.

Through segmentation of the selected images, the average speed processing was 347.84 milliseconds. For testing, a computer with intel core i5 processor and 4 GB of RAM was used. For the calculation of accuracy, the number of correct segmentations was divided by the total number of images. By means of this calculation, the percentage of accuracy of the approach reached the value of 97.25%.
It is worth mentioning that the images on which the method was not successful were those whose pupil was partially covered by eyelashes or eyelids. Images on which the pupil was totally or practically covered were eliminated and replaced by a new image of the same category. It is important to emphasize that the numeric shape descriptor used allowed 100% of these cases of pupillary occlusion to be automatically excluded.

Conclusion

This study proposes an Automated Pupillometry System (APS). The segmentation process is essential for this approach and is fast and effective, reaching a level of accuracy of 97.25%. This factor allowed the system to be able to extract 8 important features of the human pupillary behavior for each type of stimulus, totaling 32 features. All the processes from the acquisition, to the generation of the data in the file were made in automated form; fulfilling the main goal of this work. Blinking is one of the main problems in pupil segmentation and the main cause of noise in data. The usage of a shape descriptor is able to remove it in its totality. Therefore, the system represents an efficient pupillometry solution for extensive practices in medical and research investigations. In future work, the objective is to implement functions to allow the pupillometry protocol to be customized, considering the time, color and interval between stimuli. This will make procedures more flexible for even wider use.

Prescription Opioid Dependence in Western New York:
Using Data Analytics to Find an Answer to the Opioid Epidemic

Shyamashree Sinha, Gale R Burstein, Kenneth E Leonard, Timothy F Murphy, Peter L Elkin

Abstract

Opioid dependence and overdose is on the rise. One indicator is the increasing trends of prescription buprenorphine use among patients on chronic pain medication. In addition to the New York State Department of Health's prescription drug monitoring program, steps have been taken to address this. This paper uses an observational database with Natural Language Processing (NLP) based Not Only Structured Query Language architecture to examine Electronic Health Record (EHR) data at a regional level to study the trends of prescription opioid dependence. We aim to help prioritize interventions in vulnerable population subgroups. This study provides a report of the demographic patterns of opioid dependent patients in Western New York using High Throughput Phenotyping NLP of EHR data.

Keywords:
Substance-Related Disorders; Prescriptions; Natural Language Processing

Introduction

Dependence and abuse of prescription opioid pain medication has substantially increased over the last decade. The rise in opioid dependence contributes to the rising prescription drug overdose deaths over the last decade. In 2014, approximately 1.3 million adults aged 26 or older had a pain medication use disorder in the past year. According to the 2014 National Survey on Drug Use and Health, published by the Substance Abuse and Mental Health Service Administration (SAMSA) about 0.6 percent of the population aged 26 or older were opioid dependent [1].

New York State has seen a steady rise in opioid related deaths from 1 per 100,000 people in 2010 to 4.2 per 100,000 people in 2013 [2]. This is considerably higher than many other states in the United States. The state health department is taking steps towards controlling this epidemic by training first responders, fire fighters and local health officials to recognize and treat opioid related overdoses. The non-medical use of prescription drugs has been on the rise among persons 12 years and older. This has led to the challenge of clinicians treating patients with chronic pain and the decision to treat the pain with opioid medications.

The New York State Department of Health (NYSDOH) implemented a prescription drug monitoring program, I-STOP, in August 2013. This gives the prescribing providers a secure access to the patients’ registry of class II, III and IV controlled substance medication, which they are expected to consult before ordering any prescription pain medications. In 2016 NYSDOH implemented an amendment to the New York State Public Health Law §3331, that limits the prescription of controlled substances duration to seven days for the first prescription of narcotics for an acute pain condition [3].

There are many studies on the risk of opioid abuse and overdose among opioid dependent people [4, 5]. In March 2016, the Centers for Disease Control and Prevention (CDC) published chronic pain medications prescribing guidelines which presented an evidence based approach to patient assessment and prescription opioid monitoring tools [6].

On reviewing recent clinical evidence with an aim to propose adequate guidelines for prescription of pain medication the CDC concluded that there is insufficient evidence of effectiveness of long term opioid use for chronic pain [7]. In addition there is evidence of increased risk of overdose among patients using Methadone for long term opioid therapy or dependence [8]. Long term prescription opioid therapy for acute pain indications may result in higher incidence of opioid dependence [9, 10].

Knowledge about the epidemiology of local opioid dependent people may enable health care providers and population health workers to take proper actions. We used our web server based Natural Language Processing (NLP) system to identify the cases of opioid dependence among our primary care clinic population in the Western New York (WNY) area.

The study of the distribution and determinants of opioid dependence among patients who are treated with chronic pain medications prescribed by their healthcare providers would aid in answering some key questions about potential abuse and overdose on opioids. The descriptive epidemiology of opioid dependence would help in identifying vulnerable age groups, gender, race, ethnicity, regional distribution and type of opioid pain medications, that more commonly result in dependence.

Methods

Technology

We implemented an Observational Medical Outcomes Partnership / Observational Health Data Sciences and Informatics (OMOP / OHDSI) database, to hold structured EHR data from local area primary care clinics managed by Allscripts company. We also created a high throughput
phenotyping, NLP system, which can parse 7 million clinical notes in 1.5 hours. This runs as a web service and provides a modular component based NLP system. After the full semantic parse, we match the content against any number of ontologies. For each match, we tagged it as either a positive, negative, or uncertain assertion. We then performed automated compositional expressions. We stored the codes in a Berkeley database (BDB) NOSQL database, and the compositional expressions are stored in Neo4J (a graph database) and Graph DB (a triple store). This flexibility allows rapid retrieval of complex questions in real time.

In comparing the NOSQL database’s retrieval times to SQL queries with either Oracle or SQL Server, we found the NOSQL database to improve performance between 100-1000 fold. Bio surveillance of influenza from clinical encounter notes using this NLP system has been shown to be superior to the conventional tools of surveillance, by Elkin et al in Ann. Int. Med. 2012 [11]. Evidence of effective monitoring tools for post-operative complication in patients in the VA hospital systems with this method has also been published in JAMA, 2011 [12].

Analysis

The retrospective analysis of EHR data from local clinic patients was performed using queries on the problem list, demographic data and medication list of all the patients in the data base. The OMOP/OHDSI data base was collected from Allscripts EHRs from 2010 to 2015. This common data model helps in the systematic analysis of disparate observational data bases of clinic records from the primary care and family medicine clinics in WNY region.

The database contained 212,343 patient records that were parsed and deidentified. Specific research IDs were assigned to each of the patient records and stored in a secure firewalled device for data analytics. The entire 212,343 records were queried for opioid dependence from the ICD9 and 10 diagnostic codes and SNOMED CT codes mapped to both the clinical notes and the problem list for each patient based on the mapped ICD and SNOMED CT codes. 1356 patients were identified as to having opioid dependence. Based on the age distribution (age range of 19 to 89 years) the population was divided into eight age groups (Table 1).

High Throughput Phenotyping

The High-Throughput Phenotyping (HTP)-NLP subsystem is a software that produces, given biomedical text, semantic annotations of the text. The semantic annotations identify conceptual entities - their attributes, the relations they have with other entities and the events they participate in, as expressed in the input text. The conceptual entities, relations, attributes, and events identified are specified by various knowledge representations as documented in Coding Sources. Examples of coding sources are medical terminologies [e.g., SNOMED CT, RxNorm, LOINC] and open biomedical ontologies foundry ontologies, e.g. Gene ontology, Functional Model of Anatomy]. The annotation results may be displayed or output in formats suitable for further processing. Entity identified is assigned a truth value from zero to one. Values from the text are assigned to entities from ontologies such as SNOMED CT. Where applicable data were combined into post-coordinated compositional expressions. These are fit into clinical models such as a) Course of Illness, b) Course of Treatment, and c) Course of Hospitalization. This method provides the most accurate NLP solution for health available based on published numbers. It is the only system that handles uncertainty and handles automated post-coordination which has been proven to be required for 41% of the problems with which clinicians commonly have to deal [13]. The system will be used to generate semantic triples for use in referent tracking and overlaying of clinical research models.

Results

Of the 212,343 patients in the database, 1356 patients revealed opioid dependence on the problem list, ICD9-10 codes and prescription opioid pain medication with or without Buprenorphine or Suboxone in the medication list. The prevalence of opioid dependence in the clinic population was 0.64% (95% CI:0.61%-0.67%) over a five-year period.

The highest numbers of opioid dependence were seen in the 29 to 38 years’ age group. That comprised 39.38% (95% CI: 36.78% to 41.98%) of the total opioid dependent population but accounted for only 2.03% of whole clinic population in this age group (95% CI:1.86% to 2.2%) (Table 1).

The subjects were then stratified by gender, race and ethnicity. There were 1005 patients with opioid dependence, among the Non-Hispanic population (total number 108,402).

Among the white Non-Hispanic population with opioid dependence, 41.33% (95% CI: 38.27% to 44.39%) were 29-38 years old. The next common age group among the White Non-Hispanic opioid dependent subjects was 19 – 28 years, comprising of 22.48% (95% CI: 19.88% to 25.08%) of the total number of white Non-Hispanic or Latino opioid dependent population (Figure 1) (Table 2).

A total of 35/1356 patients with opioid dependence were from the Hispanic community. The rest of the 311 opioid dependent patients in the clinic did not have any race ethnicity records. The distribution of opioid dependence among the Hispanic population is shown in Figure 2.

![Figure 2 – Distribution of Opioid Dependence among Hispanic population (x axis- age and ethnicity, y axis-number)](image)

We also queried the database to identify the names and quantity of opioid medication(s) used and the provider identification numbers associated with that prescriptions. The most commonly written prescription pain medication was of Hydrocodone Acetaminophen 7.5-500 mg tablets. The providers writing the most prescriptions could also be identified based on the provider identification numbers (Table 3). This information can be useful in following providers with a higher rate of prescription for opioid pain medications. The first three numbers of the zip codes were obtained for these patients and one particular area was found to be more affected than others (Figure 3).

![Figure 3 - Distribution of opioid dependent patients (y axis) according to first three numbers in zip codes (x axis)](image)

### Discussion

The trends of opioid dependence among the WNY clinic population in our study indicate that the prevalence is more in a certain section of the population. The predominance is among the Non-Hispanic, white population in the 19 to 38 years of age group. The prevalence in younger age implies that the complications related to opioid dependence would become a costly burden of disease for a longer duration of time. The prevalence of dependence in this clinic population will rise if this trend continues. Interventions at curbing prescription opioid dependence is necessary in this area.

The recent CDC [7] and SAMSHA [1] reports on drug overdose related deaths all indicate the urgent need to have a multidisciplinary approach for guidelines implementation, access to medication assisted treatment programs and naloxone training and distribution to first responders. In order to prevent overdose related deaths our HTP-NLP method of knowledge extraction from EHR is useful in cost effective and timely implementation of intervention.

There is a significant body of evidence indicating that short term acute pain medication prescriptions can lead to opioid dependence [9,10]. In addition, more people die of overdoses from prescription medication than from heroin, which is a rapidly growing problem [4,6,8].

Observational databases with codified data from the clinical notes using standardized ontologies such as SNOMED CT can be very useful for identifying problems of high socioeconomic impact, like prescription opioid addiction. NOSQL databases can make accessing large databases with billions of values practical for real time retrieval. We have knowledge from prior studies that robust ontology based SNOMED CT has
good coverage of clinical thoughts and concepts in terms of surveillance [11, 12]. This study paves the way towards further development of real time bio surveillance with the tools of informatics.

There were a few limitations to this study. As it was a retrospective study on an existing database, the time to create an expert system and testing it out was not factored in. The dates and exact duration of the prescribed medications were not available. The indication for prescription and duration of symptoms were not clear. The question of potential illicit drug abuse or access and availability of methadone or buprenorphine for medication assisted treatment is not known. The potential confounders of alcoholism, smoking and or history of major depressive episodes were not taken into consideration. We assumed these are distributed uniformly over age groups, ethnicity, race and geographic distribution.

Conclusions

This was a retrospective analysis of provider EHR data from local WNY area primary care clinics looking at the epidemiology of the opioid dependent population, the rate of opioid prescriptions that may be monitored through the EHRs and the geographic distribution of the population in question.

This could provide insights into patient care patterns on a real time basis. The distribution of the opioid dependent population identified in this study indicate a disparity by age, ethnicity and race. The geographical distribution of the dependent population shows a peak in a particular region. These informations could be used to allocate resources for special preventive programs in these areas.

The young age of many of the addicted patients gives rise to the question whether legitimate opioid prescriptions are leading these age groups towards addiction. This emphasises the need for routine screening for substance abuse in patients who are on opioid pain medications. The evidence of overdose and risk of abuse with other illicit agents in this population indicate the needs for realtime intervention among opioid dependent population. Future health informatics based research should be directed towards the surveillance and intervention of patients on long term opioid pain medication.

Observational databases linked to codified NOSQL datastores powered by high throughput phenotyping approaches are a useful mechanism for warehousing translational datasets such as EHR data including codified clinical notes and reports. This mechanism can be used to implement clinical decision support tools that would provide information tailored to specific patient needs. Prior studies in this area on monitoring post operative complications within electronic medical records and biosurveillance of influenza have established evidence for this method [11,12].

Further translational studies and implementation efforts are needed in the area of opioid prescribing and addiction in order to find a cost effective and quality intensive strategy for the nationwide opioid epidemic.

Phenotyping and Visualizing Infusion-Related Reactions for Breast Cancer Patients

Deyu Sun, Gopal Sarda, Steven J. Skube, Anne H. Blaes, Saif Khairat, Genevieve B. Melton, Rui Zhang

Abstract

Infusion-related reactions (IRRs) are typical adverse events for breast cancer patients. Detecting IRRs and visualizing their occurrence associated with the drug treatment would potentially assist clinicians to improve patient safety and help researchers model IRRs and analyze their risk factors. We developed and evaluated a phenotyping algorithm to detect IRRs for breast cancer patients. We also designed a visualization prototype to render IRR patients’ medications, lab tests and vital signs over time. By comparing with the 42 randomly selected doses that are manually labeled by a domain expert, the sensitivity, positive predictive value, specificity, and negative predictive value of the algorithms are 69%, 60%, 79%, and 85%, respectively. Using the algorithm, an incidence of 6.4% of patients and 1.8% of doses for docetaxel, 8.7% and 3.2% for doxorubicin, 10.4% and 1.2% for paclitaxel, 16.1% and 1.1% for trastuzumab were identified retrospectively. The incidences estimated are consistent with related studies.

Keywords:
Phenotype; Patient Safety; Algorithms

Introduction

Infusion-related reactions (IRRs) and hypersensitivity are adverse drug events (ADRs) that can occur during chemotherapy administration. Nearly all chemotherapeutic agents have the potential to induce an IRRs with various severity [1]; more frequent and severe IRRs are labeled in black box warnings of the package inserts. Hypersensitivity is defined as an immune reaction to an antigen; in this case, a component of a chemotherapy drug. An IRR is an unexpected reaction to a drug [1]. These terms are often used interchangeably in reference to adverse events, although the definition of hypersensitivity refers to an allergic reaction to a previous exposure. Here we include infusion-caused hypersensitivities as a type of IRRs. The incidence of these reactions varies widely among reports, for example, an estimate of IRRs incidence of general medications is 2-15% [2] and an estimate of IRRs incidence of trastuzumab is 0.7-40% [3]. There is lack of estimates of IRRs incidences of other medications against breast cancer. The signs and symptoms of these adverse events are broad, often difficult to define, and include all organ systems. Examples include anaphylaxis, rash, respiratory distress, hypotension, nausea, flushing, and fatigue. The severity of these reactions is mild to severe, in rare instances leading to death [1].

Currently, the detection of IRRs is based on manual chart review [3-5]. An appropriate phenotyping algorithm not only would assist clinicians increase performance to detect IRRs, avoid information overload, and ultimately improve patient safety, but also benefit researchers in modeling and analyzing risk factors of IRRs.

Moreover, in the highly time constrained clinical care setting, visualizing patients’ active medication status and associated IRRs may assist clinicians in avoiding medication errors and would also assist researchers in understanding clinical correlations. Most current visualization systems focus on showing structured data alone, without integrating additional knowledge and phenotyping algorithms, such as serious ADRs associated with medication usage. In this pilot study, we developed and evaluated a phenotyping algorithm for identifying IRRs with four first-line breast cancer drugs, namely, docetaxel, doxorubicin, paclitaxel, and trastuzumab. In addition, we further developed a visualization prototype for correlating associated IRRs with the drugs for individual patients.

Methods

As illustrated in Figure 1, the methods consist of four parts: (1) extracting IRRs from structured drug product labels; (2) collecting relevant EHR data; (3) detecting IRRs by the designed phenotyping algorithm; and (4) rendering IRRs detected by visualization prototype and evaluation.

![Flowchart of the method](image-url)
In this study, we focus on the 63 brands of medications with 28 different chemical makeup approved by Food and Drug Administration (FDA) to treat breast cancer [6]. Using a previously described approach, we first extracted all IRRs (including infusion-caused hypersensitivities) from the current package inserts, i.e., FDA Structured Product Labels (FDA SPL) annotated by natural language processing (NLP) algorithms [12]. Five medications (i.e., docetaxel, doxorubicin, epirubicin, paclitaxel, and trastuzumab) among these have black box warnings of IRRs (including infusion-caused hypersensitivities) [7-11]. Since epirubicin is not found in our patient cohort, we only focus on other four medications in this study.

Clinical data for breast cancer patient cohort stored in the Fairview Epic EHR were extracted from the University of Minnesota clinical data repository. Using the domain knowledge, we categorized the IRRs into 17 symptoms according to their similarity in medicine (Table 1) and listed all the related ICD-9-CM and ICD-10-CM codes, which would be used in our phenotyping algorithm (Figure 2).

As shown in Table 1, the symptoms of the IRRs are quite broad, e.g., from chills to nausea, from hypotension to fatigue. To include comprehensive information from EHR data, we used various heterogeneous data (e.g., diagnosis, lab results, and clinical notes) for IRRs detection. Collaborating with clinical experts from University of Minnesota Medical Center (UMMC), we developed a phenotyping algorithm using related concepts mentioned in the unstructured clinical notes, dynamic changes of lab tests from baseline, and related diagnosis codes (Figure 2).

Clinical notes were found containing important indicators of IRRs during the retrospective chart review by clinicians. We used open-source natural language processing (NLP) tool, BioMedICUS (Biomedical Information Collection and Understanding System) [13], to search related biomedical concepts in patients’ clinical notes. BioMedICUS is an open-source NLP system based on the Unstructured Information Management Architecture – Asynchronous Scaleout (UIMA-AS) architecture specialized in NLP-related information extraction and understanding of clinical notes. BioMedICUS identifies UMLS Metathesaurus concepts (concept unique identifiers, or CUIs) from lexical variants expressed in the notes, and whether the identified concepts were used in a...
negated context. As shown in Table 2, we include CUIs related to the synonyms of IRRs (Table 2) within the 24 hours of infusions of docetaxel, doxorubicin, paclitaxel, or trastuzumab from patients’ clinical notes as inputs illustrated in our phenotyping algorithms (Figure 2).

</table>

In addition to clinical notes, patients with IRRs usually show abnormal lab test values, vitals, or diagnoses of abnormal syndromes. However, as shown in Table 1, such syndromes are not specific to IRRs. To precisely attribute reactions to infusions, we not only apply temporal constraints (i.e. abnormal syndromes should happen within 12 hours of infusions), but also consider the change from baseline (i.e. only the syndromes that break out after infusion but not exist one month before infusion (baseline) are viewed as evidence of IRRs). The baseline of lab tests and vitals is defined as the most recent measurement within one month before infusion. The abnormal change from baseline within 12 hours can be found in two scenarios.

- First, the qualitative change, a change from a negative state at baseline to positive after infusion, e.g., a type of syndrome (diagnosed by ICD-9-CM or ICD-10- CM) shown in Table 1 that did not exist within one month before infusion but broke out right after infusion. Similar cases include WBC changes from normal (≤ 11×10^9/L) at baseline to abnormally high after infusion (> 11×10^9/L), lactic acid changes from normal (≤ 2.0mmol/L) to abnormally high (> 2.0mmol/L), and oxygen saturation changes from normal (≥ 90) to abnormally low (<90).

- Secondly, quantitative change, a sufficiently large change in measurements from the baseline, e.g. the blood pressure in Mean Arterial Pressure (MAP = (2 x diastolic + systolic) / 3) with a change of no less than 10 mmHg, or a change in temperature of more than 2 Fahrenheit, or a change in respiration rate of more than 5, or a change in heart rate of more than 20 beats/min.

Only the abnormal syndromes meeting both the temporal constraints and the requirement of sufficient changes from baseline serve as evidence of IRRs. For evaluation, 42 doses of the four medications were randomly selected, the clinician then manually reviewed the charts and labeled each case as true IRR (13 cases) or false IRR (29 cases). The detection results of the phenotyping were then compared with the expert curated gold standard. The sensitivity, positive predictive value (PPV), specificity and negative predictive value (NPV) were reported. We also compared the incidence rates of IRRs on patients who used these four medications in our EHR data.

We have also created a visualization prototype to render the entire medications, vitals, labs and diagnosis data for a patient over time by using Grails framework. The interface of the visualization tool is shown and detailed in the Results section. We randomly selected two patients with true positive IRRs detected by our phenotyping algorithms and visualized their breast cancer medications and any related lab values and symptoms existed in Fairview EHR data.

Results

We applied our phenotyping algorithms into the cohort consisting of 4,084 breast cancer patients treated from the fourth quarter of 2000 to the second quarter of 2016. There are total 236,069 doses of all medications. Table 3 shows the total patients and doses of docetaxel, doxorubicin, paclitaxel, and trastuzumab. Note, epirubicin is not used in UMMC.

Table 3–Number of patients and doses on docetaxel, doxorubicin, paclitaxel, and trastuzumab in UMMC

As an evaluation, a clinician from UMMC manually diagnosed 42 doses by chart review. Table 4 shows the detection results by our phenotyping algorithms. The sensitivity and PPV of the algorithm are 69% and 60%, respectively, while the specificity and NPV are 79% and 85%, respectively.

Figure 3 renders two IRRs events. The visualization supports viewing two types of data at a time. The time axes for all the types of data are aligned. With medication information always displayed, clinicians can select one of the Vitals/Labs/Diagnosis panel as the other data source. Each medication consumption information is represented by a horizontal bar, with length of the bar reflecting the duration of consumption and height of the bar reflecting the dosage of the medicine. Since, there can be many interesting vitals/labs corresponding to a patient, the visualization provides an option to select one of the many vitals/labs available. Normal ranges for a lab/vital are also marked using the red and blue dotted lines as can be seen in Figure 3. The diagnosis data is displayed in a grid format with rows as different type of diagnosis and columns as time. A dot in a cell indicates a type of diagnosis reported on the date. The IRRs in Figure 3(a) was detected by abnormal change in blood pressure from the baseline. We can see the baseline blood pressure is 75.67mmHg measured at 9:50 am; after the patient gets infusion at 4:24 pm (labeled by the blue bar inside the block denoting a paclitaxel infusion), the blood pressure increases by 11.66mmHg, up to 87.33mmHg, which indicates an IRRs. Figure 3(b) shows another IRRs detected by the breaking-out of a syndrome. We can see after getting infusion at 12:49 pm on 3/12/2012, the patient experienced chills and nausea on 3/13/2012; considering the clinical note of the patient also mentions the IRRs, the phenotyping algorithm classifies the reactions as IRRs.

**Discussion**

The incidences of the IRRs detected by our phenotyping algorithm are consistent with other researchers’ studies. The incidence of four medications (docetaxel, doxorubicin, paclitaxel, and trastuzumab) varies from 6.4% to 16.1% of patients, which is consistent with the results reported (a wilder estimate, 0.7%- 40% [2], and a more precise estimate 2-15% [3]). By manual chart review, L. M. Thompson et al detected 33 patients with 33 IRRs out of 197 patients with 1.788 doses of trastuzumab, resulting in an incidence of 16.2% of patients and 1.8% of doses; our method has quite close incidence to these results (16.1% of patients and 1.1% of doses).

Developing phenotyping algorithm to detect IRRs is vital for patient safety. Compared to the manual review in time-constrained clinical setting, automatic detection would greatly improve the performance of clinicians in finding

ADRs. Accessing various types of EHR data for patients in a short time would potentially aid clinicians in making decision or changing treatment plans.

According to evaluation results, our phenotyping method has a better performance of classifying negative cases (with specificity of 79% and NPV of 85%), indicating it would be useful in reducing clinicians’ workload by filtering out negative doses. On the other hand, we analyzed the relatively high false positive cases and found that most of the false positive cases are detected by changes in diagnoses (i.e. ICD codes), which is due to inaccurate time of diagnoses. The time of diagnosis recorded in the EHR database is usually one day delayed after the syndrome actually broke out (since coding takes time), as a result, some IRGs caused by previous doses were falsely identified to be caused by later doses.

Our pilot work is limited by the collection of gold standard. Since chart review is time-consuming and expensive, we only have a small size of labeled cases (42 for now) created by one physician, which limits the precision of our evaluation. Currently, the parameters of the phenotyping method are estimated based on expert’s domain knowledge without referring to guidelines. In future, we are going to collaborate with more domain experts and incorporate more information, such as allergy history, and more knowledge, such as the guidelines, to automatically generate more labeled cases and improve parameter estimations by using data-driven methods.

Conclusion

In this study, we proposed a phenotyping algorithm to detect IRGs for breast cancer patients who took docetaxel, doxorubicin, paclitaxel, and trastuzumab. The phenotyping algorithm was evaluated by expert chart review. The sensitivity, PPV, specificity, and NPV are 69%, 60%, 79%, and 85%, respectively. We also developed a visualization prototype, which integrates and visualizes multiple information such as medications, vital signs, and lab test results over a specific period in one interface. The phenotyping algorithm and visualizing prototype developed in the study have potential to be adapted to detect IRGs caused by other medications. Such phenotyping algorithm and visualization method can also be applied to the clinical decision support system to improve the healthcare efficiency and patient safety.

A Deep Learning-Based Method for Similar Patient Question Retrieval in Chinese
Guo Yu Tang, Yuan Ni, Guo Tong Xie, Xin Li Fan, Yan Ling Shi
*IBM Research, China, Beijing, China
+Pfizer, Beijing, China

Abstract
The online patient question and answering (Q&A) system, either as a website or a mobile application, attracts an increasing number of users in China. Patients will post their questions and the registered doctors then provide the corresponding answers. A large amount of questions with answers from doctors are accumulated. Instead of awaiting the response from a doctor, the newly posted question could be quickly answered by finding a semantically equivalent question from the Q&A archive. In this study, we investigated a novel deep learning-based method to retrieve the similar patient question in Chinese. An unsupervised learning algorithm using deep neural network is performed on the corpus to generate the word embedding. The word embedding was then used as the input to a supervised learning algorithm using a designed deep neural network, i.e. the supervised neural attention model (SNA), to predict the similarity between two questions. The experimental results showed that our SNA method achieved P@1=77% and P@5=84%, which outperformed all other compared methods.

Introduction
People are likely to encounter various health-related questions during their daily life. For example, patients with diabetes may want to know how to manage their diet or whether two kinds of drugs will interact. Recently, there has been a significant increase in the popularity of the online patient Q&A service worldwide. The service is provided as a website at the PC (personal computer) side or as an application on the mobile phone. In China, the most popular website of this kind is called 好大夫在线 (www.haodf.com) which has more than 130,000 registered doctors and has accumulated more than 18 million Q&A pairs; and the most popular mobile application 春雨医生 (ChunYu Doctor) has 92 million registered users and 490,000 registered doctors, and it has built up a question and answer archive of 95 million pairs. A similar situation has arisen in the U.S. as a study by Pew Internet Project’s research reported: 87% of U.S. adults reported internet use, and 72% of Internet users sought health information online [1].

Given the large number of accumulated Q&A pair archive, it is likely that a newly posted question by a user would be asked by another user previously. However, the patients lack of professional knowledge or laziness for searching the archive to find a similar history question, and instead they wait for hours for the response from a doctor. To avoid the lag time and to reduce the workload on the doctors, a better method is to automatically retrieve the semantically equivalent question from the archive. Then the answer to the equivalent question could be replied to the user immediately.

However, it is not trivial to measure the equivalence between two questions. The major challenge is the so-called lexico-syntactic gap. Two questions that are semantically equivalent may be represented in very different ways. For example, both the question “我有高血脂，如果使用食疗，应该怎样配餐?” (I have the hyperlipidemia, if I want to use the food therapy, what can I eat?) and the question “高血脂的病人怎样调整饮食?” (How to adjust the diet for hyperlipidemia patients?) are asking the same thing, i.e. how to manage the diet for hyperlipidemia patients. However, they have few overlapping terms.

Several methods have been proposed to address the similar question retrieval problem, which could be classified into three categories. The first category of methods model this task using machine translation models [2-4]. The word-based/phrase-based translation model is trained and the similarity of two questions is measured by the probability of translating one question to another. The second category of methods use topic models [5-7]. These methods use the question corpus to train a latent topic model and the similarity of questions is measured by the similarity of mapped vectors in the latent topic space. More recently approaches explore deep neural networks. The deep learning can learn high-level feature representations by designing a deep neural network. It has achieved the state-of-art performance in many tasks. Das et al. [8] used a twin convolutional neural network with shared parameters to train the question similarity model. Lei et al. [9] designed a recurrent and convolutional model with adaptive gating to map the questions to their semantic representation. The resulting question vectors are compared with other questions via cosine similarity.

However, the above proposed approaches are applied on the general domain while there are additional challenges in handling the questions within health care domain. Firstly, the collection of training corpora is not as easy as in the general domain. For example, the word embedding used in the deep learning-based method in the general domain could use Wikipedia, while the generated word embedding is not suitable for the health care domain. Secondly, the questions in the health care domain are more complicated which involve the descriptions of diseases, signs and symptoms, etc. SimQ by Luo et al. [10] is proposed to address the retrieval of similar consumer health questions. Their method makes use of the UMLS (Unified Medical Language System) to annotate the semantic types and medical concepts from the questions. Then the similarity of questions is calculated using both semantic and syntactic features. Wongchaisuwat et al. [11] have proposed a semi-supervised method to improve the similar question retrieval and apply it in alcoholism related questions.
In this paper, we proposed to use a deep neural network model with a supervised learning to determine the similarity between patient questions. We focus on the patient questions in Chinese, which brought additional challenges. For example, Chinese does not have a space to separate the word, then we need an accurate word segmentation to guarantee the final performance. We have crawled Q&A pairs from the top four online service websites. This corpus is used to generate the word embedding using via unsupervised learning. Then the word embedding is used as the input to another deep neural network leveraging supervised learning to determine the similarity between questions. The second neural network makes use of the recurrent neural network (RNN) encoder to encode the input questions and then on top of these encoders, word-by-word attention is employed to get word alignment and compare measurement for words from questions. Then an output long short-term memory (LSTM) layer is used to summarize the compare results and output the labels. A labeled dataset from human experts is used to generate the training and testing dataset for question similarity judgement.

**Methods**

In this section, we introduce the preparation of the corpus and how this corpus is used to generate a word embedding for patient question data. Next, we describe how we generate the training and testing dataset for the supervised learning. Finally, we illustrate the approaches we have compared and designed for similar patient question retrieval.

**Word Embedding Generation**

The first step of our method is to generate the word embedding for the terms in the health care domain. This involves a mathematical embedding from a space with one dimension per word to a continuous vector space with much lower dimensionality. The semantically related terms will be close to each other in the mapped space. The word embedding has been shown to be useful in various natural language processing tasks.

A large corpus that covers most of the terms in the scenario is required. In our work, we have crawled the top 4 online Q&A service websites. The obtained number of Q&A pairs (62.9 Megabytes in total) is listed in Table 1. In this work, we focus on the cardiovascular medicine related questions, thus we only crawled Q&A pairs in this area. Please note that the number of Q&A pairs on these websites is larger than what we have crawled. As these websites only expose 200-1000 pages of the most recent questions, we are not able to crawl all historical questions. But our crawler continues to crawl periodically, we will accumulate more Q&A pairs.

<table>

</table>

After the Q&A pairs corpus is obtained, we need to pre-process the data before feeding the data to the neural network. The pre-processing includes punctuation removal and word segmentation. We use regular expressions to remove the punctuation. The word segmentation required is different with English there is no space between words in Chinese. We have tried the available word segmentation tool in Chinese.

However, the results are not satisfying as the dictionary used in the word embedding tool does not cover enough medical terminologies. Zhang et al. [12] also proved the necessity of domain dependent word segmentors and the effectiveness of word embedding in dealing with clinical notes. Thus, we need to prepare a medical terminology to extend the dictionary. There are two challenges here; firstly, most well-defined terminologies in English do not have a Chinese version, e.g. SNOMED CT. Secondly, as the questions are from patients, the professional terminology from domain experts may not cover most of the terms from patients. In our work, we have collected the medical terms from three sources: (1) the Chinese version of the well-defined terminologies such as ICD-10 and LOINC; (2) the drugs that are crawled from the China Food and Drug Administration; (3) the drug names and the diagnoses names in the health information system. Our final dictionary contains 2732 disease names, 6021 symptom names and 5821 drug names. In addition, we have identified 33745 synonyms for these terms. We use this dictionary to extend the existing word segmentation tool and use it to do the word segmentation on the corpus.

Finally we use the Skip-Gram model in [13] to generate the word embedding. As based on Mikolov [13], the Skip-Gram is better for infrequent term representations. In our scenario, drugs, symptoms, and diseases are important terms while they may occur infrequently in the corpus. The content window size is set to 9 and the dimension of word vectors is set to 200. Table 2 shows some examples of semantically related terms captured by our word embedding.

**Dataset**

We invited domain experts to annotate the semantically equivalent questions. We selected 1688 questions in the hyperlipidemia area and asked the domain experts to group the semantically equivalent questions. Finally, the domain experts divided these questions into 241 groups. We randomly selected 1488 questions for training 100 questions for validation and 100 questions for testing. For the 1488 questions in the training dataset, we generated the equivalent question-question pair for each pair of questions in the same group. This is treated as the positive example. Then, we randomly sampled negative examples. Assume a question q in a group contained r equivalent questions, we randomly choose 2^n questions in different groups with q as negative sample set.
for question \( q \). And for each question in the training dataset, we get a negative sample set following the sampling strategy above and join all sets together as negative examples for supervised learning approaches.

**Approaches**

This section introduced the detailed methods we have explored and designed in this work. The first two methods, i.e. cosine similarity with Bag of word model (BOW-COS) and Word mover distance with word embedding (WE-WMD) are unsupervised methods and the other two methods, i.e. Supervised Siamese Recurrent Neural Network Model (SSRRN) and SNA, are supervised methods using deep neural networks. The BOW-COS is the baseline method and the SNA is an innovated neural network structure for calculating the similarity of two questions.

**Cosine similarity with Bag of word model (BOW-COS)**

BOW is a traditional text representation used in natural language processing and information retrieval. In this model, a question is represented as a vector of \( n \) dimension where \( n \) is total number of words in the corpus. Each dimension corresponds to a word, if the word appears in the question, the dimension is set to 1; otherwise it is set to 0. In addition, the Term Frequency-Inverse Document Frequency (TFIDF) weight is used to weight each word. This weight is a statistical measure used to evaluate how important a word \( t \) is to a document \( d \) in a corpus \( D \) contained \( N \) document and can be calculated as follows:

\[
\text{tfidf}(t, d, D) = f_{t,d} \cdot \log \left(1 + \frac{n_t}{n_d}\right)
\]

where \( f_{t,d} \) means the frequency of word \( t \) in document \( d \) and \( n_t \) means the number of document containing word \( t \) in document collection \( D \).

Cosine similarity is a traditional similarity algorithm for calculating the similarity score between two sentences or articles. The similarity score has a value of range 0-1. A score of zero means two questions are not similar at all, and a score of one means that they are completely the same. Assuming that there are two feature sets \( F_1 \) and \( F_2 \) that are generated from two different patient questions, the cosine similarity can be calculated as follows:

\[
\text{COS}(F_1, F_2) = \frac{\sum_{i=1}^{m} f_{i,1} f_{i,2}}{\sqrt{\sum_{i=1}^{m} f_{i,1}^2} \sqrt{\sum_{i=1}^{m} f_{i,2}^2}}
\]

**Word mover distance with word embedding (WE-WMD)**

The traditional BOW-COS calculates similarity of two questions based on their lexical overlap. However, the method failed to capture the semantic similarity of terms that are different. As the example mentioned previously, the BOW-COS method could not capture that the similarity between \( \text{diet} \) and \( \text{food} \). This section introduces the word mover distance with word embedding (WE-WMD). This approach calculates word mover’s distance which can leverage semantic relationships between words using the generated word embedding as aforementioned.

Word mover’s distance (WMD) [14] is a distance function between two documents, which measures the minimum traveling distance from the embedded words of one document to another one. It allows each word embedding to be partially aligned to multiple word embedding of the other text. WMD achieved good performance in the document classification task. Specifically, given two document \( d \) and \( d' \), WMD can be calculated by optimizing the following equation.

\[
\min_{\pi} \sum_{i=1}^{n} T_{ij} c(i, j) \text{ subject to: } \sum_{i=1}^{n} T_{ij} = d_i \forall i \in \{1, ..., n\} \\text{ and } \sum_{i=1}^{n} T_{ij} = d'_j \forall j \in \{1, ..., n\}
\]

where \( d_i \) means the weight of word \( t \) in document \( d \) and similarly, \( d'_j \) means the weight of word \( j \) in document \( d' \), \( c(i, j) \) means the distance between word \( t \) and word \( j \) and can be provided by Euclidean distance in the word2vec embedding space.

**Supervised Siamese Recurrent Neural Network Model (SSRRN)**

WE-WMD tries to solve the lexical gap problems by aligning similar words in word vector space. Recently, research interests have shifted toward learning word level similarity to the similarity of larger bodies of text such as sentences directly. Many supervised deep learning based models such as [8,9,15,16] use variants of neural network architectures to model question-question pair similarity.

In this research, we adopted one of the most popular architectures [15], Siamese RNN structure, to learn question similarity. The network structure consists of two share-weights LSTM networks each process one of the questions in a given question pair and a similarity measurement is used to calculate the similarity between the last states of the two LSTMs. Figure 1 shows the network architecture in this research. Different from the original research which used Manhattan Distance and Mean Squared Error as loss function in sentence similarity task, we use similarity measurement as follows:

\[
\text{Sim}(x, y) = \frac{1}{2} \left(1 - \frac{\text{L2Euclid}(x, y)}{\sqrt{x^T x + y^T y}}\right)
\]

where \( \text{COS} \) and element-wise multiplication measure the distance of two vectors according to the angle between them, \( \text{L2} \) Euclidean distance (\( \text{L2Euclid} \)) and element-wise absolute distance difference measure magnitude differences. In another perspective, COS and \( \text{L2} \) Euclidean distance measure the sum distance and element-wise multiplication and absolute distance measure the element-wise distance in each dimension of the vectors. These four-measurement functions reflects similarity from different respect. Then we use a linear layer to combine these measurements together. In this research, \( \text{L2} \) is set as 0.01. To train these model, we consider a classification task: given a pair of questions, the model will give a label of similar or not and use a log-sofmax layer on top of the similarity measurement to output the label. After training, we use the probability of similar label to get question retrieval results.

We use stochastic gradient descent (SGD) to minimize the negative log likelihood loss function and the back propagation algorithm to compute the gradients. For the output layer, we employ dropout with a constraint on \( \text{L2} \)-norm of the weight vectors. The dropout rate is 0.2 and the \( \text{L2} \) constraints is 3.

Training is done through stochastic gradient descent over mini-batches with the size of 100 and Adadelta update rule [17] and the number of epochs is set to 200. The LSTM layer we use in this paper are bidirectional LSTM and the numbers of cell are all set as 20. The hidden state in the output linear layer is set as 50. We keep the word vectors static during training.

**Supervised Neural Attention Model (SNA)**

Recently, neural attention networks have demonstrated success in a wide range of tasks such as machine translation [18], image captioning [19], and sentence inference [20]. The idea is to allow the model to selectively focus on the most
task-relevant parts of input sequence, assign important weights to those parts, and join them into a single representation. In this research, we design a novel supervised neural attention model for similar question retrieval. Figure 2 shows network structure. Instead of calculating similarity between the last LSTM states, word by word attention mechanism is used to soft align words in the two questions. Specifically, the output state of the first LSTM attends the second LSTM’s output vector and attention weights $a_i$ and similarity measurement are calculated overall output vectors of Question 2 for each output state $h_i$ in the Question 1. The word by word attention mechanism can be modeled as follows:

$$h_i^e = \left( \text{Sim}\left( \sum_{j=1}^{m} a_{ij} h_j, h_i \right) \right) \sum_{j=1}^{m} a_{ij} \text{Sim}(h_j, h_i)$$

(5)

$$a_{ij} = \frac{\exp(e_{ij})}{\sum_j \exp(e_{ij})}$$

(6)

$$e_{ij} = W^e \cdot \tanh \left( W^2 h_j + W^1 h_i + W^s \text{Sim}(h_j, h_i) \right)$$

(7)

where $h_i^e$ is the similarity result between output state $h_i$ of Question 1 and the output vectors of Question 2 of all matrices $W$ contain weights to be learned and the function Sim is same as Equation (4). Note that the similarity result $h_i^e$ is a concatenation of two parts: 1) the similarity result between $h_i$ and an aggregate of vector $h_j$ with the attention weights; 2) an aggregate of similarity result between $h_i$ and each state $h_j$.

We also assume the soft align weight of $a_{ij}$ is relevant to the similarity of $h_i$ and $h_j$.

After word by word attention, each output state of Question 1 has a similarity result with the Question 2 and then another LSTM is used to sequentially summarize the similarity result. We take and the last state of the LSTM as similarity result and on top of the LSTM layer, we also use a linear layer and a log-softmax layer to output the label. The number of LSTM cell is also set to 20 and other setup is similar as SRRNN.

Table 3 shows the performance on the test dataset for the BOW-COS, WE-WMD, SRRNN with random initialized word embedding (SRRNN_RW), SRRNN with pre-trained word embedding, SNA with random initialized word embedding (SNA_RW), and SNA with pre-trained word embedding. Besides the supervised RNN models, we also compared our models with another state of art deep learning model RCNN for question retrieval proposed in general domain [9], which designed a recurrent and convolutional model (gated convolution) to effectively map questions to their semantic representations. We retrieved the 100 test questions in 1488 training questions and 100 validating questions and evaluated the performance with three evaluation criteria: Mean Average Precision (MAP), Mean Reciprocal Rank (MRR), and Precision at K ($P@K$). From the result, we can see that approaches with word embedding (WE-WMD, SRRNN, and SNA) perform better than the similar approaches with random initialized word embedding (BOW-COS, SRRNN_RW and SNA_RW) and supervised deep learning models with pre-trained word vectors (SRRNN and SNA) perform better than unsupervised approach BOW-COS and WE-WMD. SNA with word by word attention mechanism performed best. Compared with the state of art RCNN approach, SNA also has superior performance.

For question retrieval proposed in general domain [9], which designed a recurrent and convolutional model (gated convolution) to effectively map questions to their semantic representations. We retrieved the 100 test questions in 1488 training questions and 100 validating questions and evaluated the performance with three evaluation criteria: Mean Average Precision (MAP), Mean Reciprocal Rank (MRR), and Precision at K ($P@K$). From the result, we can see that approaches with word embedding (WE-WMD, SRRNN, and SNA) perform better than the similar approaches with random initialized word embedding (BOW-COS, SRRNN_RW and SNA_RW) and supervised deep learning models with pre-trained word vectors (SRRNN and SNA) perform better than unsupervised approach BOW-COS and WE-WMD. SNA with word by word attention mechanism performed best. Compared with the state of art RCNN approach, SNA also has superior performance.

Discussion

In this study, we investigated a novel supervised attention model to retrieve similar patient questions in Chinese. When only word features were used, approaches which utilized word embedding derived from another unlabeled corpus achieved better than the traditional BOW model. The performance improvement was from the semantic information automatically captured by word embedding. For example in Table 2, the semantically related words captured through word embedding may not have any relation in the bag of words representation space.

The supervised learning approaches, SRRNN and SNA performed better than the other unsupervised approaches. This may be because the supervised deep learning approaches can learn important features from the corpus automatically. But
SSRN compares the last state between each LSTM and only captures a global-level representation of each questions. SNA compares each word from Question 1 with Question 2 through word by word attention mechanisms and can leverage details information of the two questions; SNA had the best performance.

Table 4 – An example for comparison between four approaches

<table>
<thead>
<tr>
<th>Approach</th>
<th>(I am a patient with coronary heart disease. Does Atorvastatin have an effect on this?)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOW-COS</td>
<td>1) Arterioflex is a medicine for heart disease? (Is Atorvastatin a heart care product?)</td>
</tr>
<tr>
<td></td>
<td>2) 20mg Atorvastatin is a medicine for heart disease? (Does 20 mg Atorvastatin have two kinds of packages?)</td>
</tr>
<tr>
<td>WE-WMD</td>
<td>1) Are there any difference between the pharmacodynamics of the two kinds of Atorvastatin?</td>
</tr>
<tr>
<td></td>
<td>2) Two kinds of Atorvastatin have any difference? (Are there any difference between the pharmacodynamics of the two kinds of Atorvastatin?)</td>
</tr>
<tr>
<td>SSRNN</td>
<td>1) What is the main usage of Atorvastatin? (Can Atorvastatin be used for treating hyperlipemia?)</td>
</tr>
<tr>
<td>SNA</td>
<td>1) Disease is Atorvastatin used to treat?</td>
</tr>
<tr>
<td></td>
<td>2) Arterioflex has the main role? (What is the main usage of Atorvastatin?)</td>
</tr>
</tbody>
</table>

In Table 4, an example for comparing between the four approaches is shown. The top two questions retrieved by BOW-COS are both irrelevant with the query question. In WE-WMD, as the word effect (effect) and the word drug (pharmacodynamics) is semantically-related in word embedding, the irrelevant question, two kinds of Atorvastatin's effect are retrieved by the system. In SSRNN, the two retrieved questions are about Atorvastatin’s effect on blood lipids. This is because SSRNN focuses on the global representation such as Atorvastatin’s effect but ignores the details such as blood lipids vs. coronary heart disease. However, the SNA model considers the difference of details through word by word attention.

As current research about question retrieval in the health care domain still focuses on feature engineering such as medical concept annotation by UMLS or sentence parser, but obtaining such features could be time consuming and sometimes not feasible in other languages such as Chinese. However, using a deep learning based approaches requires minimal effort on feature engineering.

Although the deep learning methods in this work show superiority in performance, human annotation dataset is still need for supervised learning. And the difference between train and test data will cause performance reduction. In the future, we plan to investigate different approaches to further reduce human effort such as transfer learning and integrate medical knowledge with the deep learning network structure.

Conclusion

In this study, we investigated a deep learning-based model for similar patient question retrieval in Chinese. Our results showed that our SNA model performed best. Further analysis showed semantic information automatically captured by word embedding is helpful and word by word attention mechanisms which can model detailed differences can further improve the performance.

Automating the Identification of Patient Safety Incident Reports Using Multi-Label Classification

Ying Wang², Enrico Coiera², William Runciman²,³, Farah Magrabi²

³ Centre for Population Health Research, School of Health Sciences, University of South Australia, Australia

Abstract

Automated identification provides an efficient way to categorize patient safety incidents. Previous studies have focused on identifying single incident types relating to a specific patient safety problem, e.g., clinical handover. In reality, there are multiple types of incidents reflecting the breadth of patient safety problems and a single report may describe multiple problems, i.e., it can be assigned multiple type labels. This study evaluated the ability of multi-label classification methods to identify multiple incident types in single reports. Three multi-label methods were evaluated: binary relevance, classifier chains and ensemble of classifier chains. We found that an ensemble of classifier chains was the most effective method using binary Support Vector Machines with radial basis function kernel and bag-of-words feature extraction, performing equally well on balanced and stratified datasets, (F-score: 73.7% vs. 74.7%). Classifiers were able to identify six common incident types: falls, medications, pressure injury, aggression, documentation problems and others.

Keywords:
Machine Learning; Risk Management; Patient Safety

Introduction

Approximately 10% of admissions to acute-care hospitals are associated with unnecessary harm to patients [1, 2]. Events that could have resulted, or did result in unnecessary harm are called patient safety incidents [3]. The reporting and rapid analysis of patient safety incidents is important to prevent similar events from occurring in the future [4]. However, the volume of incident reports has dramatically increased over the last 20 years with wide implementation of incident monitoring systems [5]. Retrospective review of these incident reports by human experts is highly resource intensive and can no longer keep up with the growing volume of incidents being reported. To facilitate timely analysis, many incident monitoring systems now ask reporters to assign incident types so that reports of a specific type can be easily grouped for detailed classification by experts. However, incidents are reported by many different groups of health professionals who generally have limited expertise in classification [3, 6, 7].

One way of improving the efficiency of identifying incidents of a specific type is to automatically classify reports using text classification techniques. We have previously shown the feasibility of using statistical text classification to identify reports about three types of incidents: patient identification [8], clinical handover [8] and health information technology [9] using binary classifiers based on Naïve Bayes, logistic regression and Support Vector Machines (SVM). We have subsequently shown that extreme-risk events could be identified using a similar approach [10]. However, these studies have focused on distinguishing specific incident types from all others, e.g., patient identification. In reality, there are multiple types of incidents reflecting the breadth of problems in patient safety. Moreover, a single report can describe problems in more than one patient safety area, i.e., it can be assigned to multiple incident types [3, 11]. For example, “Episode label A for patient X was placed incorrectly onto the specimen that belongs to patient Y,” describes an error in patient identification that also relates to documentation.

The use of automated methods to identify multiple incident types remains largely unexplored. Some studies have sought to apply topic modelling [12, 13]. However, the mapping between topics and incident types is not straightforward. In this paper, we evaluated the feasibility of using multi-label classification to automate the identification of two labels or two incident types per report. Such multi-label problems are typically decomposed into one or more binary problems to simplify decision boundaries [14, 15]. In this study, classifiers were trained, validated and tested on balanced datasets. We then examined generalizability by applying the classifiers to imbalanced, i.e., stratified datasets which represented the real-world distribution of incidents.

Methods

Multi-label classification was decomposed into a number of binary classification problems, one for each label. We sought to evaluate the performance of three decomposition methods: 1. Binary Relevance (BR) is a widely used decomposition method which is theoretically simple and intuitive. For a given set of labels L, BR learns L binary classifiers (e.g., SVM). Each classifier is trained independently for a specific label against the rest of labels (one-versus-rest scheme) [15]. However, it does not preserve dependencies between labels. 2. Classifier Chains (CC) is another decomposition method which is based on the BR but considers dependencies between labels [16]. CC learns L binary classifiers like the BR method. However, these binary classifiers are linked in a chain through a feature space where additional features with binary values indicate which other labels are assigned to a report. Testing begins with the first classifier and processes to the Lth classifier by passing label information between classifiers through this feature space. Hence, the inter-label dependency is preserved. The performance of CC is very sensitive to the choice of label order in the chain, as the label dependency is demonstrated by label order in the feature space.
3. Ensemble of Classifier Chains (ECC) were introduced to reduce the influence of label order and improve classification performance [16]. Multiple CCs can be trained using different random chain ordering (determined by the order of labels) on a random subset of data. The final decision is the average of the multi-label predictions of CC. In general, the performance of ECC tends to improve and converge by combining more CCs with diverse label structures. However with increasing ensemble sizes, ECC becomes unnecessarily large, and imposes an extra computational cost. Although there are several variants of CC which consider complex structures for label dependence and use different random search methods [17], we took a more practical solution by using a subset of CCs in the ensemble, which also improved classification performance.

**Database**

We used 6,000 randomly selected reports from 137,522 submitted to the Advanced Incident Management System (AIMS) across an Australian state between January and December 2011 [4]. Ethical approval was obtained from university committees as well as a committee governing the hospital and state datasets. Reports were de-identified and then labelled by three experts in the classification of patient safety incident reports. Experts provided a primary label and where applicable a secondary label was also given. These labels were used as a “gold standard” for classifier training and testing. Only descriptive narratives in reports were retained for experiments including incident description, patient outcome, actions taken, prevention steps, investigation findings and results. All system-specific codes, punctuation and non-alphabetical characters were removed and text was converted to lower case.

The distribution of incident types from AIMS is imbalanced i.e. "stratified", and their real-world ratio is shown in Table 1.

**Table 1: The composition of incident types in balanced and stratified datasets. N1 is the number of reports based on primary label. N2 is the number of reports by considering both labels.**

To build reliable classifiers which capture characteristics of rare incident types, for training we used balanced AIMS datasets where each of the 10 types were evenly distributed (Table 1). Applicability to real-world conditions was then examined by testing on stratified data. The distribution of balanced and stratified datasets was based on primary labels.

**Experimental workflow**

Figure 1 shows an overview of our approach. Datasets were first decoded into 11 subsets according to one-vs-rest ensemble schemes [18, 25]. For the BR, 11 base classifiers were trained for each two-class subset involving feature extraction, classifier training and cross validation. A threshold-based decision-making scheme was applied to identify testing reports by combining the predicted probabilities from all base classifiers. With CC, the feature space was extended to represent label connections using binary values that indicated label co-occurrence [18, 19]. With ECC, incident types were randomly reordered and several ensembles of CC were generated. The hard decision for each report was made based on the probability values provided by all CCs.

1. Feature extraction: To provide informative features for classification, removal of stop words and short words with fewer than two characters, stemming and lemmatization were applied to reports [18]. The bag-of-words model, commonly used in document classification, was adopted to extract features [19]. Irrespective of grammar, incident narratives were represented as an unordered collection of words and unique words were used as features. The bag of words was then transformed into a numeric representation interpretable by classifiers. A binary count, transforming the bag of words representation into 1 or 0 corresponding to word occurrences, was used, as it was the most effective feature representation along with the SVM classifier in practice [9, 10].

2. Feature space extension for CC and ECC: The feature space of each link in the classifier chain was extended with the binary label associations of all links in the training procedure [16]. The order of the chain itself affects accuracy.

3. Base binary classifier training and validation: For base classifiers, we chose discriminative classifier of SVM with radial-basis function kernel, as the SVM-based methods perform better for smaller datasets with a large feature space [20, 21]. Especially in text classification, documents are typically represented as a bag-of-words, where each feature captures crucial information but in a very sparse format [20]. Furthermore, in our previous incident classification work, SVM outperformed other binary classifiers, such as a logistic regression model [21]. To train the base classifiers, a ten-fold repeated random sub-sampling, cross-validation method was used to assign reports...
to training (80%), validation (10%) and testing (10%) sets. Given that, with random assignment, a testing report for one base binary classifier might be used in the training set of another base classifier. For example, a report about a fall incident which was used for training a base classifier (fall vs. medications), may also be assigned to the test set of another base classifier (fall vs. blood product). To avoid potential overlaps between training and testing sets, we first randomly selected 10% of reports for each type and set them aside for testing. Then we created the folders using repeated random subsampling for training and validation sets. Classifiers which outperformed others by achieving higher classification accuracy were adopted for testing.

4. Probability threshold based decision-making scheme: For ECC, the hard decision was made by averaging multiple predictions from individual CC. Two labels were predicted if the average classification probability exceeded a predefined threshold. If the threshold is reached only for one label then predictions from individual CC. Two labels were predicted if ECC, the hard decision was made by averaging multiple accuracy were adopted for testing.

5. Performance evaluation: Evaluation metrics for multi-label classification performance are inherently different from those used in multi-class or binary classification, due to the additional degrees of freedom that the multi-label setting introduces. Overall performance was examined using two types of evaluation measures, example-based and label-based measures [20]. Example-based measures are based on the average difference of the true and the predicted sets of labels over all testing reports. On the other hand, label-based measures evaluate classification performance separately for each incident type and then average the performance over all types. We used six example-based measures including [20]:

1. **Hamming loss** evaluates how many times an incident is misclassified, i.e. label not belonging to the report is predicted or a label belonging to the report is not predicted. This is a loss function, so the optimal value is zero:

\[
\text{Hamming loss} = \frac{1}{N} \sum_{i=1}^{N} \sum_{j=1}^{L} \text{XOR}(T_{ij}, P_{ij})
\]

Where \( L \) is the total number of incident types and \( N \) is the number of testing reports. \( X_n \) means the symmetric difference between two sets. \( T_{ij} \) denotes the set of true labels and \( P_{ij} \) denotes the set of predicted labels.

2. **Accuracy** is micro-averaged across all reports and is defined as the number of correct labels divided by the union of predicted and true labels.

\[
\text{Accuracy} = \frac{1}{N} \sum_{n=1}^{N} \frac{|P_n \cap T_n|}{|P_n|}
\]

Note that any predicted label matches the real labels, count 1; so the size of correct labels for a report could be 0, 1, and 2 if there are two real labels. However, the number of correct labels in this way does not consider label orders.

3. **Exact match score** (0/1 loss) is a very strict evaluation measure as it requires the predicted set of labels to be an exact match of the true set of labels.

4. **Precision** is the correct labels divided by the number of predicted labels.

\[
\text{Precision} = \frac{1}{N} \sum_{n=1}^{N} \frac{|P_n \cap T_n|}{|P_n|}
\]

5. **Recall** is defined as the correct labels divided by the number of true labels.

\[
\text{Recall} = \frac{1}{N} \sum_{n=1}^{N} \frac{|P_n \cap T_n|}{|T_n|}
\]

6. **F-score** is the harmonic mean between precision and recall.

\[
F_{\beta} = \frac{(1 + \beta^2) \text{precision} \cdot \text{recall}}{(\beta^2 \cdot \text{precision}) + \text{recall}}
\]

Where \( \beta \) enables the F-score to favor either precision or recall. Precision and recall are given equal weight by setting \( \beta \) to 1.

We also used six label-based measures, which are defined below. Given two labels per report, the classification performance of individual types was evaluated based on OR logic when matching the predicted and true set of labels per report.

1. **Macro-precision** is defined as precision averaged across all labels:

\[
\text{Macro - precision} = \frac{1}{L} \sum_{j=1}^{L} \frac{|tp_j|}{|tp_j| + |fp_j|}
\]

Where \( tp_j \) and \( fp_j \) are the number of true positives and false positives for the label \( j \) considered as a binary class.

2. **Macro-recall** is defined as recall averaged across all labels:

\[
\text{Macro - recall} = \frac{1}{L} \sum_{j=1}^{L} \frac{|tp_j|}{|tp_j| + |fn_j|}
\]

Where \( fn_j \) is the number of false negatives for the label \( j \) which is considered as a binary class.

3. **Macro-F-score** is the harmonic mean between precision and recall where the average is calculated per label and then averaged across all labels.

\[
\text{Macro - F - score} = \frac{1}{L} \sum_{j=1}^{L} \frac{2 \cdot \text{precision} \cdot \text{recall}_j}{\text{precision}_j + \text{recall}_j}
\]

Micro-precision and micro-recall are defined as general definitions of precision and recall but the number of true positives, false positives and false negatives are averaged over all the labels, respectively. Micro-F-score is the harmonic mean of micro-precision and micro-recall, defined as below:

\[
\text{Micro - precision} = \frac{2 \cdot \text{micro}_\text{precision}}{\text{micro}_\text{precision} + \text{micro}_\text{recall}}
\]

\[
\text{Micro - recall} = \frac{2 \cdot \text{micro}_\text{recall}}{\text{micro}_\text{precision} + \text{micro}_\text{recall}}
\]

\[
\text{Micro - score} = \frac{2 \cdot \text{micro}_\text{precision} \cdot \text{micro}_\text{recall}}{\text{micro}_\text{precision} \cdot \text{micro}_\text{recall}}
\]

Results

We examined the performance of three multi-label classification methods on balanced and stratified datasets. Using the most effective classifiers, we then evaluated performance when identifying different incident types.

ECC performance with increasing ensemble sizes

Using SVM RBF with binary count we examined the ECCs using different ensemble sizes ranging from three to forty. We found that six classifier chains obtained much smaller ensembles while achieving better or at least comparable performance on balanced and stratified datasets (Table 2, columns 3-7).

Performance of BR, CC and ECC

We compared BR, CC and ECC with six CCs (Table 2). Performance improved from BR to CC to ECC with both balanced and stratified datasets. Considering exact matching between the predicted and true sets of incident types, ECC (balanced/stratified: 39.9%, 44.4%) outperformed BR (35.7%, 39.0%) and CC (36.7%, 37.8%), indicating that better label dependency was maintained by ECC. Hamming loss value also showed that ECC was more efficient than BR. Example-based F-scores and label-based Macro-F-scores and Micro-F-scores increased slightly from BR to ECC with both testing datasets, for instance, F-scores of BR: 73.7%, CC: 74.2% and ECC: 74.7% on the stratified datasets. The most effective ECC performed equally well on both balanced and stratified datasets, considering example-based measures and Micro-F-score, indicating that this approach is generalizable. However, it obtained a relatively worse Macro-F-score of 59.2% on stratified datasets (balanced: 73.7%).
Table 2: Classifier performance of BR, CC, and ECC with different ensemble sizes on balanced and stratified AIMS datasets, where hamming loss, accuracy, recall, precision, F-score, exact match score, Macro/Micro-averaged measures were considered. Base binary classifier was SVM RBF with binary count representation of bag-of-word features.

Performance on identifying stratified incident types

The most effective ECC based on six CCs achieved high F-scores above 81% on balanced datasets when identifying falls, pressure injury, infection and deteriorating patients (Table 3). This ECC trained on balanced datasets was very robust in identifying six types of incidents (falls, medication, pressure injury, aggression, documents and others), achieving similar F-scores on stratified datasets. For blood products, patient identification, infection, clinical handover and deteriorating patients, recall was similar on both balanced and stratified datasets. Where hamming loss, accuracy, recall, precision, F-score, exact match score, Macro/Micro-averaged measures were considered. Base binary classifier was SVM RBF with binary count representation of bag-of-word features.

Discussion

We evaluated three multi-label text classification methods using binary classifier ensemble on both balanced and stratified datasets from a state-wide incident reporting system. The most effective classifiers performed equally well in identifying reports from six common types including falls, pressure injury, aggression, documents and others. These types made up 93% of all reports (Table 1). Even so, it should be emphasized that automated identification of incident reports is not intended as a replacement for expert review but as a first step in grouping incidents and identifying clusters when human resources are lacking [22].

Comparison between BR, CC and ECC

Although the ECC achieved the best performance, the performance difference between BR, CC and ECC was relatively small (Table 2). Compared to CC and ECC, BR is more computationally efficient as it requires less dimensionalties of features and no classifier chain for training. However the BR completely ignores the possible correlations among labels, so the binary classifiers make decisions independently from each other. The other hand, it makes BR very flexible in practice, e.g., evolving more incident types, because it can add labels without affecting the rest of classifiers. Thus, BR is more suitable for problems with only a small number of labels associating with each other.

The CC method can be seen as a direct extension of the BR, capable of exploiting label dependencies. Similar to BR, CC involves training a group of $L$ binary classifiers. Nevertheless, instead of being kept isolated from each other, these $L$ classifiers are linked in a chain structure, which allows each one to pass their predictions to the other binary classifiers connected in the chain. Compared to BR, CC did not improve much of classification performance in this study. BR was even slightly better than CC according to hamming loss and exact matching score on the stratified datasets. This might be due to the original text feature space being huge and the label relationship in such a sparse space not being captured well by classifiers with limited training datasets.

ECC keeps relationship of patient safety types in reports by building multiple CCs using random label orders. Obviously, the larger ensemble size leads to higher computational cost. We tried to reduce the ensemble size whilst keeping or improving the performance. In training, we built several ECCs with ensemble sizes ranging from three to forty. We found that the classification performance became stable when the size of CC was greater than six (Table 2). Thus the most effective ECC used six CCs was used for testing.

Identification of common and rare incident types

An important finding of this study is that the most effective ECC trained on balanced datasets appears generalizable to unseen datasets. The ECC achieved similar F-scores on stratified datasets in identifying the common incident types including falls, medication, pressure injury, aggression, documentation and others (43-33% Table 1, 93% of reported incidents in total). Especially for falls and pressure injury, the ECC achieved high F-scores (above 85.4%). However the ECC tended to be weaker when identifying rare types in stratified datasets such as patient identification, infection, clinical handover and deteriorating patient (<2% Table 1, 7% of all reported incidents). This explains why similar example-based measures were achieved on balanced and stratified datasets because the common types dominate the performance measures. On the other hand, the label-based measures showed relatively worse performance on stratified datasets, as the averaged measures were based on individual performance.
of each type. Given the imbalanced nature of incident distribution, automated identification can reduce the effort spent in identifying common types and provide small volumes of like incident reports for further investigation by experts.

Limitations and future work

There are several limitations. First, we used datasets from one Australian state. Our classifiers may not be generalizable to other regions with different linguistic styles and terminology. Secondly, we use the balanced dataset for classifier training because a limited number of incidents had been reported over a 12-month period. Given the imbalanced nature of multiple incident types, a stratified training set may work better in real-world conditions. To improve the identification of rare classes, one solution might be to review rare classes flagged by classifiers, which is practical because overall volumes in real-world datasets will be low. Another possible way is to use rule-based methods that involve expert knowledge and incorporate specific criteria for identifying incidents.

Conclusions

The use of text-based ECC is a feasible approach for automatically identifying multiple incident types. Evaluation of BR, CC, and ECC using binary classifiers of SVM RBF with binary count feature extraction, showed that the most effective combination was the six ECC of binary SVMs. Despite the limitations listed above, automated identification can provide a more efficient way to categorize the common incident reports, so that human resources can be redirected to detailed classification, allowing remedial actions to be triggered more quickly to respond to emerging safety issues.

Abstract

The adverse events of the dietary supplements should be subject to scrutiny due to their growing clinical application and consumption among U.S. adults. An effective method for mining and grouping the adverse events of the dietary supplements is to evaluate product labeling for the rapidly increasing number of new products available in the market. In this study, the adverse events information was extracted from the product labels stored in the Dietary Supplement Label Database (DSLD) and analyzed by topic modeling techniques, specifically Latent Dirichlet Allocation (LDA). Among the 50 topics generated by LDA, eight topics were manually evaluated, with topic relatedness ranging from 58.8% to 100% on the product level, and 57.1% to 100% on the ingredient level. Five out of these eight topics were coherent groupings of the dietary supplements based on their adverse events. The results demonstrated that LDA is able to group supplements with similar adverse events based on the dietary supplement labels. Such information can be potentially used by consumers to more safely use dietary supplements.

Keywords: Dietary Supplements; Natural Language Processing; Pharmacovigilance

Introduction

According to a recent cross-sectional study using the data from the National Health and Nutrition Examination Survey (NHANES) over the time period from 199-2012, 52% of U.S. adults use dietary supplements [1]. Americans spend more than $28 billion annually on dietary supplements in the belief that they are able to improve health and are generally harmless in their side effects [2]. However, a study conducted by the Food and Drug Administration (FDA) and the Centers for Disease Control and Prevention (CDC) has shown that dietary supplements caused on average about 23,000 emergency room visits every year [3].

The distinct regulatory framework for dietary supplements is one of the major reasons why dietary supplement safety requires scrutiny. In 1994, the Dietary Supplement Health and Education Act (DSHEA) was passed. According to DSHEA, dietary supplements belong to a subcategory of food, and can be waived from the premarket approval for efficacy and safety testing that are required for new drugs and food additives [4, 5]. While the DSHEA did give the consumers a great variety of choices in dietary supplements, it also exposed consumers to considerable risks in terms of dietary supplement safety [6].

A major clinical concern is that the adverse events of the active ingredients in the supplements may be unknown. For example, the sexual enhancement supplement Zotrex, which had been recalled by FDA in 2011, contained sulfoalidnenafil, an ingredient whose adverse effects on humans were never tested. It is estimated that more than 50,000 new dietary supplements have been available on the market since the DSHEA became law [2]. DSHEA implementation addressed dietary supplement safety concerns by requiring manufacturers to provide adequate proof to the FDA that the new ingredients introduced are safe [4, 5]. The regulation was poorly enforced, as the FDA received appropriate notifications for only 170 new ingredients [2] potentially making consumers more vulnerable to these potential supplement adverse events.

Literature review has been used to study the adverse events of dietary supplements. Pittler, Schmidt, and Ernst conducted a systematic review on the adverse events of herbal food supplements for body weight reduction including 33 case reports and 48 clinical trials dating from 1995 to 2004 [7]. Seven ingredients were covered in this review and their adverse events were reported in detail. However, literature-based studies suffer from several drawbacks. Firstly, literature-based reviews can only cover a few dietary supplements. In the example above, the authors could only focus on seven ingredients intended for body weight reduction, which is only a tiny portion of the dietary supplement ingredients currently available on the market. Secondly, the qualities of the literature are inconsistent. The literature that reported the adverse events did not explain the related mechanism or establish any cause and effect relationship. Finally, incompleteness of the literature is an intrinsic limitation of literature-based studies [7, 8].

Alternatively, dietary supplement product labels contain vital information on the adverse events of dietary supplements. The FDA has stringent rules on dietary supplement labeling information including statement of identity, active ingredients, manufacturer information, structure or function claims, and health claims to make sure the information is truthful and not misleading [4,5,9]. Consequently, the supplement labels provide an opportunity for more efficient methods of supplement adverse event related research. However, unlike drug labeling, adverse events related to the supplements typically exist in the precaution section of labels in free text format. Thus, text mining techniques are required to extract adverse events information from supplement labels.

Topic modeling is a set of text mining methods that automatically discover the underlying themes of a collection of documents without prior document annotation or labeling. Implementations of topic modeling includes latent semantic indexing (LSI), probabilistic latent semantic analysis (PLSA) [10], and latent Dirichlet Allocation (LDA). LDA is one of the more common topic model techniques in the current literature. A topic is defined as a “distribution over a fixed vocabulary” [11]. LDA is a statistical model, which assumes that all the
documents in the collection can be described by a group of topics, but each document is a different distribution of these topics. As a generative graphic model, LDA can discover the underlying topic distribution for a large document collection.

Topic modeling has been applied to social media and drug product labeling to discover new knowledge. Sullivan et al. have recently applied LDA to Amazon.com nutritional supplement reviews to find potentially unsafe dietary supplements [12]. Bisgin et al. have used LDA on FDA drug labels to group drugs with similar safety concerns and therapeutic uses [13], and this information was later used to discover drug repositioning opportunities [14]. However, the methodology has to the best of our knowledge not been applied to dietary supplement labels. Product labels provide useful information to group dietary supplements based on the listed adverse events. Thus, in this study, we tried to demonstrate that the application of the LDA technique on the precautions statements of dietary supplement labels can yield useful groupings of adverse events without any prior knowledge to analyze the adverse events.

**Dietary Supplement Label Database (DSLD)**

The DSLD is created and managed by Office of Dietary Supplement (ODS) and U.S. National Library of Medicine (NLM) in the National Institutes of Health (NIH) [15]. The database includes complete label contents among 55,456 dietary supplement products currently marketed, off the market, and consumed by NHANES participants. For each supplement product, there are four distinct label sections: namely, product information (including product name, statement of identity, serving information, and target groups); dietary supplement facts (including active ingredients); label statements (including formulation, precaution, and suggested use); and contact information (including manufacturer information).

DSLD provides a web application programming interface (API) for an efficient extraction of the labeling information in JavaScript Object Notation (JSON) format. It also provides a comma-separated value (CSV) file including database identifiers (DSLD ID) for all the products in the database.

**Side Effect Resource (SIDER)**

The SIDER database is a free resource that contains 5,868 adverse drug reactions (ADRs) of 1430 drugs. It uses the Medical Dictionary for Regulatory Activities (MedDRA) terms to describe the drug side effects. The list of side effect MedDRA terms was extracted from the drug labels and downloaded in CSV using SIDER version 4.1 [16].

Although the SIDER database is not designed for dietary supplements, the adverse events encountered with the dietary supplements are similar to those with drugs. Therefore, the SIDER MedDRA terms list was used to recognize adverse event keywords in the DSLD labels.

**Methods**

Figure 1 illustrates the overview of the methods. We extracted the supplement label information from the DSLD, preprocessed the label statements to create a collection of supplement documents represented by a list of SIDER MedDRA terms, and then grouped supplements using LDA. The adverse events topics generated by LDA were further evaluated by human annotation.

**DSLD Label Preprocessing**

The labels of 55,456 dietary supplements available in DSLD were extracted via the API in JSON format. Two criteria were applied to generate a subset of dietary supplements products for topic modeling analysis.

1. Products that only have one active ingredient entry in the dietary supplement facts section were selected for further preprocessing to prevent interactions between ingredients from confounding our analysis.

2. Products that have one or more statements under the “Precautions” subsection of the label statements section.

The “Precautions” statements of each supplement in the subset were split into a list of single sentences with the punctuation marks removed and all words lowercased. We mapped terms (allowing a window size of 5 for multiple-token terms) to the MedDRA terms listed in SIDER for each supplement product. A windowed mapping was used since a multiple-token phrase may be expressed noncontiguously or in different order. For example, the following statement, “Beta-alanine may cause a harmless, temporary tingling or flushing sensation”, should match the word “tingling sensation” in the MedDRA terms list although the two words do not appear next to each other. A windowed mapping will yield the correct result, while an exact match will not.

It is noteworthy that although the supplements in the dataset all have only one active ingredient entry, some of the ingredients are actually blends. For example, “chocamine” was registered as a single ingredient, but in fact it consists of a mixture including theobromine, caffeine, theophylline, phenylethylamine, tyramine, phenylalanine, tryptophan, and tyrosine. This type of supplements was excluded in our analysis due to the complexity of the components in blends.

The windowed mapping generates a “document”, which is a list of the MedDRA terms appeared in the label statements. Therefore, to better define a topic in terms of adverse events, the topic keywords with probabilities lower than 0.05 were not considered to define a topic. Due to the probabilistic nature of the LDA model, the training was repeated 10 times to see if there are significant differences among the generated topics.
The conditional probability of each topic given a particular supplement was calculated, and the supplement was assigned to the topic that has the maximal conditional probability. The distribution of the supplements over the topics was then derived by counting the number of supplements under each topic.

**Topic Evaluation**

Since the topics generated by LDA are not based on any prior annotation or labeling of the statements, it is necessary to evaluate the topics by checking if the supplements assigned to a certain topic are actually related to the adverse events the topic represents.

Two criteria were used to select the topics to be evaluated:

1. The chosen topics all have more than one keyword with probabilities greater than 0.05. This study is focused on grouping of dietary supplements by their adverse events. If a topic is defined by more than one adverse event, then it is necessary to examine if these adverse events are related in terms of supplement function.

2. The number of supplements under the chosen topics should be within the range of 10-50. If there are too few products under a certain topic, there would be insufficient data points to generate any significant grouping patterns; on the other hand, if there are too many products under a certain topic, the grouping may not be meaningful, as a group may contain a mixture of completely different supplements.

Eight topics out of 50 were chosen accordingly for evaluation based on the group of adverse events indicated by the topic keywords. The largest topic contained 46 products, while the smallest topic contained 13 products.

Two human annotators manually reviewed the active ingredients and the health claims in the statements on each supplement labels under the eight topics. Annotators made a consensus on their annotations when there was a disagreement on a product assigned for a given topic. To quantitatively evaluate the performance of topic modeling, we used the metric called topic relatedness, defined as the percentage of products (or ingredients) related to the topic keywords out of the total number of products (or ingredients) assigned to the same topic.

**Results**

**DSLD Label Preprocessing**

There are 6,123 side effect terms that were extracted from the drug labels in the MedDRA term list. Among 55,456 dietary supplements available in DSLD, 27.9% (15,452) of the supplement products have only one active ingredient entry. Only 3.6% (2,014) of these single ingredient supplements whose “Precautions” label statements contained adverse events were matched to a total of 3.9% (239) terms within the MedDRA term list.

**Topic Modeling Analysis**

The distribution of the 2,014 supplements over the 50 topics generated by the LDA was shown in Figure 2. The topic with the most supplements has 234 products, while the topic with the least supplements has only 1 product. The median of the supplement counts over the 50 topics is 21, and the first quartile and the third quartile is 8 and 39, respectively.

The top three topics in supplement counts grouped 663 (32.9%) supplements that have precautions related to pregnancy and breast feeding, and all of these three topics have only a single topic keyword to represent their adverse events. However, these topics did not satisfy the criteria for further evaluation. Therefore, another eight topics including 210 products were selected for evaluation as shown in Table 1. The number of one-ingredient products and the unique ingredients of each topic was shown in Table 2.

**Topic Evaluation**

The topic relatedness of each topic on the product and the ingredient level was shown in Figure 3. Topic 24, 29, and 47 have reached a topic relatedness of 100% at both product level and ingredient level. This suggests that all the supplements grouped under these topics have mentioned the adverse events given in the topic keywords in their statement.

---

**Figure 2– The distribution of the supplement counts for the 50 topics**

**Table 1- Topic keywords and the representative ingredients of eight topics chosen for manual evaluation. The topic keywords were listed in decreasing order by their probabilities generated by LDA. The bolded topics are coherent ones where the topic keywords are closely related.**

<table>
<thead>

<td>Epilepsy, blood disorder, St. John’s Wort</td>
<td></td>
</tr>
</tbody>
</table>
The topic relatedness of the remaining five topics indicates that there exist supplements that do not contain statements relevant to the adverse events mentioned in the corresponding topic keywords. The discrepancies between the product and the ingredient level relatedness are also different among the topics. For Topic 1, 33, and 42, the product level topic relatedness is higher than the ingredient level one. The opposite is true for Topic 11 and 12. Topic 12 had the lowest product level topic relatedness at 58.8%, and Topic 33 had the lowest ingredient level topic relatedness at 57.1%.

</table>

The inconsistent differences for topic relatedness between product level and ingredient level relatedness among different groups are due to the fact that some products in the same group share the same ingredients. If there exist several products containing the same ingredient that are related to the adverse events in the topic, a lower topic relatedness at ingredient level is expected. For example, there are 22 products that contain vitamin D3 under Topic 1 and vitamin D3 was deemed a related ingredient that may cause these adverse events. Therefore, a lower ingredient level relatedness for this topic was obtained.

Conversely, if there exist several products containing the same ingredient that are irrelevant to the adverse events in the topic, a higher ingredient level topic relatedness will be observed. The opposite example could be found in the topic related to obstruction, inflammation, intestinal obstruction, pain, and abdominal pain. Four products containing celandine were grouped under Topic 12, but celandine is an ingredient that was judged as not related to the adverse events mentioned in the topic. As a result, a higher ingredient level topic relatedness was observed.

### Discussion

The adverse effects of dietary supplements were brought under more careful scrutiny due to the rapid growth of the supplement market and consumer base. The special regulatory framework for dietary supplements has led to both challenges and opportunities for research in supplement adverse events. The challenge lies in the fact that the soaring number of new supplement products introduced to the market demands more efficient ways to study the adverse events of a wide variety of dietary ingredients, while the opportunity arises in the supplement labels where relevant information of adverse events was provided as strictly required by the FDA. Topic modeling, specifically LDA, is a powerful method to find hidden grouping patterns within a series of documents without any prior knowledge or annotation. Therefore, the objective of this study is to utilize LDA as an effective method to generate useful groupings of dietary supplements based on the adverse events found in their supplement labels.

Since each topic generated by LDA is represented by a list of adverse events, we evaluated a subset of these topics by human annotation whether the supplements under each topic were actually related to the adverse events indicated by the topic keywords. If a topic is represented by multiple adverse events, the relationship among them was further examined to determine if there are multiple sub-topics.

Our evaluation results have shown that LDA was able to find similar supplement products and categorize them into the same topic based only on the adverse events mentioned in product labels. These supplements may contain the same active dietary ingredient or different ingredients with similar functions. For instance, in Topic 11, four different products with the same ingredients SAMe and six products containing dietary ingredients that are all different derivatives of androstenedione were grouped together due to their potential risk of causing anxiety and depression.

We also found that LDA could associate clinically related adverse events with each other within the same topic. Among the eight topics listed in Table 1, five were highlighted in bold because the adverse events representing each topic were related and forming a single coherent topic. For example, in Topic 1, hyperparathyroidism, lymphoma, and sarcoidosis are able to cause hypercalcemia [18]. Bipolar disorder patients who are taking lithium medication are at risk of lithium-induced hypercalcemia [19]. This suggests that the dietary supplements reviewed under this topic were all linked to calcium metabolism. Although hypercalcemia did not appear in the dietary supplement labels, it is the hidden commonalities among the four adverse events that represent the topic. The most frequent ingredients that appeared under this topic is vitamin D3, which is an important factor in the calcium metabolism [20]. This suggests that consumers with any one of the pre-existing conditions mentioned in the topic may expose themselves to adverse events by taking vitamin D3. Thus, the above examples demonstrated that LDA had successfully grouped dietary supplements based only on their possible adverse effects listed in the product labels into a coherent topic. The topics can give insight into further literature-based studies on the adverse effects of a particular set of dietary supplements.

The study has its limitations. Firstly, the MedDRA terms included in the SIDER does not cover all possible synonyms.
that may appear in the label statements. For example, loss of hair or hair loss, which are the synonyms for alopecia, are not included in the MedDRA terms list, but were present in supplement labels. The windowing mapping method requires every word in the MedDRA terms to be present in the statements, and therefore was not able to capture all the variations of the same adverse effects present in the labels.

Since LDA is an unsupervised machine learning method based only on the word frequencies in a document, the topic model cannot differentiate supplement indications from adverse events of supplement as it does not take context into account. For example, in Topic 12, *Cascara sagrada* was used as an anthranoil laxative to treat constipation [21], and celandine was indicated for spastic discomfort of the gastrointestinal tract [22]. The topic keywords, obstruction, intestinal obstruction, abdominal pain were not adverse events, but indications of these herbal supplements.

Our LDA analysis only considered the supplements with only one active ingredient entry. According to DSLD, more than 70% of the supplements contain at least two active ingredients. Therefore, it is of our interest to analyze this portion of the dietary supplements while addressing the entity recognition issue (the indications, the adverse events, and the interactions between ingredients) in the future. We may consider using existing knowledge base content to find the known interactions of ingredients in products.

**Conclusion**

In summary, we extracted the precautions statements from the labeling information of 2,014 dietary supplements that have only one active ingredient in DSLD. The MedDRA terms list was used to convert the statements into documents represented by a list of adverse events. The collection of supplement documents were analyzed by LDA topic models and eight out of the 50 resulting topics were evaluated by two human annotators. The product level topic relatedness ranged from 58.8% to 100%, while the ingredient level topic relatedness ranged from 57.1% to 100%. Five topics have shown considerable coherence among the topic keywords, and the representative ingredients have been demonstrated to be closely related to the topics. These results indicated that LDA could effectively group the dietary supplements by their adverse events, and the grouping information could provide insight for further literature-based studies.

An Early Infectious Disease Outbreak Detection Mechanism Based on Self-Recorded Data from People with Diabetes

Ashenafi Zebene Woldaregaya, Eirik Årsandb, Taxiarchis Botsisa, Gunnar Hartvigsenb, a

a Department of Computer Science, University of Tromsø – The Arctic University of Norway, Tromsø, Norway,
b Norwegian Centre for E-health Research, University Hospital of North Norway, Tromsø, Norway

Abstract

People with diabetes experience elevated blood glucose (BG) levels at the time of an infection. We propose to utilize patient-gathered information in an Electronic Disease Surveillance Monitoring Network (EDMON), which may support the identification of a cluster of infected people with elevated BG levels on a spatiotemporal basis. The system incorporates data gathered from diabetes apps, continuous glucose monitoring (CGM) devices, and other appropriate physiological indicators from people with type 1 diabetes. This paper presents a novel approach towards modeling of the individual’s BG dynamics, a mechanism to track and detect deviations of elevated BG readings. The models were developed and validated using self-recorded data in the non-infection status using Dexcom CGM devices, from two type 1 diabetes individuals over a 1-month period. The models were also tested using simulated datasets, which resemble the individual’s BG evolution during infections. The models accurately simulated the individual’s normal BG fluctuations and further detected statistically significant BG elevations.

Keywords:
Blood Glucose; Disease Outbreaks; Diabetes Mellitus, Type 1

Introduction

Diabetes mellitus is a chronic disease that causes blood glucose (BG) metabolic disorder [1], either due to failure of the pancreas beta cells to produce insulin (type 1) or failure of the body to react to insulin in the proper way (type 2) [2]. Many people with diabetes strive to control their BG levels as close to the normal range as possible to avoid medical complications. In this regard, many diabetes self-management applications and devices have been developed to support this patient group, of which almost all of them take the ubiquitous nature of mobile devices as an advantage to base their development [3-6]. Moreover, diabetes self-management applications and devices have shown feasible to integrate with the patient’s Electronic Health Record system [7-9]. The advent of information technology and availability of bio-sensors and point of care technologies have also paved the way for quantified self and an easy near patient testing [10; 11]. These advancements have further enhanced the opportunity of using the individual’s diabetes data and other physiological indicators for secondary purposes.

People with diabetes experience elevated BG levels when in infectious state [12; 13]. A positive correlation between high BG levels and infections has been demonstrated in the cases of Influenza, Cholera, Plague, Ebola, Anthrax and SARS [14; 15]. Use of BG levels for an early outbreak detection has been suggested in works of literature [13; 14; 16-19]. For example, Granberg et al. [19] introduced an automatic infection detection system based on the individual’s BG levels. Årsand et al. [14] described the system architecture, model and requirements of disease surveillance based on patient observable parameter, i.e. blood glucose. Botsis et al. [20] assessed the development of electronic disease surveillance systems for detecting infections at the early stages, i.e. during the incubation period. Aside from these potential methods, no practical way of facilitating this has been identified.

We propose the development of an Electronic Disease Surveillance Monitoring Network (EDMON), which may support the detection of infections before the onset of the first symptoms. The system incorporates data gathered from diabetes apps, CGM devices, and other appropriate physiological indicators from people with type 1 diabetes. It consists of five different modules, as shown in Figure 1, with different functionalities; data collection, BG profile, analysis, reporting, and information dissemination modules. The task of the data collection module is to gather the individual’s diabetes data and other physiological indicators from diabetes apps, wearables, and sensors, whereas BG profile module will make a prediction of individuals’ upcoming BG levels based on past status. The analysis module will analyze the individual’s physiological indicators and compare the predicted and actual BG levels for
any statistically significant deviations. It also aggregates and determines the presence of any aberrant pattern within a cluster of people based on a spatiotemporal basis. If outbreak is detected, the reporting module will prepare the information in a way suitable for the end users, whereas the information dissemination module will handle the delivery of the information for the end users. Generally, the objective of the EDMON project is to design and develop an electronic disease monitoring network based on inputs from people with diabetes, which can track real-time BG levels of each individual independently and detect a cluster of infected people with statistically significant BG deviations on a spatiotemporal basis. This paper presents the first step of the EDMON development with modeling of the individual’s BG dynamics. We consider the development of the personalized model as the core part of the EDMON system and describe the details of our approach in the next sections.

Materials and Methods

Materials

The models were developed using one-month BG data from two type 1 diabetes people, as shown in Figure 2, sampled using Dexcom CGM devices. The actual self-recoded data were used to develop and validate the model fit with individuals’ BG dynamics in the non-infection state. We also generated simulated datasets that resemble the individual’s BG fluctuations during infections, as shown in Figure 3. The simulated datasets included unexpected elevated BG levels for a certain period of time with some random and steady increments per hours. The unexpected BG variations were defined as 1) any unstructured variations outside of the individual’s modeled structured variations and, 2) inherent stochastics phenomena of the BG dynamics that cannot be quantified with the developed models using the key diabetes parameters (e.g., BG, insulin intake, physical activities, and dietary habits). The simulated datasets were used to test the model’s performance in capturing the assumed infection-related, unexpected, elevated BG readings. The algorithm was developed using Matlab version R2015b.

Methods

Our models combined a novel approach for BG monitoring and outlier detection, which was based on a set of autoregressive models and predicts the individuals’ expected BG values on an interval basis. The actual BG value was compared with the predicted intervals, which was generated using autoregressive (AR) model \[21\], Eq. (1), and autoregressive moving average (ARMA) model \[21; 22\], Eq. (2).

\[
g_y(n) = \sum_{i=1}^{q} \phi(i) g_y(n-i) + e(n)
\]  
\[
\sum_{i=0}^{q} \phi(i) g_y(n-i) = \sum_{i=0}^{q} \psi(i) e(n-q)
\]

Where, \(\phi(q)\) are autoregressive coefficients, and \(g_y(n)\) is \(n^{th}\) BG value.

\[
\sum_{i=0}^{q} \phi(i) g_y(n-i) = \sum_{i=0}^{q} \psi(i) e(n-q)
\]

Where, \(\phi(q)\) are autoregressive coefficients, \(\psi(q)\) are moving average coefficients, and \(g_y(n)\) is the \(n^{th}\) BG value, and \(e(n)\) are Gaussian noise with zero mean and constant variance \(\sigma^2_e\).

The prediction intervals \[23-25\] were computed based on the empirical distribution of errors between the predicted and actual BG values for the prediction horizon under consideration, using Eq. (3).

\[
g_y(n) = g_y(n) \pm z_{\alpha/2} \sqrt{Var[\epsilon(n)]}
\]

Where, \(g_y(n)\) is the predicted BG intervals, \(g_y(n)\) is the model’s point BG prediction, \(z_{\alpha/2}\) is the assumed errors distribution, \(\alpha\) is level of significance, and \(Var[\epsilon(n)]\) is variance of the errors for a specific window size, \(\sigma^2\). The prediction interval was computed and compared to various values of window size and level of significance. The optimal prediction interval was reported with a window size (\(\sigma^2\)) and level of significance (\(\alpha\)).

MATLAB system identification toolbox along with partial autocorrelation function (PACF) were used to identify the optimal model order. The empirical distribution of errors between the actual and predicted values were assumed to follow a normal distribution.

![Figure 2 - Plot of the CGM data.](image)

![Figure 3 - Simulated BG values in response to infections.](image)
Results

Autoregressive (AR) Model

For both the first and the second subject, an autoregressive (AR) model of order five ($p = 5$) was found to be optimal for the point BG prediction and fitted best with a root mean square error (RMSE) of 0.2159 and 0.3068 respectively. For the first subject, the predicted interval was found to be optimal with a window size of $\omega = 100$ and a statistically significant level of $\alpha = 0.01$, see Figure 4. The predicted interval for the second subject was also found to be optimal with a window size of $\omega = 200$ and a statistically significant level of $\alpha = 0.01$, see Figure 5.

Autoregressive Moving Average (ARMA) Model

For both subjects, the optimal autoregressive moving average (ARMA) model order was found to be an autoregressive order of 6, and a moving average order of 2. The point BG prediction for the first subject resulted in a RMSE of 0.2114. The predicted interval was found to be effective with a window size of $\omega = 100$ and a statistically significant level of $\alpha = 0.01$, see Figure 6. The point BG prediction for the second subject also resulted in a RMSE of 0.2915. The predicted interval was found to be effective with a reasonable window size of $\omega = 200$ and a statistically significant level of $\alpha = 0.01$, see Figure 7.
Deviation Detection/ Surveillance

The algorithm was tested with simulated datasets, for its capability of detecting unexpected BG variations that may occur during infections, as shown in Figure 3. The developed algorithm successfully detected statistically significant elevated BG readings, as shown in Figure 8. As clearly shown in the Figure, the algorithm was highly sensitive to the slope, and clearly captured the rise and fall of the individual’s BG readings.

Discussion

The recent advancement, syndromic surveillance uses health-related data that precede diagnosis and laboratory verification to produce signals with sufficient probability of outbreaks to warrant further actions [26-30]. The development of strategies for early detection of outbreaks is worthy, given the limitations of the existing disease surveillance systems. We presented a modelling approach for the early detection of infections in people with diabetes. This set of models were developed as part of the EDMON system that will rely on real-time data collection from people with diabetes. Our approach was capable of detecting statistically significant and unexplained BG elevations of various size and duration. One of the limitations of our study is the sample size. We also have used only BG as the input variable. Furthermore, the assumption of a normal error distribution could be a limitation, which needs further exploration. To alleviate these limitations, we plan to explore other more robust approaches and involve real infection related BG data, more input variables (insulin intake, physical activity, and diet) along with a larger sample size.

Conclusion

EDMON is an early outbreak detection system that relies on self-gathered health-related data from people with type 1 diabetes. In this paper, we presented a novel approach that can track BG levels and detect statistically significant BG elevations. The testing and validation of this approach on a large-scale basis could support the development of an outbreak detection system based on real-time data collection from people with diabetes. We believe such efforts may lay the foundations for the next generation disease surveillance systems and provoke further thoughts in this valuable field.

cDepartment of Systems Engineering and Engineering Management, City University of Hong Kong, Hong Kong, China
dJC School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, China

Abstract

Uncovering clinical research trends allows us to understand the direction of healthcare services and is essential for long-term healthcare planning. The Hospital Authority Convention is a mainstream annual healthcare conference that gathers up-to-date Hong Kong medical research. We propose to use state-of-the-art medical document mining and topic modelling methods to uncover latent themes and structures in the publications. We collected 742 articles from HA Convention from the year 2013 to 2016 and selected 56 publications from the category of “Clinical Safety and Quality Service” for further analysis. Applying natural language processing and Latent Dirichlet Allocation (LDA) methods, we identified 7 potential topics, namely: surgical operation, hospital discharge, medical error, nursing procedure, service performance assessment, patient and staff engagement, and admission algorithm and standardisation. This exploratory study demonstrates that key themes exist in the annual HA Convention and we observe potential changes in healthcare services focus over the years in the selected category.

Keywords:
Data Mining; Unsupervised Machine Learning; Medical Informatics

Introduction

Uncovering clinical research foci and trends can allow healthcare providers, policy makers, researchers and general public to gain an overall picture on the direction of public health. For policy makers, through better understanding of health trends and services provided, new policies can be devised in order to meet the needs of ever-changing health market. For healthcare service providers, understanding health trends and shifts in focus provides good guidance on their current practice and may direct their future health services or business models. For the general public, gaining an appreciation of new innovations and trajectories in healthcare organisations allows them to exercise improved judgement in their consumption of health care products and services.

In Hong Kong, the Hospital Authority (HA) Convention is an annual conference and research exchange platform that gathers and shares up-to-date medical research among local public and private hospitals, government departments, and local and overseas businesses. This convention acts as a parameter of development in the local healthcare system and quality improvement trends. This allows experience sharing and introduction of new healthcare-related services across inter-organisational levels to enhance the quality of Hong Kong healthcare services. Through an improved understanding of the active healthcare services provided and research carried out by different service providers, researcher and related parties, we may be able to better match between local demand and services. Therefore, the potential shifts on the focuses on the HA convention could give brief insights on the caused impacts.

Current research advances in natural language processing and topic modelling allow us to catalogue raw data into libraries for classification, aggregation, identification and document location. This can enable resource discovery and serves for archival and managerial purposes. The key challenge is that these documents are usually analysed in a large-scale manner and previous studies have revealed several unique problems in uncovering medical documents topics [1]. Discovering major themes from the corpus of data would facilitate retrieval of documents on the same topic with and without a query. We do not observe any similar health informatics studies in Hong Kong that aim to reveal the shifts of the focuses on healthcare sector, in particular on the angle on reviewing articles over the years using document text mining and topic modeling methods systemically.

We propose to apply state-of-the-art text mining and topic modelling techniques on medical documents to uncover latent themes and structure from HA Convention publications. In this probing study, we analyze metadata and abstracts from HA Convention publications, in particular the category of Clinical Safety and Quality Service research – that includes projects aimed to (1) improve efficiency and effectiveness of care delivery/resources management and (2) enhance clinical safety and outcomes/clinical governance.

Methods

Unsupervised topic modelling

Topic modeling is a statistical tool that is frequently used in text mining for identifying common themes in a collection of documents [2]. This method retrieves information based on statistics of words in the documents and has been widely adopted in the
healthcare informatics discipline. One of its key potential applications is to identify health related topics from numerous articles. Wang et al. research on a typical topic modelling approach - Latent Dirichlet Allocation (LDA) model - to identify latent topics from the life science publications extracted from electronic databases [3]. Paul and Dredze [4] applied Ailment Topic Aspect Model (ATAM) and LDA models to identify coherent clusters with the Twitter data and demonstrated strong correlations with independent surveillance and survey data. Hashimoto et al. [5] incorporated topic model to identify keywords and support active learning in systematic reviews. Speier et al. [6] demonstrated that the application of topic modelling is useful for automatic summarisation system for clinical reports.

In this probing study, we applied a classical LDA model with the following procedure and assumptions [7-8]:

1. The generative process for a document \( \omega = (\omega_1, \ldots, \omega_N) \) of a corpus \( D \) containing \( N \) words from a vocabulary consisting of \( V \) different terms, \( \omega_i \in \{1, \ldots, V\} \) for all \( i = 1, \ldots, N \).
2. The term distribution of each topic, \( \beta \) is determined by \( \beta \sim \text{Dirichlet} (\delta) \) and it contains the probability of a word occurring in a given topic.
3. The proportions \( \theta \) of the topic distribution in a document, \( \omega \), are determined by \( \theta \sim \text{Dirichlet} (\alpha) \).
4. For each of the \( N \) words \( \omega_i \):
   - (i) A topic was chosen from the distribution, \( z_1 \sim \text{Multinomial} (\theta) \).
   - (ii) A word \( \omega_i \) was chosen from a multinomial probability distribution conditioned on the topic \( z_i: p(\omega_i | z_i, \beta) \).

Variational expectation-maximisation (VEM) procedure has been adopted and its estimation on the log-likelihood for one document \( \omega \in D \) is for LDA given by

\[
\ell(\alpha, \beta) = \log(p(\omega | \alpha, \beta)) = \log \left( \sum_z \prod_{i=1}^{N} p(\omega_i | z_i, \beta) p(z_i | \beta) \right) = p(\theta | \alpha) d\theta
\]

In comparison to other black-box algorithms, the strength of topic model is that it interprets clusters by the word probability distributions over topics. Furthermore, it allows terms associated with a mixture of topics rather than only one single topic. This characteristic was regarded as a key advantage for various real life applications, including bioinformatics [9].

**Metadata, modelling procedure and underlying assumptions**

All the contributions from the HA Convention offered metadata information and context of the research that included year of publication, session, authors and their corresponding affiliations, research topic, abstracts and keywords. The data was extracted from the online HA Convention programme books published from 2013 to 2016.

According to medical text structuring method conducted by Wong [10], we pre-processed the textual medical publications into structured data output (i.e. bag of word format). LDA is one of the typical topic models and is an unsupervised generative graphical model [2, 11]. We assumed the potential latent topics were uncorrelated and documents were considered as random mixtures over latent topics, which each topic is characterised by a distribution of various keywords. Those keywords are generated via repeated sampling on a topic based on the topic distribution and selection of a word given the chosen topics.

In order to identify the latent topics among these abstracts without specifying the keywords, an unsupervised topic modelling method (i.e. the LDA model with the VEM procedure for maximum likelihood estimation and Gibbs sampling method) was applied. Topics and the representing keywords were then discovered. The entire analysis was conducted on a R v3.3.2 (64-bit) platform using ‘NLP’, ‘tm’, ‘tau’, ‘Rstem’, ‘SnowballC’ and ‘topicmodels’ [12] packages. The modelling procedure is shown in Figure 1.

![Figure 1– Data preparation and modelling procedure](image)

**Results**

In this section we arrange our findings into two parts. The first part presents descriptive statistics of metadata information and summarises document data mining outcomes and the second part shows the uncovered topic structure, including per-document topic distributions, the per-document per-word topic assignments, and the corresponding potential topics/research themes.

**Descriptive statistics**

We collected 742 articles from the HA Convention from the years 2013 to 2016. The numbers of participating organisations and articles increased gradually from 2013 to 2016. In 2016, there were 229 included articles from 84 organisations in the HA Convention. Most articles were categorised under the sessions of “Special Topics” and “Masterclasses” while the “Service Enhancement Presentations” was the session with the largest number of publications over the 4 years, as shown in Table 1. In total, 2,087 authors from 921 affiliations have submitted their works to the Convention. Twelve percent of overall affiliations from local hospitals were from New Territories East cluster and 16% were from local hospitals in Kowloon Central cluster.
The convention has several research categories, for instance: “Clinical Safety and Quality Service / Quality and Safety in Healthcare”, “eHealth and Healthcare”, “Palliative Care”, “Al­lied Health Service – Technology and Innovation”, and “Com­mitted and Happy Staff”. Among these, “Clinical Safety and Quality Service” is the largest category with the highest number of contributions over the 4 years - which accounts for about 8% of the all publications. Fifty-six articles under this category were extracted for further natural language processing and topic model analysis. After removing stop words and punctuation and applying stemmer, 2,200 terms were identified and these were the inputs to build a document matrix. The top 10 TFIDF stemmed terms are reported as “drug”, “fall”, “count”, “vap”, “consent”, “speci­men”, “nurs”, “admiss”, “duti”, and “group”.

**Topic model**

We developed LDA model with VEM procedure for maximum likelihood estimation and Gibbs sampling method through Statistics R. The document matrix summary indicates sparsity of 54% - which is lower than the threshold value of 95%. We did not remove words from the matrix for the subsequent construction of topic modelling and we adjusted the number of topics manually by trial and error in order to maximise the number of the topics. Seven topics were identified and Table 2 shows the representative keywords of each identified topic.

These findings were further discussed and verified with local Public Health and Health System experts in Hong Kong. Based on the top keywords of each topic, we suggested that the possible seven themes of topics under ‘Quality and Safety in Healthcare’ / ‘Clinical Safety and Quality Service’ session are: (1) surgical operation, (2) hospital discharge, (3) medical error, (4) nursing procedure, (5) service performance assessment, (6) patient and staff engagement, and (7) admission algorithm and standardisation, as shown in Table 3.

* Study preliminary finding requires further investigation

We summarised the per-document topic distributions annually using the identified topics and Figure 2 shows the annual document topic distributions for each topics under the session of “Quality and Safety in Healthcare” / “Clinical Safety and Quality Service”. This result indicates that that each of the Topics 1 to 4 (i.e. potentially surgical operation, hospital discharge, medical error, nursing procedure) offers more than 30% contribution to a corresponding year - which can be potentially considered as the key topics in those years. Topic 6 (potentially patient and staff engagement) is considered as the common topics found over the 4-year programmes as the keywords show similar and significant contributions over years, while Topic 5 (potentially service performance assessment) can be catalogued as minor topic of this theme in 2014 HA programme book. Topic 7 (potentially admission algorithm and standardisation) is considered as another minor topic covered in year 2014 to 2016.
Discussion

We selected 56 articles from HA Convention programme and incorporated document text mining and topic modelling to uncover 7 potential topics for the category of “Quality and Safety in Healthcare”, “Clinical Safety and Quality Service”. The possible topics include: “Surgical operation”, “Hospital discharge”, “Medical error”, “Nursing procedure”, “Service performance assessment”, “Patient and staff engagement”, and “Admission algorithm and standardisation”. The finding suggests that there may have at least one dominant key topic for each year’s publication, which implies that in the context of enhancement of quality and safety of the clinical services provided, the focus of research topics may potentially be different annually. Some topics’ contribution distributed relatively equal among years and this implies those are relatively long term and ongoing research issues over several years. These findings fulfill one of the major objectives on uncovering the potential trends and shifts on health research studies in Hong Kong via the use of informatics and modelling techniques.

With a better catalogued theme, we can analyse the development (and their causes) in the number and proportion of clinical studies over time in Hong Kong that projects the need of the healthcare. By analysing differences in trends, future study can be designed to demonstrate the cause of different trajectories over years and to answer some policy research questions, such as clinical development continues to evolve against any pattern of increasing development timelines and associated costs. In addition, it is also believed that these publication trends could reflect how the healthcare providers responded to the implementation of new policies. In this explorative study, we demonstrated that key focusing topics exist in the abstracts from presentations of annual HA Convention and potential changes on the focus of the healthcare services have been identified over the years. We foresee that the local research trend may potentially point to topic on safeguarding consumers in the future while the planned accreditation professional scheme for allied health professionals was raised by the Hong Kong government recently in 2016.

Although we have identified the latent topics in the category of “Quality and Safety in Healthcare / Clinical Safety and Quality Service”, there are several potential research directions for our further investigation. Currently, we cannot be certain if the interpretation of the identified topics is absolute. It is necessary to scrutinise this results in a careful manner – not just evaluate the outcome on the basis of the keywords found. It appears that the keywords found under each topic are relatively diversified, which make the key focused themes unclear through pure inspection over the top key terms. To improve this study, we plan to validate this preliminary finding via other complementary unsupervised learning methods. Furthermore, we will carry out in-depth discussion with further hospital practitioners and experts in healthcare quality and safety to interpret the public health and clinical meaning of the model outcomes. The modelling and knowledge extraction procedure can be rectified to improve the representativeness of the mined outcomes [13]. For instance, some of the indentified keywords with little or no clinical relevance could be filtered out under the consensus of 2 investigators.

An improved design text extraction procedure may be necessary to effectively select potential text variables for topic modelling. For instance, further studies can be carried out to incorporate other state-of-the-art natural language processing techniques, such as ‘n-gram’ and ‘wordnet’ to improve the accuracy on the identification and interpretation of the topics. “n-gram” is a package that commonly used in document text mining to identify co-occurring words within a given window while synonyms can be identified with the use of the package of “wordnet”. In addition, term associations can be tested in order to provide more comprehensive meanings on the identified keywords. This systematic approach can be designed in order to avoid introduction of selection bias through training-up the model.

Another future direction could be to compare the model outcomes using unsupervised machine learning and supervised machine learning. Since the LDA model is an unsupervised machine learning method and its accuracy highly depends on the occurrence of the keywords with representatives on specific topics. For example, the authors may not include the words “blood pressure” in an abstract on the evaluation of the performance on newly developed drugs on handling hypertensive patients, but the article could fall under the sub-category of cardiology. Therefore, it may be useful to explore and evaluate the strengths of various machine learning and topic modelling approaches and incorporate a suitable modelling procedure to better reveal the potential nature of hidden topics.

The “topics” discovered in an unsupervised manner may not always genuinely reflect the true topics from the data. Also, the classical LDA method instinctually does not consider the order of words in a document. Apart from the classic unsupervised topic discovery explored in this study (that do not involve any prior annotations or labeling of the documents), we suggest to investigate the possibility to use other supervised learning methods, such as supervised LDA (sLDA), and incorporate topic hierarchies from data via hierarchical LDA (hLDA) method for further analysis. The performance of various methods can be evaluated by experiments with text datasets of medical documents. The model performance can also be evaluated quantitatively through log-likelihood on held-out data approach. We will also collect expert views and independent health research indicators and materials for validating the model outcome. A better structured analytical framework is potentially useful for analysing other global clinical research papers from mainstream clinical databases, such as PubMed and Medline.

Conclusion

We used the HA Convention publications to infer the hidden topic structure in healthcare quality and safety research in Hong Kong. This explorative study provides opportunities to reveal the major focus and trends on the healthcare services provided by different organisations from year 2013 to 2016. This research contributes to the emerging field of understanding the characteristics of the medical documents and how to account for them using health informatics methods. This work potentially enhances our ability to interpret medical publication information and trends in Hong Kong and globally.

Abstract

Search techniques in clinical text need to make fine-grained semantic distinctions, since medical terms may be negated, about someone other than the patient, or at some time other than the present. While natural language processing (NLP) approaches address these fine-grained distinctions, a task like patient cohort identification from electronic health records (EHRs) simultaneously requires a much more coarse-grained combination of evidence from the text and structured data of each patient’s health records. We thus introduce aligned-layer language models, a novel approach to information retrieval (IR) that incorporates the output of other NLP systems. We show that this framework is able to represent standard IR queries, formulate previously impossible multi-layered queries, and customize the desired degree of linguistic granularity.

Keywords:
Natural Language Processing; Information Storage and Retrieval; Electronic Health Records

Introduction

Search (i.e., information retrieval) techniques in clinical text face the challenge of coarse vs. fine granularity. In a setting such as electronic health records (EHRs), the goal is usually to find a broad characterization of a whole patient from that patient’s diverse assemblage of text and structured data. How to combine these pieces of evidence into a patient-level judgment is an area of active research. Moreover, in clinical text, dictionary matching for a symptom like “hypertension” must be augmented by fine-grained algorithms to ensure that the symptom is not negated (e.g., “no complaints of …”), about someone other than the patient (e.g., “family history of”), or a host of other possibilities. Textual variants of these fine-grained patterns abound as well, spawning natural language processing (NLP) methods to find concepts of interest from acceptable textual contexts.

Therefore, we aim to incorporate arbitrary NLP-derived features into information retrieval (IR) methods on clinical text, allowing for greater control of the granularity in search. Our main contribution is the aligned-layer information retrieval model, which we specify by defining the “layered” nature of text and the nature of phrases in this setting. This model is a straightforward extension of the language modeling approach to IR and its feature-centric successors.

We adopt the “layer” terminology from the language resources community in which, for example, treebanking and propbanking are different layers of annotations on the same text. The crucial contribution in our work is a model in which all text-derived “layers” are aligned by token, and can be utilized and scored simultaneously during search.

After describing our aligned layer approach, we report on a preliminary system implementation and evaluation of the model. For our evaluation, we focus on the problem of cohort identification within clinical notes from the EHR.

Related Work

Preliminary explorations with concepts (from the Unified Medical Language System (UMLS)) in language modeling have met with moderate success [1-3] in the past. Language modeling in IR [4-6] builds on a rich tradition of probabilistic IR [7], and has a successful history of ranking documents based on well-motivated textual features. The most commonly-used textual features are from Metzler and Croft’s dependence model, modeling the probabilistic relationships between query terms (and a candidate document) as Markov Random Fields (MRFs). These term–term dependencies significantly outperformed the original bag-of-words language modeling approaches to IR from which they arose[4; 5].

Subsequently, query hypergraphs made it possible to model higher-order dependencies (e.g., multiword–multiword or multiword–term dependencies) [8]. While the representational power of these feature-based models allows for arbitrary non-textual features as well (e.g., named entities or dependencies, such as we introduce here), non-textual features have received minimal attention in the literature.

Recent work on joint text and concept search [2] and split-layer language models [1] extended the notion of mixing different document representations together [9; 10]. Arising out of the medical domain, these techniques all showed some benefit to considering multiple “layers” simultaneously. Our work here extends the discussion of language modeling layers, pushing the question of what semantic representations (or granularity thereof) are effective for IR.

Positional language models [11] attempt to model the intuition that closer textual proximity can correspond to greater association. This shares an important intuition with aligned-layer models: position is important in IR. However, our accounting of position is not to model the textual distance, but the content and relationships that are latent within text at the same locations. A number of existing studies [1; 2] require an NLP preprocessing step prior to indexing the collection, and utilize these text-derived features in search. However, these attempts fail to allow navigation among, and correspondences between, those structures.

The task of query formulation [12] is somewhat upstream task to our layered models; query formulation can include the introduction of term dependencies [13], weighting of terms [14], query expansion [15], and the parameterization of associated weights according to additional corpora [16; 17]. Our hope is that future query formulation techniques will make use of aligned-layer structures.
needs, and judgments. Language modeling techniques have been successful in this clinical text setting [2], as well as in health-related web search exemplified by the CLEF eHealth challenges [20].

Methods

We now turn our attention to the aligned-layer retrieval model and its implementation for our experiments. Let us assume that we run an NLP pipeline as a preprocess; e.g., the clinical Text Analysis and Knowledge Extraction System (cTAKES) [21]. Developed specifically for clinical text, this pipeline produces NLP artifacts as illustrated in the left and middle Figure 1.

Indexing: Aligning text and NLP artifacts

We represent this NLP-preprocessed text as a finite sequence of multiple aligned layers. Specifically, a document or query is composed of multiple layers $L_0, L_1, L_2, \ldots$ We reserve $L_0$ to be a base layer of the original text; namely, a sequence of tokens (optionally stopped and stemmed) by which all other layers are aligned. Figure 2 illustrates a query text (tokens) as a base layer, with several underlying layers—part-of-speech (POS) tags, named entities (NEs) with mappings to concept unique identifiers (CUIs), and two types of dependency parses (left). It then shows their translation into aligned layers (right).

Other than the base layer, each layer is an artifact layer, and is composed of a sequence of artifacts. For example, in Figure 2, $L_2$ is named entities, and $L_2 = I_{2,0}\cdot I_{2,1}\cdot I_{2,2}\cdot \ldots = C0032961, C0151526, C0011209, \ldots$. The artifacts are aligned with the base layer by storing 2 additional numbers: start index and length. Thus, a function $\text{span}(\cdot)$ on $I_{2,3}$, a named entity entity spanning the words “preterm delivery,” would have $\text{span}(I_{2,3}) = (2, 2)$ since the artifact concerns “preterm delivery” and starts at index 2 with a length of 2 tokens.

Additionally, we define a special relation artifact with a slight modification of other artifacts. For relation layers like $L_3$ (stanford dependency parses, in Figure 2), artifacts are relations between two other artifacts’ locations. We will write these as $r_3 = r_{3,0}\cdot r_{3,1}\cdot r_{3,2}\cdot \ldots$ to emphasize that these artifacts are relations. Then, $\text{source}(\cdot)$ and $\text{target}(\cdot)$ give the position and length of each of the relation’s arguments; $\text{source}(r_{3,0}) = (0, 1)$ points from “pregnancy” to target $(r_{3,0}) = (3, 1)$ “delivery.”

Note that the transformation to aligned language layers is slightly lossy. In Figure 2 the $L_3$ artifacts corresponding to the head and dependent of each dependency relation are not preserved—only the $L_0$-aligned spans. The loss is minimal in most NLP structures of interest.

Scoring: Terms and phrases

In IR language models, it is common to rank according to $\text{score}(D, Q) = P(D) \cdot P(Q|D)$. The conditional probability encapsulates the intuition that an ad hoc user trying to find document $D$ will try to write an effective query $Q$. We focus our attention on the conditional probability $P(Q|D)$. This is most simply expressed in the standard query likelihood model with Dirichlet smoothing (with the parameter $\mu$), a baseline for language modeling approaches. We write single-term queries with the notation of the aligned layers above, where the $a$ variable in $l_a$ simply indicates that such term queries can be written for any single layer:

$$p_t(l_a|D) = \frac{\alpha_{l_a} + \#f_D}{\#D + \alpha}$$

(1)

where $\#f_D$ is the number of occurrences of the argument (a query term $l_a$) in the document; $\#f_D$ is the number of occurrences of that argument in the whole collection. Similarly, $\#D_a$ is the number of artifacts in the document from layer $L_a$; $|D|_a$ counts the same layer’s artifacts in the whole collection.

With a layered representation of both queries and documents, these term operators allow for querying of artifacts in any layer $L_a$. The standard query likelihood model in other texts [5] is then just a special case of our term query utilizing only text layer artifacts $L_0$ (i.e., from $L_{\text{base}}$). The smoothed
probability is also calculated with respect to frequencies in layer $L_0$. Term queries do not require aligned layers — they consider each layer separately.

Probabilities for individual query terms can be calculated separately and combined to produce an overall probability. This is done implicitly, but can be made explicit with a list query; items in the list need not be in the same layer because they are each considered individually. A list query also groups the items in the list for use in other queries.

However, list queries ignore the collocation of layered artifacts; thus, we define the phrase query. A phrase is two or more artifacts from an arbitrary combination of layers, e.g., $l_{a1}b_{j1}$, the $i$th artifact in $L_a$ and the $j$th artifact in $L_b$. Phrases must be specified with ordering $o$ as ordered or unordered (True or False), with a window size $w$ to search within (measured according to positions in the base layer $L_0$).

$$P_{ph}(l_{a1}b_{j1}... | D; o, w) = \frac{\prod_{i=1}^{n} p_{ph}(l_{ai}b_{ji})}{\prod_{i=1}^{n} p_{ph}(l_{ai}b_{ji})} \frac{\prod_{i=1}^{n} \text{symp}(l_{ai}b_{ji})}{\prod_{i=1}^{n} \text{symp}(l_{ai}b_{ji})}$$

(2)

The function $\text{#ph}$ counts the number of cross-layer phrase matches in a document. Having aligned $l_{a1}b_{j1}$... to the base layer $L_0$, we can check across layers for matches within a window. Window length is between the end of the first matched artifact, and the beginning of the last matched artifact (i.e., the last artifact only needs to have start index within the window length; it can end outside the window). Writing $l_{a1}b_{j1}$ illustrates that artifacts need not arise from the same layer, and will be in different positions within their respective layers (though aligned to the base layer $L_0$). However, ordered phrases with $o=\text{True}$ must additionally consist of only non-overlapping, sequential artifacts.

Whereas in single-layer queries, a probability estimate would consist of all items in that layer, there are now two or more layers to consider. It may at first seem that the denominator should be the product $|D|_a \cdot |D|_b \cdot ...$. This would mean: “out of all possible multi-layered phrases that could be constructed in document $D$, how likely is the specific construction we are looking for?” This choice of denominator would yield sparse probability estimates. Instead, we have chosen the size of the largest layer stipulated in the phrase. This answers the question: “of the artifacts in the largest layer, what proportion participate in a phrase consistent with the query?” This may be thought of as a backed-off estimate, and is more tractable. The choice of a denominator is an interesting area of further investigation beyond the scope of this work.

We should also note that this aligned-layer phrase queries subsume ordered and unordered phrases of feature-centric IR models [6], since those features are simply functions of $L_0$.

**Implementation**

The fundamental aims of the aligned-layer IR model require significant extension in any search engine. We implemented an aligned-layer language model via a plugin to Elasticsearch with multiple layers, tested with Elasticsearch 1.7.2. We used CTAKES v3.2 as a preprocess [22], producing character-aligned artifacts (based on Apache UIMA). Aligned-layer models are similar to searching over these UIMA-based data structures, but with scored ranking, across multiple documents, and aligned on tokens instead of characters.

For indexing, each layer was represented as a field within a document. For our evaluation and analysis, we generated the an index with the following fields:

- $L_{txt}$: Word tokens, as identified by the CTAKES tokenizer; this is considered the base layer $L_0$
- $L_{cui}$: Concept Unique Identifiers (CUIs), as mapped from the UMLS Metathesaurus by CTAKES
- $L_{tui}$: Type Unique Identifiers, a many-to-one mapping that groups concepts (CUIs) into semantic types (TUIs)
- $L_{tui}$: Normalized by a version of the National Library of Medicine’s (NLM) Lexical Variant Generator (LVG)
- $L_{ev}$: Cont-U dependency parses from Clear Parser [23] trained on treebanked clinical text from Mayo Clinic
- $L_{mix}$: Part-of-speech tags produced by the OpenNLP$^3$ MaxEnt POS tagger, trained on treebanked clinical text from Mayo Clinic

Each artifact was marked with its span (position and length, in tokens) via Lucene Payloads; this is a trivial marking for the base layer of text $L_0$, but can be significant in other layers, such as for multi-word expressions in the CUI layer of Figures 1 and 2. In addition, the size of each field within a document was stored as metadata with that document at indexing time.

Queries are scored in Elasticsearch and Lucene via a highly optimized scoring interface. However, our scoring functions cannot be represented within that original structure; for example, the Lucene implementation of Dirichlet smoothing on a language model fails to divide by the collection frequency in some cases. Therefore, we implemented scoring via Elasticsearch Script Queries, which are typically used in a filtering context but here provide us the flexibility to score according to the models defined above.

Because they make use of aligned-layer terms and phrases, queries must be constructed and parsed differently than in other search systems. We implemented our own query parser in JavaCC to term and phrase operators in the aligned-layer query language.

**Task and Experiments**

We provide a preliminary evaluation of aligned-layer language models, and of our Elasticsearch-based implementation in particular, on the task of patient cohort identification as exemplified in the 2011-2012 Text Retrieval Conference (TREC) Medical Records Track, or TREC-Med [18; 19]. In brief, there were 81 topics (34 from 2011, 47 from 2012) such as “patients with hearing loss,” and the task was to return lists of relevant patient visits (a de-identified surrogate for whole patient records) from among 17,198 possible visits. System-produced lists of visits were compared with human relevance judgments (which were gathered for the TREC-Med 2011-2012 competitions).

Table 1 shows how the same query is represented across our evaluated approaches. As a baseline test TXT, we used unstemmed, stopped TREC-Med queries with the standard query likelihood model -- namely, term queries on $L_{txt}$. A second baseline was CUI, where we used term queries on $L_{cui}$.

In aligned-layer IR, term operators on multiple layers can be weighed together simultaneously for results. We replaced all named entity mentions in the query with the first-matched CUI, mixing the two layers in MIX. Since the CTAKES Named Entity Recognition (NER) module actually returned a set of CUIs per named entity, we included a model CUI-LS in which named entities were replaced with all of the CUIs associated with the same span, combined in a list. Next, we augmented

Searching for an optimal formulation and weighting of queries is outside the scope of this paper. However, for each of the above approaches, we also implemented a version with the Markov Random Field (MRF) “term” dependence model [24], which attempts to move beyond bag-of-words (BOW) models. Comparing the TXT-MRF row to the TXT row in Table 1 illustrates the behavior of this model: it tries out, with appropriate weights, the possibility that a multi-layered query may have phrases within it. We implemented a sequential dependence model with a limit of 5 aligned-layer components. These “term” dependence versions are marked as -MRF.

Results

We used mean average precision (MAP) as the primary evaluation measure for evaluation. MAP provides a single-figure measure of quality across recall levels [25]. While TREC-Med 2011 reported bpref [26] as its primary evaluation metric, and TREC-Med 2012 reported infrad [27], we here report the mean average precision (MAP) due to its stability for both training and testing in previous work [28; 29]. Table 2 shows the MAP scores, where we have separated the topics from TREC-Med 2011 (left) and 2012 (right).

Table 2 - Retrieval performance for a range of possible aligned-layer models

</tbody>
</table>

While this performance is below the state-of-the-art, it is interesting to note that it is layers with CUIs that obtain the highest performance in these tests (CUI-BOW on 2011 queries, and PH-LS-BOW on 2012 queries). Without text-layer query expansion, query logs, clickthrough data, or the like, another well-motivated, semantically-rich layer seems to be beneficial.

Discussion

For aligned-layer language models, it is interesting to ask whether there is the possibility of fine-tuning results on individual queries. Here, then, we consider one of the worst-performing queries, topic 121, and seek to write aligned-layer queries that would improve those particular topics.

Topic 121 is “Patients with CAD who presented to the Emergency Department with Acute Coronary Syndrome and were given Plavix.” The CUIs found were C0948089 (acute coronary syndrome), C0010068 (coronary heart disease), and C0039082 (syndrome) – note the NER did not find the medication Plavix, or its generic form, clopidogrel. The highest scoring model on this topic was MIX-BOW=0.0639. In the event of a failed detection, we may consider using some kind of backoff model to less-specific expressions.

- In place of plavix, we searched for a dependency relationship where the head word has a lemma “give,” and the child is any word with a proper noun. It then weights that relation alongside the term plavix. This brought the MAP to 0.0803.
- In place of presented emergency department, we considered any verbs that might describe a patient’s arrival. We stipulated that there should be some verb in a dependency relationship with the phrase “emergency department.” This brought the MAP to 0.0867.

The multi-layered queries clearly allow for greater coarseness or fineness according to the needs of a query.

Conclusion

We have introduced aligned-layer language models, a novel approach to IR that incorporates the output of other NLP systems. Core to this contribution are the definition of layers, alignment, and multi-layer scoring models. We have shown that this system can represent standard IR queries, as well as formulate multi-layered queries that were previously impossible. A case study demonstrates how the aligned-layer approach may feasibly be further extended to customize linguistic granularity to specific queries.

An open question of the proposed approach is how to design the layers for different corpora. Since different corpora contain variegated domain knowledge, we could design individualized layers for each corpus. In future work, we will further explore how our aligned-layer index can serve as a
corpus analysis tool for quantitative representativeness of linguistic features; this would further drive a model to automatically design and select layers. In addition to this manual approach to exploring the linguistic content, we will learn parameters and weights for the model to optimize performance on IR tasks. Finally, we will release the code for aligned-layer language models to the open-source community.

A Bayesian Network Model of Head and Neck Squamous Cell Carcinoma Incorporating Gene Expression Profiles

Shuyang Wu, Anthony Law, MD, PhD, Mark E. Whipple, MD, MS

Abstract

Radiation therapy allows precision targeting of certain groups of lymph nodes and is a treatment for metastatic head and neck squamous cell carcinoma. In current practice, there is approximately 15% probability that physicians inadvertently treat healthy tissue or leave the cancerous lymph nodes untreated. The aim of this work is to improve the accuracy of medical decision-making by extending existing predictive models to capture the probabilities of finding cancerous lymph nodes at each of the six image-based surgical neck level using a patient’s genetic profile, primary tumor site and tumor size. Our model was trained with publicly available data extracted from the Cancer Genome Atlas (TCGA) and validated against the TCGA dataset both with and without genetic information. Results show that genetic profile data improves model accuracy. These findings suggest that our predictive model may improve the accuracy of clinical decision-making, especially for patients with more advanced metastasis. However, more data is needed to ensure significance of the proposed effects, as well as to improve accuracy of the overall model.

Keywords: Carcinoma, Squamous Cell; Clinical Decision-Making; Lymph Nodes

Introduction

Head and neck cancers account for approximately 3% of all cancers in the United States [1]. More than 90% of head and neck cancers are squamous cell carcinoma [2]. Head and neck squamous cell carcinomas (HNSCC) have broadly varying survival rates, depending on the primary site, disease stage and the occurrence of metastasis [3]. HNSCC initially metastasizes to the lymph nodes in the neck, following lymph drainage pathways. The regions of the neck containing lymph nodes are classified into six imaging-based surgical neck levels I - VI as shown in Figure 1a [4][5]. If PET or CT scans show evidence that the cancer cells have spread to any of the lymph nodes, radiation therapy can be targeted to treat the area of interest. Radiation therapy is also prescribed if the tumor has reached a certain size, even if there are no detectable signs of lymphatic metastasis. This is because with current technology, small amounts of cancer cells in the lymph nodes do not appear on scans, but there is enough risk in these areas to warrant treatment. The ability to predict locations of lymphatic metastasis is critical for both minimizing the risk of recurrence and minimizing the complications resulting from unnecessary radiation.

Since not all lymph nodes are equally likely to be involved in metastasis, physicians determine which lymph nodes to target based on prior knowledge and personal experience. The decision-making process requires them to estimate many variables including which lymphatic channels the tumor cells have taken and how far along they have spread within the channels [6]. A study by Crosskerry showed that physician judgment can vary from reality by 15% on average [7]. In other words, there is approximately 15% probability that physicians make either over-conservative decisions and treat the healthy area or leave the cancerous lymph nodes untreated. Several studies have examined the likelihood of certain groups of lymph nodes having cancer based on their prior state. For example, a hidden Markov model was developed based on lymphatic anatomical structure, the primary tumor location and T-stages [6]. A predictive model applying the Bayesian network approach was also established with the same predictors and evaluated to show clinical significance, meaning it could successfully improve accuracy for medical decision-making [8]. With the promising results of both predictive models, we suspected that additional information could be added as a predictor to improve model performance. Studies have shown that there is a genetic expression profile predictive of nodal metastasis of HNSCC [9][10]. The proposed profile is identified through differential analysis of Affymetrix Human Genome Focus arrays and confirmed by immunohistochemical analysis for transglutaminase-3 and keratin 16 [9][10]. We hypothesized that integrating genetic profile information into our predictive model would improve its performance, leading to more accurate decision aids for clinicians. We were also able to quantify the effects that different genetic profiles play on metastasis by comparing the performance of models with and without genetic information.

We proposed to extend existing predictive models to capture the probabilities of finding cancerous lymph nodes at each of the six image-based surgical neck levels using a patient’s genetic profile, primary tumor site and tumor size. Such a model could potentially help physicians to make improved evidence-based decisions while performing targeted treatments such as radiation therapy. The studied effects of a genetic profile on metastasis may enable physicians to adopt more individualized treatments. In addition, future studies can incorporate other risk factors, such as smoking, alcohol and human papillomavirus (HPV) status [11], as predictors in the model via the same method.

Methods

Model construction

The inputs of the model are based on existing research and our hypothesis: tumor origin, the size and local involvement of the primary tumor represented by T-stage, and the patient’s tumor-associated genetic profile. The output of the model is the predicted levels of nodal metastasis. Figure 1a shows the surgical neck dissection levels, which are used to delineate regions of cancerous tissue targeted for treatment. Nodal
metastasis tends to follow well-delineated pathways that map to the regions described by the surgical levels.

Based on the physical connectivity of the lymphatic system, cancer cells can only travel to lymph nodes that drain from the primary tumor, and to other lymph nodes through connected drainage channels. We were able to draw from detailed anatomic knowledge on lymphatic connectivity from the Foundational Model of Anatomy (FMA) [12]. We also assumed that despite primary sites or T-stages, once the cancer cells enter the lymphatic system, the metastasis pathway remains consistent and unidirectional, which means the spread of cancer occurs only along described lymphatic channels, and in a direction away from the primary tumor. Clinically, there are rare exceptions due to skip lesions and branching, but because our focus is on studying model performance with additional predictors, we made the decision to exclude these scenarios in the current study. The model outcome is generalized to indicate the highest level of metastatic prognosis. This means for each level below the highest, the estimated probability of that level containing cancer cells is the sum of the probabilities of all levels at or above it.

We developed a Bayesian network model with the structure shown in Figure 1b. In our original model construct, the observed lymphatic level of positive nodal metastasis is conditionally dependent on primary site, T-stage and genetic profile. The weights of the directed edges indicate the probabilistic measures between variables and were obtained by utilizing the available data to learn the network structure in order to validate our assumptions about the predictors. In the learned and final model, the T-stage shows a strong conditional dependence over the primary site. Genetic profile and primary site present a predictive relationship that remains to be investigated.

**Data sources**

We used two data sources. The first data source was from University of Washington tumor board (UW TB). We obtained records of 383 patients with untreated, non-recurrent squamous cell carcinoma (SCCA) of the head and neck presented to the UW head and neck tumor board over a 3.5-year period. Since this dataset did not contain patient genetic information, we used it to train the baseline model.

The second data source was from the Cancer Genome Atlas (TCGA) [13]. We obtained 528 subjects’ clinical data including demographic information, treatment information and disease status, HTSeq-FPKM-UQ (upper quintile of normalized gene expression values), HTSeq-Counts (raw gene expression values) and pathology reports. All data were exported from the TCGA data portal.

**TCGA data preparation**

Unique identifiers, clinical T-stages, and primary site information were extracted from subjects’ clinical data. Because of the limited sample size and the relatively wide range of different primary sites, the number of subjects for each primary site was too small to be statistically significant. Hence, the primary sites were aggregated into larger regional sites as follows: “Tongue”, “Floor of Mouth”, “Oral Commissure”, “Lip”, “Alveolar Ridge”, “Buccal Mucosa” and “Mandible” were represented as “Oral Cavity”; “Base Of Tongue”, “Tonsil”, and “Retromolar Trigone” were represented as “Oropharynx”; “Supraglottic larynx” and “Glottic Larynx” were represented as “Larynx”. Some primary sites (e.g. “Palate”) contained too few samples and were not included. Subjects with unknown T-stage were dropped. Those with stages “T4a” and “T4b” were combined into stage “T4”.

Nodal metastatic level information was extracted from pathology reports, linked to corresponding subjects based on the TCGA manifest, and reviewed by two team members for accuracy. Only 349 out of 528 subjects had data on their nodal metastatic level information. Studies performed by Mendez et al. identified differential gene expression profiles of tumor-specific genes in metastatic versus non-metastatic lymph nodes [8][9]; we applied this established gene expression profile to the TCGA dataset. For the purpose of validation, the HTSeq-counts of the subjects in this dataset were also analyzed to identify differentially expressed genes between patients who had lymphatic metastasis and those who did not. The differential analysis was performed using the R “DESeq2” package from Bioconductor (version 3.4). The resulting genes were ranked based on p-value and used to cross-reference with the tumor-specific genes determined in the Mendez et al. studies [8][9]. Of the genes we identified from the TCGA data, 53 genes match genes discovered in the previous Mendez studies. All 53 matched genes were associated with small p-values that fall within the first half of the ranked gene list, thus validating the application of the gene expression profile established from previous studies to the current data set.

**Dimension reduction for genetic information**

Because the 53 genes are not equally predictive of the level that the lymph nodes were affected, having all of them as individual predictors would mean including those with only a small effect. However, without the biological knowledge on the gene-gene interactions and mechanisms, disregarding any of them using the dimension reduction methods such as PCA and random forest model seemed presumptuous. Therefore, we applied the multivariate logistic regression model published in Dr. Mendez’s studies to fit our HTSeq-FPKM-UQ data and the metastatic status [8][9].

The log odds calculated from fitting the logistic regression model were used as propensity scores for each patient to indicate the risk of metastasis associated with his or her genetic profile. The normalized propensity scores of the 349 subjects have the following distribution (figure 2). They were then categorized based on standard deviation to help clinicians to identify patients who are more prone to develop metastasis. Specifically, subjects with propensity scores that are one
standard deviation above the mean are classified as “high risk” (n = 56), subjects with propensity scores that are one standard deviation below the mean are classified as “low risk” (n = 54), and the rest of the subjects fall under the “regular” risk category (n = 239) (supplement figure 2).

From the two data sources, TCGA and UW tumor board, we produced four datasets as follows:

1. TCGA data with genetic expression profile/risk category, sample size = 349, training set = 233.
2. TCGA data without genetic expression profile/risk category, sample size = 349, training set = 233.
3. UW tumor board data without genetic expression profile/risk category, sample size = 383, training set = 255.
4. Combination of TCGA and UW tumor board data without genetic expression profile/risk category, sample size = 482, training set = 321.

Each dataset was trained and tested using the R “inlearn” package (Version 4.0) with 3-fold cross-validation. When combining the datasets we kept same primary site distributions from the two sources to reduce heterogeneity, data points were randomly selected but reproducible.

Conditional probability tables were produced from fitting Bayesian network models with the training sets above; predictions were made on their corresponding test sets. The Bayesian network models with the training sets above; Conditional probability tables were produced from fitting from the two sources to reduce heterogeneity, data points were combining the datasets we kept same primary site distributions each dataset was trained and tested using the R “bnlearn” decision support tables, and whether it improves clinically relevant decision-making. The decision support tables were only constructed for subjects with T3 “Oral Cavity” tumors because data on these subjects was most complete and the decision support tables had the least number of missing values.

Results

Table 1 demonstrates the distributions of primary sites, T-stages, and positive nodal metastasis of patients in the training datasets.

The cosine similarities of different data sets (see Table 2) indicate some heterogeneity between TCGA and UW tumor board data. Specifically, the TCGA dataset contains a larger proportion of subjects with “Oral Cavity” tumors (70% in TCGA; 37% in UW TB), whereas the UW tumor board dataset has a larger proportion (10% in TCGA; 42% in UW TB) of subjects with “Oropharynx” tumor (Table 1). The difference in distribution may have affected our results for clinical decision making comparison as only subjects with “Oral Cavity” cancer were investigated. The comparison of model prediction accuracies learned from the four datasets is shown in Table 3.

The estimated probabilities of having positive lymph nodes in each level were categorized into “treat,” “maybe treat,” and “do not treat” based on a consensus reached by physicians (< 7% = do not treat, between 7% and 15% inclusive = maybe treat, > 15% = treat) as reported in a previous study [14]. We also evaluated the effect of adding genetic information to these decision support tables, and whether it improves clinically high cosine similarities, meaning the differences between the predictions and the observations were relatively small.
The weighted AUC result shows that the model trained with TCGA data with genetic information and the model trained with the combination dataset had the highest weighted AUC values, meaning these models resulted in the least amount of classification errors.

Shading of the cells indicates treatment decisions. Red represents “treat”; yellow represents “maybe treat”; green represents “do not treat”.

Table 5 shows the comparison of the estimated probability of finding positive lymph nodes in each level for subjects with T4 “Oral Cavity” cancer and the treatment decision based on decision thresholds. Comparing to subjects with “regular” risk genetic profiles and subjects from datasets without genetic information, the ones with “high” risk genetic profiles show a change in decision at level V (from “do not treat” to “maybe treat”), subjects with “low” risk genetic profiles show a change in decision at level IV (from “maybe treat” to “do not treat”).

Discussion

All three accuracy measures (correlation, cosine similarity and AUC) showed evidence that having genetic profile as an additional predictor improved our model’s prediction accuracies compared to models trained without genetic information. The improvement seems to be equal to that of having a larger training set when we compared the test results between TCGA (n = 233) and Combination (n = 321) dataset. This is promising since it’s often more difficult to recruit a larger sample population than to examine all possible predictors in a relatively smaller sample.

Because we used the genetic profile identified in the Mendez et al. [9][10] studies and the associated parameters while preparing the training sets for our model, our results further proved the validity of using the genetic profile to predict metastasis in HNSCC patients. It remains to be investigated whether the genetic profile predictive of metastasis can also be predictive once the cancer cells have spread into the lymphatic system. If there exists a genetic profile that associates with more aggressive cancer cells that lead to higher level of metastasis, it could provide a future research direction.

Due to the sample sizes being too small, we aggregated the primary sites into regions. Because primary sites have differences in metastatic potential even within a region, poorer performance is expected from aggregating into regions than if we had enough data to model individual primary sites. Also, the current model could not reflect the differences in metastatic pathway for each primary site, the results are under the generalized assumption that tumor metastasizes in a linear fashion. For the same reason, even though we were able to
quantify the effects of genetic profile on metastasis, we could not show evidence that such effects are significant and can lead to changes in treatment decisions. However, because the treatment decisions did not change much depending on the dataset used to train the model (see Table 4), it is reasonable to assume that our basic model is consistent in terms of treatment granularity across all data.

The major limitation of this study is the small sample sizes. Because not all pathology reports include the recording of metastatic level, it was difficult for us to gather this data. Data including patient genetic information is even sparser as only certain research studies currently collect patients’ genetic information for analysis. Therefore, we needed to use cross-validation rather than using a separate dataset with both genetic profile information and metastatic level information to validate our model. Perhaps future research should include more data for significant results.

Despite the limitations, our study is the first to quantify the effects of genetic profiling on metastasis in HNSCC patients. It is also an indication that genetic information can be used to assist medical decision making in this domain, although the effect size is inconclusive. This calls for increased collection of relevant data to determine significance. Further, we aim to investigate other potential predictors of HNSCC such as smoking, alcohol use, and HPV status to further improve our model performance.

Conclusion

Our predictive model depicted and quantified the relationships between the metastatic level in patients with HNSCC and potential predictors such as tumor primary site, T-stage and metastatic risk propensity derived from patient genetic profiles. Results supported our hypothesis that gene expression has effects on metastasis and including the patient’s genetic profile can improve model accuracy. However, there was not enough data to show significance of the effects different genetic profiles have on treatment decision making. All in all, our predictive model can improve scientific knowledge and clinical practice in HNSCC treatment and can be extended to examine more potential risk factors.

Applying Risk Models on Patients with Unknown Predictor Values: An Incremental Learning Approach

Abstract
In clinical practice, many patients may have unknown or missing values for some predictors, causing that the developed risk models cannot be directly applied on these patients. In this paper, we propose an incremental learning approach to apply a developed risk model on new patients with unknown predictor values, which imputes a patient’s unknown values based on his/her k-nearest neighbors (k-NN) from the incremental population. We perform a real world case study by developing a risk prediction model of stroke for patients with Type 2 diabetes mellitus from EHR data, and incrementally applying the risk model on a sequence of new patients. The experimental results show that our risk prediction model of stroke has good prediction performance. And the k-nearest neighbors based incremental learning approach for data imputation can gradually increase the prediction performance when the model is applied on new patients.

Cluster Analysis; Theoretical Models; Risk

Introduction
Risk prediction models are used in clinical decision making to help patients make an informed choice about their treatment. Risk prediction models typically use a number of predictors based on patient characteristics to predict health outcomes. For example, traditional risk models, e.g., CHA2DS2-VASc score [1] and Framingham score [2] for predicting thromboembolism (TE) in Atrial fibrillation (AF), were developed on well-known risk factors that are grounded in previous evidence and experience. Li et al. [3,4] used feature selection methods in machine learning to automatically identify potential risk factors from original features, and achieved more accurate prediction than traditional models. These risk prediction models are developed from well curated registry data.

Advances in information technology has led to the increased availability of large amounts of clinical data, such as the Electronic Health Record (EHR). EHR data contain important information about patients, such as demographics, medical history, medication, lab test results, and billing information. With the prevalence of big data analytics, EHR data is a potentially rich, underutilized source of information that can aid in clinical decision support. The previous work [5] combined expert knowledge with data driven insight for risk factor identification using Electronic Health Records. Works [6,7] used a deep learning approach to extract effective predictors for risk prediction on EHR data.

In clinical practice, the developed risk prediction models cannot be directly applied on new patients, because some of the predictive risk factors are unknown in the new patients. Either the predictor value is missing, or the predictor is not even tested. Data imputation is the process to impute the missing data to yield a more complete dataset. There are various data imputation methods to estimate the missing values [8-10]. These methods commonly use mean, average, or the most frequent values from the whole training data to do imputation. However, when applying developed risk prediction models on new patients, we do not have training data to estimate the missing values. All we have is the dynamic test data and the patients in test data come sequentially. To address this problem, we propose an incremental learning approach to estimate a patient’s unknown predictor values based on k-nearest neighbors (k-NN) [11].

In this paper, we develop a risk prediction model of stroke for patients with Type 2 diabetes mellitus (T2DM) from EHR data. We first preprocess the raw EHR dataset to construct the cohort of interest. Then we use information gain (IG) to identify predictive risk factors, and use logistic regression (LR) to build a risk prediction model based on the selected risk factors. Finally, we propose an approach to apply the developed risk prediction model on new patients with unknown predictor values. We impute missing data using an incremental learning approach based on k-nearest neighbors. The experimental results show that our risk prediction model of stroke has good prediction performance. And the k-nearest neighbors based incremental learning approach for data imputation is effective.

Methods
Figure 1 gives an overview of our method. We first preprocess the EHR data to design the cohort of interest. Then we use feature selection to identify predictive risk factors, and build a risk prediction model based on the selected risk factors. We apply the developed risk prediction model on new patients with unknown predictor values. We impute the missing data using an incremental learning approach based on k-nearest neighbors. In the following, we will describe our method step by step in more detail.

EHR Data
EHR data contain important information about patients, such as demographics, medical history, medication, lab test results, and billing information. We conduct experiments on a real world EHR dataset collected from August 1 2011 to March 31 2016.
The multi-relational EHR data involves four medical entities (patient, diagnosis, medicine and labtest), which constitutes major information to describe patients’ condition. The data is actually a collection of medical events where each event can be described as a patient $p$ required to take a medicine $m$ for a diagnosis $d$.

We first preprocess the EHR data. In the raw EHR data, a large amount of features have non-standardized and dirty values. Many features are missing due to unknown values or errors in data collection. We perform data cleansing and missing data normalization before predictive analysis. The raw EHR data is heterogeneous and includes different types of data items: binary type (e.g., medication), nominal type (e.g., gender) and numeric type (e.g., labtest). For different data types, we standardize data formats, correct input errors, and discard the values that are not structured as the target types. As the dataset is collected from different hospitals, a numeric feature may have different units, we unify these features to the same unit. Finally, we also discard the numeric values that are out-of-range.

After data cleansing and missing data normalization, the patient entry consists of 7 demographic features, i.e. “gender”, “age”, “blood”, “blood_rh”, “education”, “occupation”, “marriage”. The diagnosis entry consists of 270 ICD 10 codes. The labtest entry consists of 124 labtests. For diagnosis, medicine, and labtest, we remove features with a frequency less than 1%. There are 489 features in the training and test set including patient id.

**Cohort Design**

We define the index event as the stroke onset of a patient. The cohort is T2DM without stroke observed before the index event. The outcome is stroke. The ICD 10 codes for stroke are [I60, I69]. The number of cases and controls are 17,852 and 93,909, respectively.

We set the observation window to 2 years before the index event and the prediction window to 1 year after the index event. Figure 2 shows the cohort design.

**Feature Selection**

Feature selection is the process of selecting a subset of relevant features for use in model construction. We use the filter strategy to identify predictive risk factors. The filter strategy calculates a score to represent the relevance of each feature against the outcome, and then ranks and filters the features based on the score. In this study, we use information gain (IG) as the relevance score, which is the change in information entropy when a feature is given.

**Predictive Modeling**

We use logistic regression (LR) to build a risk prediction model based on the selected risk factors. LR is a generalized linear model with a logit link function and a binomial distribution, which is widely used in both medical statistics and machine learning, because of its good prediction ability and interpretability.

The standard metric AUC is used to evaluate the performance of the risk model based on information gain (IG) selected features. In addition, we also compare AUPR, the area under the precision recall curve, with a baseline model. In many cases of risk prediction, the number of positive samples are much smaller than that of negative ones. For these highly imbalanced datasets, AUC may provide an overly optimistic view of performance, while AUPR can provide a more informative assessment [12]. We also report the accuracy of our risk prediction model.

**Incremental Learning for Data Imputation**

In clinical practice, developed risk prediction models cannot be directly applied on new patients, due to unknown predictor values. Data imputation is the process to remedy missing data, which is usually necessary for building a reasonable prediction model. In this study, we propose an incremental learning approach to impute the missing data based on $k$-nearest neighbors ($k$-NN). Specially, when a new patient comes, we first find his/her $k$-nearest neighbors using non-missing features from existing patients.

Here we use the commonly used Euclidean distance as the distance metric. The Euclidean distance between patient $x$ and $y$ is defined as follows.

$$d(x, y) = \sqrt{\sum_{i=1}^{n} (x_i - y_i)^2}$$  (1)

where $x_i$ and $y_i$ is the $i^{th}$ feature of patient $x$ and $y$ respectively. As the labtest data is very sparse, we normalize the distance by the number of non-missing features that both patient $x$ and $y$ has.

$$d(x, y) = \frac{\sqrt{\sum_{i=1}^{n} (x_i - y_i)^2}}{n}$$  (2)

Given a patient, we first find his/her $k$-nearest neighbors using the normalized Euclidean distance. Then we use the average value of the non-missing features of the $k$-nearest neighbors to impute the missing feature of the patient. In this way, we can reduce the bias introduced by the imputation.

For example in Table 1, suppose patient $P_1$, $P_2$ and $P_3$ are the 3-nearest neighbors of patient $P_4$. The underlined feature value in the table indicates that the feature is missing and its value is imputed. When imputing the missing feature $a$ of patient $P_4$, we do not use the feature $a$ value of patient $P_2$, as it is imputed. Instead, we use the average value of feature $a$ of patient $P_1$ and $P_3$ to impute that of patient $P_4$, which is 4.

![Figure 1 - Method Overview.](image1)

![Figure 2 - Cohort Design.](image2)
When the first patient comes or a patient has no k-nearest neighbors, we use prior knowledge, e.g. a feature’s normal value, to impute the missing feature of the patient.

Using the average feature value of a patient’s k-nearest neighbors to impute a missing feature does not consider the importance of different k-nearest neighbors. To address this problem, we can use the weighted average value of k-nearest neighbors to do the imputation as shown below.

$$x^a = \frac{\sum_{i=1}^{k} s_{xy} y_i^a}{k}$$  \hspace{1cm} (3)

where $x^a$ is the feature a value of patient $x$, $s_{xy}$ is the similarity between patient $x$ and $y_i$, and $y_i^a$ is the feature a value of patient $y_i$.

We can also combine the weighted average value of a patient’s k-nearest neighbors and prior knowledge to do the imputation by introducing a parameter $\pi$. Parameter $\pi$ controls the importance of the weighted average feature value of k-nearest neighbors and the feature’s normal value.

$$x^a = \pi * \frac{\sum_{i=1}^{k} s_{xy} y_i^a}{k} + (1 - \pi) * K(a)$$  \hspace{1cm} (4)

where $K(a)$ is the normal value of feature $a$ from prior knowledge.

### Results

We perform a case study using our method on the real world EHR data. We use logistic regression (LR) to build a risk prediction model from a training set based on information gain selected risk factors. The number of predictors is set to 30. We have tried different numbers of predictors and found that the models have similar performance. Three standard metrics, AUC, AUPR and Accuracy (ACC), are used to evaluate the prediction performance of our model. In the experiment, we set the threshold to 0.5.

We first compare the prediction performance of our model with another two models. One model is built using all the features in the dataset. Another model is built using only the age feature.

Table 2 shows the AUC, AUPR and accuracy (ACC) results of different models. We can see that our model has better prediction performance than the other two models, as the AUC, AUPR and accuracy of our model are all higher than that of the other two models. The AUC and accuracy of our model is slightly better than that of the model using all features, indicating that the features selected by information gain (IG) are more relevant against the outcome, i.e. stroke. Top predictors selected by information gain with corresponding scores are shown in Table 3.

<table>
<thead>
<tr>
<th>Model</th>

<td>0.8548</td>
</tr>
</tbody>
</table>

Table 4 shows the evaluation results (AUC, AUPR and Accuracy) of our model using incremental learning for data imputation by varying the number of patients from 10 to 1000.

Next, we compare k-nearest neighbor based data imputation (EHR-based model_knn) with an existing data imputation method, i.e. using the average value to handle missing data (EHR-based model_avg).

We first plot the AUC value for every 100 patients as shown in Figure 3. We can see that for the first 100 patients, the average value based data imputation has better AUC than the k-nearest neighbor based method. However, after 100 patients, k-nearest neighbor based data imputation performs better.

For k-nearest neighbor based data imputation, there is a drastic increase in AUC value from 10 to 200 patients. After 200 patients, the AUC value tends to be stable. The turning point at 200 patients indicates that as the number of incoming patients increases, the k-nearest neighbor based missing data imputation will be more accurate before 200 patients. However, after 200 patients, more incoming patients do not help to improve the AUC value significantly.

We also find that as the number of incoming patients increases, the runtime of imputing the missing feature values of a patient based on k-nearest neighbors also increases. Therefore, when the AUC value gets stable, the patient set is enough to find k-nearest neighbors for new incoming patients to do imputation, saving runtime and resources.

</tbody>
</table>

We further zoom in to investigate the AUC value from 10 to 200 patients. As can be seen in Figure 4, the k-nearest neighbor based method has better or comparable AUC than the average value method. When the number of incoming patients is less than or equal to 200, more patients will help improve the AUC value using incremental learning for data imputation based on k-nearest neighbors.

<td>0.7848</td>
</tr>
</tbody>
</table>
As in our dataset, the number of positive samples are much smaller than that of negative ones, AUC may provide an overly optimistic view of performance, while AUPR can provide a more informative assessment. So we report the AUPR for every 100 patients in Figure 5.

We compare the AUPR of $k$-nearest neighbor based data imputation, average value based data imputation with a baseline, which is the average precision of randomly predicting the risk. We can see that the AUPR of the $k$-nearest neighbor based method increases from 10 to 200 patients, and tends to be stable after 200 patients. The $k$-nearest neighbor based method outperforms the average value based method after 100 patients. The AUPR of average value based data imputation decreases as the number of incoming patients increases. Both methods have better AUPR than the baseline.

As with the AUC, we also report the AUPR for every 10 patients as shown in Figure 6. We can see that the AUPR of both $k$-nearest neighbor based data imputation and average value based data imputation are not stable for the first 200 patients.
We also evaluate the prediction performance by accuracy. Figure 7 shows the accuracy for every 100 patients. We can see that there is a slight increase in accuracy from 10 to 200 patients for both methods. After 200 patients, the accuracy does not change much. However, the k-nearest neighbor based method has better accuracy than the average value based method.

Figure 8 shows the accuracy for every 10 patients. We can see that the k-nearest neighbor based data imputation and average value based data imputation have comparable accuracy. And the accuracy value of both methods increases as the number of patients increases.

Our incremental learning approach for missing data imputation gives a direction to applying developed risk prediction models on new patients with unknown predictors. Here we use k-nearest neighbors to handle missing data. Other data imputation methods can also be used.

Conclusion

In this paper, we proposed an incremental learning approach to apply a developed risk model on new patients with unknown predictor values, which imputes a patient’s unknown values using his/her k-nearest neighbors (k-NN) from the incremental population. We performed a real world case study by developing a risk prediction model of stroke for patients with T2DM from EHR data, and incrementally applied the risk model on a sequence of new patients. The experimental results show that our risk prediction model of stroke has good performance. The k-nearest neighbor based incremental learning approach for data imputation can gradually increase the performance when the model is applied on new patients.

Discussion

We propose an incremental learning approach to apply a developed risk model on new patients with unknown predictor values, which imputes a patient’s unknown values based on his/her k-nearest neighbors (k-NN) from the incremental population. As a new patient comes, we find his/her k-nearest neighbors from all the existing patients to estimate the missing values. There is a trade off in this approach. With more existing patients, the k-nearest neighbors we find will be more accurate, leading to a better estimate of the missing values. However, it is also very time consuming. In order to balance accuracy and efficiency, we can use a sliding window to keep the most recent patients to find k-nearest neighbors. k-nearest neighbor based missed data imputation also requires good data quality. If the patient data is very sparse, we cannot even find the k-nearest neighbors for a new patient.

We perform a real world case study by developing a risk prediction model of stroke for patients with T2DM from EHR data. The sparse, heterogeneous, and noisy data stored in the EHR present a multitude of technical challenges for analysis. EHR data contain many heterogeneous medical events, such as diagnosis, procedures, medications and labtests, making the dimensionality of the EHR very high. EHR data is also very noisy due to non-standardized physician practices, missing values, etc. As a result, some features selected from the EHR data may be uninterpretable, not classic, or even irrelevant for CVD. So before feature selection, it would be better to perform pre-selection to remove unreasonable, duplicate features. Non-discriminative features, in which most of the instances have identical values, should also be removed. Domain knowledge is also important; with the help of clinicians, we can select features of interest, and discard others.

When developing the risk model, we use ICD 10 codes [160, 169] for the outcome stroke. However, ICD coding is incorrect between 23% and 40% of the time. Although T2DM is a risk factor for stroke, the time course and severity of illness are necessary to know whether stroke is truly related to CVD.

Our incremental learning approach for missing data imputation gives a direction to applying developed risk prediction models on new patients with unknown predictors. Here we use k-nearest neighbors to handle missing data. Other data imputation methods can also be used.

Conclusion

In this paper, we proposed an incremental learning approach to apply a developed risk model on new patients with unknown predictor values, which imputes a patient’s unknown values using his/her k-nearest neighbors (k-NN) from the incremental population. We performed a real world case study by developing a risk prediction model of stroke for patients with T2DM from EHR data, and incrementally applied the risk model on a sequence of new patients. The experimental results show that our risk prediction model of stroke has good performance. The k-nearest neighbor based incremental learning approach for data imputation can gradually increase the performance when the model is applied on new patients.

Abstract

Semantic relations have been studied for decades without yet reaching consensus on the set of these relations. However, biomedical language processing and ontologies rely on these relations, so it is important to be able to evaluate their suitability. In this paper we examine the role of inter-annotator agreement in choosing between competing proposals regarding the set of such relations. The experiments consisted of labeling the semantic relations between two elements of noun-noun compounds (e.g. cell migration). Two judges annotated a dataset of terms from the biomedical domain using two competing sets of relations and analyzed the inter-annotator agreement. With no training and little documentation, agreement on this task was fairly high and disagreements were consistent. The results support the utility of the relation-based approach to semantic representation.

Keywords:
Natural Language Processing; Evaluation Studies as Topic

Introduction

Linguists have tried to discover the basic building blocks of semantic relations between nouns for decades, but there is still little consensus about what the set of these building blocks might be. This is an important problem for biomedical natural language processing and biomedical ontologies, because those building blocks are at the heart of our information extraction tasks and the structure of our ontologies.

Compound nouns are crucial to practical tasks like knowledge representation and to theoretical problems like understanding compositionality in semantics \cite{1,2}. However, one of the most difficult problems in semantic representation and in language processing is the nature of the relations between the two parts of a compound noun \cite{3-6} (see examples in Table 1). Compound nouns are formed by a sequence of two or more nouns \cite{7}. In writing, they may appear as two tokens (\textit{knockout mouse}), a hyphenated word (\textit{nucleotide-excision}), or a single token (database) \cite{7}. They are about twice as common in written English as they are in spoken English (248/million words in newswire text versus 123/million words in conversation)\cite{7}. They are quite common in scientific writing. Linh (2010) \cite{8} reviews a number of studies of the incidence of compound nouns in technical texts, reporting that one study found that 27\% of words in scientific abstracts were in compound nouns; another study found that 11.86\% of anaphors are compound nouns; and another found that 15.37\% of a technical corpus was made up of compound nouns.

The study of compound nouns dates back to Pāñini and Kātyāyana and Patañjali \cite{9}, but an enormous amount of work remains to be done, particularly on the semantics of the relations between the nouns in a compound, and they remain the topic of a considerable amount of research in both linguistics and natural language processing \cite{3}. Various authors have attempted to describe the relation between the elements of compound nouns from a theoretical perspective \cite{10}. Likewise, a number of studies in language processing have shown the difficulty of classifying the relations in these compounds automatically \cite{11-15}. All of these studies are based on specific representations of the relations that can hold between the nouns in a compound. This raises a question: are those relations valid? One way to answer that question is by measuring whether humans can reliably label the relation that holds in any specific compound. If they cannot, then we must question the validity of the representation itself, and we must consider the possibility that any principled investigation of the relations in compounds, whether from a theoretical or a practical perspective, is impossible (see, for example, the logical positivist perspective and how inter-annotator agreement responds to the problems of “observing” semantics \cite{16}. On the other hand, if they can, then it might be possible to train computers to do the same task, which could enable considerable advances in natural language processing.

We can address the reliability of labeling through examining inter-annotator agreement when two or more analysts label the relations in a sample of compound nouns. However, we are not aware of any studies that have looked at inter-annotator agreement in compound nouns. Identifying relations in compound nouns, whether done by humans or by computers, is a non-trivial task because there is an enormous amount of ambiguity in the correspondence between semantics and syntactic structure. For example, Table 1 gives a number of examples using the biomedical term \textit{forceps}. We note that \textit{forceps} can exist in at least five relations with another noun in a compound—that is to say, the same noun-noun syntactic structure can correspond to at least five relations between the first noun and \textit{forceps}. 

Consider the term *chondrocyte development*. The relation between the two nouns is an activity and a process—development—that is undergone by chondrocytes. *Motor activity* and *thrombin activity* have the same syntactic structure as *chondrocyte development and as each other*, but the relationships between the nouns in all three of them are different: an activity that is undergone in the first, the result of the second, and the action of the third.

This article investigates the ability of humans to reliably label semantic relations between the elements of noun compounds in the face of this semantic ambiguity in identical syntactic structures. The motivation for this is that inter-annotator agreement on labelling the semantic relations in compound nouns is a useful indicator of the validity of the proposed set of relations and can be used in choosing between two competing theories. The experiment was done using two sets of relations with two different contexts of theoretical status and computational applications—Generative Lexicon theory on the one hand, and a model of the domain on the other—holding constant the data set and the annotators. Good inter-annotator agreement for a given set of relations would lend some credibility to that set; bad inter-annotator agreement would detract from its credibility.

**Materials**

**Generative Lexicon**

The first set of relations is the Generative Lexicon relations described in Bouillon et al., 2012 [17]. We will refer to this set as GL relations in the following, although the set in Bouillon et al. includes extensions with respect to the original GL set [18], for example the tag *argumental*. GL theory is an attempt to explain how compositionality contributes to lexical semantics. Bouillon et al., 2012 [17] posited two basic elements of lexical semantic representations: Qualia and/or Argumental. Qualia relations involve predicates and their arguments, as well; we will re-visit this issue in the discussion. They identified four basic Qualia relations: Formal, Constitutive, Telic, and Agentive. We used the set of Generative Lexicon relations described in Bouillon et al., 2012 [17]. These relations are meant to be general and elementary, embodying a hypothesis about the fundamental building blocks of semantic representations.

**Rosario and Hearst**

Rosario and Hearst (2001) [4] identified 38 relations broadly inspired by linguistic theory, but the motivation for the relations is less language-theoretic and more application-oriented. Specifically, it is intended to represent the semantics and knowledge structures of biomedical literature. Where GL theory is meant to be cross-linguistically valid, the set of relations proposed by Rosario and Hearst is meant to be domain-specific—thus, it does not attempt to be valid even for all of the English language, but just for English-language scientific literature. In comparison to many other proposed sets of semantic relations, including that of Generative Lexicon theory (Table 2), the Rosario and Hearst relations do not posit a set of semantic primitives. Rather, they embody a knowledge representation schema that is specifically tailored to biomedical science without making any claims about what relations might exist in other domains.

**Methods**

To select the sample, all of the terms in the GO were tagged with their part of speech using the CLEAR suite of language processing tools [21; 22]. Tagging errors are noted in the data set. All terms with exactly two words, such that both words are nouns—that is, compound nouns—were pulled from the full set. We then selected a random sample of 101 words from the compound nouns (intending 100, with an extra in case of tagging errors).

**Results**

The Generative Lexicon relations from Bouillon et al.

The annotators used eight of the 15 possible relations to annotate the 101 GO terms (see Table 3). The most commonly used relation by annotator 1 was *argument* followed with *played by*. The most commonly used relation by annotator 2 was *played by* followed with *used for*. Annotation 1 thought there were no proper relations available for four terms: *larval development, predatory behavior,
lymphocyte anergy, and lymphocyte homeostasis. Table 4 shows the results in terms of true positives (1 for each match between the two annotators), false positives (1 for each mismatch between the two annotators), and false negatives (also 1 for each mismatch between the two annotators), and the corresponding measures of inter-annotator agreement. Cohen’s Kappa value was 0.47 and the inter-annotator agreement, calculated as F-measure, was 0.58 The Cohen’s Kappa value indicates a fair/good level of reliability according to the Green scale (1997). The annotators agreed that the Telic relation was the most frequent relation, followed by the Argumental relation. Annotator 1 thought 54.45% of the terms were Telic and annotator 2 thought 70.29% of the terms were Telic (Table 3). 36.63% of the terms were annotated as Argumental by annotator 1 and 19.80% of the terms were annotated as Argumental by annotator 2.

As defined by Cohen (1960) [23], unweighted kappa was calculated using the following equation (Eq.1):

$$k = \frac{p_o - p_e}{1 - p_e}$$

</table>

Table 6 shows the confusion matrix for these relations. Note that disagreements between the two annotators are largely systematic. For example, Annotator 1 and Annotator 2 used the aims at relation a similar amount of times (22 and 19), agreeing in the case of 10 noun compounds (Annotator 1 10/22 (45.45%); Annotator 2 10/19 (52.63%)). Of the disagreements, 8/22 times that Annotator 1 labelled instances of the aims at relation, Annotator 2 labelled the used_for relation; 7/19 times that Annotator 2 labelled the aims at relation. Annotator 1 annotated the argument relation. Thus, refining the guidelines such that it is clearer when to use aims at versus argument and used for would have a large effect on the inter-annotator agreement for all three of these relation types.

The Relation Ontology relations corresponding to the Generative Lexicon relations are shown in Table 5. We observed that there were no corresponding ontology relations for most of the Generative Lexicon relations. This is consistent with the suggestion that the Relation Ontology is missing content that is fundamental to representing the biomedical domain.

Rosario and Hearst relations:

The annotators used 10/38 of the Rosario and Hearst relations to annotate the 101 GO terms (Table 7). The inter-annotator agreement, calculated via Cohen’s Kappa, was 0.37 (Table 8). Table 8 shows the confusion matrix for these relations.

Table 8: Overall inter-annotator agreement using Rosario and Hearst relations

<td>30</td>
<td>30</td>
<td>0.70</td>
<td>0.70</td>
<td>0.70</td>
<td>0.37</td>
</tr>
</tbody>
</table>

The inter-annotator agreement calculated using the F-measure was 70.29%. The maximum number of terms were annotated as Activity/Physical Process followed by Characteristics and Material: Bind. The annotators observed that there was no good representation for movement terms (for example, cilium movement). The inter-annotator agreement is good, given the fact that no training was provided. Again, the disagreements were quite systematic. Of the 30 disagreements, 20 (2/3) were from one cell of the table: Annotator 1 classified 20 compounds as having the Material: Bind relation, while Annotator 2 classified the same 20 compounds as having the Characteristic relation.

Discussion

The inter-annotator agreement was much higher for the Rosario and Hearst relations than for the Generative Lexicon relations. This is surprising, since the set of Rosario and Hearst relations is much larger than the set of Generative Lexicon relations.

It’s premature to say why this is the case, but we can propose some avenues for future investigation: (a) This result might be related to the fact that the Rosario and Hearst relations are domain-specific, while the Generative Lexicon relations are not; (b) this result might be related to the fact that the Generative Lexicon relations are abstract and theoretically motivated, while the Rosario and Hearst relations are concrete and motivated by practical considerations; (c) it might be related to the observation that the annotators only used 10 of the Rosario and Hearst relations, implying that the difference in size might not be as big as it seems and the difference in IAA might not be quite as surprising; (d) the difference IAA might go away with actual annotation guidelines and training; and (e) we should also point out that the affordances of the two are different—in particular, the Rosario and Hearst relations might be better for defining information extraction tasks while the Generative Lexicon’s relations might be better for supporting inference.

Conclusion

The assumption behind the methodology that was applied here is that inter-judge agreement on annotation task is capable of finding problems in a set of semantic relations. The inter-annotator agreement in the cases of both proposed sets of semantic relations approached that of many completed and published corpus annotation projects, even with very minimal guidelines and no real training. The agreement on this task was fairly high in both cases and disagreements were quite consistent, supporting the basic soundness of the relation-based approach to semantic representation and suggesting that it is not overly subjective. From a methodological perspective, the results suggest that higher levels of agreement and reliability can be reached with some training and refinement of the guidelines. IAA was different between

---

2 Table 9 is on the GitHub Repository: https://github.com/KevinBretonnelCohen/SemanticRelationsCompoundNouns.git
the two sets of relations, suggesting that IAA can differentiate between semantic representations, although a number of possible explanations for those differences should be pursued in future work.

The relatively high IAA suggests that the descriptions and examples of the relations in the Bouillon and Rosario and Hearst papers were easy to follow and that the annotators were able to clearly delineate the relations and the tags in most cases. This is consistent with the claim that they are precise and not overly subjective in their interpretability and applicability. Disagreements between the analysts were quite consistent. This suggests that a higher level of agreement and reliability can be achieved with a little training and refinement of the guidelines. This study should be replicated on a larger scale with proper guidelines and training to achieve a higher level of reliability.

An additional benefit of approaching the evaluation of a set of relations through an annotation task was that we uncovered some shortcomings of the relations. We noted that (a) there is no good representation of movement in the Rosario and Hearst relations, and (b) some of the GO terms were not representable at all with those relations. In the case of the Generative Lexicon relations, we observed frequent confusion between Qualia and Argument (especially used for and aims at). This suggests that there is a need to clarify the demarcation between the two. A fruitful direction for future work would be to evaluate the nature of any correspondences that might exist between the two sets of relations. The work reported here contributes to the basis for such an effort.

Abstract

The progressive digitization of medical records has resulted in the accumulation of large amounts of data. Electronic medical data include structured numerical data and unstructured text data. Although text-based medical record processing has been researched, few studies contribute to medical practice. The analysis of unstructured text data can improve medical processes. Hence, this study presents a clustering approach for detecting typical patient’s condition from text-based medical record of clinical pathway. In this approach, the sentences in a cluster are merged to generate a “sentence graph” of the cluster after classified feature word by Louvain method. An analysis of real text-based medical records indicates that sentence graphs can represent the medical treatment and patient’s condition in a medical process. This method could help the standardization of text-based medical records and the recognition of feature medical processes for improving medical treatment.

Keywords:
Critical Pathways; Data Mining; Mathematical Computing

Introduction

The digitization of medical treatment has resulted in large amounts of medical data to be accumulated. Electronic medical data includes structured numerical data and unstructured text data. Disease diagnosis, medical examination results, and prescriptions are typical examples of structural numerical data that can be used for secondary purposes. In contrast, daily medical records, admission records and discharge summaries are typical examples of unstructured text data. One problem with text data is that there is no unified format for describing the contents. This is, a wide variety of expressions can be used express one idea depending on who writes the contents. However, text-based records include factors that are essential, such as the daily status of patients and medical treatments. Thus, the secondary use of text data is a significant issue.

A clinical pathway in the field of medicine can be thought of as a critical path in engineering. A clinical pathway determines the standard medical procedures for an inpatient with respect to each disease and medical treatment. It clarifies the role of medical staff and provides a schedule. As a result, systematic and high-quality medical treatment can be provided. Furthermore, clinical pathways should improve medical management by providing efficient medical treatment. The Japanese Society for Clinical Pathway [1] promotes the construction of a standard electronic clinical pathway to standardize medical treatment and improve medical processes. They also encourage the adoption of clinical pathway methods for team medical treatment.

The “all-variance type outcome-oriented clinical pathway” (Figure 1) is a series of medical treatment units that comprise three layers: (a) outcomes, (b) assessments, and (c) tasks. A unit represents a minimal process and is scheduled by combining multiple units. An outcome determines the condition of a patient. Multiple outcomes are the goals of medical staff and a patient for the scheduled duration of hospitalization.

Doctors or nurses in medical practice maintain records of their tasks and assessments of patients’ conditions. A variance is recorded in an outcome layer when a patient’s condition does not meet the criteria of goal of an assessment layer. When a variance occurs, the staff record the patient’s symptoms and future treatment plan as free text in the medical record. This medical record is called a “text-based variance record”. Thus, the abnormal condition of the patient and change in the medical intervention plan can be understood within the clinical pathway. The clinical pathway is hence useful for managing medical treatment [2]. In this study, we focus on text-based variance records written in Japanese and apply text mining and visualization for the ultimate goal of treatment standardization.

Several studies on medical record text mining have been conducted. They are mainly used for classification and performance evaluation. However, only few studies have been conducted wherein specific sentences and words are used to extracted patients’ conditions [3-5]. An analysis of unstructured free text could potentially extract a large amount of information regarding patient health status and medical histories [6,7]. Although feature words extracted using machine learning and feature selection can be evaluated, a patient’s condition is not extracted from the text-based record [8,9]. Applying text mining to Japanese is difficult because Japanese is not easy to judge the boundaries of words.

The present study proposes a visualization system for text-based Japanese records of clinical pathway so that an overall picture of the variances can be understood. We developed a system that classifies the sentences in the variances and generates a “sentence graph” or template that describes each cluster. We confirmed that the feature words in a sentence graph correspond to the tasks and assessments in the pathway data. This visualization method can be used as a guide for the standardization of variance description.
Related Work

In order to extract information from a large set of documents, search engines have become indispensable. In some search tasks, the user is satisfied by only one item of information. However, the situation is different when search is performed to gain an overall understanding of a topic such as research trends and or a reputation. For such tasks, there are two approaches: document summary and key sentence extraction. For the scientific articles, reputation information and FAQ documents, it is known that utilizing characteristic phrases and words in a field improves extraction performance [10]. Alternatively, a method to extract phrases has also been proposed [11]. Important word and sentence extraction is a major theme of text mining. Radev et al. [12] applied sentence clustering using feature words and extracted the centroids of each cluster as the important sentences. Mihalcea and Tarau [13] proposed the TextRank method, which considers the network of keywords and uses a HITS-like algorithm [14] to evaluate keyword importance. Pantel and Pennacchiotti [15] considered the problem from a different viewpoint and proposed the Espresso-type bootstrapping method to extract information from documents.

These methods were developed independently. However, they can be considered within the same framework of word and document co-occurrence graphs analysis [16;17]. Both approaches extract the important keywords and sentences as tightly connected sub-graphs of a bipartite graph that comprises sentences and words as their nodes and the edges between them.

The text-based variance records analyzed in this study are very short sentences of 18 characters on average. Simple key sentence extraction is not suitable for these sentences. We need something similar to a template comprising similar multiple sentences. Hence, we first composed a bipartite graph of sentence and word nodes. We then partitioned the graph into a set of dense sub-graphs and obtained a set of clusters. Finally, we constructed the “sentence graph” by merging the words using the Louvain method [19;20], an improved version of the Newman method.

Data and Methods

Text-based variance records

In this study, we analyzed text-based variance records of inpatients from the clinical pathways of Kumamoto-Saiseikai Hospital from April 2014 to April 2016 (Figure 2).

We collected 163,004 sentences from text-based variance records written in Japanese. We then applied morphological analysis to the sentences and obtained 174,145 words. In this study, we focused on 756 words that represent more than 100 of the sentences to obtain the common templates. In addition, we considered the 98,004 sentences that contain two or more of these words.

Clustering of sentences

First, we applied the Louvain method [19;20] to cluster the sentences. For each cluster, we then constructed a graph whose nodes are either sentences or words and whose edges are pairs comprising a sentence and a word. An edge of the graph is a pair \((s_i, w_j)\) of sentence \(s_i\) and word \(w_j\), where \(w_j\) occurs in \(s_i\). Further we partitioned the graph using the Louvain method to obtain 532 dense sub-graphs: \(C_1, C_2, \ldots, C_{532}\). Table 1 shows the top 20 clusters according to the number of sentences. For words of \(C_{18}\) and \(C_{19}\), although it is a different word in Japanese, it is a word of the same meaning in English (Table 1).

Merging sentences

For the common template of each cluster, we constructed the sentence graph \(G(C_k)\) of cluster \(C_k = \{s_1, \ldots, s_m\}\) using the following procedure. First, we transformed a sentence \(s_i\) in cluster \(C_k\) into a sequence \(\sigma(s_i) = (w_{j_1}, w_{j_2}, \ldots, w_{j_n})\) of words, where \(w_j = w_{j_1}, \ldots, w_{j_n}\). Next, we created a line graph \(G(s_i)\) with an edge in the form of \((w_{j}, w_{j+1})\) for \(j = 1, \ldots, n-1\) and obtained line graphs \(G(s_1), \ldots, G(s_m)\). We merged the nodes with the word of their labels and merged edges that have the same start and end nodes. Finally, we discarded the edges with a frequency of less than 20% of the most frequent edges and selected a node associated with the top edge to obtain \(G(C_k)\).
Results and Discussion

Sentence graphs

The sentence graphs were generated by the above method represents typical medical treatment described in text-based. Figure 3 shows the sentence graphs of clusters C1, C3, C7, C17, and C20. Each line in a graph represents a sentence in the cluster. The word of red colored node belong to the cluster. The numerical value in the node represents the number of words, and the numeral on the edge represents the number of combinations between the nodes. For example, we can read the path in the sentence graph of cluster C3 as "bradycardia / symptom / no / because / observe the progress / to (particle) / suru (verb)". Note that the words "bradycardia", "symptom" and "observe the progress" are the feature words of cluster C3 in Table 1. In C7, we can read as "amezinium / effect / poor or effective / observe the progress". Note that the words "amezinium", "effect" and "poor" are the feature words of cluster C7 in Table 1.

The system displays the sentence graphs as well as the frequent sentences of each cluster. The following sentences are typical frequent sentences extracted by the system:

- "To observe (careful, confirmation) circulation dynamics, swallowing disorder, dysarthria, paralysis, respiratory condition"
- "Observe the progress because there are no bradycardias symptom"
- "Urine volume normal, observe the progress of the condition"
- "Observe the progress of the condition with amezinium effect"
- "Observe the progress of the condition after transfusion"
- "Observe the progress of the condition because diastolic blood pressure is not high"
- "Defecation yesterday; observe the progress of the condition"
- "Observe the progress of the condition after administering analgesic (suppository)"
- "Follow on fever type"

The visualization of "sentence graph" helps to interpret the typical sentences from a cluster. Because these sentences are described when variances occur, they have the same pattern "observe the progress of the condition". In particular, many words were represented with many sentences, and it was not the same content classification in C1. It is necessary to narrow the target.

Characteristic task and assessment words

An interesting point about these sentence graphs is that most of the feature words that appear in the graphs are either some tasks that doctors or nurses should do later or that have been done previously, or some assessment that they must observe. Thus, the sentence graphs capture the lower clinical pathway layers of task and assessment.

Furthermore, we found the following two kinds of words and phrases in the sentence graphs after or before the term "observe progress":

1. "Administering analgesic (suppository)”, “killing pain”, “transfusion” and “follow on fever type".
2. "There are no bradycardias symptom,” “defecation,” “urine volume normal”, “amezinium effect” and “blood pressure id not high”.

The phrases in the first list describe the tasks of medical treatment. The phrases in the second list are the assessments or observations of medical treatment. Thus, the extracted keywords and phrases capture the feature words of the task and assessment layers in the clinical pathway.

Conclusion and Future Work

This study reports a visualization system for text-based variance records that describe a patient’s condition using free- style text. We applied the Louvain method to cluster the variance records and words and constructed sentence graphs of each cluster of text-based variance records. The sentence graphs display typical task and assessment patterns. Previous studies on medical documents have focused mainly on the words in the documents [8-9]. However, it is difficult to interpret a patient’s condition from documents using words alone. This study demonstrated a new approach that uses sentences and sentence graphs. The text-based variance records contain valuable information regarding the patient because they are written by medical staff. One of the challenges to making good use of these records is that they have no structure. We found that the sentence graphs and feature words in the graph correspond to the task and
assessment layer of a three-layer clinical pathway. However, it is necessary to confirm the validity because this system expresses only by the word frequency. Ultimately, the sentence graphs and their templates can be adapted into templates that can be filled in by medical staff. The input time and diversity of text expression will be reduced, which will also improve mechanical analysis.

![Sentence graph pattern by using clustering](image)

Figure 3 – Sentence graph pattern by using clustering

We plan to evaluate the performance of the proposed method. This analytical method will then be extended to other text- based medical records or focus on clinical cases in further research.

Research on Ratio of Dosage of Drugs in Traditional Chinese Prescriptions by Data Mining

Yu Xing-wen, Gong Qing-yue, Hu Kong-fa, Mao Wen-jing, Zhang Wei-ming

College of Information Technology, Nanjing University of Chinese Medicine, Nanjing, Jiangsu, China

Abstract

Maximizing the effectiveness of prescriptions and minimizing adverse effects of drugs is a key component of the health care of patients. In the practice of traditional Chinese medicine (TCM), it is important to provide clinicians a reference for dosing of prescribed drugs. The traditional Cheng-Church biclustering algorithm (CC) is optimized and the data of TCM prescription dose is analyzed by using the optimization algorithm. Based on an analysis of 212 prescriptions related to TCM treatment of kidney diseases, the study generated 87 prescription dose quantum matrices and each sub-matrix represents the referential value of the doses of drugs in different recipes. The optimized CC algorithm can effectively eliminate the interference of zero in the original dose matrix of TCM prescriptions and avoid zero appearing in output sub-matrix. This results in the ability to effectively analyze the reference value of drugs in different prescriptions related to kidney diseases, so as to provide valuable reference for clinicians to use drugs rationally.

Keywords:
Medicine, Chinese Traditional; Prescriptions; Data Mining

Introduction

Biclustering algorithms is a field of research that is being developed and its algorithm is widely used in gene expression data analysis [1-3], literature research hotspot analysis [4-6] and biological data analysis [7-8]. Using double clustering algorithms can obtain doses in different traditional Chinese medicine TCM prescriptions, elaborate scientifically dose-effect relationship, give a reasonable choice of TCM dose, and lay the foundation for the safe and effective medication [9].

Current biclustering algorithms can be divided into traditional clustering, iterated greedy search biclustering, exhaustive enumeration biclustering and mathematical modeling biclustering [10]. Among them, traditional clustering, such as coupled two-way clustering (CTWC) based on hierarchical clustering [11], cannot avoid the influence of global clustering nor can generate favorable local submatrices, despite of their simple realization. This paper adopts the improved CC algorithm based on the iterated greedy search for the prescription dose analysis. The computing speed of the algorithm is faster than the exhaustive enumeration biclustering [12], and can effectively avoid global disturbance to obtain valid biclustering submatrices.

Methods

CC biclustering algorithm

Being one of the earliest biclustering algorithms, Cheng-Church biclustering algorithm [13] was first proposed by Cheng and Church in 2001. Sticking to the principle of iterated greedy search, this algorithm can generate a submatrix meeting the regulated threshold value in each search.

Mathematical description of CC algorithm

CC biclustering algorithm introduces the concept of mean squared residue to describe degree of internal similarity or consistency of submatrices. \( H(I,J) \) refers to a mean squared residue of the submatrix whose row number is \( |I| \) and column number is \( |J| \).

\[
H(I,J) = \frac{1}{|I||J|} \sum_{i \in [I]} \sum_{j \in [J]} (a_{ij} - \bar{a}_i - \bar{a}_j + \bar{a})^2
\]

\[
a_{ij} = \frac{1}{|I|} \sum_{i \in [I]} a_{ij}
\]

\[
\bar{a}_i = \frac{1}{|J|} \sum_{j \in [J]} a_{ij}
\]

\[
\bar{a} = \frac{1}{|I||J|} \sum_{i \in [I]} a_{ij}
\]

\[
\text{RS}_{ij} = a_{ij} - \bar{a}_i - \bar{a}_j + \bar{a}
\]

In a submatrix, \( \text{RS}_{ij} \) is a residue; \( a_{ij} \) is the mean of Row \( i \); \( \bar{a}_j \) is the mean of Column \( j \); \( \bar{a} \) is the mean of the submatrix. Where, the larger the value of \( H(I,J) \), the smaller the degree of similarity within the submatrix is. The smaller the value of \( H(I,J) \) is, the more consistent the internal value of the submatrix is. Set \( \epsilon \) to be maximal threshold value of the mean squared residue. All matrices satisfying the condition of \( H(I,J) \leq \epsilon \) is adopted as the target output submatrices of CC biclustering algorithm.

To find a submatrix satisfying the condition of \( H(I,J) \leq \epsilon \) in one search. First, the target matrix should undergo row and column deletion. When the mean squared residue of certain row (column) of the submatrix is larger than \( \epsilon \), then:

\[
R = \{i \in I : \frac{1}{|J|} \sum_{j \in [J]} \text{RS}_{ij} (I,J)^2 > H(I,J) \}
\]

Then, the row (column) is deleted to efficiently reduce the value of its mean squared residue. During the whole column and row deletion process, every iteration deletes the maximum column or row with the maximal mean squared residue until the mean squared residue of the submatrix is smaller than the threshold value, \( \epsilon \). Then, the qualified matrix can be preliminarily obtained.
Since the submatrix obtained by deletion of columns and rows is not the maximal submatrix, it is necessary to increase rows and columns of the submatrix:

If the average of mean squared residue of the column (row) within the submatrix is smaller than the threshold value, then:

\[
R=\{i|\sum_{j=0}^{n} RS_{ij}(i,j)^2 < H(I,J)\}
\]

Then, substitute the column (row) into the submatrix. The mean squared residue of the newly-generated submatrix is smaller than or equal to \(\varepsilon\), so qualified columns and rows are added to generate the maximal submatrix satisfying the output condition.

After the qualified submatrix is output, the random number substitution is conducted before the next round of searching. To be specific, a random number matrix whose size is similar to the submatrix is used to substitute the submatrix to destroy the original consistency of the matrix and to obtain different qualified submatrices in every search.

Applications of CC biclustering algorithm to prescription dose analysis

The research made the dose of the prescription dose into the dose of the original matrix, according to the horizontal axis name and the vertical axis square name. Each element in the matrix corresponds to the dose of a drug in a prescription, as shown in Table 1.

Table 2 is the use of traditional CC algorithm for traditional Chinese medicine prescription data on the double-cluster analysis to output some sub-matrix. The analysis set the random number range out of the prescription dose range (0-500g), excluding the effect of the random number on the resulting submatrices. In the analysis results, the sub-matrix contains more 0 values, and the number of iterations increases with the algorithm. The proportion of 0 values gradually increased, seriously affecting the generation of effective results. The reason for the above results is mainly due to the unique nature of TCM prescription dose analysis and the limitations of ordinary CC algorithm, and the specific existent problems are the following two aspects:

<table>
<thead>
<tr>
<th>Table 1 – Prescription dose original matrix</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Dendrobium Powder</td>
</tr>
<tr>
<td>Guoxia Pill</td>
</tr>
</tbody>
</table>

First, since the number of drugs in every prescription is smaller than the total number of drugs in all prescriptions, 0 appears in many places of the matrix. The submatrix composed of 0 is exactly the output submatrix of CC biclustering algorithm, so the output result using the traditional CC biclustering algorithm is mostly a submatrix composed of 0. However, 0 does not make any sense for the TCM dose analysis. Worse still, it might influence validity of the target submatrix.

Second, in each search, CC biclustering algorithm should conduct the random value substitution. In the traditional CC biclustering analysis, though these random numbers might impose certain inference on the submatrix output, the results obtained are still reliable. However, in the prescription dose matrix, the original matrix has too many 0s. The interference of the random number might seriously influence the output of valid submatrices. Worse still, the random number submatrix might be output, thus seriously influencing reliability of results.

To sum up, the key to optimizing biclustering algorithms is to exclude the interference of 0 on the prescription dose matrix and to seek a method more effective than the random number substitution method.

Optimization of CC algorithm

Improvement of CC in this paper refers to the improvement strategy of the POBA [14]. The punishment strategy is introduced to eliminate 0 from the matrix during the calculation process.

First, a punishment matrix, \(W\), with a size similar to that of the prescription dose matrix is built. Let the initial value of the matrix element be 0. If the original prescription dose matrix element is 0, let the element value at the same position of the punishment matrix be 1.

Then, the calculation process of the mean squared residue by CC biclustering algorithm is optimized:

\[
H(I,J) = \frac{1}{|I||J|} \sum_{i\in I,j\in J} (a_{ij} - a_i + a_j)^2 + (W_{ij} * \theta)
\]

The above equation adds the “punishment formula” to the original calculation equation of the mean squared residue. \(W_{ij}\) stands for the element of the punishment matrix in Row \(i\) and Column \(j\); \(\theta\) controls the degree of punishment. In practical applications, 0 makes no sense to TCM prescription dose analysis. On the contrary, it might influence the output of the target submatrix. Therefore, in order to guarantee full cleaning of 0 in the output submatrix, let \(\theta\) be:

\[
\theta = ||\theta||_{\text{max}}
\]

Then, there will contain no 0 in the output submatrix. In the following part, it is necessary to improve the column and row deletion and adding process of the submatrix so as to guarantee smooth generation of the target submatrix:

\[
R=\{i|\sum_{j=0}^{n} RS_{ij}(i,j)^2 + (W_{ij} * \theta) > H(I,J)\}
\]

The above equation can delete columns or rows containing more 0s in advance during the column and row deletion process.

\[
R=\{i|\sum_{j=0}^{n} RS_{ij}(i,j)^2 + (W_{ij} * \theta) \leq H(I,J)\}
\]

The above equation can guarantee adding of columns or rows not containing 0s during the column and row adding process. In practical applications, let \(\theta\) be:

\[
\theta = ||\theta||_{\text{max}}
\]
Finally, after the end of every search, let the element value of the punishment matrix whose position is the same to the output submatrix be 1. Replacing the random number substitution method with this method can guarantee full cleaning of 0s in the output submatrix and satisfy demands of outputting valid target submatrices.

Results

An original matrix was built for relevant TCM prescriptions to treat kidney diseases. The improved CC algorithm is used for biclustering analysis. The prescription dose submatrix is output to obtain referential value of different drugs in different prescriptions.

Building of the prescription dose original matrix

All prescriptions are from TCM Prescription Dictionary[6] with “stranguria”, “impotence”, “turbid semen”, “kidney essence deficiency” and “retention of urine” as search terms. In total, 212 TCM prescriptions to treat kidney diseases are screened out.

The prescription data are further screened. With the prescription name as the row and the drug name as the column, the prescription dose original matrix is built. This is shown in Table 1 above.

Generation of the prescription dose submatrix

Using the improved CC clustering algorithm and setting the iterations to be 120 and ε be 10, the prescription dose original matrix outputs 87 prescription dose submatrices in total. Every submatrix stands for the mean dose of different drugs in different prescriptions. This is shown in Table 2 below:

Discussion

Take one last submatrix as an example. Radix Achyranthis Bidentata Pill and Tianxiong Powder contain shaved cinnamon bark and notopterygium incisum. In the former prescription, the dose of shaved cinnamon bark and the notopterygium incisum is 22.5g and 30g, respectively. The ratio between the two is 3:4. This prescription highlights the function of notopterygium incisum to relieve pains and treat rheumatism. In the latter prescription, the dose of shaved cinnamon bark and notopterygium incisum is 30g and 22.5g. The ratio between the two is 4:3. This prescription highlights the function of shaved cinnamon bark to treat wind-pathogenic kidney diseases. Thus, different doses of different drugs in a prescription follow certain rule. The flexibility of TCM prescriptions lies in its dose. Different doses focus on different treatment functions. Even if the same drugs are included in different prescriptions, different doses can result in different functions. In the clinical medication, the doctor should be based on the actual situation of each patient, according to the results of data analysis, and flexibly choose a different dose ratio to achieve different therapeutic purposes.

The iterated greedy search has its inherent defect, which is prone to get the local optimal solution. Even the optimized CC biclustering algorithm in this paper cannot get rid of the limitation. It is impossible to output high-quality submatrix in every iteration. Thus, it is necessary to increase iterations and further filter the final output submatrix using programming techniques.

However, the optimized CC algorithm can effectively eliminate the interference of 0s in the TCM dose original matrix, thus avoiding outputting meaningless submatrices containing 0s. This can greatly promote applicability of biclustering algorithm to TCM dose analysis. Meanwhile, without using the random number substitution method, the algorithm proposed in this paper can avoid negative influence of the random number on the output submatrices obtained through iterations.

Conclusion

The prescription dose ratio is an important part of the TCM prescription compatibility. A drug can have different doses in different prescriptions, thus playing a different role. Drug dose forms the soul of the prescription compatibility. Moderateness of drug doses can directly influence functions and clinical effects of prescriptions, and even life safety of patients. ZHANG Jiebin (1563~1640), a doctor of the Ming Dynasty, said that, “To create a disease, drug dose should not be too little nor too much. If being too little, the drug dose cannot help treat a disease; if being too much, the drug dose might cause other injuries and diseases.” Therefore, doctors should attach great importance to the influence of drug dose on clinical prescriptions under the prerequisite of sticking to the principle of “Jun-Chen-Zuo-Shi”. In this study, the improved biclustering algorithm was used to analyze the dose reference values of different drugs associated with nephropathy in different prescriptions. It can help clinicians optimize prescription, maximize the efficacy of prescriptions, and minimize the adverse effects of drugs on patients. To furtherly guide the physician to use drugs rationally based on the analysis results, combine with all aspects of environmental factors and the expected treatment results, flexibly choose a different dose ratio, and achieve optimal treatment.

Retrofitting Concept Vector Representations of Medical Concepts to Improve Estimates of Semantic Similarity and Relatedness

Zhiguo Yua, Byron C. Wallac, Todd Johnsona, Trevor Cohena

a The University of Texas School of Biomedical Informatics at Houston, Houston, Texas, USA
b College of Computer and Information Science, Northeastern University, Boston, Massachusetts, USA

Abstract

Estimation of semantic similarity and relatedness between biomedical concepts has utility for many informatics applications. Automated methods fall into two categories: methods based on distributional statistics drawn from text corpora, and methods using the structure of existing knowledge resources. Methods in the former category disregard taxonomic structure, while those in the latter fail to consider semantically relevant empirical information. In this paper, we present a method that retrofits distributional context vector representations of biomedical concepts using structural information from the UMLS Metathesaurus, such that the similarity between vector representations of linked concepts is augmented. We evaluated it on the UMNSRS benchmark. Our results demonstrate that retrofitting of concept vector representations leads to better correlation with human raters for both similarity and relatedness, surpassing the best results reported to date. They also demonstrate a clear improvement in performance on this reference standard for retrofitted vector representations, as compared to those without retrofitting.

Keywords: Semantics; Natural Language Processing; Unified Medical Language System

Introduction

Incorporation of semantically related terms and concepts can improve the retrieval [1; 2] and clustering [3] of biomedical documents; enhance literature-based discovery [4; 5]; and support the development of biomedical terminologies and ontologies [6]. However, automated estimation of the semantic relatedness between medical terms in a manner consistent with human judgment remains a challenge in the biomedical domain. Many existing semantic relatedness measures leverage the structure of an ontology or taxonomy (e.g., WordNet, the Unified Medical Language System (UMLS), or the Medical Subject Headings (MeSH)) to calculate, for example, the shortest path between concept nodes [7-9]. Alternatively, vector representations derived from distributional statistics drawn from a corpus of text can be used to calculate the relatedness between concepts [7; 10]. Other corpus-based methods use information content (IC) to estimate the semantic relatedness between two concepts, from the probability of these concepts co-occurring [9; 11; 12]. This raises the question of whether knowledge- or corpus-based metrics are most consistent with human judgment.

In 2012, Garla and Brant [13] evaluated a wide range of lexical semantic measures, including both knowledge-based approaches leveraging the structure of an ontology or taxonomy [7; 14; 15] and distributional (corpus-based) approaches relying on co-occurrence statistics to estimate relatedness between concepts [16; 17]. This systematic investigation used several publicly available benchmarks. The most comprehensive of these is the University of Minnesota Semantic Relatedness Standards (UMNSRS), which contains the largest number and diversity of medical term pairs of any reference standard to date [18]. Medical terms in the set have been mapped to Concept Unique Identifiers (CUIs) in the UMLS, and term pairs have been annotated by human raters for similarity (e.g., Lipitor and Zocor are similar) and relatedness (e.g., Diabetes and Insulin are related). The best Spearman rank correlation for relatedness and similarity on this benchmark reported in [13] are 0.39 and 0.46 respectively.

Neural network based models that are trained to predict neighboring terms to observed terms, such as the architectures implemented by the word2vec package [19], have gained popularity as a way to obtain distributional vector representations of terms. Vectors induced in this way have been shown to effectively capture analogical relationships between words [20], and under optimized hyperparameter settings these models have been shown to achieve better correlation with human judgment than prior distributional models such as Pointwise Mutual Information (PMI) and Latent Semantic Analysis (LSA) on some word similarity and analogy reference datasets [21; 22]. However, embedding models are trained on terms, not concepts. In 2014 De Vine [23] and his colleagues demonstrated that word embedding models trained on sequences of UMLS concepts (rather than sequences of terms) outperformed established corpus-based approaches such as Random Indexing [24] and LSA [25].

In 2014 Sajadi et al. reported that a graph-based approach (HITS-sim) leveraging Wikipedia as a network outperformed word2vec trained on the OHSUMED corpus for the UMNSRS benchmark, with Spearman rank correlations of 0.51 and 0.58 for semantic relatedness and similarity respectively [26]. Most recently, Pakhomov et al. [27] performed an evaluation of word2vec trained on text corpora in different domains - Clinical Notes, PubMed Central (PMC), and Wikipedia - and achieved higher correlations of 0.58 and 0.62 for semantic relatedness and similarity respectively, which are the best results reported to date on the UMNSRS benchmark.

However, while vector representations produced by neural word embedding models are semantically informative, they disregard the potentially valuable information contained in semantic lexicons such as WordNet, FrameNet, and the Paraphrase Database. In 2015, Faruqui et al. developed a ‘retrofitting’ method that addresses this limitation by incorporating information from such semantic lexicons into word vector representations, such that semantically linked words will have similar vector representations [28]. In our previous work, we have tested this approach as a way to
improve measures of semantic relatedness between MeSH terms using information from the MeSH taxonomic structure [29]. While retrofitted word vectors resulted in higher correlation with physician judgments, the reference set utilized was the MiniMayoSRS benchmark [7], which is a relatively small dataset (29 medical concept pairs). Furthermore, we did not apply neural word embeddings, which have been shown to outperform prior distributional models on this task.

In this paper, we extend our previous ‘retrofitting’ work in the following ways: (1) We use one of word2vec’s models to construct vector representations; (2) For construction of vector representations of UMLS concepts, we follow the approach described in [23] and train our model on sequences of UMLS medical concepts extracted from all of MEDLINE’s titles and abstracts; (3) We evaluate our approach with a more extensive reference standard, the UMNSRS benchmark. Our results show that our method achieves higher correlation with human ratings for relatedness and similarity than the best results reported so far on UMNSRS benchmark [27].

Methods

Reference Standard

We used the University of Minnesota Semantic Relatedness Standard (UMNSRS) as our evaluation data [18]. This dataset consists of over 550 pairs of medical terms. Each term has been mapped to a CUI in the UMLS. Each pair of terms was assessed by 4 medical residents and scored with respect to the degree to which the terms were similar or related to each other, using a continuous scale. There are two subsets in UMNSRS - UMNSRS-Similarity and UMNSRS-Relatedness. UMNSRS-Similarity contains 566 pairs of terms rated by 4 medical residents. UMNSRS-Relatedness contains 587 pairs rated by 4 different medical residents. Each dataset can also be divided into 6 semantic categories: DISORDER-DISORDER, SYMPTOM-SYMPTOM, DISORDER-DRUG, DISORDER-SYMPTOM, DRUG-DRUG, and SYMPTOM-DRUG pairs.

In Pakhomov al et.’s evaluation, they modified the UMNSRS dataset to retain only those medical terms that appear in all of the three corpora that they used (Clinical Notes, PubMed Central articles, and Wikipedia). This reduced the number of pairs from 566 to 449 pairs in UMNSRS-Similarity, and from 588 to 458 pairs in UMNSRS-Relatedness.

In our evaluation, we use both the entire UMNSRS dataset and the modified UMNSRS dataset used by Pakhomov et al. For the full dataset, 526 of 566 pairs in UMNSRS-Similarity and 543 of 588 pairs in UMNSRS-Relatedness were found in our pre-processed corpus. For the modified dataset, this corpus contains 418 of 449 pairs for UMNSRS-Similarity and 427 of 458 pairs for UMNSRS-Relatedness.

Semantic Lexicon from UMLS

The Unified Medical Language System is a repository of biomedical vocabularies developed by the US National Library of Medicine. It contains three components: the Metathesaurus; a Semantic Network, and the Specialist Lexicon (lexical information and tools for natural language processing). The Metathesaurus forms the base of the UMLS and comprises over 1 million biomedical concepts. It is organized by concept, and each concept has specific attributes defining its meaning and its links to corresponding concept names in the various source vocabularies [30]. In this work, we only used the UMLS Metathesaurus’ “related concepts” file. This file contains all pair-wise relationships between concepts (or “atoms”) known to the Metathesaurus. Table 1 displays different relationships and their descriptions.

<table>

For each concept in the evaluation dataset, we collected all related concepts within a one-step relationship from this related concepts file. For example, if A is our target concept and we have relationships A CHD B and B CHD C, only B will be considered as a semantic lexicon candidate for A.

Concept-Based Word Embedding Model

To prepare the background corpus for the word embedding model, we downloaded all of the citations (titles and abstracts) in PubMed published before 2016. We then ran SemRep [31], which uses MetaMap [32] for concept extraction and normalization, on each citation’s title and abstract to obtain a sequence of concept unique identifiers (CUI). In other words, following De Vine et al. [23], each sentence in this corpus is replaced by a sequence of CUIs, indicating the order in which concepts were encountered in the text.

To train this word embedding model, we used the word2vec implementation in Gensim, a Python package [33] to generate a ‘concept embedding’ for each CUI in our pre-processed corpus. We followed [27] in using the continuous bag-of-words (CBOW) model for word embedding training. The window size was set to 20, and the dimensionality of feature vectors was set at 200. We ignored all CUIs with a total frequency lower than 5.

Retrofitting Word Vector to Semantic Lexicons

Vector space word representations are a critical component of many modern natural language processing systems. Currently it is common practice to represent words using corpus-derived dense high-dimensional vectors. However, this fails to take into account relational structures that have been explicitly encoded into semantic lexicons. Retrofitting is a simple and effective method to improve word vectors using word relationship knowledge encoded in semantic lexicons. It is used as a post-processing step to improve vector quality [28].
Figure 1 shows a small word graph example with edges connecting semantically related words. The words, cancer, tumor, neoplasm, sarcoma, and swelling, are similar words to each other, as defined in a lexical knowledge resource. Grey nodes represent observed word vectors built from the corpus. White nodes represent inferred word vectors, waiting to be retrofitted. The edge between each pair of white nodes means they represent related words (according to some knowledge source). The inferred word vector (e.g., q_tumor) is expected to be close to both its original (pre-retrofitting) estimated word vector (i.e., q_rumor) and the retrofitted vector of its semantic neighbors (e.g., q_cancer and q_neoplasm). The objective is to minimize the following:

$$
\psi(Q) = \sum_{i=1} q_i \parallel q_i - q_i^* \parallel^2 + \sum_{(i,j) \in E} \beta_{ij} \parallel q_i - q_j \parallel^2
$$

where $\alpha$ and $\beta$ are hyperparameters that control the relative strengths of corpus- and lexically-derived associations, $Q$ represents the retrofitted vectors, and $(i,j) \in E$ means there is an edge between node $q_i$ and $q_j$. $\mathcal{F}$ is convex in $Q$. An efficient iterative updating method is used to solve the convex objective. First, retrofitted vectors in $Q$ are initialized to be equal to the empirically estimated vectors. The next step is to take the first derivative of $\mathcal{F}$ with respect to the $q_i$ vector and use the following to update it online.

$$
q_i = \sum_{(i,j) \in E} \beta_{ij} q_j + \alpha q_i^* / \sum_{(i,j) \in E} \beta_{ij} + \alpha
$$

In practice, it takes approximately 10 iterations to converge to a difference in Euclidean distance of adjacent nodes of less than 0.01. We used the authors’ implementation of this algorithm [28].

**Evaluation Measures**

In the evaluation, we tested different semantic lexicons (based on the categories of relationships described in Table 1) with the ‘retrofitting’ method to improve the vector quality of each concept. For each term pair in the test dataset, we extracted concept vectors and computed the cosine similarity between them using the following equation:

$$
\cos(\theta) = \frac{A \cdot B}{\|A\| \|B\|} = \frac{\sum_{i=1}^N a_i b_i}{\sqrt{\sum_{i=1}^N a_i^2} \sqrt{\sum_{i=1}^N b_i^2}}
$$

Where $A$ and $B$ are components of vector $A$ and $B$ respectively, and $N$ is the length of vector. The cosine scores computed for each pair in the test dataset were then compared to the mean of the human similarity and relatedness judgments for each pair, using Spearman rank correlation. We also tested our method on different subsets of the UMNSRS dataset consisting of pairs of different semantic types. The baselines we used for comparison are the results reported by Pakhomov et al. in 2016 [27].

**Results**

**Comparisons with different lexicons**

The results of these experiments are shown in Table 2, which shows results after retrofitting for all relationship types in Table 1. Given differences in vocabulary across corpora, we cannot compare the identical set of pairs used by Pakhomov et al. Nonetheless, our CUI-based vector representations based without retrofitting (“No Retrofitting”) perform slightly better than the results reported by Pakhomov et al. on both full and modified UMNSRS sets. Retrofitting with RO relationships results in best performance for semantic similarity, with correlations of 0.683 and 0.673 for the full and modified datasets, respectively. For UMNSRS-Relatedness, using RQ relationships achieves best performance with correlations of 0.609 and 0.621 for the full and modified dataset, respectively.

Table 2: Comparison of Spearman rank correlations between human raters and our method using different lexicons

Only lexical information concerning CHD, SY, RQ, RN, and RO relationships improved the performance of concept vector representations. Table 3 presents the performance of our retrofitting method using different combinations of productive relationships on the test dataset. Combining RN and RO relationships resulted in the best performance of 0.689 and 0.681 for the full and modified UMNSRS-Relatedness datasets. For UMNSRS-Relatedness, lexicons with all five productive relationships attained the highest correlations of 0.624 and 0.635 for the full and modified datasets respectively. Furthermore, any lexicons including RO relationship have similar performance for UMNSRS-Similarity and any lexicons including RQ obtain similar correlation scores for UMNSRS-Relatedness.

Comparison across pairs of different semantic types

From Table 3, we can see that lexicons containing RN+RO and CHD+SY+RN+RO+RQ achieved the best performances for UMNSRS-Similarity and UMNSRS-Relatedness respectively. Hence, we just used these two lexicons in the performance for disorder-disorder (Di-Di) pairs, using PMC.

As shown in Table 5, the lexicon containing CHD, SY, RN, RO, and RQ relationships resulted in the highest correlation with human raters in 4 of 6 groups for UMNSRS-Relatedness dataset. Pakhomov et al. retained the best performance in disorder-drug (Di-Dr) and symptom-drug (S-Dr), achieved using embeddings trained on clinical notes [27].

Discussion

In this study, we used a method for retrofitting of word embeddings to improve semantic similarity and relatedness measures by incorporating structural information from the UMLS. We evaluated our approach on both the full UMNSRS dataset and the modified subset used in [27]. Vector representations trained on sequences of CUIs (without retrofitting) resulted in comparable performance (with slight improvements) to those based on sequences of terms. After applying retrofitting on CUI vector representations using selected UMLS relationship types, we see clear improvements on both the full and modified dataset, compared to the CUI vectors without retrofitting.

In comparison with the best results previously reported on the UMNSRS benchmark ([27] - 0.62 for similarity and 0.58 for relatedness), we obtain better correlation with human raters on both similarity and relatedness (0.689 for similarity and 0.624 for relatedness on the full UMNSRS dataset and 0.681 for similarity and 0.635 for relatedness on the modified version). However, as our results concern a subset of the modified set only, further evaluation on matching sets is required to show this conclusively. Our codes and word embeddings are available at (https://github.com/Sssssstanley/Retrofitting-Concept-Vector-Representations-of-Medical-Concepts).

However, our results also show that external linkage information should be carefully chosen. For example, using AQ, SIB, PAR, and RB relationships resulted in worse correlation with human judgment than the original concept vectors (without retrofitting). This suggests that these relationship types are too permissive to align with human evaluation. Incorporating other relationships, such as RB, RL, RU, and XR, had no effect on the results. The reason for this is that no CUIs connected to these relationships resulted in worse correlation with the evaluation set using these relationships. CHD, SY, RO, RN, and RQ clearly have positive effects on the quality of the vector representations. RO has the largest positive effect on the Similarity dataset, and RQ improves the vector presentation the most on the Relatedness dataset. The description of RO is "has a relationship other than synonymous, narrower, or broader." For example, Ciprofloxacin and Cipro 250 MG Oral Tablet are linked by RO. These are the same drug with different dosages, so retrofitting would enhance similarity between vectors for concepts representing the same drug. The description of RQ is "related and possibly synonymous." Relatedness is a general notion that encompasses similarity, and maps well to this relationship type. Hence, it seems reasonable that incorporating this relationship would achieve the best correlation with human raters on UMNSRS-Relatedness dataset.

As noted in [27] the correlations in the 0.5–0.6 range reported for the UMNSRS benchmark are in the same range as the intra-class correlation coefficients used to measure agreement between human annotators for this set, and so may constitute the ceiling for performance that can be measured using this benchmark. However, our results are clearly over this range. What we reported are correlations with the mean rating, which
may be more readily approximated than the ratings of a single rater. In the future, we will conduct further analysis on interpreting our results in relation to the inter-rater agreement in-traclass correlations for different categories of term pairs.

Conclusions

In this paper, we introduced a hybrid method for generating semantic vector representations of UMLS concepts, by leveraging both distributional statistics and linkage information from an ontology or taxonomy (such as the UMLS). This method achieved better performance on the UMNSRS benchmark than neural word embedding alone, with the best results reported for this evaluation to date. Any application using concept vector representations could potentially benefit from the additional structural information encoding using this retrofitting approach. In the future, we will continue to evaluate the utility of retrofitting method for downstream tasks (such as word-sense disambiguation and information retrieval).

Abstract

Extracting and understanding information, themes and relationships from large collections of documents is an important task for biomedical researchers. Latent Dirichlet Allocation is an unsupervised topic modeling technique using the bag-of-words assumption that has been applied extensively to unveil hidden thematic information within large sets of documents. In this paper, we added MeSH descriptors to the bag-of-words assumption to generate 'hybrid topics', which are mixed vectors of words and descriptors. We evaluated this approach on the quality and interpretability of topics in both a general corpus and a specialized corpus. Our results demonstrated that the coherence of 'hybrid topics' is higher than that of regular bag-of-words topics in the specialized corpus. We also found that the proportion of topics that are not associated with MeSH descriptors is higher in the specialized corpus than in the general corpus.

Introduction

Motivation

Knowledge discovery is a fundamental and important activity in biomedical research. Given that unstructured data is increasing exponentially, extracting and understanding information, themes, and relationships from large collections of documents is increasingly important. PubMed currently comprises more than 26 million articles from the biomedical literature and has been widely used to help researchers keep up with the state of the art in their domains and explore other unfamiliar research areas. To help users better retrieve relevant information and manage this tremendous volume of biomedical literature, the US National Library of Medicine (NLM) has developed the Medical Subject Headings (MeSH) controlled vocabulary for indexing MEDLINE articles. MeSH has been used to improve PubMed query results [1-2]. However, users are still often overloaded by the tremendous number of relevant articles returned from their PubMed queries [3]. Hence, biomedical researchers need an efficient and convenient way to discover knowledge from large sets of documents.

MeSH Indexing vs. Topics

Latent Dirichlet Allocation (LDA) [4], is a popular topic modeling method that aims to extract the semantic themes (topics) automatically from a corpus of documents. These topics describe the thematic composition of documents and can thus capture the semantic similarity between them. In contrast, MeSH descriptors are manually created and maintained by domain experts to cover all important themes. Topics extracted from a subset of documents are subset-specific [5]. Thus, they may identify corpus-specific themes that may not be covered in MeSH. Such themes may uncover a specific set of concepts for a particular domain or sub-domain.

Related Work

Considerable research has examined the application of topic models to MeSH descriptors. Labeled LDA (labeled LDA) [6] is a supervised topic model developed to uncover latent topics that correlate with user tags in labeled corpora. In other words, each tag will be represented as a topic. Zhu et al. have used labeled LDA in an attempt to automatically assign MeSH descriptors to new publications (not yet indexed with MeSH descriptors) [7]. Elsewhere, Newman et al. presented a resampled author model that combines both general LDA and the author-topic model (in this case MeSH descriptors were treated as the ‘authors’). The resampled author model provided an alternative and complementary view of the relationships between MeSH descriptors [8]. All these investigations used topic models to interpret MeSH descriptors. However, they cannot be used to identify themes that are not covered in MeSH. In 2014, a graph-sparse LDA model [9] was developed to generate more interpretable topics by leveraging relationships expressed by controlled vocabulary structure (e.g. MeSH). In this model, a few concept-words from the controlled vocabulary can be identified to represent generated topics. Though MeSH was shown to work well for summarizing biomedical articles, this model cannot identify themes that may not exist in the MeSH vocabulary.

Specific Contribution

This work introduces an alternative LDA approach by migrating its original bag-of-words assumption to a ‘bag-of-MeSH&words’ approach. By enriching each document with its indexed MeSH descriptors, ‘hybrid topics’ (mixed vectors of words and MeSH descriptors) can be generated by LDA.

Objectives

We investigated whether the addition of labels (e.g., MeSH descriptors) to bags-of-words can improve the quality and facilitate the interpretation of LDA-generated topics. More specifically, to assess the quality and interpretability of topics, we tested two hypotheses using one large general biomedical corpus and one smaller specialized biomedical corpus.
1. The coherence (used as a surrogate for quality) of ‘hybrid topics’ is expected to be higher than that of regular bag-of-words topics.
2. The proportion of topics that are not associated with some MeSH descriptor, which reflects limited interpretability, is expected to be higher in a specialized corpus than in a general corpus.

**Background**

**Medical Subject Headings (MeSH)**

The MeSH controlled vocabulary was developed by NLM to help manage, index, and search MEDLINE articles. There were 27,883 descriptors in the 2016 MeSH, with over 87,000 entry terms that assist in finding the most appropriate MeSH descriptor (for example, ‘Vitamin C’ is an entry term to ‘Ascorbic Acid’). In the 2016 MeSH, 82 qualifiers could be attached to MeSH descriptors to describe a particular aspect of a concept, such as ‘adverse effects’, ‘diagnosis’, etc. Each year, the MeSH specialists revise and update the MeSH vocabulary to cover emerging research areas and improve indexing consistency and efficiency. MeSH specialists are responsible for areas of the health sciences in which they have knowledge and expertise. MEDLINE indexers make suggestions for new descriptors to MeSH specialists during their indexing processes. Besides, MeSH specialists also collect new terms as they appear in the scientific literature or emerging areas of research. After defining these terms within the context of the existing vocabulary, MeSH specialists recommend their addition(s) to MeSH. During each MEDLINE year-end processing (YEP) activities, changes made to MeSH are applied to MEDLINE (retrospectively) for conformance with the current version of MeSH.

**Latent Dirichlet Allocation (LDA)**

LDA is a generative model that assumes that each document is generated from a mixture of topics and that each topic corresponds to a distribution over all words in the corpus. Informally, the ‘generative story’ for LDA is as follows. First, a document is generated by drawing a mixture of topics that the document is about. To generate each word in this document, one draws a topic from this distribution and subsequently selects a word from the distribution over the vocabulary of the whole corpus corresponding to this topic. The LDA algorithm uses this generative model to uncover the latent topics contained within a given corpus. Specifically, it estimates the parameters that define document topic mixtures and the conditional probabilities of each word given each topic. Parameter estimation is usually done via sampling approaches.

The number of topics produced by LDA must be prespecified. Determining the ‘right’ number of topics for different datasets remains a challenge. When the number of topics increases, redundant and nonsense topics may be generated. Running LDA with a small number of topics will generate more general themes. In this paper, we used a topic coherence measure to determine the optimal number of topics for our dataset [10]. Details are described in the next section.

**Quality of Topics**

Recently, O’Callaghan et al. [10] reviewed a number of topic coherence studies using various corpora and proposed a general measure based on distributional semantics, TC-W2V! This measures evaluates the relatedness of a set of top terms describing a topic, based on the similarity of their representations in a word2vec distributional semantic space. Specifically, the coherence of a topic $t$ represented by its top $k$ ranked terms is given by the mean pairwise cosine similarity between all relevant term vectors in the word2vec space:

$$coh_M = \frac{1}{k} \sum_{i=1}^{k} coh(t_i)$$

An overall score for a topic model $M$ consisting of $k$ topics is calculated by averaging the individual topic coherence scores:

$$coh(M) = \frac{1}{k} \sum_{i=1}^{k} coh(t_i)$$

In this investigation, we use topic coherence to help determine the optimal number and quality of topics.

**Relations between MeSH and Topics**

Topics are generated based on the bag-of-words assumption, which ignores word order. Each topic is represented as a list of ranked words, which provides the user with a sense of what the topic is about. Each document is displayed as a list of weighted topics, which represents different aspects of the document. Since the tokens within each topic are ranked according to the conditional probabilities $P(w|t)$ learned when training the model, where $w$ is a word and $t$ is a topic, the top few words of each topic provides insight into the subject of the topic. However, the interpretation of the topics (i.e., lists of words) is left as an exercise for the user.

As mentioned earlier, MeSH was developed to cover all important themes and each article in MEDLINE is indexed with a few relevant MeSH descriptors assigned by the MEDLINE indexing staff for retrieval purposes. To capture the potential relationships between MeSH and topics, we simply added the MeSH descriptors assigned to each article to the bag-of-words for a given document, creating a modified ‘bag-of-MeSH&word’. Under this ‘bag-of-MeSH&word’ assumption, ‘hybrid topics’ are generated and each topic is represented as a list of tokens (i.e., a mixed list of ranked words and MeSH descriptors). The presence of MeSH descriptors among the top tokens for a given topic is expected to facilitate the interpretation of topics. More specifically, if a MeSH descriptor appears among the top $m$ tokens (for some $m$) of a topic, we will assume this MeSH descriptor is highly associated with this topic. We consider three types of association patterns:

1. One topic has no MeSH descriptor in its top $m$ tokens (1-0 mapping);
2. One topic has a single MeSH descriptor in its top $m$ tokens (1-1 mapping);
3. One topic has multiple MeSH descriptors in the top $m$ tokens (1-many mapping).

Examples of topics for each association pattern are shown in Table 1 along with the top 10 tokens for each topic.

**Methods**

**Data Preparation**

One large general corpus and one small specialized corpus were used in this investigation. The general corpus consisted of 200k articles randomly selected from all PubMed articles published in 2013. The specialized corpus consisted of 2,472 articles from the journal *Prenatal Diagnosis*, which focuses on fetal medicine.

**General Corpus**

There are roughly 1.2 million articles in PubMed for the year 2013. We randomly selected 200k articles (titles and abstracts) from these. This represents an appropriate amount of data given our computing resources.

To reduce the sparsity of the document-to-words distribution, we performed Part of Speech tagging on the dataset and merged several categories, including NN and NNS (e.g., patient and patients); VB, VBD, VBG, and VBN (e.g., eat, ate, eaten, and eating); and JJ, JJR, and JJS (e.g., good, better, and best).

We also removed PubMed stop-words and infrequent words (with a frequency lower than 50). A total of 21,922 unique words remained. Similarly, for MeSH descriptors, we treated specific frequently used descriptors known as check tags (e.g., human, male, female, etc.) as stop words, and ignored infrequent descriptors (with a frequency lower than 5). A total of 13,853 MeSH descriptors remained.

**Specialized Corpus**

We applied similar preprocessing to the specialized corpus, but with different cutoff values due to its smaller size. After setting a cutoff frequency of five for words, we obtained 3,623 unique words. With a cutoff frequency of one for MeSH descriptors, we obtained 919 MeSH descriptors.

**Experiment #1**

We investigated whether the addition of MeSH descriptors to bags-of-words increased the quality of topics. As a surrogate for the quality of topics, we used topic coherence [11].

In practice, to determine whether our ‘hybrid topics’ approach (i.e., ‘bag-of-MeSH&words’) outperformed the original LDA bag-of-words approach (baseline), we generated LDA models under both these assumptions for a various number of topics on the two datasets.

For the general corpus, the number of topics tested 50-600. For the specific corpus, we tested 4-100. For each number of topics, we calculated topic coherence for both the baseline and the ‘hybrid topics’ approaches.

More specifically, for the large general corpus, we used the indexed PubMed articles (titles and abstracts) published in 2013 as our background corpus when building the word2vec space for the original LDA with the bag-of-words assumption. To build the word2vec space containing both MeSH descriptors and words, we simply appended the MeSH descriptors for an article to the end of the document. In this way, we could get a mixed word2vec space of MeSH descriptors and words. In our experiment, we tested two different positions of MeSH descriptors in the citation (front and end) and obtained similar topic coherence results. Following [10], we used the same word2vec setting and the number of top terms per topic (r=10).

For the small specialized corpus, we used the full-text of these articles as the background corpus when building the word2vec space. To build the mixed word2vec space of MeSH descriptors and words for this background corpus, we added MeSH descriptors to the end of each full article. In the word2vec setting for this dataset, we set vector size to 200, cutoff frequency to three, and window size to 20.

To compare the topic coherence measures obtained within each corpus at different numbers of topics for the baseline and the ‘hybrid topics’, we used a paired t-test.

**Experiment #2**

To assess whether the proportion of ‘hybrid topics’ that were not associated with some MeSH descriptor, which reflects limited interpretability, were higher in a specialized corpus than in a general corpus, we first had to determine the optimal number of topics in each corpus.

Choosing the number of topics $k$ is a key parameter selection decision in topic modeling. Too few topics will produce results that are overly broad, while too many will lead to many small, highly similar topics. One general strategy proposed in the literature is to compare the topic coherence of topic models with different values of $k$. An appropriate value for $k$ can then be identified by examining a plot of the mean $TC-W2V$ coherence scores for a fixed range and selecting a value corresponding to the maximum coherence score. Since we only expected the MeSH descriptors to help interpret topics rather than introduce new topics, we just used LDA’s original bag-of-words assumption to determine the optimal number of topics for each test corpus.

Having determined the optimal number of topics for each corpus, we examined the ‘hybrid topics’ obtained for this number of topics and counted which ones were not associated with MeSH descriptors (i.e., which ones did not contain at least one MeSH descriptor among their top-20 tokens).

We used the chi-square statistic to compare the distribution of topics of two patterns between the ‘hybrid topics’ and the baseline.

**Results**

**Experiment #1**

Figures 1 and 2 display the difference in topic coherence between our ‘bag-of-MeSH&words’ assumption (‘hybrid topics’) and LDA’s original bag-of-words assumption (baseline) for the general and specialized corpora respectively.

For the general corpus, we computed topic coherence for 10 different numbers of topics for both the baseline and our ‘hybrid topics’. As shown in Figure 1, topic coherence scores were very close between the baseline and ‘hybrid topics’. The coherence was slightly better with ‘hybrid topics’ after 100 topics, but slightly lower for 50 and 100 topics.

For the specialized corpus, however, we saw a clear improvement on the coherence of topics in favor of ‘hybrid topics’ compared to the baseline. As shown in Figure 2, topic coherence scores were systematically higher for ‘hybrid topics’ across all numbers of topics.

Though ‘hybrid topics’ are higher the baseline after 100 topics on the general corpus, the paired t-test was not significant ($p=0.1624$). We could not properly assess the difference between the two approaches on this general corpus. With the specialized corpus, however, the paired t-test was highly sig-
significant ($p=6.8e-25$), demonstrating that the quality of the ‘hybrid topics’ was better than that of the baseline topics.

![Figure 4](image4.png)

**Figure 4-** Plot of mean TC-W2V topic coherence scores for different numbers of topics $k$, generated from the specialized corpus

**Experiment #2**

**Optimal Number of Topics**

For the large general corpus, we generated LDA models containing $k \in [50,600]$ topics and selected the value of $k$ that maximized the mean TC-W2V coherence. As shown in Figure 3, $k=200$ is the first maximum and was therefore selected as the optimal number of topics for this dataset.

For the small specialized corpus, we generated LDA models containing $k \in [4,100]$ topics. As shown in Figure 4, $k=22$ was the first maximum and was therefore selected as the optimal number of topics for this dataset.

**Proportion of Topics Not Associated with a MeSH Descriptor**

Table 2 displays the number of different patterns of association between topics and MeSH descriptors observed in the general and specialized corpus for their respective optimal number of topics.

As shown in Table 2, the proportion of topics not associated with a MeSH descriptor was higher in the specialized corpus (41%) than in the general corpus (3%). The chi-square statistic was 57.36 ($p=3.502e-13$), which suggests that the corpora had significantly different distributions.

**Discussion**

**Findings and Significance**

This investigation demonstrates that the addition of MeSH descriptors to the traditional bag-of-words approach to creating topic models (‘hybrid topics’) can improve the quality of the topics and facilitate their interpretation, but the impact is different on a general corpus and on a specialized corpus. The quality of the ‘hybrid topics’, assessed by their coherence, was better than that of the baseline topics in the specialized corpus, but it did not seem to be the case in the general corpus.

MeSH terms are created and maintained by MeSH specialists to cover all general themes in biomedicine. However, topics extracted from a subset of documents are often specific to these documents. For the general corpus, most of the topics captured by LDA were general themes. Hence, this addition of MeSH descriptors to the bag-of-words approach did not contribute too much to the topic quality. This could be the reason that we did not see a significant improvement of the topic coherence score between regular and ‘hybrid topics’ in the general corpus. In contrast, for the specialized corpus, adding MeSH descriptors can provide additional information for LDA to better differentiate between general and specific themes and to improve topics quality.

In terms of interpretability, however, the general corpus benefited from ‘hybrid topics’ more than the specialized corpus did, because over 40% (9/22) of the ‘hybrid topics’ remained unlabeled (i.e., not associated with any MeSH descriptors) in the specialized corpus, compared to 3% (6/200) in the general corpus.
Applications to Corpus Exploration

From the general corpus, we saw that only 6/200 topics (3%) contained no MeSH descriptors in their top 20 terms. For the specialized corpus, 9/22 topics (40%) were generated with no MeSH descriptors in their top 20 terms. General themes from the MeSH vocabulary may not be able to cover in detail all aspects of a specialized corpus. In contrast, the topics generated by LDA from a corpus are corpus-specific. It is therefore logical that more topics with no MeSH descriptors are generated from a specialized corpus than a general corpus. Hence LDA will be more useful for a specialized corpus on the task of exploring concepts that may not be covered by MeSH.

From the general corpus, we also saw that 178/194 topics were associated with MeSH descriptors (92%) generated with multiple MeSH descriptors. MeSH descriptors were characterized in 16 top-level categories, such as category A for anatomical terms, category B for organisms, C for diseases, etc. Of these 178 topics, 140 (79%) contained MeSH descriptors from different top-level MeSH categories. These topics were most likely interdisciplinary topics. For the specialized corpus, 7/13 topics associated with MeSH descriptors (54%) were generated with multiple MeSH descriptors. Topics associated with multiple MeSH descriptors from different top-level MeSH categories could be used to explore the intersection of multiple domains. LDA clearly offers an advantage for discovering interdisciplinary topics.

Limitations and Future Work

One limitation of this work is that we ignored the MeSH qualifiers and only considered the MeSH descriptors when constructing our ‘hybrid topics’. In the future, we will include the qualifiers to our ‘hybrid topics’ to test whether it improves the interpretation of topic models. We are also planning to run LDA with a larger number of topics.

Conclusion

In this paper, we introduced an alternative LDA model by adding labels (here, MeSH descriptors) to the bag-of-words assumption. With this setting, ‘hybrid topics’ can be generated to reveal relationships between topics and labels. In our evaluation, these ‘hybrid topics’ resulted in higher topic coherence scores compared to the original LDA, but only on the specialized biomedical corpus. For the general corpus, we did not see a significant difference on topic quality between our ‘hybrid topics’ and baseline topics. From our results, we can also conclude that LDA is more useful in the specialized corpus to explore concepts that may not be covered by the MeSH vocabulary and where topic models can capture aggregate concepts from different domains.

Topic models have a strong potential for analyzing the content of large text corpora. However, the deployment of topic models in the real world has been limited. Our goals in the future are to find more practical ways to apply topic models to help people better understand the massive amount of unstructured data available to us.

Identifying Biomarkers of Hepatocellular Carcinoma Based on Gene Co-Expression Network from High-Throughput Data

Abstract

In this paper, we proposed an approach systematically based on the use of gene co-expression network analyses to identify potential biomarkers for Hepatocellular Carcinoma (HCC). With the analysis of differential gene expression, we first selected candidate genes closely related to HCC from the whole genome on a large scale. By identifying the relationships between each two genes, we built up the gene co-expression network using Cytoscape software. Then the global network was clustered into several sub-modules by Markov Cluster Algorithm (MCL). And, GO-Analysis was carried out for these identified gene modules to further explore the genes obviously associated with the dysfunctions of HCC, and in result we find Hexokinase 2 (HK2) and Krüppel-like Factor 4 (KLF4) as potential candidate biomarkers to provide insights into the mechanism of the development of HCC. Finally, we evaluated the disease classification results via an SVM-based machine learning method to verify the accuracy of the classification.

Introduction

HCC is an aggressive disease with a high morbidity rate and mortality rate, which is a serious threat to people's lives and health. At present, the treatment of HCC is still limited. More than half of the patients will relapse in the case of surgical resection and will suffer from more and more serious postoperative complications [1]. We can see the overall therapeutic effect of HCC is not optimistic. In addition, two thirds of patients with HCC are in the advanced stage when they are treated, then surgical resection is not the best choice. Therefore, it is particularly important to strengthen the research on the occurrence and development mechanism of HCC to effectively identify the biomarkers for clinical detection of liver cancer, so that we will achieve early detection and treatment of HCC and prolong survival time of patients.

The information of HCC genes is abundant in the gene expression profile. Over the past two decades, more and more high-throughput techniques have been developed to do the genome-wide analysis of gene expression and their interactions [2]. The gene co-expression network of HCC provides a tool for studying the gene regulation based on gene expression data, which provides favorable conditions for finding more stable biomarkers and gene targets.

Many investigators have made preliminary progress in the search for biomarkers of HCC. Through the study of HCC samples, the researchers have found a number of biomarkers which have significant changes in the expression, such as alpha-fetoprotein (AFP). Tada et al found that the percentage of AFP-13 is strongly related to the stage and size of HCC [3]. These tasks have much significance to clearing pathogenesis of HCC. At present, analysis of gene co-expression network has been widely used in complex disease research. Gene network is a complex dynamic system. In order to achieve genetic relationship mining, we need to select the community structure from the complex network, which is called gene co-expression module. The genes within these modules share similarities in physiology and gene function [4]. Therefore, analyzing the co-expression network of HCC and enriching the gene modules with similar function by clustering can help us to deeply understand the gene interaction in the process of HCC, so as to get the disease-related gene modules and comprehend its pathological mechanism systematically.

Methods

Process of Research

As shown in Figure 1 we first obtained gene expression data from the public database of HCC, which contains 20,673 genes in the sample data. After the data were normalized, 328 genes closely related to HCC were selected on the basis of Student's Test and correlation analysis. Then, the co-expression network of different genes was constructed according to the relativity of these genes, and the network was clustered to divide the network into several functional gene modules. Based on the systematical study of these gene modules, the functional modules of the selected genes were analyzed for enrichment and further exploration of genes related to HCC. Next, two candidate biomarkers were identified. Finally, the support vector machines (SVM) machine learning method was used to evaluate the disease classification of the selected gene modules and candidate biomarkers.

Data Source

HCC gene expression profile data were obtained from Gene Expression Omnibus (GEO) database of the National Center of Biotechnology Information (NCBI). Its number is GSE20948, containing 20,673 genes in 14 experimental samples and 14 control samples. The experimental samples and the control samples correspond to each other, named from GSM523800 to GSM523827. Fourteen experimental samples among them are
infected cells. They were infected with the genotype 2a HCV clone, JFH-1 at a multiplicity of infection (MOI) of 3. At 6, 12
18, 24 and 48 hours’ post-infection, cellular RNA was extracted and the gene expression value was measured from the
gene expression profile. Another fourteen control samples were normal cells without HCV infection under the same
conditions as the experimental group.

Overview of Research Methods

Statistical Analysis

The expression data are preprocessed for normalization with the
gene expression console software. We apply Student’s Test to
gain the initial screening of differentially expressed genes
on a large scale. Using the R language as the data processing
tool, we calculate the P value of two vectors of the experimental
group and control group. The smaller the P value, the greater
difference between the two vectors, and the greater difference in
gene expression between the infected samples (disease state)
and the non-infected samples (healthy state). Then False
Discovery Rate (FDR) correction is performed by using the
p.adjust function to obtain the FDR corresponding to each
data. The significance of FDR is the proportion of false
conclusions that are claimed to be significant. The goal is to
control the false discovery rate below a certain value.

Gene Co-expression Network Analysis and Clustering

We use Pearson Correlation to calculate the Pearson
Correlation Coefficient (PCC) of the expression vector between
different genes to identify the first 1% of the genes with the
greatest difference in disease and health status [5]. We then use
Cytoscape to map all co-expressed gene pairs into a gene
co-expression network (Figure 1).

In the co-expression network, the nodes represent the genes,
and the edges represent the co-expression interaction[6].
The information can be transferred smoothly on these edges. A
collection of nodes means that a set of co-expressed genes
collectively carries out certain functions. In this paper, Markov
clustering algorithm (MCL) is used to cluster [7]. In order to
get the appropriate number of community sets, we choose the
Granularity Parameter of 1.8 and the other parameters of the
default parameters. After the clustering algorithm is
implemented, the clustering results are represented by a number
of modules, each of which contains a number of genes.

Identifying Candidate Biomarkers by GO-Analysis

For the four gene modules with the highest correlation, the
functional analysis of the gene network is carried out through
Network Ontology Analysis (NOA) method and Gene Card
website [8]. The NOA online website provides functional gene
analysis for free which gives static and dynamic analysis for
gene networks. Through the functional analysis of genes, we
identify two important genes, which are defined as candidate
biomarkers.

Determine the Accuracy of Classification by SVM

Our candidate biomarkers are determined by our functional
enrichment analysis of the genes in the gene modules. In order
to further confirm the relevance of HK2, KLF4 and HCC and
the accuracy of the classification, we use SVM to evaluate the
effect of the classification of disease for the four most relevant
gene modules. We choose the method of Leave-one-out to
classify the existing data and make the ROC curve to get the
accuracy index of classification [9].

Results

Screening of Differentially Expressed Gene

The t-test () function is used to test the data and get the P value
of each gene data. According to the size of the P value in
ascending order, we pick out the smallest P value of the first
500 genes as candidate genes. All the 500 genes selected with
the smallest P value meet the required FDR range (FDR <5%).
We list the first ten genes and their P value and FDR in Table
1.

Correlation Analysis

In the R software, we use the cor () function to obtain the PCC
matrix of two pairs of genes to take out the correlation
coefficient values of disease and health state and subtract the
difference to get the absolute value of the relative PPC, which
ranges between 0 to 2. There are 124750 values and the size of
the difference value means the strength of the correlation
between the two genes. Additionally, we use hist() function to
make the frequency distribution and use the lines() function to
make the fitting curve (Figure 2). The horizontal axis is the
absolute value of the relative PPC between 0 and 2, and the
vertical axis is the number of occurrences of this value.

Figure 1 - Map of research process

Figure 2 - Frequency distribution of the correlation
Figure 2 shows that the greater the absolute value of the relative PPC, the smaller the data, that is, the weaker the correlation between the two genes. Therefore, with the frequency distribution map, the absolute value of the relative PPC is arranged in descending order and the maximum 1% of the data is retained. The first 1200 pair pairs are screened and their absolute values of the relative PPC are obtained. The first twelve gene pairs are chosen to be listed in Table 2.

### Construction of Gene Coexpression Network and Clustering Analysis

To explore the co-expression changes induced by the highly relevant gene pairs, the 1200 pairs of genes selected above are mapped into the gene co-expression network with the help of the Cytoscape software (Figure 3). Each vertex in the graph represents a gene. When the co-expression of the two genes (ie, the absolute value of the relative PPC) is greater than the selected threshold, an edge is connected to indicate the significant correlation between them.

### GO-Analysis

We select the four gene modules with the strongest correlations and analyze them with the NOA online website to get the functional analysis of the genes within the modules (Table 3). In combination with the analysis of Gene Card website, we identify HK2 and KLF4 as potential candidate molecular biomarkers.

### SVM-based machine learning method

Through the systematic study of these functional modules and candidate biomarkers, we use the method of Leave-one-out to do the machine learning of the existing data in the R software and get the corresponding value of accuracy (AUC) (Table 4) and ROC curves (Figure 4).

</tbody>
</table>
From Table 4 and Figure 4, we can see that the SVM classifier has a good AUC of 0.98, 0.84, 0.97 and 0.98, which are very close to 1 after training and learning for the four gene modules. And the corresponding ROC curves are very close to the upper left corner of the highest threshold of the specificity and sensitivity. It can be seen that the SVM classifier shows good performance in the classification of the four gene modules, indicating that the four gene modules can distinguish disease state and health state. And the gene HK2 and gene KLF4 contained show significant differences in the two states and most likely can be identified as biomarkers of HCC.

Discussion

Looking for biomarkers of HCC and exploring the molecular mechanism of HCC are of great significance for early prediction and early treatment of HCC. HK2 is a Protein Coding gene which is associated with the occurrence of some tumors. Among its related pathways are Regulation of Glucokinase by Glucokinase Regulatory Protein and Translation Insulin regulation of translation. KLF4 is a tumor suppressor gene which participates in cell differentiation, cell proliferation, necrosis and angiogenesis. The encoded protein is thought to control the G1-to-S transition of the cell cycle following DNA damage by mediating the tumor suppressor gene p53. These two genes are to some degree, related with the occurrence or metastasis and invasion of the tumor and cell differentiation, angiogenesis and so on. This also confirms the reliability and accuracy of our approach from another side.

Compared with the previous studies, the molecular mechanism based on HCC in this paper should be a hypothesis of a network of gene dynamic regulation, and more consideration is given to the potential interconnections between genes. Through the construction of co-expression network to further explore the molecular mechanism of liver cancer, the method of mining effect should be more reasonable. Although the correlation between the two genes and the occurrence of HCC needs to be confirmed by further experiments, it is believed that the applicability of this method will be further demonstrated with the further accumulation and perfection of high-throughput experimental data.

The occurrence and development of cancer are caused by the mutual disturbance of multiple functional pathways. Therefore, during the occurrence and development of HCC, tumor-associated genes should be a dynamic process of mutual regulation of the network. Consequently, we analyze the microarray data of HCC with the combination of traditional bioinformatics analysis method and the increasingly active system biology analysis and use bioinformatics methods such as normalization, statistical analysis, clustering analysis, GO-analysis, SVM and so on. The construction of gene co-expression network is completed and the network is searched for genes related to HCC. As a result, the gene HK2 and gene KLF4 are obtained and the functional modules of these two genes are proved to possess a great ability of classification by using SVM, which will contribute to the future detection and personalized medicine of HCC. This will be of great help and significance for the development of precision medicine to improve the lives and health of patients.

An Interactive Platform to Visualize Data-Driven Clinical Pathways for the Management of Multiple Chronic Conditions

Yiye Zhang\textsuperscript{a}, Rema Padman\textsuperscript{b}

\textsuperscript{a} Division of Health Informatics, Department of Health Policy and Research, Weill Cornell Medical College, New York, NY, USA. \textsuperscript{b} The H. John Heinz III College, Carnegie Mellon University, Pittsburgh, PA, USA

Abstract

Patients with multiple chronic conditions (MCC) pose an increasingly complex health management challenge worldwide, particularly due to the significant gap in our understanding of how to provide coordinated care. Drawing on our prior research on learning data-driven clinical pathways from actual practice data, this paper describes a prototype, interactive platform for visualizing the pathways of MCC to support shared decision making. Created using Python web framework, JavaScript library and our clinical pathway learning algorithm, the visualization platform allows clinicians and patients to learn the dominant patterns of co-progression of multiple clinical events from their own data, and interactively explore and interpret the pathways. We demonstrate functionalities of the platform using a cluster of 36 patients, identified from a dataset of 1,084 patients, who are diagnosed with at least chronic kidney disease, hypertension, and diabetes. Future evaluation studies will explore the use of this platform to better understand and manage MCC.

Keywords:
Critical Pathways; Computer Graphics; Multiple Chronic Conditions

Introduction

Multiple chronic conditions (MCC) have significant health management and cost implications worldwide. For example, in developed nations, one in four people have multiple chronic conditions\cite{1, 2}. In the US, over one-third of beneficiaries of Medicare, the US single-payer, social insurance program, have at least 4 concurrent chronic conditions, and they alone are responsible for 74\% of total Medicare spending\cite{3}. Yet, previous literature has suggested that there is still a gap in efficient care coordination of these patients, as commonly used clinical practice guidelines (CPGs) are focused on the optimal care of each condition and not on the composite of many conditions\cite{4}. In this study, we report on the design and development of a prototype of an interactive visualization platform, based on information technology (IT) and advanced data-analytics, which captures and displays how MCC patients are treated in real settings, given their varying demographics and concurrent conditions. This approach has the potential to facilitate shared understanding and exploration of possible disease and treatment pathways and support shared decision making between clinicians and patients.

Background

Health IT has gained widespread recognition in facilitating effective management of patients through electronic health records (EHR) systems and their various functions in supporting clinical decision support (CDS)\cite{6}. Clinical pathways are multidisciplinary care plans to detail essential care delivery steps that can be embedded in the EHR, and are expected to link evidence to practice and optimize clinical outcomes while maximizing clinical efficiency\cite{5}. In this study, we place an emphasis on the fact that our clinical pathways are learned from EHR data and display data-driven clinical pathways of MCC. The learning algorithm draws on techniques from machine learning, statistics, and operations research, and combines it with innovative data structuring and modeling to handle the multiple dimensions of patient care data. In order for these data-driven clinical pathways to truly contribute to learning health systems, we must address another significant challenge, which is the usability of the clinical pathway learning algorithm and its outputs for multiple stakeholders in healthcare. Results from previous work\cite{6, 7} are presented as pathways of complex data representations, which require a sophisticated level of understanding of informatics and analytics to interpret and use. Therefore, this study aims to design and implement a prototype of an interactive, visual analytics clinical pathway platform that embeds the current methods and meets the information needs of diverse users, including healthcare professionals, researchers, and patients, without requiring such specialized knowledge. Visual analytics utilizes the high bandwidth processing capabilities of the human visual system to more efficiently support interactive data exploration, analysis, and absorption of complex information\cite{8, 9}. Through this research, we expect that (a) managers of healthcare practices, such as an accountable care organization (ACO), can easily review clinical pathways of local practices to determine variations, exceptions, and optimal care patterns; (b) clinicians and patients are provided with resources to encourage shared-decision making at the point of care; and (c) researchers can generate new hypotheses for targeted randomized clinical trials (RCT) through identification of promising pathway patterns for which strong, scientifically-tested evidence does not currently exist.
Methods

Technology Components of the Visualization Platform

The backend system of the visualization platform is based on a clinical pathway learning algorithm described in Zhang et al [6]. The algorithm particularly focuses on the co-progression of multiple concurrent conditions and associated interventions, and thus is a natural choice for the platform in modeling the clinical pathways of MCC management. Given as input the EHR data of a patient population that includes chronological information on encounter types, diagnoses, and interventions, all recorded at different points in time, the algorithm performs patient clustering, followed by Markov chain modeling, in learning the dominant patterns of clinical pathways within each patient cluster. Figure 1 displays a schematic representation of the algorithm.

As shown in Figure 1, Zhang et al used a dimension reduction approach (Step (a) in Figure 1) to summarize multiple aspects of information at each point in time. In other words, each node in the pathway, once visualized as in the output in Figure 1, is in a complex, coded-form that may be quite incomprehensible to readers of the clinical pathways. Therefore, creating an interactive visualization platform to decode this complexity is a natural extension of the study, such that users without background in clinical pathway learning can easily use and understand the outputs for management of patient populations as well as individual patients. While previous work has developed visualization capabilities for clinical pathways [8; 10; 11], our pathway learning algorithm and visualization platform distinguishes itself by particularly focusing on the need to track MCC and associated interventions over time for targeted patient subgroups and individuals.

![Figure 1 – Outline of Pathway Learning Algorithm](image)

The frontend system of the platform is created using Django (Django Software Foundation), a Python web framework. As demonstrated in later sections, users can input their EHR data and user-defined filtering information for Step (c) in Figure 1, and obtain summary statistics and visualization of the dominant clinical pathways in the identified patient population. Filtering can be done by the transition probability and frequency of pathway elements, as described in Zhang et al [6]. Visualization is created using force-layout form of D3 [12], a JavaScript library. Compared to other libraries such as Gephi [13] and Plotly [14], D3 library contains more interactive, flexible and customizable features such as allowing users to place mouse over a component in the visualizations to facilitate deeper exploration. As an extension to the methods in Zhang et al [6], we also incorporate temporal information in the clinical pathways, so that we can track the duration between clinical visits, and differentiate a pathway showing the progression of CKD stage 3 to stage 4 that took place within a month, from another pathway showing progression in more than a month, for instance. Current implementation categorizes duration into 2 categories, within and beyond 4 months, and color-coded to mark the difference. However, this categorization can be readily modified depending on the exploration of interest with distinct pathways.

Data used to Demonstrate the Platform

For demonstration, we used a dataset from the EHR of a community Nephrology practice in southwestern Pennsylvania, which contains data on 1,084 patients whose initial diagnoses in 2009 included chronic kidney disease (CKD), hypertension, and diabetes, with additional chronic conditions developing with the progression of the disease over time. The algorithm learned the pathways of these patients, consisting of the first 5 encounters from 2009 to 2016. As variable of interest in the analysis, we particularly track progression of the following diagnoses: CKD stages 1 to 5, end stage renal disease (ESRD), acute kidney injury (AKI), hypertension, and diabetes; and medications summarized by their drug classes including Angiotensin-converting-enzyme (ACE) inhibitors, angiotensin receptor blockers (ARB), diuretics, statins, among others. In this data, gender ratio of female to male is 0.42 and 0.58. Over 90 percent of the patients are Caucasian. Table 1 summarizes some descriptive statistics associated with this group of 1,084 patients, including number of diagnoses, medication prescriptions, and hospitalizations.

Results

Clustering of patients

Figure 2 shows the clustering results from the above dataset. The clusters were found using hierarchical clustering [6]. As the figure illustrates, the algorithm finds clusters of patients who have distinct characteristics, such as those with no changes in their disease over time, or those who develop specific types of complications. The clusters are color-coded in Figure 2. In the demonstration study, a cluster of 36 patients who developed acute kidney injury (AKI) is extracted from the full dataset for further analysis and visualization. AKI is a serious complication of CKD that can result in rapid deterioration of the kidney functions and even mortality. Table 2 summarizes some descriptive statistics associated with this group of 36 patients for comparison with the whole group.
Visualization of this cluster was created under a filtering of at least 3 visits for pathway length, at least 0.3 for transition probability, and at least 1 for transition frequency. These filters are described in [6].

![Figure 2 - Clustering of patient groups. Color indicates clusters](image1)

**Visualization of the AKI cluster**

Figure 3.1 shows a screenshot of visualized clinical pathways from one of the clusters identified above. Pathways originate from the blue node on the right hand side, and diverge into different directions depending on patient and treatment characteristics. Each node in the visualization represents a clinical visit, capturing information on encounter types, diagnoses, and medications prescribed from each visit. Users can hover over the node and see the exact information encoded. For example, the node highlighted in Figure 3.1 is a visit of Office (O) type, where diagnoses of AKI, CKD stage 3 (CKD3), diabetes (DM), and hypertension (HP) were noted. Vitamins were prescribed in the visit. Sizes of the nodes are relative to the number of edges it is connected to. In addition, users can drag nodes to desired locations for enhanced interpretability.

![Figure 3.1 - Visualized clinical pathways: node highlighted is a visit of Office (O) type, where diagnoses of AKI, CKD stage 3 (CKD3), diabetes (DM), and hypertension (HP) was noted. Vitamins were prescribed.](image2)

Further, the edges and arrow sizes between each node capture multiple categories of information about the transitions between clinical visits, particularly through color-coding and thickness. Green and red links indicate less than 4 months, and at least 4 months, respectively, of gap between visits, as explained in the legend on the right-hand side (Figure 3.2). Thickness of the edges reflects the probability of transitions; the thicker the edges, the more likely that the transitions are observed in the data, such as displayed by the thick, red edge in Figure 3.2.

A search function is built into the platform that allows users to identify visits with certain criteria. For example, Figure 3.2 shows a search for visits where patients’ diagnoses include CKD stage 3, and medication prescriptions include vitamins. The search bar on the top left indicates that there are 6 clinical visits that match with the specified criteria, and information of one is highlighted. The search feature can be expanded by adding more functionalities or categories as needed.

![Figure 3.2 - Search function highlighting interesting visits](image3)
Using the Visualization Platform

To use the platform, users need to enter the path to their data in JSON (JavaScript Object Notation) format, which contains each patients’ clinical events and their timestamps over a period of interest. If necessary, users can filter clinical pathways by their commonality. Currently implemented thresholds are the number of time points in the pathways, transition probability between visits, and number of transitions. For example, Figure 4.1 displays the input form with a filter, where only pathways with at least 3 time points, transition probability of at least 0.1 and transition frequency of at least 2 are included in the analysis. Figure 4.2 shows the updated pathway visualization, now much simpler compared to the initial visualizations in Figures 3.1 and 3.2 with the original filter. The resulting pathways that are visualized can be shorter than 3 time points due to the requirement on transition probability and frequency.

Displaying Clinical Pathway Statistics

Number of occurrences of each node, transition probability and frequency of each edge, and other statistics are also available for display in the platform as shown in Figure 5.1. “Source” indicates the originating visit and “target” is the transitioned visit. For example, in the pathway visualization in Figure 3, we see from Figure 5.1 that there are 15 instances among the 36 patients’ pathways where patients develop an episode of AKI (row 3). Figure 5.1 also shows that this transition, an office encounter with a hypertensive, diabetic patient in CKD stage 3 (source: V29), progressing to develop an episode of AKI (target: V13), has a transition probability of 0.21. The corresponding code information for the visit IDs can be found by clicking the “See Node/VVNode Details” button in the platform. Figure 5.2 shows the information of 7 nodes including V13. While not shown in the paper due to space limitations, visit IDs can be displayed as part of the mouse-over function to show node details, to allow easy mapping of the pathway elements with corresponding statistics.
Discussion

This study presents a prototype visualization platform that can potentially be used for other types of data with simple and easy modifications, provided the format of the input data remains the same and there are a comparable number of nodes. One challenge that we recognize is that the structure may become unstable when there are many nodes. In this case, force-layout graphs cannot be clearly displayed. This problem likely needs to be solved via the backend algorithm, which must explore options to summarize clinical pathways in a scalable and clinically valid fashion.

Evaluation of this platform with actual users in a formal experimental setting, such as through think-aloud protocol and focus groups, is an important future work. To accommodate this task, we are working on adding human computer interaction (HCI) capabilities, such as recording the number of times a node is clicked by a user in order to understand what features users are most interested in. In addition, prediction of future states in the clinical pathways is also a problem of interest, as well as managing not only the clinical aspects but also the costs of interventions. Based on our follow-up studies on prediction of outcomes, and overlaying the medical costs, following a particular pathway [15; 16], we plan to add functions for the predictive modeling and cost pathway mapping to the platform as well.

Conclusion

This paper describes an extension of our existing clinical pathway learning algorithm by developing an interactive visualization platform, which displays the co-progression of multiple concurrent disease conditions and their associated interventions such as medications. Particularly focused on use cases in a specialty care setting for patients with MCC, but equally applicable to primary care, we aim to show that the visualization platform, using information technology and data analytics, has the potential to be easily used and interpreted by diverse end users, such as clinicians, patients and researchers, for patient education and empowerment as well as for shared decision making and developing generalizable research and insights. The platform has functions for personalized filtering and searches, allowing users to explore clinical pathways of specific interest to their condition. Future work will include formal experiments as evaluation studies, and enhancement of the platform usability in terms of backend learning algorithm and added HCI capabilities.

Acknowledgements

We are grateful to the physicians and staff of the community nephrology practice who generously provided data from their Electronic Health Record for this study. We particularly thank Dr. Teredesai, MD, Dr. Xie, MD, PhD, and staff, L. Smith and A. Barletta, who gave us important clinical and technical information about the data and the key characteristics of CKD, AKI and the treatments. We also thank the two graduate students, Rohit Bandi and Ahana Sheshadri, who helped us with the implementation of the visualization platform.

Abstract

The rapid growth of digital health and welfare services demands new competences for health and social care, information technology, and business professionals. This study aims to describe the competences that students have before their studies and those they expect to gain from the study module “Developing Digital Health and Welfare Services” in multiprofessional groups during their bachelor studies. This study reports open-ended questions about students’ knowledge concerning digital health prior to the study units. The results, analyzed by QSR NVivo 10 for Windows, show that students are keen to learn about developing digital health and welfare services, and they see that multiprofessional work requires a communicative environment and respect for every profession. Students also believe that they have competences to bring to the multiprofessional group. A successful multidisciplinary development of digital health and welfare services requires changes and cooperation in education between various professions.

Keywords:
Informatics; Education; Professional Competence

Introduction

Wellbeing, health promotion, disease prevention, and citizen’s empowerment to his/her own life are the core areas of social and health politics. Health informatics plays a crucial role in accomplishing these elements [1]. New digital health services are essential in order to improve care all over the world, to increase the level of patients’ engagement in their own care, to arrange quality health services with universal access, and to create a sustainable financial ground for health care systems [2]. To achieve effective implementation, the customer-centric service culture in health care requires a human-centered design approach to co-creation innovation and also skills, such as sensitivity and attitudes [3]. Well-functioning eHealth services need new competences from professionals and citizens [4]. Nearly half of the European Union (EU) population (47%) does not have proper digital skills, yet in the near future, 90% of jobs will require it. The EU Commission supports efforts to enhance the digital skills and qualifications of the population and to increase the level of ICT professionalism [5]. An effort to achieve this has been made through the European Computer Driving License (EDCL), which since 1995, has given a worldwide format to provide general knowledge and skills about ICT to all professionals on different educational levels [6]. The biomedical and health informatics standardized curriculum developed by the International Medical Informatics Association (IMIA) is widely known [7]. Also, nursing informatics has been part of nursing education for many years [8–11]. Moreover, social workers are required to be competent in the use of informatics [12]. However, the research still shows that students need to increase their knowledge, skills, and competences in informatics [10]. The European Qualifications Framework (EQF) defined by the EU is the general framework of vocational qualifications for competence in eight different levels. A bachelor’s level is defined as college completion level 5, and it is the first level of higher professional education. The University of Applied Sciences (UAS) is level 6. The EQF defines competences, skills and knowledge related to all degrees [13], and the directive describes professional minimum competences [14].

This study aims to describe the competences that students have before studies and those they expect to gain from the study module “Developing Digital Health and Welfare Services” in multiprofessional groups. This study is part of an EU-funded project. The final aim of the whole project, called the “Developer of Digital Health and Welfare Service (DeDiWe)”, is to create a 30-credit module curriculum based on IMIA’s recommendations about Developing eHealth and Welfare Services, and to define and describe the eHealth developers’ previous knowledge, skills, and competences in bachelor’s degree programs for EQF levels five and six. The research questions are as follows: 1) What kind of competences do bachelor’s students expect to get from participating in the study module for developing digital health and welfare services? 2) What do the bachelor’s students experience as most important in multiprofessional work in developing digital health and welfare services? 3) What kind of competences do the students from the different professions bring with them to the multiprofessional group?

Methods

The questionnaire

Data for this study were collected with the help of an e-questionnaire, which was based on the IMIA’s curriculum content [7] for EQF levels 5 and 6 [13] and described the user’s information technology (IT) levels in relation to the IMIA’s curriculum content. The questionnaire is cross mapped with the EDCL’s [6] and IMIA’s [7] contents. The service design, which is part of the DeDiWe module’s curriculum, is included as an addition. Competences for design thinking have been used as a framework [15] to describe the part of the questionnaire relating to the service-design process. The DeDiWe curriculum also is cross mapped with the IMIA’s content-based competence evaluation measurement tool. This study reports on three open-ended questions about the students’ knowledge of digital health.
prior to the study units. This study is part of the students’ competence evaluation before the DeDiWe studies.

Data collection and analysis

Data were collected using an e-questionnaire answered by students who enrolled in the course in Fall 2016. The course outline, aims, learning outcomes, and the timetable were introduced to students before the data collection. Answering the questionnaire was voluntary-based. Students were informed to answer based on their own preconceptions and expectations. The e-questionnaire was distributed to all participating students through the eLearning platform used for the study unit. Research data was anonymized.

The questionnaire was sent to all students (n = 82) from the European partner schools in Finland, Latvia, and Estonia that participate in the study units and thesis work. Students’ answers from the e-questionnaire came in an Excel spreadsheet, which was transformed into a Word format, and read several times by OA and G-BL, before being loaded into NVivo. QSR International’s NVivo 10 for Windows software for qualitative data analysis was used for arranging and analysis of the open-ended questions, finding themes, coding data, and calculating word frequency. All the obtained data was screened and structured to seek the most relevant information. NVivo 10 created a data file for each question, resulting in three data files. The data was checked by seeking synonyms to the words through a text search query in every questionnaire’s data separately, which showed the trends for the inductive classification. It also used theoretical knowledge for the classification. After that, the project researchers chose the items for every node by reading the text and designating the node to the item. Some of the items could be in two nodes. NVivo10 helped by coding stripes to see how the items fitted into the nodes and data. After the nodes’ references were chosen, researchers read the text again and designated categories under the nodes by qualitative content analyses [16]. Regarding any overlaps, the researchers OA and G-BL performed the final classification.

Results

The results are preliminary and part of the bachelor’s students’ competence evaluation results. There were students (n = 64) from three countries: Finland (n = 39), Latvia (n = 13), and Estonia (n = 12). The number of students in the different study programs were nursing (n = 32), physiotherapy (n = 3), biomedical laboratory science (n = 3), midwifery (n = 3), business administration (BBA) (n = 4), BBA–IT (n = 3), engineering–IT (n = 0), doctoral assistant (n = 7), social and welfare (n = 8), environmental health (n = 0), radiography (n = 1), and other (n = 0). Of all the students, 76.6% were women and 23.4% were men. 46.9% were ages 19–29, 21.9% were 30–39, 23.4% were 40–49, and 7.8% were over 50. Most of the students (85.9%) were full-time students at the bachelor’s level, but some of the students (14.6%) were in the open level, but some of the students (14.6%) were in the open

Knowledge and skills students expect to gain

The data showed that “Health” (n = 32, 5.4%) and “services” (n = 23, 3.9%) were the two most common words in the data. There were many synonyms, such as digital and eHealth. The data were divided into two nodes: Biomedical and health informatics (96 references coded with 69.9% coverage) and Developing services (73 references coded with 54.7% coverage). Figure 1 describes the relationships of the nodes and categories, considering the content that students see as important. All nodes and categories are explained in the following sections.

Developing services

The first node in which students expect to gain more information is “Developing services”, and it is classified into four categories. 1) “Develop knowledge, skills, and competence” is the only category that has additional subcategories. The “Develop” category is spread into three subcategories: a) “Current situation” has 25 items expressing needs to understand the current situation in eHealth and eSocial services, including “advanced technologies in social services”, “artificial intelligence machine learning”, and “a greater understanding of the current innovation projects in e-Health in Europe/world”. Students also expressed needs to understand the multidisciplinary perspective: “understanding of business, technology and healthcare together”; b) The “Develop” subcategory has 25 items about the need to understand the developing perspective, such as “I would understand the concept ‘citizen as customer’ in digital health and welfare services”; and c) “Implementing” has one item: “Implementing”. 2) The “Communication” skills category has 12 items, including “improving communications methods to remove cultural barriers”. 3) The “Gain knowledge for future work” category has eight items, such as “be ahead of current trends to be able to predict coming changes in my profession”. And 4) The “Research knowledge, skills, and competence” category has five items, including “analytical skills”.

![Figure 1 – Knowledge and skills students expect to gain from studies](image-url)
Biomedical and health informatics
The second node in which students want to gain knowledge and skills is “Biomedical and health informatics”, which is classified into seven categories. There are variations between contents in these categories. 1) The “Health and social care” category has nine items, and mostly students want to know about health care and human functioning in general, but there are also some specific comments, such as “specifically learning about the brain”. 2) The “eHealth and welfare” category has 30 items and is the largest category in this node. Students mostly hope to understand the content, for example, “understanding of business, technology, and health care together”, but they also have advanced plans, such as “I wish to learn more about how to use data analysis to diagnose diseases”. 3) The “Customer’s point of view” category has 11 items explaining the desire to understand the customer’s orientation, such as “understanding customer behavior in digital the health and welfare environment” and “to know more about patient requirements in the e-platform”. 4) The “Regulations and quality” category has eight items explaining students’ hopes to gain more knowledge about a safe environment, including “patient data safety and confidentiality in eHealth”, but also trust, such as “gaining customers’/patients’ interest and trust regarding using e-health services”. 5) The “IT skills” category has nine items, including “Improve my IT-skills” and “to have skills to make tools for digital websites”. 6) The “Informatics category” has 13 items describing students’ wishes to understand how to work with data, such as “I know where to find the evidence” and “health information management skills”. 7) The final category, “Future possibilities”, has 15 items, which vary from the personal level to international development. Those include “ability to use digital appliances and skills in the future working as a nurse” and “developing health programs in Finland and abroad”.

Contents students see as important in multiprofessional work in developing digital services
When the words were counted, “different” (n = 16, 3%) and “work” (n = 13, 3.5%) were the most common. There were also many synonyms like “patient” and “patients”. The data was analyzed and divided into three categories: Biomedical and health informatics (29 references coded with 25.6% coverage), Communicative culture (78 references coded with 55.86% coverage), and High-quality services (35 references coded with 35.8% coverage). Figure 2 describes the relationships of nodes and categories, considering the content that students see as important in multiprofessional work for developing digital services. All nodes and categories are explained in the following sections.

Communicative culture
The first node is the “Communicative culture” category, and it was classified into two categories. 1) The “Team work” category has 55 items. Examples are as follows: “willing to work in a team”, “compliance”, “dedication”, and “coverage”. 2) The “Multiprofessional work” category has 25 items, such as “teamwork and collaborating with relevant stakeholder” and “understanding other professionals’ roles and competencies”.

High-quality services
The second node, “High-quality services”, was classified into four categories: 1) “Patient’s point of view” has 20 items, such as “improve my understanding about the customer in the health and welfare system”; 2) The “Development process” category has 14 items, including “development of digital healthcare and welfare services” and “leadership and management skills”; 3) The “Multiprofessional perspective” category has six items, for example, “every profession has different ideas from different perspectives”; and 4) The “Privacy” category has three items, including “privacy issues in health services”.

Biomedical and health informatics
The third node about the content that students see as important in multiprofessional work in developing digital services is “Biomedical and health informatics”. The node was classified into four categories, and there was a variation between content in the categories: 1) The “eHealth and welfare” category has 19 items, for example, “Innovation: What works well and what needs to be changed” and “research and surveys, monitoring and evaluating digital health and welfare services”; 2) The “Safety and quality” category has seven items, such as “data collection while at the same time maintaining confidentiality and privacy”; 3) The “Health and social care” category has three items, including “control of people health”; and 4) The “Patient’s point of view” category has three items, such as “respecting the right of the patient”.

Professional competences that students from different branches bring to the multiprofessional group
The most common words in the data were “skills” (n = 23, 4.7%) and three words with the same value “understanding”, “work”, and “working” (n = 9, 1.8%). There were also many synonyms. The data was analyzed and divided into four nodes. Biomedical and health informatics (17 references coded with 13.1% coverage), Communication (49 references coded with 24% coverage), Health and welfare (41 references coded with 47.5% coverage), and Management and developing (37 references coded with 24% covered). Figure 3 describes the nodes’ and categories’ relationships regarding what professional competences students from different branches bring to the multiprofessional group. All nodes and categories are explained in the following sections.

---

**Figure 2** – Content that students see as important in multiprofessional work in developing digital services

![Figure 3](image2.png)

**Figure 3** – Professional competences that the students from different branches bring to the multiprofessional group
Communication

The “Communication” node is the first node about the professional competence students from different branches bring to the multiprofessional group, and it was classified into three categories: 1) The “Teamwork skills” category has 33 items, including “spreading ideas” and “the capability to work in a multiprofessional team”; 2) The “Communication skills” category has six items, such as “communication (written, spoken, tools, social media)”; 3) The “Language skills” category has five items such as, such as “good language skills” and “writing competence”; and 4) The “Ethical point of view” category has five items, such as “compliance” and “loyalty”.

Health care and welfare

The second node is “Health care and welfare”, which was classified in four categories: 1) The “Health care category” has 26 items, including “up-to-date information about public health care” and “working with chronic diseases and use of e-compliance”; 2) The “Patient’s point of view” category has 12 items, such as “a practical skillset an understanding of how to prioritize the needs of a patient” and “inform, instruct and guide people in making the change to better in behavior and movement”; 3) The “Social care” category has four items, for example, “knowledge of social branch, law, practicals, and ethics”; and 4) The “Deep understanding” category has two items, including “a diverse work and internship experience, with an understanding of the complexity of the health care system”.

Management and development

The third node is “Management and development”, which was classified into five categories. 1) “Management and general working skills” has 15 items, such as “leadership skills” and “the capability to work in a multiprofessional team”. 2) The “Development culture” category has 10 items, including “professionality in my own branch/sector” and “service development”. 3) “Future understanding” has seven items, for example, “dedication in seeking further knowledge to improve the system” and “multidimensional insights”. 4) The “Sharing culture” category has four items, such as “give and share my knowledge”. Finally, 5) “Business culture” has two items, for example, “knowledge in business, finance”.

Biomedical and health informatics

The fourth node is “Biomedical and health informatics”, (BMHI) which was classified into two categories: 1) The “IT general skills” category has 15 items, such as “IT background from end user support and IT management, customer service and support”; and 2) “BMHI skills” has two items: “knowledge concerning possibilities using digital services in public health care” and “specification and documentation skills”.

Discussion

In the last decade, health and welfare services have become a customer-centric culture with many digital services [2]. Designing and innovating these new digital-service processes effectively require human-centered co-creation with sensitivity and motivation [3]. This study aimed to describe the competences that students had before studies and those they expect to gain from the study module “Developing Digital Health and Welfare Services” in multiprofessional groups as part of their bachelor studies.

The study results showed that the students expect to gain an understanding of the current situation in eHealth and social care services. They also want to acquire skills to communicate with customers through digital services and learn how to develop and design services. Lifelong learning has become an even more important aspect because professionals and citizens need new competences to use eHealth services in flexible ways [4]. IMIA’s biomedical and health informatics curriculum [7], EDCL [6], and design-thinking competences [14] are the framework for the DeDiWe studies. Results showed that students are interested in understanding regulations and how quality customer-oriented services are built. They want to know the future trends in eHealth and welfare services, and also connect to different service providers and meaningful networks. Students prioritized the knowledge and skills needed to develop services in multiprofessional teams. They want concrete skills that will help them work with apps, but at the same time, do want to gain an understanding of development projects on an international level.

In developing digital health and welfare services in multiprofessional teams, the bachelor’s students see as equally important biomedical and health informatics knowledge and skills, a communicative culture, and high-quality services. The results of this study are in line with the EQF [13], which provides the framework for general professional competences to all professionals to reach the requirements to be active partners in research, development, and innovation processes. IMIA’s curriculum [7] is multiprofessional, between IT and health care, but business and social professionals are not included. Also for designers [15], BMHI studies could be useful. Today’s health care services need a paradigm change to have more open and customer-oriented services, in which all can take part in designing new services and implementing them actively in society [3]. In DeDiWe studies, we have had the opportunity to allow health and social care, IT engineer, IT business, and business bachelor’s students to take part in a common study module about developing digital health care services. This project is one intervention by the EU that supports enhancing the population’s digital skills and increasing the level of ICT professionalism [5].

The results of this study showed that students believe that they can bring their own competences to the multiprofessional team and they believe in their ability to co-create safe, customer-friendly digital health and welfare services for customers. These results differ from those of the EU’s [3] Single Market Strategy, which determined that nearly half of the EU population does not have the proper digital skills for jobs that require ICT competence, but these results are in line with World Health Organization’s [2] strategy’s objectives to have eHealth services implemented globally.

The questionnaire was developed for this study and contained only open-ended questions. The next step is to analyze the quantitative data from the questionnaire. The wording and format of the questions may have influenced the results. The data were analyzed using NVivo 10; however, because of a qualitative analysis, there is always a possibility of diverse interpretation among two researchers. The results are not generalizable because of the small sample size. The sample mainly reflects the opinions of the health care sector because most of the students represent that sector. However, these results imply that students are capable of working multiprofessionally in developing digital health and welfare services. Students were informed that completing the e-questionnaire was voluntary, but that we recommended it because of the importance of the project. This and the need for adequate English skills might have affected the response rate and the results of the study.
Conclusion

Successful development of multidisciplinary digital social and health care services requires changes and cooperation in education between various professions including health care, social care, IT, and business. Digital health and welfare services development need a multiprofessional curriculum and a combination of all teachers’ competences for high-quality service development.

A User-Centered Glucose-Insulin Data Display for the Inpatient Setting

Michael E. Bowen\textsuperscript{a,b}, Umme Rumana\textsuperscript{a}, Ethan A. Killgore\textsuperscript{a}, Yang Gong\textsuperscript{a}

\textsuperscript{a}School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Texas, USA, \textsuperscript{b}The University of Texas Southwestern Medical Center, Dallas, Texas, USA.

Abstract

Inpatient management of insulin-dependent diabetes (IDD) is a complex task that requires clinicians to cognitively process information across distinct domains in different locations of the electronic medical record (EMR). Current data displays are not optimized to support insulin management by end users. We sought to develop a set of user-centered displays of capillary glucose data and insulin dose to improve inpatient management of IDD. Our proposed conceptural data display prototype is designed to simplify the presentation and visualization of key information needed for treatment decisions. The goal is also to enhance clinician’s ability to identify opportunities to optimize insulin dosing and decrease end users’ cognitive load and error rates.

Keywords:
Diabetes Mellitus; Blood Glucose; Data Display

Introduction

Glycemic control in hospitalized patients with type 2 diabetes is associated with improved outcomes [1]. Although inpatient diabetes management is a common task in clinical practice, glycemic control is often suboptimal. Physician management of inpatient diabetes involves three core tasks: a) reviewing Capillary Blood Glucose (CBG) data, b) interpreting values in relation to insulin dosing and meal intake, and c) determining if a change in treatment plan is necessary. Unfortunately, data needed to support insulin adjustments are sub-optimally organized and displayed in the electronic medical record. For example, capillary glucose measurements are reported in the laboratory results, insulin dosing and administration are presented in the medication administration record, and the relationship of glucose readings to meal intake is derived from electronic time-stamps on the glucose readings as they relate to insulin orders. This requires processing and integration of data from multiple locations, multitasking, and attention switching [2]. Given the limited memory span of $7 \pm 2$ [3], mental juggling between tasks can diminish information processing speed, resulting in inefficiencies in completing a common, routine clinical task, duplication of effort, physician burnout, and potentially suboptimal diabetes management in the inpatient setting.

Novel approaches are needed for representing and consolidating the inpatient diabetes management data into intelligent displays. In this paper, we focused on the treatment of hospitalized patients treated with basal-bolus insulin who undergo routine CBG monitoring before breakfast/lunch/dinner and at bedtime. Our proposed display will assist clinicians with the review and interpretation of CBG values by merging data (CBG results, CBG time, and insulin administration) from multiple EMR dimensions into a single location.

Background

Iatrogenic, unintentional Adverse Drug Events (ADEs) are among the most common causes of inpatient complications in the United States [4]. Hospital-acquired ADEs extend the length of stay, result in higher healthcare costs, and may cause tragic loss of life [5-6]. Injected medications, including insulin, account for 63% of ADEs and about 50% are believed to be preventable [7]. Injectable drugs are associated with an estimated 1.2 million preventable inpatient ADEs resulting in an average annual increase of $600,000 per hospital [8]. There is great concern about the high risk of preventable hypoglycemia related to insulin use [8]. Integrated data displays are needed to improve inpatient glucose control, improve safety, and increase clinician efficiency.

Fonda et al. [9], conducted a focus group study with diabetes patients to understand patients’ needs and tasks to inform the design and functionality of a diabetes personal health application. Although this study focused on outpatient diabetes self-management by patients, not providers, core principles from this study were used to inform the development of our inpatient display. In this study, patients reported that the collection, recording, and collating of glucose data for diabetes management is a burdensome process. To help address this, researchers highlighted the need for actionable, understandable, timely information to support glucose management – especially as it relates to interactions with medications, diet, and lifestyle. Fonda et al. [9] utilized flexible and reusable gadgets built on web-based applications within the data display portal, to integrate data from different domains into a consolidated display. For example, the “glucose gadget” displays data from glucose monitors, the electronic medical record, or patient-entered data on a temporal graph. The extensible “gadget” concept suggested our proposed dimensional flexibility. Kumar et al. [10] developed an approach to utilize remotely collected data from continuous glucose monitors, import, and store them into EMR flowsheets, and interface with a novel data display (GluVue). In feasibility testing, the GluVue efficiently collated large volumes of data and improved clinicians’ and patients’ ability to identify opportunities to improve glucose management [11]. It was this concept of novel display of outpatient glucose data that further informed our ideas relating to potential applicability to management of inpatients as well.

Theoretical Framework and Methods

Our proposed data display was based on three visualization theories—distributed cognitive theory, relational data display framework, and Gestalt’s principles. Glucose-insulin visuals were created using Tableau® 9.3. The following sections will describe theories and their applications in our display.
Distributed Cognitive Theory

When clinicians interact with computers, their cognition is distributed in two spaces—internal and external. The internal space represents clinician factors such as attention, memory, knowledge, experience, language, reasoning, and decision-making. The external space represents computer factors, such as user interface design, screen navigation, and data exhibition and organization, among others [12]. For improved decision-making, we aimed to reduce distributed cognitive load related to short-term memory and data display interface.

Clinicians process external, visual information by recognition and recall. Our informal task analysis done for design purposes by the authors, from the perspective of a physician’s task of inpatient management of insulin dosing of patients with Type II diabetes indicates that current physician-EMR interactions and information processing flow require 13 steps to make decisions and are discussed as follows. Our intention is to use this analysis to define the framework that informs our proposed design, which will undergo evaluation during future iterations.

1. The physician’s undivided attention is needed to process information and navigate the EMR.
2. The physician retrieves a laboratory screen to view the results; the lab screen icon/menu corresponds to an external representation.
3. The physician consults the tabular display on Table 1 to read the CBG level; the tabular layout constitutes an external representation.
4. The physician perceives CBG levels as high/normal/low, referred as pattern recognition, which is an example of an internal representation.
5. Prior knowledge stored in long-term memory is then applied to understand CBG patterns, diagnostic, and treatment criteria, all of which are derived from an internal representation. Abnormal CBG values may necessitate insulin adjustment.
6. The physician then assigns abnormal CBG values to short-term memory.
7. S/he switches task and attention to locate medication screen in the EMR.
8. S/he retrieves medication screen located on a separate tab in the EMR.
9. S/he consults the tabular display on Table 2 to read the insulin dose.
10. S/he perceives insulin levels as high/appropriate/low, referred as pattern recognition.
11. Prior knowledge stored in long-term memory is then applied to understand insulin dosage, diagnostic, and treatment criteria.
12. Again, knowledge is combined with the recalled CBG level, and a decision is made about a dose change.
13. If adjustment is needed, medication order entry screen is consulted, if not, monitoring continues.

The entire process is delayed since two screens have to be consulted with several numbers in mind. Repetition of the process for different patients results in the unnecessary investment of time, click-burden, and stress.

To reduce mental strain related to the recall, we eliminated the internal/intrinsic tasks linked to short-term memory by reducing the external/extrinsic load. A single, integrated screen model is created by merging two relational tabular displays that will limit the decision-making steps to 6, described as follows:

1. The physician’s undivided attention is needed to process information and navigate the EMR.
2. The physician retrieves an integrated data display screen to view glucose-insulin values.
3. S/he consults the new graphical displays that are introduced in the results section below.
4. S/he perceives CBG levels as high/normal/low, referred as pattern recognition in context with high/appropriate/low insulin levels.
5. Prior knowledge stored in long-term memory is then applied to understand CBG-insulin patterns, diagnostic, and treatment criteria. Abnormal CBG values may necessitate insulin adjustment.
6. If adjustment is need, medication order entry screen is consulted, if not, monitoring continues.

Relational Data Display Framework

A common theme across papers surveyed, beginning with Hutchins et al. [13] in 1985, and as recently as Gong et al. [14] in 2009, is that the closer the internal representations of a task are to the external representations depicted through the dimensions of a relational display, the more successfully a clinician can complete a search task and reach their goal [13-15]. More specifically, the proximity of scale between the represented and representing dimensions, particularly when numerical clinical data are involved, is key in providing the optimal displays [14]. This is also implicitly noted in the work of Bauer and colleagues [16] in that maximizing the degree of external representations, both as tables and graphs, can improve clinician understanding and subsequent action, though the representational effect is always a factor in creating a disparity between clinicians’ understanding of the data.

![Figure 2 - Line chart: the Trends of CBG and Average of CBG for Day](image)

Properties of the display are determined by properties of its dimensions. Dimensional properties are measured in scales. The four scales types include nominal, ordinal, interval, and ratio. Nominal scale is the lowest form of measurement scale. The numeric values classify characteristics of people, objects, or events into categories. Ordinal scales have categories arranged in some meaningful order without magnitude. In interval scales, the distance between ordered category values are equal. Ratio scales are most precise level of measurement and possess magnitude, equal intervals, and an absolute zero. The scales selected for our project are given in Table 3.

Gestalt’s Principles of Visual Perception

Relational and/or graphical displays that optimally align the cognitive and perceptions of innately distinct objects into related groups can minimize clinicians’ cognitive load while maximizing memory and recall [17]. Four Gestalt’s principles enhance cognition and improve decisions including similarity, proximity, connection, and enclosure.

Method of Evaluation for Design Purposes

An initial inspection was conducted by the authors and then an extended to group of 13 with extensive experience in the clinical informatics domain. The inspection was informal in nature, with the intention of soliciting empirical responses to guide further development.

Results

The goal of the highlighted table in Figure 1 is to facilitate pattern recognition of high and low values. The display is grouped based on Gestalt’ similarity principle. The grey CBG gradient filter is grouped based on similarity and proximity to display the glycemic values. Color distinguishes abnormal values for selective attention and hastening information processing, aligning with distributed cognition principles. We also introduced the dimension of time as an ordinal scale, according to relational data display principles. The goal of the line chart in Figure 2 is to display longitudinal CBG values stratified by time of day on the top panel and average daily glucose value on the bottom panel. This display improves upon current glucose displays in the EMR which are most commonly time-ordered tabular displays that do not clearly group values at similar time points (i.e. breakfast values at 6 am are not grouped together but time-ordered between 22:00 values and 12:00 values). Consistent color patterns are chosen to highlight correlated data across the graphs (i.e. all 06:00 glucose values are blue). The display is grouped based on Gestalt’s law of similarity, proximity, connection, and enclosure, as well as building on the distributed cognition principle of proximity compatibility.
The goal of horizontal bar chart in Figure 3 is to display both the capillary glucose reading and the corresponding insulin dose administered at the concurrent time point. This allows clinicians to correlate the insulin dose with the corresponding glucose reading to assess the appropriateness of the dosing. For example, the 30 units of insulin administered at 22:00 achieves adequate control at 06:00 (glucose range 82-118 mg/dL); however, the 14 units administered at 18:00 with dinner does not match the carbohydrate intake at dinner, as reflected by the elevated readings at 22:00 (range 190-220 mg/dL). The display is grouped using Gestalt’s similarity, proximity, and enclosure principles. Distributed internal and cognitive load is reduced by merging two disparately located data tables on a single screen.

The goal of the line chart-vertical bar chart in Figure 4 is to display the average glucose for each time period and the insulin dose administered at that time. This display is particularly important because clinicians often want to trend summary glucose data over several days prior to adjusting insulin dosing. This helps avoid over or underreacting to any single value. However, it still allows for easy recognition of hypoglycemia, an important safety concern, along with the dose of insulin administered that may be potentially related to the low glucose value. The display is grouped based on Gestalt’s law of grouping and the distributed cognitive load is lowered by merging table 1 & 2. The inherent relational data display principles are also applied in further representation of internal dimensions as external dimensions depicted in such a way as to reduce the difficulty of clinician understanding and appropriate intervention.

From the initial inspections by the authors, as well as the empirical evaluations of the extended informatics group, the set of theory-grounded data display was well received. Figure 4 below was especially commented as the easiest to interpret, because “having insulin doses and glucose values displayed in proximity reduced the need for screen switching and internal representation, appreciated by clinicians.”

**Discussion**

Optimized management of patients with insulin dependent diabetes in the hospital setting is critical to improved patient outcomes since such patients have increased morbidity, mortality, and longer lengths of stay. Clinicians must monitor patients’ capillary blood glucose level and insulin dosage, which necessitates information from different parts of an EMR system to analyze and intervene cognitively. Today’s prevailing EMR data displays are inadequate to meet clinicians’ cognitive needs, due to data storage in different places within the system that interrupt cognition or presented in tabular formats that make it challenging to identify actionable trends. This also increases cognitive load, reduces intellectual performance, increases errors, and ultimately results in sub-optimal task completion [18]. Our belief is that if related variables required for management of diabetic patients are well represented externally via a relational data display harnessing principles of distributed cognition, then the clinician tasked with managing glycemic management will have less cognitive load and fewer potential interruptions from
information foraging, which may lower or eliminate associated cognitive costs.

Limitations and Future Work

Although the proposed display is grounded in theory, the development team has the complementary expertise in clinical, informatics and programming skills. It is essential to conduct a formal evaluation regarding its effectiveness and efficiency in clinical practice. Future work including a fuller analysis of task, users, representation, and function is necessary to inform experimental design as proposed by Zhang et al. [19]. This will provide further user feedback prior to formal experimental testing. Additional work will involve options to change the representing dimension for time from an ordinal to an interval scale to expand the evaluation of variables across a wider time span.

To determine the proposed display’s effectiveness in clinical practice and potential to decrease cognitive load, it will need to be integrated into an EMR. Only then can the implementation, usability, and effectiveness be evaluated. Study results and user feedback will inform ongoing opportunities for improvements in the data display and identify additional clinical variables amenable to similar relational displays.

Conclusion

Overall, our proposed insulin-glucose data display strategy seeks to: reduce the intrinsic load by minimizing the screen navigation task and clicks, reduce the extrinsic/external load by merging insulin dosage and glucose level tables into one display, and reduce the extrinsic and germane load. Theory-based relational information displays using principles of cognition, distributed cognitive tasks, and Gestalt theory can help address challenges in inpatient glucose management. All told, design collaborations between informaticians, computer programmers, and clinicians are essential to solving common clinical problems.

Abstract
The implementation of an Electronic Health Record has many benefits; but when it is not available, it can impact patient continuity of care. If there is no support, or a failure to guarantee the continuity of services, contingency plans have to be implemented to overcome the information disruption. End users are in direct contact with the information system, and are responsible for documenting patient clinical information. Focusing on them, we propose the design, development, and validation of a survey to evaluate the beliefs, knowledge, and perceptions of end users, about the Electronic Health Record contingency plan. Preliminary results showed that even when there were less downtime periods, end users perceived that they did not have adequate training or information about how to go through the downtime event.

Keywords:
Electronic Health Records; Perceptions; Health Care Surveys

Methods
Setting
Hospital Italiano de Buenos Aires (HIBA) is a non-profit health care academic center, with over 2,800 physicians, 2,800 other health team members (including 1,200 nurses) and 1,900 administrative and support employees. HIBA has a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 1,000 home care beds, 25 outpatient clinics, and 250 associated private practices located in Buenos Aires city and its suburban area. It has a Health Maintenance Organization that covers more than 150,000 people and also provides health services to other people who are covered by affiliated insurers. In addition, HIBA is a teaching hospital, with over 30 medical residency-training programs and 34 fellowship programs [12].

Survey
This is a mixed method study that included a survey design and validation. We designed the survey in 4 phases:

- Phase 1: Literature review and qualitative research
- Phase 2: Panel Expert Review
- Phase 3: Qualitative pretest
- Phase 4: Survey Validation

Phases 1, 2 and 3 are described in [13]. We continued analyzing phase 3 in this paper, recruiting new participants. In preliminary phases, the survey was paper based, in successive iterations we used Google® Forms, and finally we implemented the survey using REDcap® platform. We recruited participants through snowball sampling and key users representatives. The validation phase was carried out on active personnel of HIBA in 2015. They performed the following tasks using the EHR:

- Data visualization
- Image and lab results visualization
- Clinical notes
- Vital signs
- Request of laboratory orders
- Drugs prescriptions
- Referral Request
- Drug administration documentation

Exclusion criteria were:
- Refusal to participate in the study
- Workers with less than 6 months in the institution
- EHR super-users

Introduction
Following the impulse given by different Electronic Health Records (EHR) Incentive Programs, the adoption of a Health Information System by organizations has increased [1]. Many benefits are attributable to EHR adoption [2,3], but when it is not available, it can impact health services costs and the patient continuity of care [4]. If problems related to standardization and protection of critical operative processes and relevant information are not solved, it is not possible to maintain the continuity of care [5]. The nature of hospital procedures has an impact over the patient's information management. If there is no support, or a failure to guarantee the continuity of services, different procedures should be initiated to protect important information [6,7]. Institutions must implement contingency plans for the maintenance of their systems during critical moments, and to overcome the information disruption. There are guides, such as SAFER, that assesses socio-technical aspects of contingency plans and identifies safety practices associated with EHR unavailability [8].

In that context an important point is the way that end users are engaged. In general, contingency plans tend to prioritize technical aspects [9,10] and responsiveness of it [11]. The importance of taking into account end users is because they are in direct contact with the information system, and are responsible of documenting the patient clinical information. Focusing on end users, we proposed the design, development and validation of a survey to evaluate the beliefs, knowledge, and perceptions from end users, about the EHR contingency plan.
• Personnel that have not used the EHR in the last 12 months

We used Stata® 13 and Microsoft Excel® for the quantitative and descriptive analysis. For validation and to evaluate the internal consistency for complete sections of the survey, we used Cronbach’s alpha. In addition, we included semi-structured interviews to respondents, looking for agreements, disagreements, and new domains.

This research did not imply any additional risks for participants, and was executed in accordance with national and international norms. All data of the study was treated with maximum confidentiality and in anonymous way.

Results

During the pre-testing phase we evaluated and assessed the post-contingency of a planned downtime. Seventeen participants that completed the survey were interviewed with a semi-structured questionnaire, and they commented aspects related to wording and semantics. The identified domains with previous phases were:

• “If there is a downtime of the system or it is unavailable”
• “About the communication of the downtime”
• “During the downtime or unavailability”
• “When the system is available again”
• “Considering the downtimes of the EHR over time”

The most important findings were related to “communication”, “an alternative work plan”, and “training”. This resulted in the creation of new variables, which were: knowledge of the procedure, plan implementation, end user’s response capacity, accessibility during downtime, post-contingency data restoration, communication between the health informatics department and other areas, workflow impact, registration possibilities and time needed to activate the plan. The result was the pre-tested qualitative survey. For this phase, participants’ characteristics can be seen in Table 1.

Table 1 – Pre-test phase participants’ characteristics

The number of resident physicians and attending physicians were balanced. 35% of physicians have an internal medicine certification, 12% were endocrinologists, 6% pulmonologists, 6% pediatricians, and 6% were orthopedists, among others. About the working place, 59% in inpatient care, 35% worked in ambulatory care, and 6% in emergency care. The length of service was between 1 to 5 years for 35%, 6 to 15 years for 22% participants, and more than 16 years for 27% of the participants. Related to the time needed in working hours to communicate a downtime, 43% of them mentioned “less than 1 hour”, 14% more than 1 hour, and 43% did not know and could not estimate the time.

In relation to the access of information needed to work from the EHR, 85% stated that they could not access needed information. 80% mentioned that during downtimes they could not record clinical or other information required, in the patient EHR. 59% considered the information documentation in the EHR was affected by downtimes.

About perceptions of the frequency of downtimes along time, four (10%) participants considered that there are more downtimes than before, twenty five (64%) that there are less downtimes, six (15%) referred that there are the same events before, and four (10%) did not give an answer.

The estimated time to complete the survey was around 5 minutes, and the estimated time to complete the interview was 15 minutes. The calculated Cronbach’s alpha for structured and completed items from the domains identified was 0.76.

In addition we compared results to assess agreement between the presented answers in the interview compared to the survey answers. The qualitative analysis of the interviews is still in progress, up to now we did not find any major discrepancies with the results of the survey.

Discussion

The unavailability of the EHR during downtimes could result in important patient safety concerns in institutions that are not prepared to confront the contingency [8], for this reason we designed a survey to evaluate beliefs, knowledge, and perceptions that end users have, in relation to the contingency...
plan of the EHR. We identified formerly ignored domains, and even with partial results of the preceding survey versions, this reassures the need of taking into account end users to design contingency plans.

In this phase the participants were from non-critical areas, with proper experience in the hospital (more than 1 year of length of work in their areas), but just half of them knew the exact procedures to apply contingency protocols, with previously described consecutive problems related to loss of information and patients’ care [14]. Likewise, we found that the majority of participants referred that they wanted to establish a work plan, either protocolized, or created according to prior experiences of their areas. In addition, most participants reported not having received training on the contingency work plan during downtimes. Although there is a work plan created in case of downtimes, the personnel find their own contingency mechanisms, which responded to the needs created among working areas, which according to participants, have been effective and sustainable over time. It is also worth mentioning the great acceptability that they have to receive training in the area of contingency.

Another interesting point is related to the communication needs between areas during a downtime, since there is evidence that communicating planned downtime in advance will minimize frustration and confusion about why the system is unavailable [15], we found that a minority had the need to communicate with the Health Informatics Department. We consider that this is due to existence of mechanisms already created in the different areas, where they can overcome the eventuality without requiring external advice. It is interesting to mention that most respondents described needing a relatively short time for downtime warnings. This may be a reflection of how organized they are with their own contingency mechanisms, to perform actions such as patient support, medical appointment assignments, and general consultations. However, in critical areas, we noted that they prefer being notified earlier in order to coordinate complex activities to preserve a good performance of their activities. As it is usual to expect during downtimes, most respondents informed not being able to access clinical records and information that they required. This could also mean a loss of data that would be impossible to recover later, with possible adverse consequences in the patient's future care. Despite this, most of the respondents mentioned that there are fewer downtimes events in relation to former years, and thus greater stability and confidence in the system and this is concordant with preceding findings that shows the expression of the stability that end users tend to demonstrate in association to periodical revision of contingency plans [16].

As a limitation of the work we find that there is certain resistance to answering the survey, apparently not because of the particular topic of the survey, but to find time during work hours to answer the questionnaire. We did not consider that there is selection bias, having recruited representative samples of different working areas of the hospital. The potential information bias that could be found in surveys was improved during each phase creation and process, with the design and identification of different domains [17]. As strengths of the survey we found that it was possible to design it to be completed in an average of five minutes. Because this is a cross sectional single-center study we cannot generalize our findings to be valid to assess similar dimensions in end users of others health centers. Future multi-centered studies are needed to assess the generalizability of our results.

The internal consistency was acceptable, but only reliability does not imply validity. The validation is a process that started in the first publication that we made before [13]: the first step was to establish face validity, and then the content validity with the Panel Expert Review; the next step was pre-testing the survey on a subset of our intended population, and finally was important to check the internal consistency of questions. We presented in this paper the pre-test and the evaluation of internal consistency. We are not using any score; therefore we did not perform any test--retest reliability. There were no possibility to evaluate convergent or discriminant validity or criterion validity because there is no gold or reference standard to compare. Iterative work is needed to develop future implementation for different institution’s structures.

The partial qualitative analysis of interviews did not show any major discrepancies at the moment. Once we finish the qualitative analysis and the survey is implemented, it could be used to assess different contingency plans in any institution that uses an EHR, as the identified domains are common in health environments related to patient care. The assessment of the different domains and subsequent knowledge could lead to new interventions that could provide adequate training to face planned or unplanned downtime events. Related to this we are planning to do simulations for training and evaluation of knowledge of contingency procedures by the second semester of 2017.

Conclusion

This paper showed the continuation of our study about perceptions, beliefs, and knowledge of end users related to the contingency plan of EHR. This is an important topic to explore, that could lead to potential actions to improve mechanisms related to proper design and execution of future contingency plans. In our case, end users perceived that they did not have adequate training or information about how to go through the downtime event. Even with less downtime periods, the end users perceived the need of training and communication.

Abstract

Despite the continuous technical advancements around health information standards, a critical component to their widespread adoption involves political agreement between a diverse set of stakeholders. Countries that have addressed this issue have used diverse strategies. In this vision paper we present the path that Chile is taking to establish a national program to implement health information standards and achieve interoperability. The Chilean government established an inter-agency program to define the current interoperability situation, existing gaps, barriers, and facilitators for interoperable health information systems. As an answer to the identified issues, the government decided to fund a consortium of Chilean universities to create the National Center for Health Information Systems. This consortium should encourage the interaction between all health care stakeholders, both public and private, to advance the selection of national standards and define certification procedures for software and human resources in health information technologies.

Keywords:
Medical Informatics; Public Health Informatics; Organization and Administration

Introduction

Health care spending in Chile has grown considerably over the last years. In 2015, Chile spent 7.7% of its gross domestic product (GDP) on health care [1]. Sixty-one percent of the total spending was allocated to public health services which covers around 80% of the population. From an administrative standpoint, public health care provision is organized into 29 independent health departments, in charge of regional hospitals and secondary outpatient clinics; primary care administration is in charge of almost 300 independent municipalities [2]. A myriad of private health care providers are also available, ranging from large, multi-hospital health care networks to single physicians’ private practices. There is significant cross-over movement of patients from the public to the private systems and vice versa, with some private providers having up to 50% of their patients coming from the public system [3]. From the financing perspective, working citizens are mandated to contribute at least 7% of their monthly income to health care coverage, which can be obtained through the public insurer, the National Health Fund (FONASA) or through multiple for-profit health care insurance companies (ISAPREs). This complex organization generates a massive fragmentation of patient information.

Until 2008, the implementation of electronic health records (EHRs) was mainly driven by individual efforts at private hospitals and academic medical centers who could afford such projects [4]. However, in 2006, and after several unsuccessful attempts, the government declared the digitalization of the health care system as a key priority. The driver for that process was, for almost 10 years, a public procurement framework called Health Care Network Information System (SIDRA, for its acronym in Spanish). Through SIDRA, public health departments could buy pre-assessed health information technology solutions [5]. Although interoperability was one of the concerns when creating the SIDRA strategy, initially there was no emphasis in the adoption of standards. Moreover, the SIDRA strategy did not include private health providers, which created additional information silos.

Although to date more than 70% of all primary health clinics have adopted some kind of electronic medical record solution [6], each one of the 29 public health departments operates as an information silo incapable of communicating actionable patient information with each other. This situation becomes more complex if we take into account existing information silos among private health care providers, making it extremely difficult to monitor the population’s health using health information technologies.

Within this context, strategies to advance the adoption of health information technologies have been recently given priority by the current government as a driver that could lead to economic growth and, at least in part, help reduce health care equality gaps. To support this effort, the National Development Agency (CORFO, for its acronym in Spanish) created the Health + Development program (S+D, for its acronym in Spanish), whose aim is to set up a public-private collaboration to establish the needs, current gaps and priorities for the health information technology sector. With the support of the RAND Corporation and different national private and public stakeholders from government, industry and universities, a roadmap emerged to streamline the development of the Chilean health information technology sector. S+D’s main objective is to promote competition and innovation among health information technology providers by facilitating the adoption of standards and promoting the coordination among the different stakeholders (see Figure 1). Towards that goal, and as the first approved project, CORFO funded the creation of the National Center for Health Information Systems (CENS, for its acronym in Spanish). The
center would initially focus on interoperability, software certification, and the promotion of formal health informatics training programs to educate and certificate advanced human capital in this domain.

Public-Private coordination as a key element

The S+D program began its operation as a government agency with no prior experience in the health information technology sector. As such, finding support from the health IT experts and government health authorities was one of its first priorities. To achieve the above, the team conducted over 100 interviews and working group meetings, promoting private-public discussions. The results of these discussions were documented and validated by all participants in several published reports [7, 8, 9]. Those reports condensed the existing knowledge and perceived needs of the country’s main stakeholders in this domain.

Additionally, and to ensure political support, the S+D program convened a diverse set of government authorities and representatives from the private sector, academia and patients to participate in its board of directors. This independent board of directors was assigned the tasks of prioritizing projects, assure the communication between the different actors of the health IT sector and, in the future, enforce the use of standards for interoperability.

After obtaining public and private commitment to the S+D strategy, the board of directors defined health care information interoperability as the main priority. In the context of a national health information technology strategy that had started almost 10 years before—which indeed advanced the adoption of electronic health records—it was now important to ensure the correct flow of patient information as a way of generating efficiencies in the use of resources and, ultimately, provide better care. Following RAND corporation’s recommendations, the S+D program (together with CORFO) secured funding for the creation, through a public call for proposals, of a National Center for Health Information Systems that should largely focus on health information interoperability.

Public funding for a private non-profit corporation

One to the main issues faced by economic development agendas are the changes that occur when new governments are installed, and Chile has been no exception. A proven mechanism to provide continuity is to involve and commit the private sector or the academia in the development of such projects. CORFO, as the agency in charge of promoting innovation and entrepreneurship has a longstanding experience in creating such alliances and was, therefore, chosen as the appropriate mechanism to fund the creation of the National Center for Health Information Systems.

Establishing such a center in the health care domain presented additional challenges. In comparison to other relevant economic activities in Chile, such as mining or agriculture, the development the health information technology sector (according to the strategy defined by the S+D program) also had to reduce the inequality gap between private and public care. Such goal was not entirely possible to meet if standards and certifications were left in hands of the health IT industry alone, as it has been the case in previous, even successful, experiences elsewhere [10]. The decision was then to invite Chilean universities to participate in the call to create the center, and to require the establishment of a new non-profit organization to host the newly constituted center. It was anticipated that this decision would also help to consolidate different teams of experts currently working in the health IT domain and, therefore, strengthen national human capacities.

Finally, Universities were required to include private entities in their proposals so they could contribute to the sustainability of the center in the long run but, through established mechanisms of participation, establishing a diverse representation and ensuring objectivity and reducing conflicts of interests.

Current Advances and Proposed Organizational Structure

The request for proposals opened in July 2016 and after a review by national and international panelists the project was awarded to consortium of five Chilean universities, with support from public and private health care providers, national and international health information technology organizations, and national and international health information system vendors.

As anticipated, the center’s governance is a key issue to ensure its sustained success and independence. To make sure this is the case, the center has been designed to have a board of directors constituted by members designated by the funding universities, as well as representatives from national public health entities (Chilean Ministry of Health, FONASA), software vendors and independent members (Figure 2). During the first year of the center’s operations, the main task will be to establish its by-laws and constitute it as a non-profit entity according to the requirements established by Chilean legislation. We anticipate that this process will be completed during 2017. One of the critical components of these by-laws will be the explicit definition of the mechanisms required to add new participants to this center, with the goal to continuously ensure a broad and diverse representation.

The main lines of action proposed by CENS are the following:

- Define interoperability standards: the center will not recreate previously existing standards but will work with internationally recognized standard definitions and organizations to identify the best available ones for the Chilean market, and broker their adaptation to the local needs when required. To accomplish this, CENS has initiated cooperation agreements with international entities such as IHE-Europe and Salud.uy.

- Establish software certification and testing procedures: the center aims to establish explicit and transparent certification criteria and testing
procedures. The center will not conduct testing activities but will outsource those activities to adequate testing facilities that already operate in Chile.

- **Establish professional certification procedures:** given the limited availability of formal training programs in health informatics in Chile, the workforce is today constituted by professionals that have mostly learned on the job. Based on international experience on the subject [11], the center will establish professional profiles and certification procedures to add transparency to the job market in health informatics.

- **Technology surveillance:** the health IT domain is changing fast and will continue to do so. As a consequence, the center will establish formal technology surveillance procedures to ensure that its standards and recommendations follow internationally respected best practices.

- **Consulting:** as a vehicle to ensure transferability of the knowledge generated through its activities, the center will establish formal consulting services that will be available to all stakeholders in the Chilean health IT market.

**Figure 2 - The proposed organizational structure is composed by a Board of Directors with members named by founding universities as well as individuals representing a set of domain expert committees. These committees will be the setting in which most stakeholders will interact to define proposals to the Board. Additionally, the center will establish a set of external international advisors.**

**Conclusions**

As a private-public strategy, achieving health information interoperability for the Chilean health system, remains a communication and cooperation challenge. As of today the success of the predefined projects and roadmap lies mainly within the “social capital” that was built by Salud+Desarrollo. Although there is broad consensus among stakeholders on the path to follow and the steps needed to do so successfully, a critical aspect is the sustained political commitment of S+D’s board of directors. Chile is facing a presidential election during 2017, and CENS will have to consolidate its role in the ecosystem and become the public space for keeping that social capital. To do so, the social capital and public trust needs to be soon transformed into concrete deliverables that prove to be useful for all actors in the Chilean health care system.

At the same time, the independent nature of the entity requires a business model for sustainability that has to consider both local and international markets, making the need to participate in the international fora, highly relevant.

Finally, the recent changes in the digitalization strategy of the Ministry of Health, changes that include the end of SIDRA as a mechanism for buying health information system solutions, creates new demand for internal capabilities since public health departments will have to create their own frameworks at the same time they are required to abide by new interoperability standards.

School of Epidemiology, Public Health and Preventative Medicine, University of Ottawa, Canada

Abstract

Colorectal cancer screening access within a rural and remote health care environment represents a complex systems problem. Existing modeling approaches are inadequate in their representation of health system complexity. A combined Collaborative Information Behavior (CIB) and Continuity of Care framework was developed to model the health care processes involved in screening access over time. This framework highlighted necessary information behavior supports and system gaps in screening access, supporting development of targeted informatics solutions to improve screening access and cancer outcomes.

Keywords:
Public Health Informatics; Models, Theoretical; Continuity of Patient Care

Introduction

Health care systems are complex adaptive systems, and understanding health system interrelationships and context may provide insights that are not readily apparent when studying system components in isolation [1,2]. In conceptualizing health system complexity, modeling can provide important insights into health system interrelationships and impacts of proposed health transformation initiatives aimed at improving quality of care [3,4]. Qualitative modeling is a necessary initial step, as complex processes must be clearly understood before they can be effectively translated into more formal modeling approaches [5,6,7].

Existing health care process modeling approaches adapted from Business Process Management literature (e.g., Workflow patterns or languages such as Unified Modeling Language or Business Process Modeling Notation) are limited in their ability to capture health system complexity, as they are often specific to data or people, assume that processes are static, and are unable to describe interrelationships between them [5,7,8,19]. Knowledge intensive processes and connected communities bring with them added complexity that cannot be modeled by rigid control flows or by assuming a common frame of reference about how participants will behave in certain roles [19, 20].

Information generation, utilization and management form much of the basis of health care. Understanding relationships between health information systems and its users and processes is necessary for successful implementation [3,9]. However, information management processes in healthcare are often dynamic and connected over time and across different tasks and providers [14].

The Northwest Territories is a rural and remote region of Canada with a large indigenous population where colorectal cancer incidence is high, outcomes are poor, and screening rates are lower than other parts of the country [10, 11]. Access to colorectal cancer screening has been identified as a strategic priority in the territory for improving screening rates and patient outcomes [12]. Colorectal cancer screening access in the Northwest Territories represents a complex health system problem, as it involves cyclical multidisciplinary health care processes within a distributed health care environment occurring over many years. Health system complexity may contribute to health outcome inequities among marginalized rural and remote, and indigenous populations [13]. The ability to effectively model health system complexity is a necessary first step to develop and implement health transformation initiatives to improve colorectal cancer screening access and patient outcomes within complex health care settings like the Northwest Territories.

As described above, existing modeling approaches often do not account for dynamic complex processes that take place over time. New modeling approaches that capture the interrelationships between people and information over time is necessary to understand health system complexity and develop targeted health transformation initiatives, such as Electronic Medical Records (EMRs) that can improve quality of care. The objective of this paper is to address the above need by developing a qualitative modeling approach integrating Collaborative Information Behaviour (CIB) and the Continuity of Care frameworks. The integrated framework allows us to describe and understand the complex interrelationships between people and information within colorectal cancer screening access and how they evolve over time.

Methods

Conceptual Framework

Collaborative Information Behaviour (CIB) provides a framework for describing information behavior within a multidisciplinary health care team, categorizing health care processes in the form of health system agents, interactions and information problems and their resulting system behaviors influenced by system context [14]. It is triggered by high problem complexity, lack of immediate information access, lack of domain expertise, and fragmentation of information resources, all of which are present in colorectal cancer screening in the Northwest Territories [14].

Continuity of Care, as a cornerstone of care access, provides a framework for conceptualizing health care access over time,
health system stakeholders. Participant validation engaging both study participants and access were also completed as an alternate method of access problems and contextual factors influencing screening general study results outlining colorectal cancer screening study participants from the study. Community presentations of through review of exploratory process models by one to two process with analysis decisions being recorded in the logbook. A codebook was iteratively developed through regular analysis meetings following the completion of data collection. A codebook was conducted concurrently with the data collection phase, while further code refinement and data analysis occurred following the completion of data collection. A codebook was iteratively developed through regular analysis meetings between research team members throughout the analysis process with analysis decisions being recorded in the logbook. Participant validation of health system models was performed through review of exploratory process models by one to two study participants from the study. Community presentations of general study results outlining colorectal cancer screening access problems and contextual factors influencing screening access were also completed as an alternate method of participant validation engaging both study participants and health system stakeholders.

Results

Qualitative Health System Model Construction

Information behavior, or the utilization of health care information within colorectal cancer screening, ultimately links all health system components. Information behavior is generated by interactions between health system components, including health system agents and decision nodes, and forms the health system interrelationships across the continuity of care streams of relational continuity (patient-provider interactions), management continuity (provider-provider interactions), and informational continuity (provider-information system interactions) that make up colorectal cancer screening access. In our study, information behavior is used to represent health system activities. By examining information behavior within the exploratory process models, it is apparent that health system information processes enable information flow through the health system to support the patient interactions required for colorectal cancer screening access.

Qualitative health system models of colorectal cancer screening access were developed as swimlane diagrams. Fig. 1 provides an example of one model and shows an example of information behavior generated from a primary care encounter interaction (relational continuity) between patients and providers (health system agents), subsequently generating the decision node sequence of screening initiation, risk stratification, and FIT initiation. Fig. 1 also highlights the complexity in colorectal cancer screening. Records of previous care may be obtained from historic documents (management continuity) or retrieved from the health centre chart (informational continuity) that inform the decision node of screening initiation for the current primary care encounter. The decision node sequence generated by the encounter is then documented in the primary care encounter note (informs management continuity) and subsequently stored in the health centre chart (informational continuity). As demonstrated by this sequence of health care processes, information flow from patient interactions through decision nodes, management continuity, and informational continuity is necessary to enable screening access.

Swimlanes were used to show sequential activities and responsibilities over time and to organize continuity of care categories of relational continuity, managerial continuity and informational continuity, with CIB components of health system agents (people and information systems) within each swimlane [8,14,16]. The model was developed according to health system processes described by participants in the interviews.

The CIB problems, labelled as decision nodes within the model, formed a link between relational continuity, shown as interactions between patients and providers, and managerial continuity, shown as provider-provider interactions. Patient-provider interactions identified health issues needing to be addressed in screening, shown as decision nodes, which generated information behaviors by providers to address the need, either by another provider or the same provider later in the colorectal cancer screening sequence. These links between different providers or the same provider at different times within the health system were achieved through medical record documents such as referrals, encounter notes, or consultation notes. Information behaviors were identified as links between health system agents, decisions and documents within the health system.

Health System Complexity in Colorectal Cancer Screening Access

The combined CIB/Continuity of Care framework provided two types of insight. First was the identification of information behavior issues to provide insight on screening access. Second was identification of contextual factors that impact screening access.
Information Behavior Issues Impacting Screening Access

Information behaviors were identified as foundational health system interrelationships involved in colorectal cancer screening access can identify areas where information behaviors may be optimized to improve screening access. Information behavior gaps in colorectal cancer screening access identified within models included poor quality referral documentation, scheduling complexity, inconsistent results reconciliation and follow-up documentation, siloed information systems and discontinuity in screening recall.

An example of information behavior issues in scheduling complexity is whether appointments are coupled or uncoupled. Coupled pre-colonoscopy consultation and colonoscopy appointments are scheduled concurrently to occur over a short timeframe (i.e. – single travel encounter) compared to uncoupled appointments, which are scheduled separately over a longer timeframe and may require multiple travel encounters. Another information behavior issue leading to system complexity within colonoscopy screening access was the number of patient and provider interactions at the time of pre-colonoscopy consultation and colonoscopy procedure and the travel required on behalf of patients and endoscopists. System complexity in colonoscopy screening access increased with the number of providers involved, as well as with increased travel requirements among both patients and providers.

Finally, patient information throughout the territory is often siloed, increasing the risk of missed or duplicate information, and requiring providers to access multiple information sources to access the information required to support decision making. As a result of siloed information some providers described getting triple copies of some results and having to keep manual records to track what reports they have seen.

Contextual Factors Impacting Screening Access

The combined CIB/continuity of care framework also identified contextual factors impacting screening access including geographic factors such as the need for medical travel, social factors such as patient awareness and residential school experiences, and health system factors such as rebooking forgiveness and locum-based practice influencing colorectal cancer screening access. For example, a locum practice environment may make screening initiation more difficult due to lack of familiarity with territorial practice guidelines, as well as lack of continuity with individual patients. Poor attention to social determinants of health including job insecurity, housing insecurity, and food insecurity, may also present a barrier to screening initiation, as patients may be less interested in preventative care when their basic needs are unmet.

Discussion

While systems modeling is an important tool in health system transformation, established Business Process Management modelling approaches are limited in their ability to fully characterize health system complexity such as dynamic and connected processes [5, 19, 20]. This paper addressed that issue and presented a combined CIB/continuity of care framework to identify and describe complex health system interrelationships and information behaviour gaps. Our modeling framework provides two key type of insight. First it enables us to understand patient flows through the health system over time through relational continuity, but also the information behaviour interrelationships required to facilitate the management and informational continuity aspects of care.
access. Second, our framework also helps identify contextual issues that may further impair information behaviour interrelationships. We provided proof of concept of our framework using a case study of colorectal cancer screening access in the Northwest Territories.

Conceptualizing the complexity of information behaviour interrelationships in colorectal cancer screening access helps identify areas of excess complexity where streamlining of processes is required to prevent system failure, or areas of low complexity where additional system supports are required. To support colorectal cancer screening access in rural and remote health system environments such as the Northwest Territories, targeted informatics tools such as endoscopy referral forms, reporting forms to support recall reconciliation, and enterprise information systems may support improved screening access by supporting sequential information behaviors within the health system. However, these informatics solutions must be considered in light of contextual factors such as geographic, social and health system factors.

Another benefit of modeling frameworks is that they provide a visual representation of complex health system processes. The systems models generated through our combined CIB and Continuity of Care modeling framework can promote common understanding of the complexity of colorectal cancer screening access among health system stakeholders including physicians, other care providers and policy-makers.

Next stages of our research are translation of these qualitative health system models into a system design framework for quantitative modeling to support quantitative measurement of the potential impacts of proposed health system transformation initiatives. Limitations of this research is that our study took place in one context and other CIB and Continuity of Care issues may emerge in other settings. Our modeling approach may be applied to other health system access problems to inform targeted health informatics solutions to optimize care access.

Conclusions

A combined CIB and continuity of care framework can be applied to qualitative modeling of colorectal cancer screening access to conceptualize health system complexity. This framework supports understanding of health system interrelationships including information behaviour complexity and associated gaps to identify targeted solutions such as health informatics tools for improving care access.

Clinical Decision Support and Primary Care Acceptance of Genomic Medicine

Dian A. Chasea, Sherry Baronb, Joan S. Asha

a Oregon Health & Science University, Portland, OR, USA, b City University of New York, New York, NY, USA

Abstract

Clinical decision support systems (CDS) have an important role in the implementation of precision medicine, particularly for pharmacogenomics. This study examines potential factors for their acceptance by primary care clinicians. For this qualitative study we purposively selected five U.S. primary care sites with a variety of sizes, electronic health record vendors, and patients. We interviewed an average of seven clinicians per site. Clinicians placed a low priority on incorporating pharmacogenomics into practice. Other themes included the potential of precision medicine, clinician unfamiliarity with genomics, minimal evidence for primary care uses, additional costs and time burdens, workload, and a need to first successfully complete other electronic health record interventions. This study outlines issues in implementing primary care precision medicine and the role for genomic CDS. Currently there are significant barriers. With more evidence and the development of effective CDS, however, there is potential for turning each of the barriers into facilitators.

Keywords:
Decision Support Systems; Clinical, Precision Medicine; Genomics

Introduction

Genomics-guided precision medicine – the ability to individualize therapies and guidance based on an individual’s genetic makeup – has been a research target for over fifty years [1]. While there have been significant breakthroughs in oncology, primary care applications of genomics precision medicine have been limited [2]. But the potential is there. Just two of the CYP450 enzymes are involved in the metabolism of ninety percent of all drugs [3]. The expression of these enzymes can be predicted using genomic data, and patients divided into fast, normal, slow and non-metabolizers for a given drug. How an individual metabolizes a drug can determine whether a “safe” dose represents an ineffective treatment, an effective treatment, or an overdose.

Clinical trials are underway to demonstrate the value of using genomics guided precision medicine in primary care settings – ClinicalTrials.gov lists several hundred trials with potential applications in primary care [4]. Once demonstrated however, the deployment of this genomics based precision medicine in primary care will still face challenges. Effective CDS can increase the usage of genomic testing for primary care. Peterson et. al. [5], found that two-thirds of clinicians who had a genomics CDS available planned to order a genomics-based test, compared to only 13% in an earlier survey of those without a robust CDS [6].

This qualitative study, based on interviews with clinicians at five very different sites, examines some of the barriers to clinical decision support systems for precision medicine.

Methods

This study was conducted within the context of a larger study on the use of clinical decision support for workers’ health issues [7]. Five U.S. sites were selected based on maximum differences in geography, experience with using an EHR, and type of parent health care organization. All of the sites were implementing the patient-centered medical home delivery model. Subjects were selected with the assistance of an inside contact person based on their roles as clinicians (MDs, DOs, PAs, and NPs).

The data were collected using a Rapid Assessment Process (RAP) [8-9]. A multi-disciplinary team visited each of the sites and conducted both semi-structured interviews and observed clinicians using the EHR. The process utilized a set of structured tools (interview guides, observation templates, and overall clinic data); results and progress were reviewed by the team every evening, and presented to the clinic at the end of our visits.

The data presented here are largely based on semi-structured interviews, as we did not observe any use of genomics data in the clinics we visited. To start the conversation clinicians were asked “How would you prioritize the implementation of meaningful use, work related data, and genomic medicine CDS?” For those who asked for clarification we provided the example of pharmacogenetic dosing for coumadin. After they replied, we would ask them to elaborate. Probes included questions about their knowledge of genomic based precision medicine and what barriers they perceived to its implementation. Their responses were recorded and transcribed.

We followed guidelines for assuring rigor by triangulating (multidisciplinary researchers, multiple sites, different types of data), member checking (feedback to sites about results), auditing (tracking data gathering), reflexivity (researchers’ awareness of their own bias), and data saturation (gathering data until little more is being learned) [10]. Data were analyzed with the assistance of qualitative data analysis software in three ways. First, a template method was used to identify answers to our interview questions. Second, a grounded hermeneutic approach was taken to discover patterns and themes across sites. Finally, comments about the factors influencing precision medicine implementation and their connection to CDS were extrated, coded, grouped by themes, and interpreted.
Approval was obtained from the OHSU and NIOSH Institutional Review Boards as well as the IRB’s at the sites we visited.

Results

Participating clinics

Five sites participated. An average of seven primary care clinicians were interviewed at each site for this portion of the study.

The number of providers (Doctors of Medicine and Osteopathy, Nurse Practitioners, and Physician Assistants) at the sites selected varied from 5 to over 2,000; the geographic locations spanned both East and West Coasts and from the Gulf of Mexico to the Great Lakes; the type varied from community clinics to large academic medical centers, and the experience with EHRs varied from three to fifteen years. The EHR vendors included NextGen, AllScripts, and EPIC.

Themes

1. Priority for genomic CDS

Although the potential of genomic medicine was a motivating factor for the inclusion of genomic-related CDS for the most of the clinicians, none of those interviewed viewed genomic CDS as a higher priority than including other data, including work-related CDS, in the EHR. Factors that influenced these lower priorities were the interviewee’s personal unfamiliarity with genomic medicine, a lack of compelling evidence for better outcomes, the increased cost of testing, potential workflow interruptions, and the need for other, higher priority, EHR related interventions. Clinicians across all sites were intrigued by the concept, but did not believe genomic-based precision medicine was ready for wide application.

2. Perceived potential

The concept of individualized medicine was appealing to the interviewees. As one said: “I’m a little wary of it but I’m also excited because I think it will help us get closer to having an individualized plan for people that really is about who they are.” This knowledge could then translate into more effective treatments: “if there’s a way to pinpoint what medication would really be the best for the patient based... genetic makeup or, you know, whatever is going on, then I think that would be great... I have seen a lot of patients where we try one, two or three different types of IV treatments and it just doesn’t work and you have to wait so many months for it to kick in and if it doesn’t, then switch over... if there’s a way to narrow it down to... find... that best drug.” And they also thought it might help with risk assessment “I think it’s important to try to identify future risks for people, not just--which you can get at with cancer risks but-- so what are the future risks of you developing diabetes?” This positive attitude was consistent across clinics.

3. Clinician lack of knowledge

There was a wide range of familiarity with genomic medicine, from those who have worked in the field to those who profess ignorance: “we did some work when we were using Naltrexone for... so I’d be interested.” “Well, genomic information. Okay. So there’s -- and maybe I don’t know enough about it. ... I don’t think there’s a specific place that I would find it except I refer a lot of people to medical geneticists.” “I mean I manage a lot of patients, you know, each month and I don’t know anything about, you know, whether their genes tell me to do a certain thing.” Although our samples were not selected to allow quantitative analysis, it did appear that the larger clinics were more likely to have practitioners who were at least aware of current work in genomics.

4. Need for evidence

Some thought that they were getting enough “genetic data” by just reviewing the family history, while others cited a lack of trials showing significant benefits for primary care providers: “We do that already. Like, if the patient when they come in for physicals, we ask them family history.” “Nobody has actually linked any of those genetic markers to anything that we do.” This pattern appeared to be consistent across clinics.

5. Cost concerns

Not only were the additional tests viewed as adding additional cost for limited value, there was also the questions of who would pay for them: “It’s the cost containment. I probably would not [use genomic testing] if there wasn’t a huge difference in patient outcomes.” “I don’t even know if MediCal [state insurance] covers things [DNA testing for breast cancers] like this.” Cost concerns appeared to be more frequently measured by the community clinics.

6. Work flow issues

Without a perceived benefit, providers were unwilling to have interruptions on their workflow: “So that would involve additional blood work... I’m not sure how that would be incorporated into my work flow.” “It is not part of the flow.” This was a concern for all clinics, and appeared to be more prevalent for clinicians with prior EHR implementation experience.

7. Current EHR implementation and priorities

Even if the providers wanted to incorporate genomic information into their CDS, there are many priorities that were viewed as more important, including work-related data: “We can’t do everything...right now the priority is to make the system work for us I think we are working too hard for it.” “I think [incorporating occupational health and social determinants of health] can help more right now than personalized medicine and at lower cost.” But there is a possibility that this could change in the future: “I probably don’t think about genomics... but in the future, if we have that kind of information, that would be awesome.” Once again, this was a uniform concern across all clinics.

Discussion

This is the first multi-site qualitative study of this topic that spans community, regional, and academic health care sites. In addition to the barriers identified in prior studies on genomic-based CDS, we found that the status of the current EHR system also affected the prognosis for genomics based CDS. Our results also differed from more generalized CDS implementation studies – the lack of evidence and provider knowledge created barriers that are more significant than for other types of CDS.

As discussed above, we identified six factors involved in the acceptance of genomic-based CDS: the potential for improving care, clinician knowledge about precision medicine, evidence that genomic based CDS improves outcomes, costs, workflow integration, and other priorities due to system status.

These factors are similar to those found in two earlier studies (by Unertl et al. [11] and Haga et al. [12]), both of which were conducted at one site and had a lower number of primary care
clinicians participating. The study by Unertl was conducted as semi-structured interviews at a large academic medical center following the implementation of CDS for genomic based dosing of clopidogrel and coumadin. The Haga findings were based on three focus groups at another academic medical center that had not implemented a genomic CDS. The Unertl study included six primary care physicians and nine cardiologists, the Haga study twelve primary care providers and six geneticists. Table 1 compares results of the three studies.

Table 1 – Comparison of factors for success

Some of these barriers have been identified in prior work on general CDS implementation. Both Bates’ Ten commandments for successful CDS [13] and Kawamoto’s review of factors for successful CDS [14] implementation cite workflow as an important element in CDS success. Only seven percent of all CDS implementations, however, had the evidence included as one of its components [14], despite the strong association with implementation success. Further, only 31% of all CDS efforts had an associated educational component; the inclusion of which was not associated with increased success [14]. We believe that genomics implementations are more likely to require an educational element based on this study’s providers’ knowledge issues.

A limitation of our work is that it was conducted in parallel with a study of the inclusion of worker-based health CDS in the EHR and this could have biased our results. But, as shown in Table 1, our results are similar to those of two prior studies. The other two studies also had two themes ours did not – the need for help in communicating results to patients and issues with data storage and usage after the initial test. This may be due to a difference in the degree of implementation of genomics testing. Our study included sites that had not implemented a robust primary care genomic CDS, the other two studies either involved medical geneticists or already had a robust implementation.

Another limitation of our work is that it was a qualitative study; our work was designed to discover the range of possible responses. As a result, any of the differences between clinics is not statistically valid and only a starting point for future work.

Of the six factors shown in Table 1, one is a facilitator – clinicians can see a potential benefit. The other five are currently barriers. But these barriers can be changed to facilitators. Clinical trials can, and hopefully will, produce clear evidence of better outcomes. Once these trials are completed effective CDS can help with the other barriers, especially those involving clinician readiness. Our results lead to the following recommendations:

**Clinician knowledge:** Effective clinical decision support can provide “just in time” knowledge to clinicians through best practice alerts before the patient encounter, alerts at the time orders are placed, pop-ups with additional information regarding labs, and linkages to more information. Continuing education of clinicians about genomic medicine is needed for increasing their awareness of the evidence as well.

**Costs:** With effective data transfer from other institutions a genomic test can be done once and shared across multiple organizations, thus minimizing costs. There are already CDS implementations that have significantly reduced duplicate lab test, similar strategies can be used for genomic testing [15].

**Workflow:** Gathering the genomic data can be implemented by adding the typical tests required to the normal order sets for new patients and incorporating them into the templates. It is encouraging to note that workflow considerations are part of several current pharmacogenomics CDS projects [5,16].

**Communication:** Customized patient handouts can assist clinicians by providing simple illustrations of probabilistic concepts. These handouts can help implement shared decision making using graphical tools (see http://shareddecisions.mayoclinic.org).

**Current EHR Implementation:** And as the EHR implementations mature and organizations become more proficient at implementing CDS, the development and deployment of genomic CDS will become easier.

**Conclusion**

Except for the potential of genomic-based precision medicine, the factors identified in our interviews are currently barriers to its acceptance. With more evidence, and education, CDS will be a critical tool in bringing the promise of genomic-guided precision medicine to fruition. The barriers – clinician knowledge, need for evidence, costs, workflow, and other EHR issues can be addressed with CDS.

The primary care clinicians we interviewed, from a wide range of clinics, want to improve the care they provide for patients. They only need to see a clear path to do so. What is needed is an easy to use, relatively low cost CDS intervention with clear evidence of improved patient outcomes for primary care. There are many clinical trials currently underway that are attempting to provide the evidence to support the CDS, but successful implementation will require both the evidence and the tools to implement. Clinical decision support is needed to make these interventions less expensive, easier for both clinicians and patients to understand, and able to fit into the clinical workflows.

An Experimental Comparison of Quality Models for Health Data De-Identification

Johanna Eicher, Klaus A. Kuhn, Fabian Prasser

Institute of Medical Statistics and Epidemiology, University Hospital rechts der Isar, Technical University of Munich, Germany

Abstract
When individual-level health data are shared in biomedical research, the privacy of patients must be protected. This is typically achieved by data de-identification methods, which transform data in such a way that formal privacy requirements are met. In the process, it is important to minimize the loss of information to maintain data quality. Although several models have been proposed for measuring this aspect, it remains unclear which model is best suited for which application. We therefore performed an extensive experimental comparison. We first implemented several common quality models into the ARX de-identification tool for biomedical data. We then used each model to de-identify a patient discharge dataset covering almost 4 million cases and outputs were analyzed to measure the impact of different quality models on real-world applications. Our results show that different models are best suited for specific applications, but that one model (Non-Uniform Entropy) is particularly well suited for general-purpose use.

Keywords:
Privacy, Personally identifiable information, Data anonymization

Introduction
The collaborative collection and sharing of sensitive individual-level data has become an important aspect of modern biomedical research. The secondary use of health data for research purposes is a typical example [1]. To protect privacy in such scenarios, a broad spectrum of safeguards must be implemented, including data use agreements and fine-grained access control [2]. On the data-level, anonymization is a central safeguard. There are various ways and definitions. One important aspect is data de-identification, which focuses on protecting data from re-identification. For this purpose, datasets are transformed in such a way that it becomes very difficult to link their records to identified individuals without investing a disproportionate amount of time and effort [3].

There are rule-based and computational approaches to the de-identification of health data. The Safe Harbor method of the US Health Insurance Portability and Accountability Act (HIPAA) [4] is a typical example for the former type. It specifies 18 transformation rules which describe the removal or alteration of attribute values that are associated with a high risk of re-identification (e.g. names and dates). In other jurisdictions, e.g. in Germany [3], regulations are less interpretable and computational methods to data de-identification are thus more important. Here, data is transformed (semi-)automatically to ensure that privacy risks are minimized.

The transformation of data inevitably leads to loss of information. Therefore, a balance has to be sought between an increase in privacy protection on one side and a decrease in data quality on the other. Privacy models and quality models are used to quantify the two aspects. The contradiction between the two conflicting optimization goals is typically resolved by specifying a risk threshold for the privacy model. This reduces the de-identification process to a simpler optimization problem, in which the objective is to make sure that risk thresholds are met while data quality is maximized [2].

Objective
Measuring data quality is a non-trivial issue as the nature of usefulness of data often depends on the use case [5]. As it is typically unknown in advance how the data will be analyzed, models are needed, which quantify data quality for general-purpose use. Fung et al. proposed to measure the similarity (which can be defined in multiple ways) between the original and the de-identified data [6]. Domingo-Ferrer et al. noted that a quality model should capture the amount of information loss for a reasonable range of data uses [7]. They introduced two characteristics, analytically valid and analytically interesting, which need to be present for a dataset to have little loss of information. In this context, analytical validity requires the preservation of certain statistical characteristics, while data is said to be analytically interesting if some useful attributes for further analyses remain intact [7].

A wide variety of general-purpose quality models, which aim to distinguish valid or interesting data from invalid or uninteresting data, have been proposed and used in scientific papers. Typically, these models define a decrease in data quality, as well as an increase in information loss, which can be quantified [5]. The notion of using information loss as an indicator for data quality is also prevalent in official statistics, namely the so-called score, which measures the trade-off between quality (information loss) and privacy (disclosure risk of the released data) [8]. Even though various papers have compared data de-identification algorithms, a systematic evaluation of quality models has not been conducted yet. Consequently, a guideline for selecting appropriate models for specific scenarios is missing. Potential application scenarios for de-identified data include the privacy-preserving sharing of data from research registries or health databases. De-identified data extracts may also be used to provide partners with an overview of data, which is potentially available for sharing in a fine-grained form. Finally, de-identified data can also directly be used for advanced analytics and observational research, e.g. for building predictive models.

As a first step towards the development of a guideline, we have implemented and evaluated several general-purpose quality models with the intention of answering the following questions:

1. How do common models for measuring data quality influence the way in which datasets are transformed?
2. If different models are used, how are the obtained results related to each other?
3. How well is de-identified data, obtained by using different quality models, suited for real-world applications?

**Methods**

**Background**

In data de-identification, the general attack vector assumed is linkage of a sensitive dataset with an identified dataset (or similar background knowledge about individuals). Identity disclosure (or re-identification) means that an individual is successfully linked to a specific data record [9]. This is a very important type of privacy breach, as it has legal consequences for data owners according to many laws and regulations worldwide. As a first step towards data de-identification, directly identifying information (such as names) must be removed [10]. The remaining attributes, which may be used for linkage, are termed quasi-identifiers (or indirect identifiers, or keys). Such attributes are not directly identifying, but they may be used in combination for linkage. It is further assumed that they cannot simply be removed from a dataset, as they may be required for analyses and that corresponding information is likely to be available to an attacker.

![Figure 1 – Generalization hierarchies for “age” and “sex”](image)

When data is de-identified, values of quasi-identifiers are transformed to ensure that the data fulfills privacy requirements. This can be performed with user-defined generalization hierarchies [11]. Examples are shown in Figure 1. Here, values of the attribute “age” are transformed into intervals, with decreasing precision on increasing age. Here, values of the attribute “age” are transformed into generalization hierarchies requirements. This can be performed with user-defined transformed to ensure that the data fulfills privacy requirements.

In order to transform the data, globally-optimal full-domain anonymization algorithms have been recommended. Such algorithms construct a search space in a structure called generalization lattice. An example for the lattice constructed from the hierarchies from Figure 1 is shown in Figure 2. The graph displays each node that represents a single transformation, which defines generalization levels for all quasi-identifiers. An arrow denotes that a transformation is a direct generalization of a more specialized transformation, which means that it increments exactly one generalization level as defined by its predecessor. The original dataset (0, 0) is at the bottom, whereas the transformation with maximal generalization (2, 1) is at the top. The search space is then traversed to find a transformation, which results in output data that fulfills all privacy requirements, and at the same time provides optimal data quality.

![Figure 2 – Example showing different transformations represented as a generalization lattice](image)

![Table 1](image)

**Quality Models**

We have implemented the following quality models (QMs) into ARX, which is an open-source de-identification tool for biomedical data [13]:

- **Average Equivalence Class Size (AECs)** is a row-oriented model, which measures the average size of equivalence classes of indistinguishable records [15].
- **Discernibility** is a row-oriented model, which measures the size of equivalence classes combined with a penalty for suppressed records [16].
- **Precision** is a cell-oriented model, which quantifies data quality by reporting the amount of distortion of attribute values. Distortion is measured as the generalization level of an attribute value relative to the height of the attribute's generalization hierarchy [17].
- **Loss** is a cell-oriented model, which measures the granularity of data by determining the fraction of an attribute's domain that is covered by the transformed values [14].
- **Ambiguity** is a row-oriented model, which measures the degree of uncertainty in the resulting data [18].
- **Kullback-Leibler (K.-L.) Divergence** is a row-oriented model, which measures differences in the distributions of equivalence class sizes [19].
- **Non-Uniform (N.-U.) Entropy** is a column-oriented model, which measures differences in the distributions of attribute values induced by data transformations [20]. It is based on the concept of mutual information, which quantifies the amount of information that can be obtained about one variable by observing the other.

We used each quality model to de-identify a publicly available patient discharge dataset [21]. The dataset contains 3,985,166 records and 10 attributes (Table 1). In our experiments, we have defined all spatial, demographic and temporal attributes as quasi-identifiers. As we will describe later, we used the remaining sensitive attribute (charge) for determining the usefulness of output data.

Privacy Protection

We de-identified the dataset with attribute generalization and record suppression to produce output datasets, which fulfill the \( k \)-anonymity privacy model. We chose \( k = 5 \), which is a typical parameter in the biomedical domain that specifies a re-identification risk of not more than 20% for each record [2].

Experimental Design

We addressed the first research question, i.e. how quality models influence the way in which datasets are transformed, analyzing how much generalization and record suppression had to be used in the de-identification process to achieve optimal data quality. The former is expressed as a generalization degree for each attribute, which is defined as the relative generalization level to which it was transformed. The latter is expressed as the number of removed records.

To answer the second question, i.e. how the results obtained with different models are related to each other, we used each model to assess the quality of the optimal solutions obtained with all other models. To make the different quantifications of quality comparable to each other, we normalized them: a value of 0% represents the original data and a value of 100% represents a dataset where all information has been removed.

Finally, to answer the third question, i.e. how well the de-identified data is suited for real-world applications, we analyzed the impact of the different methods of data transformation on typical use cases. Moreover, we employed statistical classification, which is a common application scenario for individual-level data [22]. The aim was to predict the values of a selected class attribute from a set of feature attributes. This is implemented with supervised learning, where a model is created from a training set. We used the discharge dataset to build logistic regression models [23], which were able to predict the height of the bill for hospital stays, i.e. whether the charge for a stay was below $10,000, between $10,000 and $50,000, or greater than $50,000.

To be able to quantify the analytical validity of the de-identified data, we created classifiers, which could be evaluated using the original input data; although they have only been trained with de-identified output data. For this purpose, we implemented the approach presented in [22] into ARX. For evaluating different predictors, we used 10-fold cross-validation. We normalized all resulting prediction accuracies into the range [0, 1], where 0% represents the accuracy of the trivial ZeroR method, which simply always returns the most frequent class value from the original dataset [23], and 100% represents the accuracy of a logistic regression model trained with the original, unmodified input dataset.

Results

How do common models for measuring data quality influence the way in which datasets are transformed?

Table 2 shows the generalization degrees, and the number of removed records for the outputs obtained by de-identifying the discharge dataset with each quality model.

It can be seen that the fraction of removed records varied between 0% and 25%. With each quality model, at least one attribute was preserved as-is, while just the result obtained with the Loss model did not contain at least one completely generalized attribute. The dataset was transformed with high degrees of generalization when AECS, Discriminability, Ambiguity or N.-U. were used. Entropy was used to quantify the loss of information. Just little generalization was used when quality was measured with Precision, Loss and K.-L. Divergence. No records were removed when Discriminability or Ambiguity were used, while a large proportion of the records was removed when quality was measured with AECS and K.-L. Divergence. With the models Precision, Loss and N.-U. Entropy, the dataset was transformed with a balanced combination of both attribute generalization and record suppression.

measured relative accuracies between 94% and 98%. This effects on the performance of the prediction models; we N.-U. Entropy, the de-identification process had just negligible when using Discernibility, Precision, K.-L. Divergence and obtained using the remaining quality models. It can be seen that prediction accuracies below 30%. Figure 3 shows the results AECS, Loss and Ambiguity performed not very well with patient nor the length of a stay was predictive for the prices before building the prediction models, we performed a feature selection process. The results showed that neither the age of a patient nor the length of a stay was predictive for the prices charged by the hospitals. Therefore, we built classifiers, which predicted the charge from the spatial features hospital-ID and county of residence, the demographic parameters sex, ethnicity and race, as well as temporal information in form of the admission quarter.

Figure 3– Relative accuracies of logistic regression models

The results obtained by training models with the output of using AECS, Loss and Ambiguity performed not very well with prediction accuracies below 30%. Figure 3 shows the results obtained using the remaining quality models. It can be seen that when using Discernibility, Precision, K.-L. Divergence and N.-U. Entropy, the de-identification process had just negligible effects on the performance of the prediction models; we measured relative accuracies between 94% and 98%. This means that the models performed almost as well as models trained with unmodified input data.

How are the datasets obtained with different models related to each other?

Table 3 shows how the different models assessed the quality of output data obtained using the other models. Each column represents the result of de-identifying the data with a single model as indicated. In each row, a model was used to assess the quality of the output obtained with the other models. Consequently, the highlighted values on the diagonal represent the optimum for each model.

It can be seen that, in terms of AECS, all results had comparable data quality. However, information loss was considered very low in general. When using Discernibility and Ambiguity, results obtained with the other models determined to be much worse and quality values differed by orders of magnitude. When using Precision and Loss, quality values were within a reasonable range, considering the transformations, which were applied to the data (Table 2). However, both models, as well as K.-L. Divergence, measured big differences between the different solutions. When using N.-U. Entropy, the quality of the results from the different models was placed in a reasonable range, and different solutions were considered to be of rather comparable quality.

How well is de-identified data obtained with different quality models suited for real-world applications?

Before building the prediction models, we performed a feature selection process. The results showed that neither the age of a patient nor the length of a stay was predictive for the prices charged by the hospitals. Therefore, we built classifiers, which predicted the charge from the spatial features hospital-ID and county of residence, the demographic parameters sex, ethnicity and race, as well as temporal information in form of the admission quarter.

The results obtained by training models with the output of using AECS, Loss and Ambiguity performed not very well with prediction accuracies below 30%. Figure 3 shows the results obtained using the remaining quality models. It can be seen that when using Discernibility, Precision, K.-L. Divergence and N.-U. Entropy, the de-identification process had just negligible effects on the performance of the prediction models; we measured relative accuracies between 94% and 98%. This means that the models performed almost as well as models trained with unmodified input data.

Discussion

Our experiments indicate that different models are suited best for different application scenarios. When using the AECS model, datasets were de-identified with a high degree of generalization and a high degree of record suppression. Moreover, predictive models created from the output obtained with AECS exhibited sub-optimal performance. This shows that the model is not suited well for real-world applications in biomedicine. When using the models Discernibility or Ambiguity, datasets were de-identified with attribute generalization only. This means that the models are suited well for de-identifying small datasets, e.g. from rare disease networks or data collections from sparsely populated regions, where statistical power may otherwise be reduced disproportionally. Using the models Precision, Loss or N.-U. Entropy resulted in a balanced application of both attribute generalization and record suppression. This means that the output data is well suited for providing potential data sharing partners with an overview of available data, as instance-level and schema-level information is preserved. Finally, the models Discernibility, Precision, K.-L. Divergence and N.-U. Entropy are suited well for de-identifying data that is to be used for predictive modeling. The latter two models are based on stringent information theoretic foundations, and it is thus not surprising that output obtained with them is suited well for machine learning purposes. In contrast, we did not expect to obtain such good results when using Discernibility and Precision, as both are rather simple in nature.

Our results have also shown that the utility or usefulness of data does not necessarily correlate with the degree of quality measured by general-purpose models. In future work, we also plan to investigate special-purpose quality models, which are models that have been designed with specific usage scenarios in mind. The application scenario investigated in this article, statistical classification, is a well-known example of a specific application scenario. While our results have shown that data de-identified with general-purpose quality models can be suited well for this context, specialized quality models also have been proposed. They minimize the loss of information for features, which are most discriminating for a specified class attribute [6]. This has been shown to optimize output data for classification purposes [16].

Another application scenario is the de-identification of diagnosis codes for use in association studies between phenotypic and genotypic data [24]. The transactional characteristics of such data require that irrelevant inter-attribute relationships are removed, which can be achieved with specialized de-identification algorithms that also require specific data quality models. In future work, we plan to investigate such models, e.g. utility constraints [24] as well.

Conclusion

Non-Uniform Entropy is a quality model, which has frequently been recommended for de-identifying health data, e.g. by Emam et al. [25]. Based on the results of our experiments, we can confirm that the model provides the best results for general-purpose usage. With this model, de-identified data contained instance-level and schema-level information. Moreover, statistical power was reduced by only 10%. Finally, by using de-identified data with optimal quality according to this model as a training set, we were able to build a statistical classifier with good prediction accuracy.

Evaluation of the Association Between Different Patient Indexing Strategies and Effective Indexing in Health Centers of the Public System of the Autonomous City of Buenos Aires: An Exploratory Study

Santiago Esteban, Cecilia Palermo, Leandro Alassia, M. Victoria Giussia, Analía Baum, Fernán González Bernaldo de Quirós

Abstract
During the implementation of an electronic health record (EHR) system in the public system of the city of Buenos Aires, Argentina, different patient indexing strategies were devised and implemented. We sought to assess the association between these strategies and effective indexing (proportion of patients who are indexed and have a consultation registered in the EHR). Strategies were grouped into three modalities (High, Intermediate, and Low intensity). We estimated hazard ratios (HR) comparing the High and Low intensity to the Intermediate strategies. The crude analyses showed a significant difference between the curves (p < 0.0001). In the multivariate analysis, the HRs of High and Low intensity interventions showed on average, values above 1 from 0 to 90 days compared to the Intermediate intensity strategy (High: 2.08 (1.65, 2.52); Low: 2.59 (2.29, 2.9)). From that point on, the HRs of both strategies were not different from 1.

Keywords:
Electronic Health Records

Introduction
During the implementation of an electronic health record (EHR) system, the processes of identity accreditation and the creation of a master patient index are critical in order to avoid duplication or misassignment of a person's clinical data [1-3]. In turn, depending on the implementation context, these two processes may present different levels of complexity, which conditions the strategies used to promote patient indexing [4; 5].

Beginning in June 2016, the Ministry of Health of the Autonomous City of Buenos Aires, through the Office of Clinical Informatics, Statistics and Epidemiology (OCISE), started implementing the computerization of all health records from the public health system [6]. This involves the development and implementation of an EHR, initially covering outpatient clinics but also more complex levels of care, such as hospitals. In this context, the patient indexing process is particularly difficult. Factors related to physical resources, human resources, and characteristics of the population of each center condition the indexing methodology, making the implementation of a single, common strategy for all centers, impossible.

The reason why different strategies coexist is because each primary care health center is virtually autonomous. Our team had to negotiate with the chairmen of each center on how to implement the patient indexing process. Thus, a particular indexing strategy was devised by the chair of each primary care health center taking into account the characteristics of the center and its population. With the aim of improving the future implementations, we decided to evaluate the association between the different indexing implementation strategies and effective patient indexing.

Methods

General Design and Data Source
This study utilized a prospective cohort design based on secondary data extracted from the EHR system of the city of Buenos Aires. We used the term ‘prospective’ because the intervention was defined and recorded prior to the occurrence of the result.

Population
All persons enrolled in the computerized health system (SIGEHOS) of the city of Buenos Aires, between 1/6/2016 and 11/24/2016, were included. Two health centers were excluded: one was already implemented prior to the start of the current process (prior to June 2016); the other, the implementation process has just begun (November 2016).

Intervention
During the first weeks of implementation in each center, sociologists made ethnographic observations [7] of the patient indexing process dynamics and held extensive and recurrent interviews [8] with the administrative staff involved in the process. From the information obtained, typologies [9] were constructed with a qualitative approach [10] in order to classify, structure, order, and compare the different conceptualizations of the indexing strategies [11; 12]. The differences in the strategies and their intensities gave rise to 3 types:

- **Low Intensity:** The registration is taken as an alternative instance to the usual process of attention since the use of the paper medical record predominates. The indexing process depends on the time availability of the administrative staff. Paper and EHRs coexist.

Intermediate Intensity: Indexing is offered to patients who request new appointments and to those who visit the center requesting maternal formula or need to fill in paperwork related to social security. Paper and EHRs coexist.

High Intensity: Registration is proposed as a condition in all instances of consultation at the center and the EHR is the main registration system.

Outcome

We used the time from registration to the first visit recorded in the EHR or administrative censorship (24/11/2016 or maximum of five months). This was done to account for the fact that the raw indexing total (total number of indexed patients) can reflect many patients who are indexed without actually needing to see someone from the health staff (e.g., in several centers, the handout of maternal formula was used as an instance to promote indexing). This situation is a problem for patients who need medical attention since they may decide to skip indexing because of the long waiting times and queues, thus promoting paper perpetuation of the paper records. Given the short duration of the study and the type of population (outpatient population), no competing risks such as death were considered.

Covariates

Baseline variables were extracted from the EHR at the time of each patient’s indexing, such as sex, age, type of housing, district of residence, programmatic area in which they were registered, number of professionals of the main specialties at the center of attention (Obstetrics, tocoginecology, pediatrics, family medicine), and number administrative staff.

Model Structure

Figure 1 shows the directed acyclic graph (DAG) of the defined structure to try to resolve confounding between exposure (A = indexing strategy) and the result (Y = first visit recorded in the EHR) model. In these graphs, time runs from left to right, lines denote association (bidirectional), arrows indicate causal direction and the boxes around the variables reflect controlling by that variable and therefore the rupture of the association flow through that path.

Statistical Analysis

The crude proportions of effective indexing were estimated using the Kaplan-Meier method and compared by means of the log-rank test. The level of significance for all tests was set at 0.05. A Cox proportional hazards model was used for multivariate adjustment. The proportionality of risk was assessed by analyzing the Schoenfeld residuals (graphic and test analysis) and also by means of the log-log graphs for each variable. The variables for which the assumptions did not hold were incorporated into the model through an interaction with a flexible function of time (natural cubic spline). Non-significant interaction terms were dropped from the model. All analyzes were performed using R (R Foundation for Statistical Computing, Vienna, Austria URL: https://www.R-project.org).

Results

Figure 2 shows the distribution of health centers implemented in the city of Buenos Aires. The color indicates the indexing strategy used.

Figure 2 - Map of the city of Buenos Aires with the implemented primary care health centers by indexing strategy

Table 1 shows the baseline characteristics of the patients. The distribution of age categories represents a characteristic broad-based pyramid with a clear predominance of women. In turn, the vast majority of patients reported residing in Buenos Aires (87%). 49% of the indexed patients came from four of the 18 centers analyzed (Hosp. Grierson, 5, 7 and 35). This is due to a combination of implementation time, size of the center in terms of population served, and indexing strategy. On the other hand, since the process began in the southwest area of the city, two programmatic areas of the six, account for 72% of the registered patients.

Survival Curves

The cumulative probability curves for the three strategies are plotted in Figure 3. The three strategies initially show a rapid ascent, due to those who register and have a consultation on the same day or the following day. From that moment on, the curves diverge; the High intensity is associated with a shorter time until the first visit registered in the EHR. Intermediate and Low intensity strategies initially differ, but each reaches similar levels after 60 days. The log-rank test showed statistically significant differences between the curves (p <0.0001).

Proportional Hazards Assessment

All variables were analyzed using the procedures described in the methods section. The scaled Schoenfeld residuals test was highly significant for many of the variables included in the model; however, graphical analysis in many cases did not show significant deviations from proportionality. This was probably due to the large sample size for which minimal differences were detected. The intervention variable also showed no proportionality of hazards (figure 4).

Figure 3 - Curve of cumulative probability

To resolve this situation, the follow-up time was divided into seven-day intervals and the risk of each intervention (High and Low) vs the reference (Intermediate) were calculated. Within each interval the risks proved to be proportional. Figure 5A shows the progression of the hazard ratios of the high and Low intensity strategies vs Intermediate intensity, for the crude model. An initial benefit is observed approximately during the first 30 days in favour of the High and Low intensity strategies. The adjusted model included sex, district of residence, type of housing, number of administrative staff at the indexing health center, number of professionals at the indexing health center (medical clinic, pediatrics, obstetrics, gynecology, family medicine), and programmatic area of the indexing health center. It was observed that the hazard ratios of the Low and High intensity strategies lose significance after approximately 90 days from the starting point when compared against the Intermediate intensity strategy (Figure 5B, Table 2).

**Discussion**

Our study sought to explore the association between different strategies for the implementation of patient indexing. We defined as effective indexing, the registration of patients who seek to effectively attend the health center for medical reasons. The analysis of the results of our model shows evidence in favor of the High and Low intensity interventions, at least during the first 90 days. During this period, High and Low intensity interventions were more frequently associated with effective indexing. It is possible to think that the Intermediate intensity intervention, which focused on indexing people who attended the health center mostly for non-medical reasons, does not lead to an effective indexing, since these patients do not concur with the objective of receiving care. After 90 days, all three strategies were equally effective. These results can be explained in different ways. On the one hand, it would be expected that over time all registered patients, sooner or later, will visit the clinic, independently from which indexing strategy they were exposed to. On the other hand, it could respond to intrinsic and subjective factors of the patients that we are not capturing in our model, so there would be residual confusion that would not allow us to see differences between strategies. Finally, the typology constructed does not represent a static model associated with each health center, but is subject to modifications over time. The centers can modify their strategy to political, managerial and technical factors.

It was striking to observe the relatively greater effectiveness of the Low intensity strategy compared to the Intermediate intensity strategy. The centers that adopted Low intensity strategies mainly focused on registering patients during certain hours. This, in many cases, was due to a policy of the center’s management to accompany the overall EHR implementation process, but without complete commitment. This highlights one of the biggest, if not the biggest, problems we experienced during the whole process which was the lack of governance. Even though all centers are part of the same public health system, they act independently. Even within each center, governance is a problem, since in many of them the medical management does not have governance over the administration staff or even the medical staff.

In contrast, many of the Intermediate indexing intensity centers chose to promote indexing in instances not related to health care. Therefore, the majority of the registered people did not correspond to people in need of being seen by somebody from the health care staff in the short term. This, coupled with a partial adherence to the use of the EHR by professionals, can explain the difference between both strategies.

Regarding the High intensity strategy, it basically consists of promoting indexing in all the instances (appointments and maternal formula handout or social security realted consultations) coupled with a strong motivation for the use of the EHR, which in many cases, started at the beginning of implementation process. However, even without a formal test, there did not seem to be significant differences between the High and Low intensity strategies. One possible explanation for this may be that the High intensity strategy represents a combination of the Low intensity (i.e., focused on some patients seeking attention in certain time slots) and the Intermediate intensity (i.e., focused on people who attended the center mostly without needing to be seen by the health care staff in the short term).

Like any observational study, our study has limitations, mainly related to potential residual confounding and miscategorization, both at baseline and over time. We were not able to collect information regarding characteristics of the center’s management, the attitude of the professionals towards the EHR implementation process, and the availability of appointments at the center. On the population side, we could not record data related to the level of disease burden per patient. Also, since we are in the first stage of the implementation of an EHR system we could not assess the impact of indexing on any health care outcomes. As mentioned above, classification error is also a potential source of bias in our estimates. We have confidence in the basic characterization of the centers, however, we believe that there are errors in the classification of centers that occur over time because many, due to internal or external motivations (i.e., implementation in other centers, direct intervention of the ministry of health), changed the intensity of the strategy initially chosen.

**Conclusion**

As part of the project to implement an EHR system in the city of Buenos Aires, there are still more than 25 centers to be implemented in the next year. The results of our study provide us with better information that can be used when discussing and negotiating with the management of each center. This includes the possible benefits of each strategy when selecting the one that best suits the needs of the center and the overall implementation process of the EHR.

Design and Construction for Community Health Service
Precision Fund Appropriation System Based on Performance Management

Xing Gao, Yao He, Hongpu Hu

Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China

Abstract
Allowing for the differences in economy development, informatization degree and characteristic of population served and so on among different community health service organizations, community health service precision fund appropriation system based on performance management is designed, which can provide support for the government to appropriate financial funds scientifically and rationally for primary care. The system has the characteristic of flexibility and practicability, in which there are five subsystems including data acquisition, parameter setting, fund appropriation, statistical analysis system and user management.

Keywords:
Financial Support; Information Systems; Community Health Services

Introduction
Nowadays, some problems exist in health service in China, that is, higher quality resource are mostly concentrated in metropolitan and big hospitals, and capacity of primary health service is low, hardly playing the role of “health gatekeeper” [1-2]. In order to improve the situation, China has proposed a series of health policies to guide the quality of health resources to sink at the grass-roots level such as “hierarchical medical system” and “the equalization of basic public health services”, which makes positive effects to promote the overall service ability of primary health care. Appropriate economic incentives help improve quality of care and accelerate the policies into effect [3]. For example, the United Kingdom, as early as in 2004, carried out pay-for-performance programs in family practices to improve primary care performance by financial incentives. The payments are in additional to the practices’ core funding, which is based on the number of patients, adjusted for characteristics of the patients and the area [4]. In the United States physicians are paid according to the number of population serviced and completion of performance targets. Meanwhile, additional awards are given for those with outstanding performance [5]. Unlike in Europe and America where practitioners or physicians are the object of funding [6], in China the community health service organization is regarded as the operational unit of primary health care. District governments are in charge of fund allocation for these organizations. Although it seems fair that central government spends funds to every public primary health organizations by the standard of about 45 yuan per resident per year (according to the standard of 2016) to safeguard residents’ basic health, there exist differences in the characters of population serviced and degree of economic development among these organizations, even in the same district. For example, organization A which serves for 10000 residents can receive 450 thousand, while B serves for 20000 residents can receive 900 thousand. Most residents in A are the old, children and pregnant women which bring out heavy workload to the medical staff in A, while most in B are young person who have a little demand for basic public health service. The more work to do, the less to earn. In this situation, it is not reasonable to allocate fund just by the number of population within respective jurisdictions. Therefore, it is necessary to design and construct a community health service precision fund appropriation system based on the performance management. The so-called precision refers to quantitative and refinement of the indicators related to funding appropriation [7]. In this system, the funds to be appropriated will be scientifically calculated and the change trend of key indicators of basic public health service will be analyzed.

Methods
Demand Analysis is applied to design community health service precision fund appropriation system, including business process analysis, data process analysis and function design.

Business Process Analysis
Business process analysis is a process to sort out and refine the abstract business process of the system. Through analysis, you can clearly understand the business activities and the corresponding responsibilities of the various participants in each business link. The business flow chart is an important tool for business process analysis which describes business dealing process through some provided symbols and lines, to help developers easily and quickly understand the specific business process. Based on the optimization of the original business processes, this paper draws the business flow chart of the precision fund appropriation system among relevant subjects.

Data Flow Analysis
This analysis is helpful for developers to understand the data flow including data generation, data processing and data storage, providing favorable conditions for data structure construction and function module design of the system. Data flow analysis is mostly realized through the data flow chart [8]. We use data flow analysis to clear the data process procedure including data collection, data integration and data utilization in fund allocation of primary care.

Function Design
Based on business process analysis and data flow analysis, the function design should be made in order to realize targets of system. The Function of system is constituted by some subsystems whose interfaces should be clear and functions be
independent of each other. In this paper, the subsystems include data acquisition, parameter setting, fund appropriation, statistics analysis, user management. In addition, in order to increase the practicability and flexibility of the systems, users can choose data collection method, adjust indicator system according to actual demand, which will be specifically introduced in the subsequent results.

![Figure 1 – Business Processes of Precision Fund Appropriation System](image)

**Results**

The business process analysis for fund allocation in primary care mainly involves three participants and four business links. First, in the data report link, staff of the community health service institutions is in charge of uploading data to the precision fund appropriation system. The uploading method includes automatically uploading and manually uploading. The system administrator is responsible for classifying and sorting out the data. In the parameters setting link, any setting and maintenance is done by the system administrator. This link is the core of the whole business process, but also the foundation for the precision appropriation of funds. There are three main tasks for the system administrator in this link. First, to revise and perfect the rule base, which is used to store the standardization method of each type of business data; it needs to be updated and maintained regularly. Second, to maintain the fund appropriation indicator system template and modify the indicators or the weights of the template to form a new fund appropriate indicator system. Third, to regularly summarize the fund appropriation indicator system, modify the parameters setting and establish fund appropriation model base according to user needs. In the fund appropriation link, the decision makers, according to health strategy development priorities, select the appropriate fund appropriation model to calculate the amount of the funds to be appropriated to the community health service institutions within its jurisdiction. The statistical analysis link is used for deep-level mining and analysis of fund appropriation data. In this link, decision makers can understand fund appropriation statuses, operational and developmental situations of different communities from different perspectives (as shown in Figure 1).

**Data Flow Analysis**

The precision fund appropriation data flow will include data classification, standardized processing, appropriation indicator system’s weight settings, fund calculation (as shown in Figure 2).

![Figure 2 – Precision Fund Appropriation System’s Data Flow Chart](image)

The sources of the original data of precision fund appropriation are from the community health service institutions. First the data will be classified according to the data types and characteristics after being uploaded. Data type includes uploaded data, field survey data and basic data. Among them, uploaded data is regarded as the basic public health service data uploaded directly from the information system, such as electronic health record filing rate, neonatal follow-up rate. Unlike the uploaded data, the field survey data is obtained only from field investigation rather than automatic acquisition from information systems, such as health education plan and summary, and health education activities. The basic data refers to the community health service institutions’ service scope, population characteristics and other attributes, such as important crowd proportion, population density. Second, data standardization will be conducted. That is, choose different rules from the rule base for grass-roots data standardization processing. By defining standard workload and using comparison by flexibility, standard time or service process, the administrator set the corresponding workload value of each indicator to complete data standardization and obtain standard data. Third, call the fund appropriation indicator system and set the weight of each indicator, and then multiply the standard data of each indicator by the weight of each indicator, and use their multiplication results as the total workload values of the community health service institutions. Last, after the annual basic public health service funds are confirmed, the amount of the funds which should be allocated to the primary health institutions will be provided to decision makers.

**Function Design**

Based on the business process analysis and data flow analysis, a community health service’s performance management fund appropriation system is designed. There are five functions including data acquisition, parameter setting, fund appropriation, statistics analysis, user management and etc..

**Data Acquisition**

The data acquisition module is used to collect and collate the business data and basic data associated with the fund appropriation. This module supports three kinds of data acquisition modes such as online data acquisition, local data uploading and software interface data import. Other non-online data can be manually put in or imported by other software through the system interface.

**Parameter Setting**

The parameter setting module is used for setting attributes of the business indicators related the fund appropriation, including
rules base setting, fund appropriation model base settings. The rules base is used for storage of a series of rules of business data standardization processing, such as automatic scoring rules, workload standardization rules. The fund appropriation model base is provided for setting and updating fund appropriation indicator system such as indicator increase, deletion, weight setting. Moreover, through free grouping of relevant business indicators, a new fund appropriation indicator system can be formed to meet the needs.

Currently, the indicator system for fund allocation used in the system is based on the national basic public health service item specification [9-10]. The indicator system is divided into three levels. In level one, there are three indicators, including public health services, population characteristics and regional characteristics. In level two there are 16 indicators, mainly including electronic health records, health education, preventive inoculation, population density and terrain features. In level three, there are 36 indicators, mainly including electronic health records filing rate, health education activities, early pregnancy rate, elderly health management rate, rate of health management of patients with diabetes, the elderly coefficient.

**Fund Appropriation**

The fund appropriation module, by selecting the appropriate fund appropriation indicator system, automatically calculates the amount of financial funds that governments should appropriate to the community health service institutions within their respective jurisdictions. The module includes calculation method choice, results inquiry and other functions. The calculation method selection refers to selection of the suitable appropriation models in a variety of fund appropriation models, including fee for service, work quality priority, assessment results priority and other models. Calculation results query is used for viewing and comparing the amount of funds appropriated to the primary health institutions in a same district.

In addition, the module can also call the fund allocation model base, and, according to the needs modify the indicators and weights in the indicator system.

**Statistical Analysis**

The statistical analysis module can be used to view the ranking of the key indicators of all institutions according to the development direction of the primary health services. For example, in-depth analysis can be conducted from the quantity, quality, level of technological innovation and progress and other levels, so as to provide reference basis for the provision of special awards. At the same time, the module should be used to query the historic fund appropriation indicators and related data, carry out comparison analysis graphically with the historic fund appropriation indicators, calculate input-output ratio and the change rate of fund appropriation for each institution, so that users can combine the history and current reality to make minor adjustments to the fund appropriation parameters of the current year.

**User Management**

The user management module is used for management of adding, deleting system users and of their permissions. Permission management refers to the permissions set for different users to use or access the system resources (function menu items, buttons, input controls, etc.).

**Discussion**

The results are discussed in context of present and other The UK’s pay for performance scheme is similar to the US, they are motivating family doctors to increase the quantity and quality of primary health care by linking the performance score to the bonus with a strong database. In the UK, the family sign contract with their doctor on a voluntary basis, to enhance service capabilities of family doctors. There are 146 performance indicators for the pay for performance scheme, involving chronic diseases, health care organizations, and patient experience. The indicators are not static and they will be modified, added or removed based on grass-roots services [1]. At the same time, each indicator is assigned a different score according to the degree of difficulty. The performance score of the family doctor is determined by the degree of completion of the indicators. The final performance bonus is the product of the unit score and the performance score. The data required for performance bonus calculations can be extracted directly from Quality Management and Analysis System (QMAS). Besides, there is an exceptional reporting which is applied to patients who have coexisting conditions that affect their optimal care. Family practitioners can also increase their income by inappropriately excluding patients for whom they have missed the targets. The UK’s basic health services funding is also similar to the US, the amount of payment is based on the number of service groups, the degree of completion of performance and unit standards. At the same time, US CAHPS database worked with Microsoft to provide evidence-based support and results feedback for developing performance management standards through the collection and storage of national performance management data, comparative analysis of different regions and periods of performance benchmarks.

In order to enhance the grass-roots service capacity, China is also constantly exploring the relationship between community health service performance management and funding allocation. China’s financing model, allocation methods, service groups, data collection are different from Europe and the US because of the national conditions, economic development and the degree of development of information technology.

In the financing model, China’s primary health care services are central, provincial, municipal and district finance coordination. Due to regional economic differences, funding for primary health care services varies from region to region. Take basic public health services as an example, the fund of basic public health service per person per year is 73 yuan in Nanjing, Jiangsu, while Hefei, Anhui is 45 yuan in 2016. The reason for the difference is because the economy is more developed in Nanjing, Jiangsu Province, so in addition to the central government allocated 45 yuan, as well as from the provincial, municipal and district-level financial support 28 yuan. But in Hefei, some areas follow the example of Europe and the United States to carry out the way according to the project, and some areas based on the existence of “eat big pot” situation. In the allocation of funds, Europe and the United States allocated to the object is a family doctor, in accordance with the service and service difficulty to reward, the upper limit of funding is no special restrictions. The main body of primary health care services in China is the grassroots health institutions, the district-level government allocate funds to the grassroots health institutions. Due to limited economic level and the total amount of funding is fixed, it is necessary through the performance management of the funds reasonable distribution.

In the service groups, China’s primary health care institutions are pushing the "grass-roots first diagnosis, two-way referral" strategy. But the current form of service is for the elderly, pregnant women and children to provide basic medical and basic public health services. This is the gap between Europe and the United States on the grassroots "health gatekeepers" position.
In the data collection, unlike the UK to summarize, integrate and utilize national primary health data by QMAS, as China’s system construction standards are not unified, the current grassroots health data in China only to achieve the district-level sharing, while interconnection between grassroots systems needs to be improved. Therefore, we collect data in combination with automatic and manual combination when we allocate funds.

Due to the difference of characteristics of the service population, the degree of economic development and the data sharing, we designed the Precision Fund Appropriation System Based on Performance Management based on performance management based on the principle of flexibility and intelligence. The main features are as follows: (1) There are a variety of funding estimate indices, district-level government can be combined with the actual needs of the corresponding index system, and can be added to the indicators, delete and weight configuration; (2) The quantitative index can be automatically scored according to the pre-set calculation rules, which can reduce the workload of staff to manually score. Take the example of electronic health file index, if the file rate is greater than or equal to 70% had 10 points, if less than 70% will not score. (3) Taking into account the construction of grassroots information platform, in the data acquisition both automatic acquisition function and manual upload function, which are used to compensate for the low degree of data sharing defects.

Conclusion

Allowing for the differences in economy development, informatization degree and population characteristic served among different districts, the system designs functions with a certain flexibility and practicability, which can provide support for the government to appropriate financial funds scientifically and rationally for primary care.

Abstract

National Health Data Warehouses (NHDWHs) promise to improve individual and population health. These systems are now increasingly being deployed in low- and middle-income countries (LMICs), given increased recognition of the value of data analytics in informing decision-making. However, ethical issues relevant to implementation of NHDWHs in LMICs remain largely ignored or, at best, inadequately addressed. In this paper, we highlight and critically analyze several of the key ethical issues, including privacy, informed consent and trust, confidentiality and security, secondary data use, sustainability and implementation validity, risk-benefit ratio, governance and conflict of interest, justice, equity, access, and collaborative partnerships. We then provide a set of guiding principles and points to consider for countries and implementers to guide further decision-making around ethics of implementing NHDWHs within LMICs.

Keywords:
Ethics; Information Systems; Developing Countries

Introduction

A national health data warehouse (NHDWH) is an extract of health-related information from multiple organizations and data sources within a country, which is used primarily to facilitate decision-making through various data analytics approaches.[4] NHDWHs can help in (a) strategic planning and quality improvement initiatives at the organizational, state, and national levels, (b) personalization of patient-level care services to improve clinical outcomes, and (c) support for public health and surveillance initiatives, among other activities. In the age of personalized medicine, NHDWHs are becoming key to ensuring the right treatment is provided to the right person at the right time.

Within the last few years, an increasing number of low- and middle-income countries (LMICs) have developed NHDWHs. As an example, Kenya, through its Ministry of Health (MoH) and the National AIDS and STI Control Program, has worked with international implementing partners to create a NHDWH for HIV programs. The initial aim of Kenya’s NHDWH is to incorporate all patient-level HIV data from key digital health systems from across the country. In Zambia, there was a request in 2016 for proposals for the ‘Data Warehouse for HIV/AIDS Policy and Program Decision-making in Zambia under the President’s Emergency Plan for AIDS Relief (PEPFAR)’ program.[2] These and many other examples indicate that the use of NHDWHs within LMICs will only gain increased prominence in practice. As is typical in many LMIC settings, HIV programs have taken the lead, but undoubtedly, NHDWHs will become relevant for multiple other purposes in the future.

The NHDWHs being implemented currently contain information with various levels of granularity, including patient-level data. Despite growing enthusiasm by countries and funding organizations to implement NHDWHs, very little attention has been paid to the ethical issues that surround their adoption. In fact, while the benefits of NHDWHs might look obvious, few have stopped to ask the numerous pertinent ethical questions surrounding their use in LMICs. These ethical questions are relevant at every stage of the data warehouse, including the extraction of data from primary sources, data transmission procedures (especially in settings with limited infrastructure), the creation of “data marts” where data are curated to suit particular needs, and the data analysis and dissemination stages. Countries need guidance on a systematic approach for identifying and evaluating ethical issues that arise when NHDWHs are being considered. While ethical issues in LMICs may well be the same as those in developed countries, some variability will exist given several unique considerations within LMICs. Among the differences that could impact ethical consideration are the levels of stigma associated with diseases such as HIV, poorly-defined policies to protect patient rights, central and often paternalistic mechanism for decision-making, variable literacy levels, and variable resources. Nonetheless, an examination of ethical issues surrounding NHDWHs within LMICs will still be instructive and applicable for developed countries. To date, no comprehensive and rigorous analysis exists to provide ethical guidance around NHDWHs for LMICs. In this article, we critically explore the range of ethical issues that can arise from implementation and use of NHDWHs in LMICs. For this work, we take a systematic approach guided by widely accepted ethical frameworks. We then propose a set of ‘Points to Consider’ to guide further thinking and decision-making.

Approach

Components of a NHDWH

A data warehouse consists of several components that are relevant to assuring the appropriate integration of data from multiple source systems, segmentation of these data for various uses, and reformattting to allow efficient implementation of analytic procedures (Figure 1).

Primary Data Sources:

Primary data sources are used to capture digital data mostly at the point of service. Common primary data sources for health data warehouses include electronic health record systems, pharmacy information systems, laboratory information
systems, health management information systems, logistics management information systems, and finance systems. Data from source systems are usually extracted, transformed, and loaded (ETL) into data warehouses using various mechanisms.

Data Warehouse:
The data warehouse is a collection of data gathered from one or more primary operational data systems and organized in a way that optimizes analysis and projection. In most cases, the data in the warehouse are subject-oriented, normalized, and have data/time identification to provide a snapshot at any given time.

Data Mart:
Often a subset of the data warehouse, a data mart represents a subject-specific extraction of a portion of the data in the warehouse, organized in a format that allows particular types of analyses and efficient querying. In NHDWHS, examples of data marts can include patient encounters, drugs, and laboratory-based data.

End-user Tools:
End-user tools include a range of applications to facilitate querying of the data, report writing, and a wide array of analytics. End-user tools also provide relevant interfaces and dashboards for a unified view of analytics and performance data needed. Advanced business intelligence tools now exist to facilitate data mining, statistical analyses, and reporting.

Ethical Framework
A rigorous analysis of ethical issues surrounding NHDWHS in LMICs requires a systematic approach. Several existing works can be adapted to inform a comprehensive analysis of the ethical issues surrounding NHDWHS in LMICs. Among these are: (a) ethical guidance around evaluating clinical research in developing countries;[7] (b) ethical frameworks around implementation of electronic record systems in developing countries;[10] and (c) various research highlighting ethical issues in big data analytics.[5; 6] Using a combination of these approaches, we prioritized several key ethical issues that are further outlined below.

Ethical Issues in NHDWHS in LMICs

Privacy, Informed Consent, and Trust
A key component of privacy is the control an individual has over the extent, timing, and circumstances of sharing information about themselves to others. Coordinators of NHDWHS often do not seek consent for the inclusion of individual-level information. Conflicts can easily arise regarding ownership of data within NHDWHS. It is not uncommon for Ministries of Health (MoH) to claim ownership of patient-level data, often insisting that they have no need to seek approval from the individuals to use this data. It could be argued that expectation of full consent on collection, storage, and use of data might be unrealistic, especially in settings where individuals have limited literacy and understanding of digital technologies. Whether or not individual consent is sought, custodians of NHDWHS still have the responsibility to inform individuals about the use of their data in a culturally sensitive format. Some of the information worth sharing with individuals whose information will be stored in a DWH includes the types of secondary data analytics to be conducted, information on patient rights, data ownership, and potential risks to individuals in having data within the NHDWH. Public and individual expectations should also be appropriately managed.[10]

Individuals and providers may not trust those charged with custody and analysis of data contained within NHDWHS. It is not a stretch to imagine situations in which the stored data could be used to target stigmatized groups, tribes, or individuals, such as individuals with a particular sexual orientation. In many cases, simply assuring people that their data are protected will likely not satisfy their concerns, and may heighten their concerns about privacy. Appropriate controls and clear disclosure are, therefore, needed to ensure that custodians of the data do not abuse this trust.

Confidentiality and Security
The ethical principle of confidentiality dictates that information gathered about individuals is not revealed without appropriate authorization and that it is securely maintained. Confidentiality is often best assured when information that is not required is never collected at all. At the very least, limits must be placed on the amount of individually identifiable information that is collected.

In LMICs, NHDWHS pose a risk to confidentiality as clear guidelines often do not exist to limit amounts and types of information extracted from primary sources. Often, regulations that restrict the use or disclosure of Protected Health Information (PHI), akin to the Health Insurance Portability and Accountability Act (HIPAA) in the United States, do not exist in these countries.[3] Even when primary data sources do not collect PHI or when information is de-
identified" prior to incorporation into the NHDWH, the simple act of aggregating data from various disparate sources into one DWH increases the chance of re-identification as this information can sometimes be combined in novel ways.

NHDWHs are an attractive target for data breaches given the sheer volume of data contained. With sophisticated attacks on some of the world’s largest software companies and healthcare organizations, it should be no surprise that NHDWHs in LMICs will be targeted. Beyond threats of breaches from outside the DWH, particular attention also needs to be paid to threats from within, given the potential lack of systematic, rigorous, and continued training of all personnel with access to the DWH and laxity in enforcing existing controls. The mechanisms used to transport or transmit data in LMICs may also increase security vulnerabilities. Where there is inadequate network infrastructure, insecure 'sneaker networks' (such as use of flash or external hard drives) are often employed to transfer data into the NHDWH. The use of local servers for the DWH, as is often dictated by national policies that restrict cloud-based storage, also poses a significant physical security threat.

Secondary Data Use

Secondary use of data is closely connected to several other ethical issues, particularly privacy, trust, and confidentiality. By nature, analytics conducted from within the NHDWH uses data that was initially acquired for a different purpose. To avoid unauthorized disclosures and related harm to individuals and groups, as well as their mistrust of the DWH itself, constraints must be placed on the types of analytics that are allowable. Where appropriate, data should be de-identified prior to aggregation into the DWH, and resulting analyses should not allow re-identification unless re-identification will explicitly benefit the individual or society and the process is disclosed to those individuals whose data are re-identified. Additionally, the methods and location of access to NHDWHs by secondary users ideally need to be controlled. It would also be wise for countries developing NHDWHs to constitute oversight bodies tasked with specifically reviewing the appropriateness of proposals for secondary data analysis. While the benefits of secondary analysis may be significant, care must be taken to ensure that these data are not used for mass population surveillance, to target individuals or populations, nor to restrict human and political rights.

System and Implementation Validity

Many countries are advocating for NHDWHs without the appropriate standards, guidelines, and enforcement mechanisms being in place to guide implementation of electronic databases generally. Often overlooked are critical assessments of the suitability and appropriateness of implementing NHDWHs in settings that have significant barriers around capacity, cost, and infrastructure. Best practices for data warehousing do exist, and it is recommended that the implementation of NHDWHs be gauged against these standards.[9]

Data quality presents a major challenge in LMICs where medical recordkeeping may be inconsistent and documentation incomplete. Quality can be compromised from the primary source, during the data extraction and transformation stages, and during aggregation for analysis. The saying ‘garbage in garbage out’ certainly rings true in NHDWHs with quality issues arising around completeness, accuracy, timeliness, uniqueness/duplication, validity, and consistency of the data. At the same time, the development and maintenance of NHDWHs offers a unique opportunity to uncover key gaps in data and other quality issues within the care system. Establishing and operating a NHDWH would permit systematic improvement of these shortcomings through approaches such as patient matching and data de-duplication that would not be possible where the data are not warehoused.

Favorable Risk-Benefit Ratio

When used with appropriate analytic tools, NHDWHs can provide business intelligence with the potential to improve individual health outcomes, and the efficiency, equity, and governance of health systems. At the same time, aggregating data in one place and conducting various types of analytics may present numerous risks. For these reasons, there should be a clear determination of who is expected to benefit from the implementation of the NHDWH and who will bear the risks. NHDWHs and business intelligence should have a reasonable probability of a favorable risk-benefit analysis for the individuals, with a greater social value to the community and country to justify implementation.

In an ideal world, the determination of the risks of harm and potential benefit should be explicit, objective, and based on well-outlined criteria. However, these valuations tend to have a significant subjective component, often shaped by societal and political values. There is a risk of overstating the benefits of NHDWHs as most analytics could be done with single-source systems, without the need for aggregation. Where using more data looks like an advantage, despite the dearth of evidence on the benefits and risks of NHDWHs in LMICs, countries often proceed with NHDWHs based on inadequate information.

The implementation of an enterprise-level NHDWH comes with significant initial and ongoing costs, up to millions of dollars, especially when they use market-leading but proprietary data warehousing systems like Oracle or Teradata.[1] Use of open-source systems should be considered to help reduce these costs. In many instances, countries will not have adequately considered the long-term sustainability of NHDWHs, with primary funding for their development and implementation coming from time-limited grants. An opportunity exists to implement self-sustaining business models for NHDWHs, given that there are multiple stakeholders, such as insurance and pharmaceutical companies, who have the ability to pay for knowledge derived from NHDWH.

Where resources are constrained, resource allocation among multiple competing priorities is an essential consideration. Even when the cost-benefit of a NHDWH is evident, the decision whether to allocate resources for its implementation has to be evaluated against using those resources on other proven interventions, such as immunizations or safe water. Through this comprehensive resource-allocation lens, a NHDWH might end up being lower on the priority list.

Governance and Conflict of Interest

Good governance at multiple levels is essential for success of any NHDWH project. The primary implementing team needs to be well qualified and managed and stakeholders appropriately involved. A multi-stakeholder technical working group should guide implementation, while an independent body should be engaged for ethical review. Significant financial oversight is also necessary, given the large amounts of money often involved in these projects. Accountability and transparency thus go hand in hand.

NHDWHs present multiple potential areas for conflict of interest. The MoH, often the primary custodian of the data, might be resistant to data analytic practices that uncover deficiencies within the system or that might portray the
Ministry or other government agencies in a bad light. Further, as an arm of the state, there might be undue pressure to use the data within the NHDWH for politically motivated surveillance. NHDWHs, also offer a significant opportunity to make money, raising in turn the potential for financial conflicts of interest, especially when those charged with making financial decisions work within a culture that may struggle with corruption. Monitoring by regulatory bodies and other oversight systems are, therefore, needed to ensure that both real and perceived conflicts of interest are avoided.

**Justice, Equity and Access**

Through data analytics, NHDWHs can be used intentionally or unintentionally to reveal injustices in the distribution of resources involving personnel, finances, supplies, equipment, and health care facilities. In LMICs, where unequal access to resources is often a significant ethical challenge, NHDWHs can be an important tool in achieving distributive justice and health equity. NHDWHs can be appropriately used to identify such issues as the prevalence of domestic violence, untreated marginalized populations, geographic health disparities, and abusive practices such as female genital mutilation, in order to address them. However, the quest to discover distributive injustices through NHDWHs should be deliberate, and coordinators of the DWH need a plan for using this information to ensure improved access to quality care services for all.

**Collaborative Partnerships**

Multiple stakeholders are directly affected by or involved with the implementation of NHDWHs, ranging from individuals and communities whose data are placed into the warehouse, the MoH and other government bodies, technical support and implementing organizations, researchers and funders. Collaborative partnership requires that these stakeholders be appropriately engaged in ethical discussion, especially regarding the aspects of the NHDWHs that have direct impact on them, before, during, and after implementation. True collaborative partnership requires adequate and appropriate representation of each group. Community representatives and leaders can be entrusted to act on behalf of individuals, even when these individuals might not completely comprehend the various dimensions of the NHDWHs and its associated knowledge discovery processes.

Defining how the data within the NHDWH is used also must be a shared responsibility, to ensure that priorities and concerns of all parties are adequately represented. There is always a temptation of professional paternalism around the use and management of data, with a risk of exploitation by the custodians of the data. In essence, analytics should be done ‘with people and not on people’. Use of consultative forums and groups, and assembling of working groups on various questions can help to maintain mutually respectful participation by relevant stakeholders, with all voices listened to and heard appropriately. This type of engagement is key to the sustainability of the NHDWH and ongoing trust in its greater purpose and management.

**Guidance and Points to Consider on NHDWHs**

It is evident that a range of ethical issues arises with the growth of NHDWHs in LMICs. MoH and key stakeholders must consider and be equipped with ethical guidance on how to approach these issues, with specific attention to differences between LMICs and industrialized countries where DWHs are now common. Below, we provide a set of points to consider that form a basis for guidance on how to approach some of these ethical issues. However, as noted by Fife et al. about their recommendations for faculty ownership of medical facilities, these points “are neither a set of decision rules that mechanistically resolve issues at stake, nor are they a set of principles from which interpretation can be manipulated by various parties to support their particular points of view”.[8]

This guidance aims to help policy makers reach sound and principled ethical judgments and to begin a conversation about ethically defensible approaches for implementing NHDWHs in LMICs.

**Confidentiality and Security**

It would be advisable for LMICs to develop their own clear guidelines on how to manage, protect, and secure the large volumes of data contained within their NHDWHs. Identifiable information that has to be collected also has to be explicitly outlined a priori, with justification as to why they are needed. Whenever possible, data stored within the NHDWH should be de-identified and controls placed on procedures that would risk re-identifying PHI. Appropriate technical, training, administrative, and physical security systems and procedures should be part of any implementation, and these should be continuously updated to fit the dynamic environment of health data warehousing.

**Privacy, Informed Consent and Trust**

Individuals and communities in LMICs might not be very familiar with particular technologies, and different approaches will likely be required to help them understand what it means to have their data as part of the NHDWHs. Culturally-sensitive educational approaches for the population, use of key community representatives, and transparency are key to ensuring that custodians of the data can gain trust from stakeholders. Decisions have to be reached collaboratively on the rights and ownership of the data stored within the NHDWH. In the western world, individuals are typically able to consent to have their data incorporated into a Health Information Exchange, and such a model of consent can be considered at the point of primary data collection.

**Secondary Data Use**

There should be clarity on how NHDWH data will be used and by whom. An independent body can help to oversee the appropriateness of requests for analytics and access procedures. Identifying potential harms to different populations and communities will be an important role for community engagement, and the principle of first doing no harm (non-maleficence) should always take precedence when dealing with secondary use of data within the warehouse.

**System and Implementation Validity**

The implementation of NHDWHs needs to be evaluated against internationally accepted best practices for data warehousing generally. Given that most existing national health information standards do not touch on health data warehousing, revisions to these standards are needed to incorporate the multidimensional considerations to data warehousing, with attention also paid to ethical issues. Strict data quality assurance (DQA) procedures should be implemented at each stage of the data warehousing process. Data analytics procedures should also aim to inform improvements on quality and validity of data collected from primary sites into the DWH.

**Favorable Risk-Benefit Ratio**

Each country needs to assess clearly the financial and social costs of implementing and sustaining a NHDWH. Alternative approaches, such as doing analytics on primary data systems,
should be adequately explored. A NHDWH must be prioritized in the context of other proven interventions, as it will likely compete for limited resources. There should also be clarity on who will bear the costs over time and who will benefit from implementation of the NHDWH. Long-term sustainability plans should be addressed at the outset to avoid huge disruptions that will occur should funding dry up. Finally, a rigorous evaluation agenda, focusing on the benefits and costs of NHDWHs, is needed. Even when the evidence does not exist from the start, continuous re-assessment of costs and benefits are invaluable to justifying continued expense on a NHDWH.

Goveriance and Conflict of Interest

Appropriate governance structures call for clear assignment of responsibilities for key important tasks related to the DWH. Mechanisms for assigning responsibility and roles have to be above board and attentive to potential conflicts of interest. Relevant oversight should be in place, and an independent body empowered to evaluate appropriateness of implementation and analysis requests. Where significant breaches occur, heavy penalties should be imposed and corrective actions taken to prevent future such events. Proper accounting and procurement procedures are needed, as are independent audits of expenses and activities. Conflicts of interest at organizational and individual levels should be identified early and relevant training provided to all personnel. Transparency and accountability should remain a basic responsibility for every stakeholder.

Justice, Equity and Access

Countries need to work towards appropriate distribution of risks and benefits of data warehousing. Analytics should be used to uncover inequities in access to health services and related resources, and should highlight when one group is favored over others. Care has to be taken not to use the data in NHDWHs to discriminate or to impinge on rights of individuals or communities, even when there are political pressures to do so.

Collaborative Partnerships

Appropriate decisions on whether and how to implement the NHDWH should be reached with input from all stakeholders. Individuals who are vulnerable and whose personal health information will form a core part of the NHDWH should have trusted representatives for them. Concerns and interests of the different stakeholders should be handled and addressed, and the community should be made to feel a sense of ownership of the NHDWH.

Conclusion

Ethical concerns remain largely ignored in ongoing conversations around NHDWHs in LMICs. Without appropriate attention to some of the above ethical principles, implementations of NHDWHs are likely to be plagued with numerous problems. Should the needed attention be paid to these ethical issues, the potential benefits of these NHDWHs will be truly realized, with improved outcome for the individuals, better personalization of their care, and overall improved health of the population.

Abstract

The number of eHealth services for patients is rapidly increasing worldwide. This paper describes the status of a very important eHealth service for patients in Sweden, the Patient Accessible Electronic Health Record (PAEHR). As many countries are facing an introduction of national eHealth services providing health information to the patients, lessons learned from Sweden may improve the deployment and use of PAEHRs and similar eHealth services. Challenges that remain in Sweden relate to local differences in the implementation that lead to fragmentation and unequal access to information. Initiatives have been taken to reconcile some of the problems, e.g. an updated national regulatory framework for PAEHR. To date, evaluations are often performed from a healthcare provider perspective, focusing on aspects that are considered important by healthcare professionals and decision makers. Based on experiences of this nation-wide implementation we argue for the need to also base evaluations of eHealth on the perspective of the patients.

Keywords:
Patient Portals; Electronic Health Records; Health Information Exchange

Introduction

eHealth is often suggested to have the potential to revolutionize the way healthcare and prevention is provided, shifting the balance of power and responsibility from healthcare professionals to patients and citizens [1], [2]. Yet, many of the applications developed for patients are either designed from a healthcare providers’ perspective, or completely independent from healthcare. Patient involvement in the design of eHealth has been stressed as important to achieve usable and useful eHealth solutions [3]. Experiences of the nation-wide implementation of one of the most important eHealth services for patients in Sweden accentuate the need to also base evaluations of eHealth on the perspective of the patients, rather than, as it today often is, only perform evaluations from a healthcare provider perspective, focusing on aspects that are considered important by healthcare professionals and decision makers.

 Patients’ online access to EHR

Sweden recently updated the national eHealth vision that now states that all residents from 16 years of age should by 2020 have access to all health related information documented in county-funded health and dental care [4]. However, implementing these eHealth services are controversial for the healthcare professionals [5] and it is challenging to realize on a national scale [6]. Internationally, there is also a drive towards providing Patient accessible EHRs (PAEHRs), but it has been limited in part by professional resistance and concerns about security and privacy [7][8], legal constraints [9] and low uptake of other online resources for patients. In a systematic review from 2014 [10], a lack of evidence from high-quality studies about the impact of online access was noticed, yet it was clear that the tensions between the growing consumer demand to access data and healthcare systems not yet ready to meet these demands have increased in recent years [10]. Many of the studies identified in the review originated from the USA, from large health plan-based programmes, whereas a minority of studies originated from Europe. The review indicated that patient online access to their EHR and other services offer increased convenience and satisfaction [10]. However, professionals are often concerned about impact on workload and risk to privacy, which is also the case in Sweden [11]. The authors of the review article conclude that a redesign of the business process to engage health professionals in online access and of the EHR may be required to make it easier to use and provide equity of access to a wider group of patients. Another review published in 2015 called for more empirical testing regarding the effect of PAEHRs on health outcomes for patients and healthcare providers [12].

Aim

The purpose of this paper is to present the current state of the nation-wide PAEHR implementation in Sweden, to describe the challenges in the implementation, and finally to discuss the need for patient-centered evaluation of PAEHRs as proposed in the PACESS project.

Methods

The results presented in this paper are based on a retrospective analysis of national projects in Sweden focusing on the design, implementation and evaluation of PAEHR. The authors have been engaged in the research projects described below over the past 7 years, and have had opportunity to observe the debate and decision making processes both in national and regional organizations. We base our description of the implementation projects and e-services on our participation in the projects as well as on publicly available resources provided by e.g. Inera regarding the current usage of the national e-services [13]. Over the years, the authors have also organized several international workshops, where challenges of implementing these types of eHealth services have been
discussed [14], [15], leading up to the analysis presented in this paper. The authors are part of the DOME consortium from which researchers of six Swedish universities to date have published over 50 articles on the introduction of the PAEHR (https://domeprojekt.wordpress.com).

**SUSTAINS**

Already in 1997 Uppsala County Council (UCC) in Sweden started a project with the aim to give patients access to their medical data. The project was called Sustains and had financial support from the European Commission [16]. In 2002 a pilot study of PAEHR was run in Uppsala County, however it ran into legal problems and was shut down by the Data Inspection Board as the legislation at the time did not allow individuals to have online direct access to their medical records [17]. However, ensuing discussions resulted in the introduction of the Patient Data Act in 2008, which solved this problem. Work continued, and as part of the EU-project Sustains [17] (ICT-PSP 297206, during 2012-2014), UCC extended the deployment of public eHealth services, and all 300 000 patients were given access to the PAEHR in 2012.

**The PAEHR Journalen**

‘Journalen’ was originally developed and deployed in Uppsala County [17]. From 2015, the national eHealth organization (Inera AB) has the responsibility for development and maintenance of all public eHealth services and the national patient portal, further described in the Results section. Through this portal ‘Journalen’ is currently (December 2016) accessible by the citizens of 17/21 county councils.

**My Care Pathways**

The Swedish research project “My Care Pathways” [18] was another project running in parallel with the EU Sustains project also focusing on giving patients access to information from their medical records. This project aimed to create new mobile public eHealth services that allow patients to follow, own, and manage their care process-related information. The project also aimed to adapt and further develop the National Health Information Exchange (HIE) platform for citizen e-services and provide an open software development kit (SDK) for developing new e-services [19]. Several patient groups were involved in a patient-centered design process; stroke patients [20], lung cancer patients [21], and hip surgery patients [22].

**Vårdhändelser**

In parallel with the Sustains project, the My Care Pathways project also developed e-services for patients, the most notable called ‘Vårdhändelser’. This service included similar health information as ‘Journalen’, but presented it to the user in the form of a time-line that was intended to be both backward and forward looking, indicating planned events, and including information from the patients’ own health devices.

**Results**

In this section, a brief overview of the Swedish implementation of the PAEHR is presented, followed by challenges identified as essential during the implementation process. Finally, we introduce the PACESS project, which proposes that a patient-centered evaluation approach of PAEHRs is necessary to complement research in this area.

**One way to access healthcare for the citizens – 1177.se**

Although the county councils are autonomous and could prioritize which eHealth services to focus on, there is a national decision that patients should only have one way in to healthcare [4]. Thus, a patient portal ‘1177.se’ is available for everyone seeking healthcare or health-related information in Sweden. The patient portal consists of three parts:

1. **1177 on the phone** - a telephone advice service reached through the national phone number 1177,
2. **1177.se on the web** - without authentication the public can access and search among information about illnesses, symptoms and treatments, as well as information about healthcare in the region. The virtual portal is national, but each region or county council in Sweden can adapt the information to its inhabitants. As a user, it is also possible to choose which region you would like to view and change between regions.
3. **1177.se personal e-services** – after authentication (using a nationally approved BankID) you have access to personalized e-services where you can e.g. add your primary care centres or hospital units, and send secure messages to them. Depending on what e-services the care providers of your region offer, you may also e.g. request, reschedule or cancel appointments, renew prescriptions and access documents such as sick-leave.

Sweden has approximately 10 million inhabitants whereof 34.1 % (N=3 354 806) have created their own account for the 1177.se portal to use the personal e-services [13]. In September 2016, 1 427 576 log-ins were made to the personal e-services, and as an example 26 943 appointments were booked online [13].

Figure 1 shows an example of the different eHealth services a user can access via 1177.se (in this case the first author’s own view when logged in). It is also possible to act as a proxy for children under 13 years, so parents can manage their children’s appointments and contacts with healthcare.

![Figure 1– An example of a citizen view of the patient portal 1177.se after valid authentication (partially translated).](image)

**PAEHR in Sweden – retrospect and current challenges**

Sweden has a decentralized healthcare system allowing for regional decisions.

For some time, both Journalen and Vårdhändelser (the alternative PAEHR service developed within My Care Pathways) were accessible to patients through 1177.se.
However, connecting to the respective e-service as an information provider was a costly process, and most care providers chose to publish their information to either Journalen or Vårdhändelser. This caused a fragmented view for patients; if you visited care providers that used the different services, some of your information would be visible through Journalen, and some through Vårdhändelser. Finally, all county councils agreed that Journalen is the national PAEHR service, to create one common view for the patients. Journalen has also been migrated from its UCC platform to the National HIE platform which also increased the incentives for the other, self-governing, care providers to connect their EHR systems.

Today (December 2016), 17 of the 21 Swedish counties have given access to EHR data through Journalen, and the service is expected to be truly national in the near future. Figure 2 gives an overview of the Swedish counties that have currently implemented and provide access to this service (in blue).

The maturity of the implementation varies among the counties, e.g. Stockholm County Council, one of regions with most inhabitants in Sweden, have begun pilot testing during late 2016 and will implement the service throughout the county during 2017, whereas UCC has had Journalen in place for more than 5 years.

Currently, when a patient is logged into 1177.se, and chooses to access the PAEHR the user finds the service shown in Figure 3. Journalen can contain notes from the EHRs (from all healthcare professions and all regions), a list of prescribed medications, lab results, warnings, diagnosis, maternity care records, referrals and vaccinations. In addition, there is a log list showing everyone that has accessed the record. The patient also has the possibility to share their EHR with anyone they choose, e.g. a close relative or an agent, and parents can access their children’s records until the age of 13.

Agreeing on a national regulatory framework

One of the major challenges in the implementation process has been to achieve national consistency in the guiding rules for PAEHR. A National Regulatory Framework (NRF) was developed to support the deployment of the PAEHR in the 21 regions. However, from the point of view of the patient, the first version of the NRF was less successful as it contained electable paragraphs that were interpreted and applied differently in the counties [23], [24].

The PAEHR is one of the most important services for the patients and consequently the NRF needed an update [23]. In the recently launched second version of the NRF, the goals of the European and national eHealth strategies are used to create a number of principles, thereby giving the citizens the same opportunities regardless of where you live, where and when you seek care. Further, it should be possible for the regions to update their solutions to adhere to version 2.0 by 2020 [24].

Fragmented views of healthcare data

Despite the national HIE platform and the intention to provide patients with a complete overview of their health related data, the view remains fragmented depending on where, when and why a patient seeks treatment [23], [24]. There are important differences in how much information each care provider gives access to. Figure 4 provides an example of what information types some of the counties have chosen to provide (not including all information types and counties). For a complete list, please visit Inera’s web site [25].

Local initiatives

Despite the national eHealth strategy, development and implementation of PAEHR in Sweden is based on local initiatives. Research and development projects, although funded by European and national funds, have been run in different regions in Sweden and decisions on a national level have only been made when absolutely necessary. Whether a top-down or a bottom-up approach to national eHealth implementation is best can be debated, but we will here describe some challenges observed in the implementation.

Different PAEHR services; different local initiatives running in parallel resulted in different solutions for accessing your health-related data. This would not have been a problem if all healthcare providers made their data accessible through both e-services, but due to cost and maintenance issues this was not feasible.
Limited support for patient participation and communication

One of the expected benefits of PAEHR is to increase patient participation in healthcare. Having access to one's own data is an important first step, but participation requires more. A dialogue and collaboration between patients and healthcare professionals is required, and PAEHR does not automatically create this – in Sweden, the implementation has rather been performed under the premises that this is a tool for patients, so healthcare professionals will not need to change their way of working.

Focus in the PAEHR is also very much on giving patients access to information, not to support a two-way information exchange. Basic forms have been implemented in Uppsala that enables patients to fill out questionnaires that healthcare ask for, and a functionality for patients to comment on notes in the health record is also available – but not implemented or used outside Uppsala. In order to support patient participation and communication, more interactive ways to exchange information would be required. In addition, integration of data from personal health apps or self-trackers could also be useful.

Discussion

Sweden has a decentralized healthcare system and the county councils and regions have great autonomy. Despite the national eHealth strategy, development and implementation of PAEHR in Sweden is based on local initiatives. Research and development projects, although funded by European and national funds, have been run in different regions in Sweden and decisions on a national level have only been made when absolutely necessary. Whether a top-down or a bottom-up approach to national eHealth implementation is best can be debated, but we have described some challenges that have been observed in the Swedish implementation; agreeing on a national regulatory framework, fragmented views of healthcare data, resistance from healthcare professionals, limited support for patient participation, and lack of long-term evaluations.

Healthcare professionals’ resistance to PAEHR is also well-known from international literature [10]. When PAEHR is implemented, actual experiences are however mainly positive, especially patients experiences. In Sweden, despite the decentralized healthcare, decisions to implement PAEHR have mainly been politically driven, and resistance from healthcare professionals have often been strong. Health and digital literacy are often listed as risks, as are concerns that information in the PAEHR will cause worry for the patient. However, we argue that patients need to be allowed to make the decision of whether or not they want to use the PAEHR themselves, that actual patient experiences is an essential part of evaluating PAEHR’s.

In order to harness the powers of eHealth, we need a better understanding of how roles, relationships and organizational structures are affected on micro, meso, and macro levels through the introduction of such eHealth services. In the recently funded research project PACESS, the main objective is therefore to explore the impact of information access and innovative eHealth on patients and healthcare. 2 work packages are planned: (1) long-term evaluation of PAEHR in Sweden, and (2) co-creation of innovative e-services that empower citizens. Throughout the project we will establish a theoretical framework to explain how implementation of eHealth services impact different patient groups and healthcare on different levels of the health system. Furthermore, patient-centered quality indicators will be created to facilitate joint assessment of deployment and use of PAEHRs.
Conclusion
The Swedish path to a nationally available PAEHR has been long and challenging, and still we’re not quite there yet. Challenges that remain have to do with local differences in the implementation that lead to fragmentation and unequal access to information. Initiatives have been taken to reconcile some of the problems, e.g. an updated national regulatory framework for PAEHR, but further efforts are needed to evaluate the implementation from a patient perspective.

What Do They Mean by “Health Informatics”? 
Health Informatics Posts Compared to Program Standards

Abstract

There is a lack of alignment between and within the competencies and skills required by health informatics (HI)-related jobs and those present in academic curriculum frameworks. This study uses computational topic modeling for gap analysis of career needs vs. curriculum objectives. The seven AMIA-CAHIIM-accepted core knowledge domains were used to categorize a corpus of HI-related job postings (N=475) from a major United States-based job posting website. Computational modeling-generated topics were created and then compared and matched to the seven core knowledge domains. The HI-defining core domain, representing the intersection of health, technology and social/behavioral sciences matched only 45.9% of job posting content. Therefore, the authors suggest that bidirectional communication between academia and industry is needed in order to better align educational objectives to the demands of the job market.

Keywords:
Employment (D004651), Curriculum (D003479), Medical Informatics (D008490)

Introduction

The field of health informatics (HI) is a relatively new area of study and practice closely related to, and sometimes used interchangeable with clinical informatics, medical informatics, and biomedical informatics. Currently only the American Medical Informatics Association (AMIA) and the Commission on Accreditation for Health Informatics and Information Management Education (CAHIIM) provide a curriculum competency framework [1] describing the minimum knowledge and skills graduates of a HI program must attain. No governmental entity provides an official labor classification for professional in health informatics nor is there an agreement on the job titles.

The question arises if the competencies set forth by the curriculum framework are in harmony with the knowledge and skills required by the job market; Kulikowski et al [2] brought in one of the broadest definitions of health informatics then coined as biomedical informatics (BMI). In this 2012 white paper, the authors proposed that core competencies in BMI would include basic biomedical science, information technology, computing, professionalism, and knowledge of the social science of information usage. More recently, Fridsma [3] published a viewpoint in the Journal of the American Medical Informatics Association (JAMIA), using the concept of HI and no longer BMI to refer to the domain. HI is described as “intersections creating a continuum” ([3], p. 855) between various knowledge domains of application including healthcare, biosciences, computing, and social sciences and ranging from a disease management to public health applications and research.

The broadly stated competencies described in the 2012 AMIA white paper [2] were not yet in a form usable for formal accreditation processes. Since 2016, the AMIA Accreditation Committee (AAC) has been reframing and redefining through an iterative process the curriculum requirements as graduate outcomes. The resulting revisions [1] set forth 10 foundational domains, each with accompanying knowledge, skills, and attitudes necessary to succeed as health informatics professionals in an ever-changing job market. The three base domains are: Health (“F1”; biomedical and health sciences), Information Science & Technology (“F2”; methods and technologies for storage and exchange of information), and Social & Behavioral Science (“F3”; psychology, sociology, organizational behavior).

Three second-level intersected domains are formed by the joining of any two of the above base domains: F1 and F2 combine to form Health Information Science & Technology (F4), F2 and F3 combine to form Human Factors & Sociotechnical Systems (F5), and F1 and F3 combine to form the Social & Behavioral Aspects of Health (F6).

The unique core of health informatics is at the intersection of F1, F2, and F3; the intersection is known as “Social, Behavioral, and Information Science and Technology Applied to Health” (F7), and its specific knowledge, skills and attitudes are considered the defining and differentiating foundation HI program. [1]

The AAC added three domains: Professionalism, leadership, and interprofessional collaborative practice. The relationships and intersections among the original seven domains are visualized in Figure 1. The AAC’s three added domains, although important, are not considered in this analysis as these domains are considered intrinsically required by most jobs, regardless of field. The foundational domains of HI education are depicted in figure 1.

Yet still the question remains: do the knowledge, skills and attitudes set forth in the most recent recommendations [1] cover the demands of the job market?
Objective
Due to the inconsistencies in job descriptions and the recent revisions in HI program outcomes and related competencies, the need arises to perform a gap analysis between the knowledge and skill domains identified for the HI curriculum and actual posted job requirements.

Methods

NLP: Computational Topic Modeling
A convenience sample of US-based job postings made as of mid-November 2016 from the website Indeed.com [4] was searched and mined using the Publisher Toolkit’s application programming interface [5] connected to a proprietary Python-based script. To extract the HI-related postings, the terms “health informatics”, “clinical informatics”, and “medical informatics” were used to filter the resulting corpus. The resulting filtered data were then organizing into individual documents, each document containing one job posting.

MALLET (Machine Language Learning Toolkit) [6] is an open-source topic modeling software tool that utilizes an algorithm that computes baskets-of-words (named topics) that frequently occur across a set of documents. MALLET assigns individual weights to each basket-of-words within each document. For this study, MALLET output was exhausted at 30 topics co-occurring across these 475 job-posting documents.

Qualitative Second-Level Matching
Following MALLET categorization, second level matching was performed: Two HI graduate students independently assigned one of the seven core AMIA/CAHIIM knowledge domains [1, 2] to each MALLET-generated keyword basket. The inter-rater agreement was calculated at this stage (23/30 topics; 76.7%). Disagreement was resolved by mutual adjudication. A similar process was used for labeling spurious topics such as those referring to marketing publicity.

The topic weights were then summed to determine the weight of each individual domain from F1 through F7, including the spurious topics, within each job posting. For example, if a job matched to the three MALLET generated topics for foundational domain F2 at strengths 0.0528 (software development), 0.000140 (data science), and 0.00044 (software application) respectively, the overall weight for domain F2 would be 0.0534.

Binary Model Generation
The matrix was simplified into a binary matrix – potential combinations of the foundational domains excluding the nucleus of HI - by only including relative job-domain strengths that exceeded 0.242 (equivalent to one standard deviation above the median). These strengths were coded as “1”, while lower associations were coded as “0”.

Reclaiming Missed Postings
In order to verify that all potential HI job postings were extracted from the original list, we analyzed those jobs that did not match F7 in the binary model but matched entirely one of the combinations below:
• F1 + F2 + F3
• F3 + F4
• F1 + F5
• F2 + F6
• F5 + F6
• F4 + F5
• F6 + F7

Results

NLP: Computational Topic Modeling
The retrieval procedure (downloading from Indeed.com) yielded 475 job postings that matched the search query. MALLET determined 30 topics. In order to determine the relative weight of each domain across the corpus, the document-topic strength file generated by the software was analyzed.

An example of the data job-topic data generated by MALLET is seen in the following table:

<table>
<thead>
<tr>

<td>0.0004</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

Table 1. Document (Job posting)-to-Topic Weights.

Qualitative Second-Level Matching
Each topic was qualitatively assigned a domain by the panel of two graduate assistants. A list of topics, along with the qualitatively assigned knowledge domains, is available in Appendix A.

During the rating of the MALLET-generated topics, the graduate assistants also excluded by consensus any topics they determined to be unrelated to actual core knowledge domains. Specifically, 8 out of 30 topics generated were deemed by consensus to be spurious as shown in the table below.
Table 2. Spurious Topics and Frequencies.

The topics were then collated into cumulative strengths that represented the strength of each domain across the postings. The median of all job-domain strengths was found to be 0.024; the standard deviation of job-domain strengths was 0.218. An example of cumulative strengths by domain for job postings 0, 1, 2, and 3 across F4, F5, and F6 is below.

<td>F7</td>
<td>40</td>
<td>8.4%</td>
</tr>
<tr>
<td>(Spurious Topics)</td>
<td>173</td>
<td>36.4%</td>
</tr>
</tbody>
</table>

Table 5. Binary Results for Matching of Job Postings to Topics Related to Each Competency Domain.

The domain (F7) considered the unique core of HI matched 8.4% postings at an overall strength of 0.242 or higher. 36.4% of postings matched spurious topics, although only 43 (8.8% of corpus total) job postings matched only the spurious topic set. The most job descriptions (79.2%) match the competencies expressed in foundational domain F6: social and behavioral aspects of health systems. One job posting (0.2%) did not match any of the topics at a binary threshold of 0.242, meaning that the total adjusted match rate for any non-spurious topic was 90.9% (N=433).

Reclaiming Missed Postings

The lack of postings (8.4%) that initially matched the F7 domain is of concern. This deficit, however, was amended by reclaiming postings that missed classification as F7. In order to increase the match rate for job postings that potentially related to the F7 domain, combinations of co-matches between topics that together would make up F7 were sought, increasing the F7 match rate from 8.4% (N=40) to 24.2% (N=115).

Table 6. Job Postings Recovered by Combinations of Domains that Could Represent F7.

Discussion

The analysis revealed certain matches between the curriculum competencies and the skills and knowledge desired in 475 real life job postings on health informatics and/or related terms. The least frequently matched domain was Social & Behavioral Sciences (F3), matching 2.5% of job postings. This finding implies that employers looking for HI-related professionals may seek fewer individuals who solely have social-behavioral science competency. The most popular competency domain correlated to these job postings, on the other hand, was observed to be Social & Behavioral Aspects of Health (F6), which matched 79.2% of all job postings in the binary model, indicating that combined competencies bridging Social & Behavioral Sciences with Health Sciences are in relatively high demand.

Match Rate for F7 – Social, Behavioral and Information Science and Technology Applied to Health

The reclaimed postings, while they only partially match to the core of HI [1,2], will still be considered related to Health Informatics.
The F7 match rate (maximum of 24.2% even after reclamation) remains lower than the F6 match rate (79.2%) suggesting that there exist many health informatics-related jobs that employers describe as requiring knowledge of social sciences and health while requiring little to no technology competency.

Use of Qualitative (Second Level) Matching

It also follows that qualitative matching analysis to interpret the keyword baskets generated by NLP software such as MALLET may have its pitfalls due to potential bias on behalf of the raters. Nonetheless, qualitative secondary matching has been shown of use in health related applications including coding medical concepts from clinical free text entries [7] and classification-annotation of mentions of pharmaceutical treatments [8] the authors of both of these studies implore that qualitative analysis is required following computational NLP.

Limitations: MALLET Analysis

It is also noted that there is required a future qualitative analysis in terms of quality assurance of the MALLET-generated results. In the future, other analyses should be undertaken in order to study this and similar corpora: Further study may include synonym-based (synset) literal term searching, as well as qualitative analysis of a reduced corpus in order to perform an expert categorization of job postings.

Limitations: Spurious Topics & Posting Bias

The presence of what the authors term spurious topics (those that exclusively advertised the employer, location, or legal requirements) must also be addressed, as these spurious topics matched to 36.4% of all job postings in the binary model. In fact, 8.8% of all job postings matched only the spurious topics.

The corpus that was searched and processed may therefore represent a biased sample. Specifically, it likely represents the wording chosen by the writers of the job postings. While the postings did contain information about the core knowledge domains required to satisfy job demands, it is also observed via the strength and content of spurious topics that significant amounts of advertising and legal information was present in the job postings. Furthermore, if there is any inaccuracy or inexperience on behalf of those writing the job postings, such error cannot be taken into account by the study design at hand.

Limitation: Incomplete Coverage of Domains

The authors also note that a limitation exists in the coverage of all competency domains and their expressions of knowledge, skills and attitudes... While the CAHIIM-AMIA competency classification includes 10 domains, only the 7 domains from the overlapping Venn diagram were covered in this proof of concept study. Future studies will need to cover all 10 competency domains in order to better match job requirements to curriculum competencies.

Conclusions

The study reported was able to create a connection between a major upcoming curriculum competency domains and real life job postings for health informatics and related areas. Computational topic modeling/NLP followed by qualitative (second level) consensus analysis has here shown the ability to process a large corpora (N = 475) of job postings and assign academically-meaningful topics to 433 (90.9%) of them.

Therefore, the authors recommend that NLP via computational topic modeling, followed by qualitative second-level analysis, be used to analyze further corpora of job postings in order to match them to curriculum frameworks. Such matching analysis is likely to reveal the similarities and differences between curricular needs and the job market; this information can be used to tailor curriculum frameworks as well as employer job postings.

Acknowledgements

The authors would like to acknowledge the AMIA Accreditation Committee for their revisions of the foundational domains of Health Informatics.

Design of a User-Centered Voluntary Reporting System for Patient Safety Events

Hong Kang, Yang Gong

School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, Texas, USA

Abstract

As the third leading cause of death in the U.S., patient safety events (PSE) are difficult to control due to multiple inputs from healthcare providers, systems, or even patients. Inspired by the success of reporting systems in other fields, PSE reporting systems could be a good resource to share and to learn from previous cases. However, the success of such systems in healthcare is yet to be seen due to the low report quality and the lack of interoperability and communication. A knowledge-based and user-centered PSE reporting system is needed to organize the scattered knowledge and improve user-friendliness. We described the development of a knowledge base for patient falls, the most frequent PSE. Based on the knowledge base, user-centered design features were incorporated into the system to improve the reporting accuracy, completeness, and timeliness. This prototype holds promise in improving PSE reporting quality and facilitating human-computer communication.

Keywords:

Patient Safety; Medical Errors; Knowledge Base; Medical Informatics

Introduction

A patient safety event (PSE) is an event or circumstance that could have resulted, or did result, in unnecessary harm to a patient [1]. An estimated number of 15 million PSEs occurred in U.S. hospitals each year, as high as 40,000 per day, which exceeds the combined number from motor and air crashes, suicides, poisonings, and drownings [2]. With more than 251,000 annual deaths which are about 9.5% of all deaths, PSE, the third leading cause of death in the U.S. closely following heart disease and cancer, costs more than 9 billion dollars every year [3; 4]. Although most patients do not die from PSEs, they suffer from the PSEs for a long period of time or even the rest of their lives [5]. For example, patients may get a fracture after a serious fall in hospital or have a worsening medical condition by taking the incorrect dose of medications. PSEs, including near misses or close calls that are recognized before they actually occur, may be related to systems, operations, drug administration or any clinical aspect of patient care [6]. In the latest version of Common Definitions and Reporting Formats Version 2.0 (Common Formats, CFs) released by Agency for Healthcare Research and Quality (AHRQ), PSEs were categorized into nine subtypes including 1) blood or blood product, 2) device or medical/surgical supply including health information technology, 3) fall, 4) medication or other substance, 5) perinatal, 6) pressure ulcer, 7) surgery, 8) anesthesia, and 9) venous thromboembolism [7]. Different from diseases, which could be effectively controlled in accordance with clinical procedures, PSEs are difficult to control due to multiple inputs including healthcare providers, systems, or even patients [8]. Therefore, PSE is a major threat to the healthcare quality.

Event reporting has been proven effective by many high risk industries such as aviation, nuclear, and rail industry, for improving safety and enhancing organizational learning from errors. In healthcare fields, PSE reporting systems would enable safety specialists to analyze events, identify underlying factors, and generate actionable knowledge to mitigate risks [9-11]. Dozens of PSE reporting system have been established based on this purpose. In the U.S., the Institute of Medicine (IOM) recommended using patient safety reporting systems (PSRS) [12] to evaluate why patients are harmed by health care [13]. AHRQ created the CFs [7] to help healthcare providers uniformly report PSE. Since 2000, at least 30 other PSE reporting systems have been established in the U.S., the initiatives to improve patient safety based on the common belief that data supports further learning and actionable knowledge. However, the success of such systems in healthcare is yet to be seen due to the identified barriers such as low report quality and the lack of interoperability and communication [14].

In addition to the no-blame no-shame safety culture that needs to be further enhanced, a lack of effective and efficient human-computer interaction (HCI) may largely account for the issues of low user acceptance and low-quality data currently confronting the PSE reporting systems [15]. Improved HCI in the systems may include individualized interfaces according to the user roles and requirements, increased sensitivity to the needs of the current clinical scenario, or even patient interfaces to enhance the patients’ self-efficacy and awareness and thereby reduce PSEs. Our previous work indicated that the retrospective think-aloud user testing method is a useful usability evaluation method by which multidimensional measures can be synthesized to gain an insightful understanding of the usability in a voluntary patient safety reporting system [16]. However, generic PSE systems do not incorporate user-centered design (UCD), which is a major barrier to collect event data from frontline practitioners and to learn from previous events.

Thanks to the advancement of machine learning and web programming techniques, increasing UCD features have been incorporated into PSE reporting systems, such as spreadsheets, keyword searching, and automatic error correction. Nevertheless, investigating and learning from the reported events still largely rely on manual approaches due to the lack of an integrated view of PSE [17]. Developing a PSE knowledge base is necessary because it could acquire, organize and generate actionable knowledge to mitigate risks. The story of *the blind men and the elephant* [18] is often told to PSE reporters. In the story, each man had touched only a part of the elephant thus making it impossible for him to know the whole animal. The same is true for
unintegrated reporting systems. The PSE knowledge base holds promise for organizing PSE knowledge and supporting advanced UCD features toward shared learning.

In our preliminary study [14], we developed a PSE similarity searching model by utilizing the semantic similarity measures on the PSE datasets of AHRQ WebM&M (Morbidity and Mortality Rounds on the Web) [19] and CFs [7]. Based on this model, we proposed a novel schema which can process the comparison tasks for PSEs and provide the reporters pertinent comments. As a follow-up study, this paper focused on the development of PSE knowledge base and UCD features. We developed a knowledge base for fall events, based on which we incorporated multiple UCD features into the reporting system.

Methods

Prototype a PSE knowledge base

The PSE knowledge base we prototyped was the collection of PSE reports, solutions, and the potential connections among them (Figure 1).

![Figure 1 – An infrastructure of PSE knowledge base](image)

The knowledge base establishment was started from the most common PSE subtype, patient falls. In our preliminary study, we collected more than 7,000 fall reports from an institute from Patient Safety Organization (PSO) and developed a similarity searching model based on semantic similarity methods to make connections among reports, among solutions, and between reports and solutions [14]. To enrich the knowledge base for patient falls, we identified solutions for patient falls from multiple authoritative resources, such as the AHRQ WebM&M [19], Joint Commission Center for Transforming Health Care’s Targeted Solutions Tool [20], Pennsylvania Patient Safety Authority [21], National Safety Council and National Patient Safety Agency’s Patient Safety Observatory report [22], and synthesized them by building a connection between the entry-based solutions and the AHRQ CFs. These solutions were summarized and grouped into two types: general solutions (for all patient fall event reporters) and specific solutions (customized according to the reporting contents). We also initiated a survey with the Missouri Center for Patient Safety to evaluate and extend our solution entries. In the survey, we provided a text box following each solution for experts to comment on the adequacy of the solutions to the corresponding questions and answers in CFs. Five experts who are familiar with PSE reporting process and patient safety data participated in the survey. The contents of the solutions and their connections to the CFs were improved according to the expert comments.

Review current PSE reporting systems

To figure out the status quo of PSE reporting systems and propose an improved reporting system toward high-quality reporting, we investigated the current systems from peer reviewed publications and publicly accessible web pages. Resources for publications included three databases: Ovid MEDLIINE, PsycoINFO, and Health and Psychological Instruments. Keywords including “patient safety event”, “medical error/incident/event”, “report/reporting system”, “electronic report”, “healthcare”, “information system” were applied with different combinations to all field search (title, abstract, keywords, etc.). As this strategy may include articles with high sensitivity and low specificity, we set restrictions on the MeSH Subject Heading to match such term clusters as “Risk/Safety Management”, “Quality of Health Care”/“Quality Assurance” and “Patients or Medical Records Systems”/“Computerized or Hospital Information Systems”. We used Google search engine to identify publicly accessible PSE reporting systems and other information sources that contain substantial system descriptions (e.g., screen shots or demonstration videos) as supplemental information. Results from these additional materials were merged into the results of the literature review. Two domain experts filtered the initial results and generated a finalized review list.

Design a user-centered voluntary reporting system for PSE

The input quality of PSE reporting system relies on the UCD since UCD has been proven effective in user acceptance [16; 23]. Guided by the reporting quality-related factors derived from the review of current PSE reporting systems, we applied UCD to our reporting system with the support of the PSE knowledge base.

Results

A PSE knowledge base for patient falls

32 general and 137 specific solution entries for patient falls were determined after the survey results were analyzed. The survey also helped us assess the mapping rules between reports and solutions. Each specific solution entry will be displayed to the reporter only when the corresponding condition is met. The condition consists of combinations of users’ answers to the 13 questions in the fall event CFs. Table 1 shows an example of the activation condition of a specific solution $S_j$.

Three data quality dimensions for PSE reporting systems

48 unique PSE reporting systems in the United States, Netherlands, Canada, United Kingdom, Germany, Australia, China, and Japan were identified and reviewed by domain experts. Based on which, three data quality dimensions were defined as follows.

- Accuracy: the degree of proximity of a given PSE report to corresponding real world occurrences. The reporting accuracy is subject to user error and cognitive limitations in memory and reasoning, including but not limited to typographical errors, memory decay, casual attribution and hindsight biases. Accuracy of reporting could be improved if these contributing factors are incorporated into design consideration with good usability and functionality.

- Completeness: the degree to which a given PSE report includes necessary information describing the corresponding real world event so as to be
sufficiently valid for the purpose of analysis and generation of intervention. The completeness could be enhanced if its criteria are explicitly delineated and properly represented to the reporters with the help of interface features.

- **Timeliness:** the degree to which a PSE is reported in a timely manner for root cause analysis and generation of real-time intervention. It can be enhanced by improving the efficiency of the reporting process and offering a smooth process to generate actionable knowledge as soon as the report is identified by reviewer.

A user-centered PSE reporting system

To improve the accuracy, completeness, and timeliness of PSE reporting systems, a set of UCD features determined in our preliminary studies [24; 25] were developed and incorporated into our system. Table 2 shows a summary of the available and under-development UCD features in our reporting system.

</table>

(Features in an *italic* font are under development)

**Validator**

Multiple validators were incorporated into the reporting system. For example, the completeness validator can check whether all necessary fields have been filled by the reporter before the final submission to ensure the completeness of the report (Figure 2a). The spelling validator can identify spelling mistakes to avoid unnecessary accuracy loss during the similarity searching (Figure 2b). We initialized a terminology list in patient safety domain to standardize the words and phrases which may be applicable for reporters to choose from during reporting. The spelling validator was further improved toward text prediction based on the terminology list. Over time of individual and group use, nonstandard inputs are expected to be identified by this validator, and the possible standard terms will be prioritized for further selection (Figure 2b), which holds promise in improving the reporting accuracy, consistency and efficiency. Furthermore, the system can track new terms and update their frequencies to inform the system administrator periodically. The terms with high frequencies will be reviewed by domain experts and then put into an updated terminology list to enhance data entry quality.

**Knowledge support and user feedback**

With the support of the PSE knowledge base, the user can either choose an existing case or report a new PSE as a query, and the system will retrieve similar cases and customized solutions for promoting shared learning.

**Figure 2**— Screenshots for the validators. (a) Completeness validator (the IP address of local server was de-identified); (b) Validator for spelling and text prediction.

**Figure 3**— Screenshots for the knowledge support and user feedback. (a) Timely statistical analysis during reporting; (b) Providing similar cases for a new report; (c) Providing customized solutions based on user’s reporting.
As shown in Figure 3, the knowledge support and user feedback are offered for fall events in our system. Reporters can receive timely notifications about the distribution of each answer option during reporting (Figure 3a), as well as similar cases (Figure 3b) and actionable solutions (Figure 3c) after reporting. The similar cases provide previous experiences and evidence-based suggestions from healthcare experts to prevent the potential consequences of the query event. The customized and actionable solutions can offer an interactive way to solve the current event. Users are allowed to send their feedback by clicking the thumb-up buttons to let the system know their preferences. The weights of the selected similar cases and solutions will be automatically enhanced in the similarity matrices. Therefore, the knowledge support is expected to become more precise enhanced by increasing number of user feedback.

User-friendly layout

The layout of user interface was an important factor we considered during the development. A user-friendly layout could improve the reporting system in terms of completeness and timeliness. For example, the hierarchical question layout during reporting reduces reporters’ memory load for the particular task operation and decreases the likelihood of skipping correct answers.

Role-based reporting and learning

To provide customized solutions according to the various roles of healthcare providers (e.g., managers, clinicians, and staff) or even patients, we are classifying the solution entries into 3 categories: direct actions (for clinical staff to make specific actions), principles (unspecific actions, may be actionable for managers) and patients (patient actions). The system will retrieve similar cases and customized solutions based on the query and the reporter’s role.

System interoperability

Lacking considerations on system interoperability and communication indicates a poor integration of event reporting procedure into clinicians’ work flow, organizational quality control, and risk management process. Interfaces with other clinical applications (e.g., drug-drug interaction system) are under development.

Instant communication

Timeliness could be enhanced by instant communication between reporter and expert, and feedback access or notification. Both internal message module and live chat module will be developed to facilitate such communication.

Discussion

The evolution of PSE reporting systems

Similar to the evolution of electronic health record (EHR), PSE reporting systems started from an electronic copy of paper-based reporting forms. In this phase, the reporting systems can be viewed as a primitive alteration of paper-based reporting forms toward an intelligent reporting system. The use of drop-down lists, check boxes, or radio button replaces unnecessary free text boxes accelerates the electronic entry process and improves data accuracy by reducing data entry errors. The AHRQ CFs are designed to support operational systems at three levels: (1) support patient safety event reporting, which is currently a self-contained part of any EHR, (2) support surveillance based on the data derived from EHR and, (3) enhance analytics of safety and quality toward clinical decision support by linking PSE with EHR. Therefore, future PSE reporting systems should evolve toward knowledge-based and user-centered systems which could improve reporting quality by offering timely knowledge support.

A shift from quantity to quality of event reports

When the quantity of reports is the only factor addressed in a safety culture discussion, an increase in event reports might be regarded as a reflection of an improved reporting culture, while others may consider a reduction in event reports as an indication of a safer environment. Nonetheless, underreporting, low quality and fragmented reports have not been adequately addressed in event reporting. We envision that the user-centered and knowledge-based design will revolutionize the traditional event report strategy, advancing from simply counting events into a new era of understanding, trending, integrating, and resolving the events through a synchronous and collaborative platform.

A no-blame no-shame culture beyond reporting system

Patient safety is as much about behavior, value and attitudes as it is about physical action. Another challenge for improving safety is to cultivate a no-blame no-shame culture. The characteristics of a positive safety culture include communication founded on mutual trust and openness, good information flow and processing, shared perceptions of the importance of safety, and recognition of the inevitability to error, etc. More efforts should be made to help healthcare providers understand their roles in improving patient safety. The first step may be to ensure patient safety is of high priority for each healthcare organization. Opportunities have to be created for people to freely state their opinions, and this openness then needs to be transferred to systems that allow all individuals to report and discuss. A no-blame no-shame culture will allow individuals to report and discuss in a comfortable atmosphere.

Limitations

All the assessments in this project were processed through expert review since there is no gold standard for PSE similarity measurement and solution recommendation strategy. Each expert might bring a different perspective which may result in bias toward the variation among similarity scores and solution mapping rules. For example, a physician may judge the similarity between PSEs by measuring severity, while a nurse may judge the similarity based on suggested solutions. The biases are inevitable but should have been minimized based on the common understanding of safety and quality. Thereby, we provided targeted introductions before every round of expert review and use face-to-face interviews instead of questionnaires to help the experts better understand the common understanding and our research goal.

Future work

We will further develop the UCD features such as role-based reporting and learning, system interoperability and instant communication, and will incorporate other UCD features which could improve reporting quality into the proposed system. Besides patient falls, more PSE subtypes, such as pressure ulcer, medication reconciliation will be supported by the system. The effectiveness and efficiency of UCD features will be initially evaluated through usability inspection and heuristic evaluation. Then, we will conduct population-based, individual-based, and group-based evaluation through user survey [24], interview and testing [25], and focus groups respectively.
Conclusion

We prototyped a user-centered PSE reporting system based on a PSE knowledge base, which includes PSE reports, solutions, and their connections. In this system, users can either choose an existing case or report a new PSE, then the system will retrieve similar cases and customized solutions based on the query and the reporter’s role (e.g., manager, clinician, staff, patient). The user preference may be diverse for different purposes. The system allows the user to click the feedback button to indicate their preferences to a certain similar case or solution. All feedback will be returned to the algorithm implementation step in order to update the weights of similarity matrices and dynamically upgrade the system performance. This mechanism, similar to the ranking strategy of the Google search engine, will gradually stabilize the similarity matrices, making them more convincing as the feedback increases. It will be a win-win situation that both users and the system keep getting benefits from each other toward the common overarching goal of improving the PSE reporting quality and patient safety.

Abstract

The Universal Health Coverage (UHC) is at the center of the 2030 Sustainable Development Goals agenda. In this study, the authors made an evaluation of the patient health coverage indicators in eight Burundian hospitals from 2011 to 2016. The relevant UHC indicators were calculated on the basis of patient administrative and health insurance data, collected via OpenClinic GA, an information and communication technology (ICT) supported health management information system (HMIS). The results show that the patient health services coverage rate was 70.8\% for inpatients and 46.0\% for outpatients. The patient health services payment rate as the proportion of total health service costs was above the 25\% threshold recommended by WHO for inpatients (30.2\%) and for outpatients (43.1\%). The patient out-of-pocket payment was below the threshold of 180USD per patient per year for public hospitals. This study demonstrated the possibility to assess the degree of UHC in developing countries, by using routine data extracted automatically from the electronic HMIS.

Keywords

Universal Coverage; Insurance, Health; Health Expenditure; Developing Countries

Introduction

The Universal Health Coverage (UHC) has become at the center of 2015-2030 Agenda for Sustainable Development Goals (SDGs) and has gradually integrated into health policies of countries [1-6]. Under UHC framework, there would be no patient out-of-pocket payment (POOP) that exceeds a given level of affordability for the patient financial risk protection. According to WHO, people in developing countries should not spend in average of 25\% or more of their total health expenditure and a maximum of 40\% of 1.25USD per capita per day (i.e. 180USD per year) as POOP (set at zero for the poorest and most disadvantaged people) to avoid the impoverishment [7, 8, 21]. Some sub-Saharan Africa countries have made remarkable efforts to move towards UHC. In Ghana, a tax-funded national health insurance system covers 95\% of diseases that affect Ghanaians, enabling financial protection and expanding coverage [6]. By implementing ambitious reforms that started in 2000, with the goal of UHC, Rwanda currently sustains one of the most elaborate health insurance schemes: the Community Based Health Insurance Scheme (CBHI), which covers over 90\% of the population [9]. The Burundian government’s effort to spread a scheme similar to CBHI preceded the Rwandan state-driven approach by a decade and a half, but was far less successful [10]. Currently, small CBHI plans cover less than 1\% of the population specifically among local associations (farmers, bicycle drivers, etc.). Four types of health insurance plans are currently observed in Burundi:

- CAM insurance plan (Carte d’Assurance Maladie). This is a national program, with revenue collection and management at the community level similar to CBHI. According to the Ministry of Health, in 2014, 23\% of the population had adhered to the CAM.
- MFP (Mutuelle de Fonction Publique) insurance plan provides health insurance for public employees. This public insurance plan covers 3\% of the population [43].
- Private health insurance plans initiated by commercial health insurance companies in the formal sector. The classic private insurance plans (ASCOMA, JUBILEE, SOCABU and SONAVIE) cover almost 2\% of population.
- Free health services insurance plan initiated by the Government for all children under 5 years and pregnant women.

According to the "Demographic and Health Survey" conducted in Burundi in 2010, 22.5\% of the population reported to have at least one health insurance coverage scheme [11]. The health coverage in Burundi has increased (23-30\%) substantially following the integration of “Free healthcare” policy for pregnant women and children under 5 years in 2006. The World Bank and WHO statistics (2014-2015) reported in Burundi a POOP of 4.39USD per year representing 20.9\% of total expenditure on health [21, 22]. Monitoring health coverage indicators on UHC remains a challenge because the primary information of UHC comes from household surveys and health facility data but not health services data. Although most countries have functioning health facility-based health management information systems (HMIS), the HMIS data continue having a number of weaknesses, including incompleteness, inaccuracy and untimeliness, and therefore are not often used [12-14]. Appropriate application of Information and Communication Technology (ICT) can improve data quality by the computerization of the HMIS data [15, 16]. The introduction of open source ICT solutions for hospital management in several sub-Saharan health facilities prove that sub-Saharan countries move towards ICT development in health facilities [16, 17]. OpenClinic GA implementations are recorded in several health facilities over the world, and...
monitored in more than fifty health facilities both public and private in sub-Saharan Africa [16, 18, 20]. OpenClinic GA is an open source integrated hospital information system developed by the project ICT4Development of Vrije Universiteit Brussel (VUB) and put in the public domain [19, 20]. The system covers management of administrative, financial and clinical patient records; lab, x-ray, and pharmacy data; and includes an extensive statistical and reporting module. OpenClinic GA was developed in Java connecting over JDBC to the most popular ANSI SQL 92 compliant database servers (such as MS SQL and MySQL Server). It offers an easy to use web interface facilitating HMIS deployment in often challenging technological settings commonly found in developing countries [16, 19].

This study attempts to show that UHC has been adequately evaluated in Burundian health facilities using OpenClinic GA-based HMIS based on structured patient administrative and financial data (patient identification, type of encounter, insurance information, health services invoicing, etc.). The study analyzed data from eight hospitals among which district and national reference hospitals. Those hospitals joined the OpenClinic GA implementation projects since 2011. Most of them have been funded by the PAISS program (Programme d’appui institutionnel au secteur de la santé) of the Belgium Cooperation to start their ICT development [25].

Methods

The study was conducted during a 5-year period from 2011 to 2016. The process of OpenClinic GA implementation was applied and included (1) project management team set up, (2) OpenClinic GA software installation and configuration including security of the system, (3) users training and follow up; and (4) quality control, monitoring and evaluation. The implementation period was followed by a period of maintenance and assistance according to the needs of the hospital. The hospitals included in this study were:

• Three District hospitals (DH): Ngozi regional hospital (NGORH), Muramvya (MUDH) and Kirundo (KIDH) district hospitals, all started implementation in 2015.

• One Private hospital (PH): Centre medico-chirurgical of Kinindo (CMCK, 2011)

We set up the OpenClinic GA software and configured the financial module by standardizing health insurance formats and health service components for all hospitals to facilitate the extraction of UHC indicators. We then collected and analyzed UHC-related data from the 8 hospitals in the period between 1/1/2013 and 30/06/2016.

The analysis of the collected patient information was performed in the OpenClinic GA statistics module. The pertinent indicators on UHC were centralized on the Global Health Barometer (GHB), a data warehouse installed on our servers at the VUB [20].

The most essential UHC indicators were:

• The patient health insurance coverage (PHIC) by evaluating patient’s health insurance schemes; (1) Free health services (FREE) where the patient did not pay anything, (2) Social health insurance (SHI) represented by the MFP plan, (3) Community based health insurance (CBHI) including the CAM plan, (4) Private health insurance (PHI), and (5) No health insurance (PATIENT) where the patient paid the total of his health service expenditures.

• The patient health services coverage (PHSC) by evaluating patient’s health services consumed and coverage of these services by health insurance schemes. We identified two categories of patients: (1) Insured patients for whom the POOP did not exceed 25% of the health services costs, and (2) Uninsured patients who covered 75% or more of the total consumed health services with POOP.

• The patient health services payments rate (PHSP) as the proportion of amounts paid by the patient for uncovered health services divided by total amounts of health services consumed.

• The patient out-of-pocket payment (POOP) as average amount paid directly by the patient for health services not (fully) covered by the health insurance scheme.

We separately calculated these metrics for out-patient and in-patient encounters. Comparative Chi Square testing was applied to compare the coverage rate of different health insurance schemes within the hospital and between different hospitals. The correlation analyses were applied to compare the distribution of health insurance schemes for out- and in-patient encounters and examine the relationship between insured and uninsured patient statuses. Finally, the UHC indicators’ means were compared using the ANOVA test.

Results

Patient health insurance coverage (PHIC)

We analyzed more than 1.1 million electronic patient records in the course of our 4 years’ study. The distribution of out and in-patients and their encounters is shown in table 1.

For each out- and in-patient encounter, part of the health service costs is paid by the health insurer and the remainder by the patient, according to the patient’s health services coverage plan. We analyzed the health insurance schemes that have been used by patients for each encounter. Figures 1 shows the health insurance schemes coverage used for outpatient encounters in the eight hospitals.
Patient health services payment rate (PHSP)

The PHSP in the eight hospitals is represented in Table 3.

</tbody>
</table>

The highest PHSP was found in the private hospital CMCK (59.3%) for outpatients and in the military hospital HMK (56.7%) for inpatients due to the high costs of health services in these hospitals that offer a high quality of healthcare compared to other hospitals in the country. The PHSP was normally lower in district hospitals (27.5%) than in national reference hospitals (35.4%). Averages of PHSP for outpatients (43.1%) and inpatients (30.1%) were above the threshold of 25% of the total amount of health services consumed by patients recommended by WHO.

Patient out-of-pocket payment (POOP)

The POOP in Burundian hospitals is shown in table 4.

</table>

The POOP’s were higher in the private hospital CMCK and in the three national reference hospitals (HMK, CHURK and HPRC) than in district hospitals. They exceeded 90USD for inpatients in the first hospitals where health service tariffs applied were highest. Although the tariff of health services was almost the same in district hospitals of Burundi, the POOP was different in the 3 studied hospitals following to the level of health services coverage. The POOP average for inpatients (99.64USD) was significantly higher than the outpatient POOP (8.89USD). The largest differences of POOP between in- and outpatients were observed at CMCK and HMK. As seen above, the two hospitals offer health services that are expensive because of their (private) status and the quality of services they provide to the patient. The inpatient POOP’s for the two hospitals were the highest and exceeded the threshold of 180USD for inpatients at CMCK.

Discussion

This study focused on the health services coverage monitoring by collecting and analysing data using OpenClinic GA-HMS implemented in eight Burundian hospitals. The results showed that patient health services coverage (PHSC) was globally...
70.8% for inpatients and 46.0% for outpatients. It was higher in the public hospitals compared to the private hospitals due to the important intervention of health insurance coverage plans oriented towards FREE (6.0%-55.6%) and SHI (5.8%-69.1%) schemes. We noted the intervention of CBHI (7.5%-26.0%) schemes in district hospitals especially for outpatient encounters. The CBHI scheme was predominantly higher based on the use of the CAM insurance plan. The results of health coverage found in the studied hospitals are higher than those in the reality at national level where the population health coverage is between 23-30%. The group of patients in the population is apparently better assured than the general population. This likely resulted from the adverse selection observed in certain health insurance contexts [23, 24] causing high costs for health insurance. Bearing in mind that the hospitals studied were at the second and third reference level, the PHSP remained globally above the 25%-threshold both for inpatients (30.2%) and for outpatients (43.1%) due to health services not covered by certain health insurance plans at those levels. This situation has been also observed in Rwanda [18, 24]. The POOP was also higher in these hospitals (89.99.64USD) than the national average (4.39USD) as could be expected. Although POOP was below the threshold of 180USD per year in all hospitals, it remained high for inpatients in private hospitals due to the high costs of health services in those health facilities. An effort is still needed for Burundian health insurance schemes to reach the patient financial protection in the framework of UHC.

Conclusions

In this study, we have demonstrated the feasibility of evaluating the UHC level in developing countries using ICT-HMIS routine patient data recorded by the health facilities themselves. Specifically, the implementation of an ICT-HMIS has enabled the monitoring and evaluation of UHC in eight hospitals of Burundi. The methods used allowed extraction of routinely collected patient data for secondary use in this health insurance coverage study. The study showed that the level of patient health services coverage was significantly higher for inpatients than outpatients. It was also high in hospitals where the patients were covered by more solidarity-based health insurance schemes especially by Free health services and social health insurance plans. We suggest that more efforts are needed to achieve good patient financial risk protection in Burundian hospitals since none of the hospitals involved in the study has reached all the thresholds recommended by WHO.

User Centred Design and Nosocomials in Surgical ICUs: A Mobile Application for Peer Monitoring and Training in Hand Hygiene

Nadish Kariyawasam*, Ming Chao Wong*, Paul Turner*

*eHealth Services Research Group, University of Tasmania, Tasmania, Australia

Abstract
Nosocomial infections are a global public health risk. In low and middle-income countries the problem is acute with very high infection rates commonly contributing to poor patient outcomes including mortality. Organisational, cultural, and individual factors have been identified in these high rates, with poor hand hygiene compliance amongst clinicians a major risk factor. New approaches to achieving clinician behaviour change are required. User-centred approaches have proven effective to engage and support changes in clinician behaviours through the use of electronic tools. This paper reports on the experience of co-designing and implementing a mobile application with clinicians to enhance hand hygiene compliance. The peer monitoring and training supported by the application aims to directly contribute to evidence on reductions in infection rates in two surgical ICUs in Sri Lanka.

Keywords:
Mobile Applications; Cross Infection

Introduction
Nosocomial infections are a major public health concern throughout the world. Nosocomial infections contribute to elongation of hospital stay, long-term or permanent disability and death [1]. Each year health systems spend a considerable amount of resources, including high-end antibiotics, health professional work time, and hospital space to treat the consequences of nosocomial infections [2].

Previous research has already identified multiple factors contributing to differential rates of nosocomial infections in different clinical contexts. These include:

- Improper antibiotic usage and increasing antibiotic resistance;
- Congested and crowded healthcare facilities;
- Ineffective medical device cleaning and/or contamination during usage;
- Poor hand hygiene compliance amongst clinicians.

Numerous interventions have been implemented to reduce nosocomial infections with varying degrees of effectiveness. Infection rates, however, continue to be a significant burden on hospitals and patients, especially in lower and middle-income countries. Nosocomial infection rates in these countries continue to remain around 10 to 20 cases per 100 hospital admissions [3]. Sri Lanka, a ‘low’ middle-income country, continues to exhibit relatively higher rates of nosocomial infections in the cases/100 admissions scale. Explanation of these higher rates forms part of the investigation, however, previous anecdotal evidences appear to be intimately related to organisational and cultural factors. It is also evident that within intensive care units (ICUs) where patients are more immobile and more immunocompromised, infection rates tend to be highest [4]. As a result, this research has focused on exploring mechanisms to contribute to reducing infection rates in Sri Lankan Surgical Intensive Care Units (SICUs).

Information technology in health care, (eHealth) has already opened up opportunities to increase health care safety and quality [5]. eHealth is also already extensively used to improve various situations associated with hospital-acquired morbidities. These include improving patient handover [6], reduce medical and medication errors [7], antimicrobial stewardship [8], electronic surveillance of nosocomial infections [9], and post-operative monitoring [10]. However, inadequate usage, over usage, and inappropriate usage of eHealth can also contribute unintended negative consequences. These include contributing to safety risks through technology-induced errors and medication errors [11].

In optimising the development, implementation, and impact of eHealth, human factors engineering and user centred design (UCD) approaches have been used extensively to ensure technology user attributes, needs and work contexts are adequately understood and addressed as part of information technology development life cycle [12,13]. In healthcare, UCD has contributed to emergence of eHealth systems that are versatile, user-friendly, safe and dependable and that integrate more seamlessly into clinical work environments [14,15].

This paper reports on the experience of co-designing and implementing a mobile application with ICU clinicians developed utilising user centred design with the aim of contributing to improving hand hygiene compliance in two hospital surgical ICUs in Sri Lanka. The peer monitoring and training supported by the mobile application aims to directly contribute to evidence on reductions nosocomial infection rates.

Methodology

Project Overview
This research involved using a multi-centred and multi-phased approach [16].
Phase one involved establishment of baseline quantitative nosocomial infection data across six surgical intensive care units in six Sri Lankan hospitals. Information from patient records were entered into an online data collection form that comprised data pertaining to demographic information, separation diagnosis, antibiotic usage, clinical interventions performed, culture reports as well as any other significant clinical findings indicative of infections.

In phase two, several observation sessions were carried out in two surgical intensive care units. During these sessions, hand hygiene compliance behaviours of unit staff were observed according to the ‘five movements’ of hand hygiene [17,18]. The observations were recorded using the World Health Organization, hand hygiene monitoring observation form. Semi-structured interviews and focus group discussions were carried out to determine staff attitudes and perceptions towards hand hygiene compliance and perceptions of nosocomial infection rates and ‘best practice’ for infection rate reduction. Staff were invited to consider whether they felt the current situation in their ICU should be changed and if so, what measures they would recommend to improve the situation. Staff were generally very supportive of trying to reduce infection rates and recommended the need for measures that would target improved hand hygiene compliance. Following further user-led discussions the idea of intermittent peer monitoring and iterative training in hand hygiene compliance was agreed and interest shown in how an eHealth system could be developed and deployed to support this desired behaviour change.

A mobile application was developed using rapid prototyping and iterative design with staff, based on their requirements and evolving feedback. The developed application was implemented in two surgical intensive care units as part of the commencement of phase three of the research methodology. The developed mobile application was implemented over a four month period in both ICUs. Alongside data collected by the application itself, data pertaining to behavioural and attitudinal changes associated with its implementation were also collected at the start of the second and fourth month of the application’s implementation. Post-implementation observations and interviews/focus groups were conducted to explore perceptions around improvements in hygiene compliance rates, staff attitudes and perceptions towards hand hygiene compliance. The overall impact on compliance rates and perceptual and attitudinal changes will be compared against baseline data on completion of six months after application’s implementation.

Phase four will involve further collection of patient record data pertaining to demographic, diagnosis, antibiotic usage; interventions performed, culture reports, and other clinical findings indicative of infections to contribute to baseline comparisons about the nature, type, and severity of nosocomial infections.

Utilising UCD in a mobile application for peer monitoring and training on hand hygiene to improve compliance

The design of the mobile application was an iterative process that involved co-design with, decision-making by and guidance from intensive care unit staff, hospital infection control staff, hospital administrators and microbiologists. At the initial stage of the research, users identified nosocomial infections as a major reason for the worsening of patient conditions while being treated. Then they identified leading causes of nosocomial infections including poor hand hygiene compliance. Hand hygiene was ultimately identified as one of the major contributing factors. Staff further anticipated that proper intervention could significantly improve hand hygiene compliance. eHealth was identified as a potentially useful tool in the intervention. Staff suggested changes to the current ‘Hand hygiene compliance observation form’ and advocated incorporating this form into a more user-friendly and accurate mobile application for ease of access and use in the ICU environment and with staff workflow. A small tablet computer that could be easily cleaned with soft wipes was selected.

Development and Implementation of the Application

The mobile application was actually coded up using an agile development approach combined with iterative user feedback [19].

The application was based on the WHO hand hygiene compliance observation form but modified to accommodate local user needs and contexts of use. The iterative prototyping and user testing led to changing the app several times to reduce the ‘number of clicks’ and to improve the ease of ‘repeated data entry’. The application collected hand hygiene compliance data during each peer monitoring session in each ICU and allowed time, staff member category, gender, and compliance with ‘five movements of hand hygiene’ to be easily and quickly recorded. This data was locally saved in the mobile device and synchronised to online system when connected to the internet.

Figure 1 shows the registration page of the developed application. New users registered their credentials while revisiting users can use their saved credentials to access the application.

![Figure 1 – Registration screen of mobile application](attachment:image.png)
Figure 2 shows the hand hygiene compliance monitoring screen of the application. Users can monitor up to four staff members at any given time. After multiple usability testing, the application was implemented in two surgical ICUs in two hospitals in Sri Lanka. The application is currently being used mainly by nursing staff to monitor fellow nurses and other staff. Unlike most of the other monitoring methods where one person is always the observer and the others are always observed, in this instance observer/observed iterate their roles as part of the training component around enhancing hand hygiene compliance. The staff were keen to ensure a supportive, learning and collaborative implementation rather than a more punitive, error-checking approach. Therefore, every participant who conducts observations will also at some other time themselves be monitored for compliance.

During the initial phase of implementation, a decision was made to not provide any feedback on the observational findings. However, feedback is provided during the later part of the implementation to enable researchers to assess the impact of feedback on behavioural change. It is hoped this will contribute to enabling subsequent application roll-out to other hospital sites.

Results

Preliminary results of the research prior to provision of feedback are shown in tables 1-3. According to table 1, 12% of patients who were admitted to the SICUs had at least one positive culture report during their stay in the SICU or within 48 hours after leaving the SICU. However, regardless of the percentage of culture reports, 79% of patients who did not have any antibiotics prior to admission to SICU were started on antibiotics during their stay in SICU. Further, 60% of patients had signs, symptoms or investigations indicative of infections.

Table 2 demonstrates hand hygiene compliance rates observed by peers amongst a few categories of participant clinicians during the observations conducted prior to the provision of feedback. Based on these observations, nurses had a compliance rate of 42% while medical consultants and officers had a compliance rate of just above 20%. However, none of the electrocardiogram (ECG) technicians who visited SICU during observation sessions cleaned their hands.

As reported in table 3, hand hygiene compliance rates are lowest during morning busy hours of 8 am to 12 noon closely followed by 12 noon to 4 pm. During the night-time hand hygiene compliance rates are relatively high with the highest rates reported during the hours of 8 pm and 12 midnight.

This research is currently in progress, and therefore the final outcomes are still unknown. However, several inferences can already be drawn from the available preliminary data:

1. Nosocomial infection rates appear to be high. However, when established filters are used to determine nosocomial infection rates using CDC guidelines the real infection rates found seem to be significantly lower than currently projected rates.

2. These discrepancies are mainly due to incomplete retrospective data hindering establishment of diagnoses.

3. Hand hygiene compliance is between 20% to 45% among health professionals. Compliance is comparatively high among Nurses while very low among ECG Technicians. Female professionals appear to comply better than males.

4. Out of five movements of hand hygiene, staff appear to be complying with proper hand hygiene measures with movement two and three (i.e., before aseptic procedures and after touching bodily fluids) but are least compliant with hand hygiene measures after movement five (i.e., after touching patients’ surroundings).

5. Compliance rates are comparatively better during the night than when the ICU is busy during the daytime.

6. Almost all health care staff interviewed want an improvement in the situation to have better hand hygiene compliance and lower nosocomial infections. However, there seem to be huge differences in the level of commitment to change from individual to individual.

7. There is a marked difference between what health professionals perceive they are doing and their actual behaviour. Self-awareness of poor hand hygiene compliance seems to be lacking among most health professionals.

8. After implementation of the application, self-awareness of poor hand hygiene compliance has improved. Further, month to month hand hygiene compliance data appears to be on a positive trend.

9. Surgical Intensive Care Units staff seem to be more vigilant regarding potential introduction of infections from outside sources such as visiting staff and relatives of patients.

**Discussion**

This research is still in progress but provides a clear example of the benefit of utilising a user centred approach to ensure strong adoption and use of eHealth in a sustainable and inclusive manner. The UCD approach facilitated users to take more ownership of the application and contributed to improved awareness and support for the intervention. However, preliminary results have yet to indicate any marked improvement in compliance. Although quantitative analysis of how the changes and intervention have impacted on reducing nosocomial infections is yet to be done.

Further, this approach and ultimately the developed application help in supporting peer to peer mentoring among the health care workers, that is markedly different from Sri Lankan work culture which still exhibits significant hierarchy. This monitoring method may prove to be more beneficial in inculcating self-awareness of the issue. Moreover, it is hoped the approach will assist in supporting sustained behavioural change compared to routine hand hygiene monitoring strategies assigned to infection control staff. Critically, it may be that the application enables a move away from an ‘examination’ approach to one that stimulates genuine and sustained behavioural change where participants can support one another to improve overall compliance.

In peer to peer observations, inculcating behavioural change happens in two ways. Firstly, staff tend to be more aware of complying when being observed. Then while they observe others, they identify how frequent compliance errors are and learn from others’ mistakes and try to avoid them while they are at work. Regular feedbacks give the staff re-enforcement about good hand hygiene practice.

Together, this intervention may prove holistically to raise awareness of the existence of the problem, and provide staff with practical re-enforcement to improving behaviour.

**Challenges around Nosocomials and Baseline Data**

Pre-interventional hospital records are being analysed to provide a statistical baseline on nosocomial infection rates. In analysing these records it was initially found that relatively low nosocomial infection rates were recorded. However, this is primarily due to inability to formally establish genuine nosocomial infections due to the following reasons:

- Non-availability of appropriate culture reports conclusively validating the nature of any infection
- Poor recording of appropriate signs, symptoms, and investigations in the patient record that hinders ability to establish infections
- Non-availability of pre-infection reports inhibiting ability to definitively differentiate nosocomial infections from other types of infections
- Irrational antibiotic usage that inhibits use of some of the criteria conventionally deployed for formally establishing nosocomial infections

Given these limitations, the research team developed with a micro-biologist some criteria that could be used to get an indication of infection rates. In this context, a concept “SigNS, Symptoms and Investigations Indicative of Nosocomial Infections (SSINI)” was developed and utilised. The following criteria were used to consider a patient as having SSINI:

1. No sign, symptom or investigation finding indicative of infections before admission to SICU or during first 48 hours at the SICU.
2. No record of antibiotic usage up to the first 48 hours at SICU.
3. A positive sign, symptom or investigation indicative of an infection first recorded at least 48 hours after admission to SICU.
4. Patients with signs, symptoms or investigations indicative of infections before spending 48 hours in the SICU or patients who have received antibiotics before spending 48 hours in the SICU (unless just one dose) were excluded from the analysis.
5. Patients who have spent less than 48 hours in SICU were also excluded from the analysis.
Limitations of research scope and scale

Quantitative analysis involving just six hospitals may not generate statistically significant data for generalisation of the results to all surgical ICUs. However, it is anticipated that any trends associated with the intervention may be used to predict the outcome of similar interventions in other locations.

This research is also being carried out as part of the doctoral thesis, i.e. this primarily involves one researcher. Therefore, there were some limitations in terms of finance, time, and trained personnel to conduct a larger and more comprehensive research investigation. However, adopting a multi-centred approach has contributed in excluding the possibility of any recorded outcomes caused purely by chance.

Conclusion

This research is contributing to efforts to reduce nosocomial infection rates. Using a UCD in co-designing a mobile application has led to strong and sustained adoption and use of an application perceived as user-friendly and efficient. It is anticipated that the research will also enhance understanding of how peer assisted monitoring can be used in inculcating behavioural change. Though final outcomes of the research are still unknown, preliminary insights show important steps towards change in user behaviour associated with this eHealth intervention. A future research paper will discuss the quantitative outcomes of the research and overall impact of the research in contributing to improved hand hygiene compliance and its relationship to overall reductions in nosocomial (SSNI) infections.

Abstract

Providing patients with specific information about their own drugs can reduce unintentional misuse and improve compliance. Searching for information is time-consuming when information is not personalized and is written using medical vocabulary that is difficult for patients to understand. In this study we explored patient information needs regarding visualizing of drug information and interrelationships by conducting a total of four co-design workshops with patients, other users and pharmacists. We developed a prototype and drug ontology to support reasoning about drug interactions. We evaluated individual performance in finding information, understanding the drug interactions, and learning from the provided information in the prototype compared to using patient information leaflets (PILs). We concluded that interactive visualization of drug information helps individuals find information about drugs, their side effects and interactions more quickly and correctly compared to using PILs. Our study is limited to co-morbid patients with transient ischaemic attack with several chronic diseases.

Keywords:
Drug Interactions; Patient Medication Knowledge; Computer Graphics

Introduction

Patients’ misunderstanding about their prescribed medicines and their interaction can cause unintentional misuse, poor adherence and less effective treatment [1]. According to the pharmacists’ association in Norway, over 1,000 patients die each year as a result of side effects and inappropriate use of drugs. Adverse consequences of the use of drugs are in addition to death or injury. Errors can occur because the patient is using medicines incorrectly due to insufficient information and miscommunication, and patients who are not in charge of their own medication are especially vulnerable to failure [2; 3]. Studies show that patients with limited literacy were more likely to misinterpret instructions, and precise wording on drug label instructions can improve patient comprehension [1]. On the other hand, according to the pharmacists’ association in Norway, patients’ poor compliance caused one out of three patients in Norway to not take their medicines due to fear of side effects. The number of patients with several chronic diseases is increasing and this has caused a decrease in the likelihood of good compliance due to the difficulty of keeping track of the reasons for taking drugs and how or when to take the medicine, especially by elderly patients [4; 5]. Studies show that better and more accessible information on drugs can help increase patient compliance [6].

There are many drug information sources available in Norway, including patient information leaflets (PILs) and websites for patients. Sources such as PILs, helsenorge.no, Legemiddel-handboka.no and interaksjoner.no are available for drugs prescribed and marketed in Norway, however the available information is not individualized for each patient and often uses many medical words and phrases that might be difficult for individuals without knowledge in medicine to understand.

Although presenting and visualizing drug information to the healthcare professionals about adverse drug reaction, drug overdoses and drug combinations for multi-drug users has been a subject of interest for many years, enabling patients to easily access their drug information and be informed about adverse reactions has largely been neglected. Therefore, in this study we explored the individual’s information needs regarding their medication, and how to visualize drug information (including drug interactions) in a way that is understandable for individuals without a medical background. Based on the collected data and involving patients and pharmacists, we developed a prototype that visualizes personal drug information. We evaluated individuals’ performance in finding information, understanding the drug interactions and learning from the provided information in a prototype, compared to using PILs. To limit the scope, we focused on patients with transient ischaemic attack (TIA).

Material and Methods

In order to envisage concrete application examples we developed personae and user stories in collaboration with a senior pharmacist to describe the target audience of the prototype. Use of personae in an interview with patients and users is a useful approach in order to avoid asking personal questions related to the interviewee’s health condition and medication. The experiment was conducted in two parts. The goal of the first experiment was to identify requirements via co-design workshops in order to develop the prototype. The second experiment was performed to compare the visualization of drug information in the developed prototype to the PILs. In each of the experiments we applied different methods that are explained in this section.

Personae

In order to cover the largest possible number of common patient traits, a total of five personae were developed illustrating different types of patients. Three of the personae experienced transient ischemic attacks while suffering from other chronic diseases with the age range of 27 - 87 years old. The other two personae were: one female persona with epilepsy was planning to become pregnant, the other persona
had multiple diseases (high cholesterol, diabetes, urinary tract infections) and therefore used number of other drugs with different symptoms such as headaches and depression.

**Identifying Requirements through Co-Design Workshops**

To identify requirements and explore how to visualize drug information, we applied co-design principles [7]. Hence, we conducted a total of four co-design workshops. Two of the co-design workshops were conducted together with pharmacists, and in the other two workshops we recruited participants (patients and volunteer participants) in order to include their perspectives on the design and visualizing of drug information. Results of the co-design workshops have been used to design and develop the digital prototype and competency questions [8] in order to design the drug ontology for the prototype. Details about the designated ontology based on the competency questions are provided in the “Design of the Ontology” section.

**Co-Design Workshops with Pharmacists**

A total of two pharmacists (one pharmacist who works at the counter at the hospital pharmacy and one clinical pharmacist) participated in our workshops. They were selected based on the purposive sampling method [9]. The goals of the workshops with the pharmacists were to understand patients’ information needs about medicines, explore alternatives on presenting drug information to patients, identify functional requirements that the prototype needs to support, identify the competency questions that the ontology needs to answer, and create the conceptual design [10] of the prototype.

The first workshop consisted of five steps: 1) semi-structured interview on how pharmacists interact with patients; 2) semi-structured interview about what the pharmacists expected the patients’ information needs to be; 3) pharmacists were asked to make a sketch of a system that would introduce personal drug information to a patient while thinking aloud; 4) discussion about the designed sketch from part 3; and 5) ranking the identified requirements based on their importance to be considered in the design of the prototype. To ensure the results were not affected by the order of the performed tasks, we reordered steps 2 and 3 for each pharmacist. The goal of the second workshop was to test the designed paper mock-up [10] and receive the pharmacists’ feedback on the presentation and user interface.

**Co-Design Workshops with Users**

Since our project focused on patients with TIA, we contacted St Olav Hospital in Trondheim to recruit patients for our co-design workshops. A total of two patients diagnosed with TIA voluntarily participated in our case study. In addition, we recruited a total of ten students, employees and their families from the Norwegian University of Science and Technology (NTNU). Participation in our case study was voluntary, as we requested volunteer participation. The goal of the workshops with patients and other volunteer participants was to identify drug information needs, elicit requirements for a user-centred design by involving users in the design of the prototype and to test the paper prototype. Furthermore, we also focused on identifying the competency questions that the ontology needed to answer in the workshops.

In the first user-workshop, the personae and user stories were given to the participants and we conducted a semi-structured interview in order to identify requirements with regard to the participants’ information needs. In the second workshop, the designed paper mock-up was presented to the participants, and in the semi-structured interview they could give feedback on the presentation, including the detail of the presented information, user interface and navigation, all based on the defined task set to evaluate whether all the tasks could be enacted. Results of the workshops contributed to the conceptual design of the prototype.

**Design of the Ontology**

To implement the prototype, we built a knowledge model of drug information in the form of an ontology. Competency questions define ontology requirements by indicating which questions the ontology should be able to answer with high-level coverage [8; 11; 12]. The competency questions are the questions that end-users would ask given the ontology about the drugs; hence in the four mentioned workshops we identified a set of competency questions.

We conducted a literature search to investigate the potential available ontologies. We identified Drug Ontology (DrOn) [13; 14], Drug-drug Interaction and Drug–Drug Interaction Evidence Ontology (DIDEO) [15], Drug Interaction Ontology (DIO) [16], Drug–Drug Interactions Ontology (DINOTO) [17], and one comprehensive collection of marketed drugs in Japan, the USA and Europe (KEGG DRUG database) [18]. The ontology for our prototype was required to support reasoning and answer all the competency questions, and support Norwegian clinical terminologies (ordnett.no, ICD-10, MeSH terms, finnkode.no and Norsk Legemiddelhåndbok (the Norwegian Drug Handbook)). Since we could not address our requirements based on the identified ontologies and database, we designed our own ontology based on the personae, the competency questions and the Norwegian Drug Handbook. We note that since the project scope is limited, our ontology is only able to support medical terms and reasoning for the personae we developed for this project. Therefore, information about symptoms treated by a selected list of drugs related to personae (patients with TIA and multiple chronic diseases taking several drugs), active ingredients, adverse effects and dosage, are included in the ontology.

**Comparison of Patient Information Leaflet and Prototype**

We recruited a total of 13 participants by contacting St Olav Hospital and students at the NTNU. In order to reduce the risk of learnability of the scenario subjects, we divided the participants into two groups: one group (seven participants) only used the PILs while the other group (six participants) only had access to the developed prototype. We applied different methods to analyze and compare the PILs and the prototype that visualized the information about the drugs. The applied methods were: 1) pre-test questionnaire (questions about participants’ age, their competence using a computer, and previous knowledge about the drugs we were questioning about in the case study to control for previous experience and its effect on the results); 2) scenarios and tasks (persona was given to participants followed by a total of seven tasks); 3) usability questionnaire (System Usability Scale (SUS) forms [19]); 4) semi-structured interview; 5) learning outcome questionnaire (to examine the extent to which the participant learned something from the given tasks without access to the prototype or PILs). In the last step (measuring learning outcome), we considered both ‘learning by remembering information’, which is linked to the given statements, and ‘learning that goes beyond the statements’. This was performed to investigate whether users acquire more knowledge using the prototype with intuitive visualization than with the PILs.

**Data Analysis Methods and Metrics**

For analyzing the collected data from semi-structured interviews and workshops, we applied the open coding method [20] in order to identify a list of concepts, group them based
on their similarities or related phenomena, explore the relationships between them and generate categories of concepts. We evaluated participants’ task success rate by reviewing their written responses to the given questions in the scenario. We also measured the task completion time for each participant and calculated a geometric mean to present overall performance of the participants in task completion time, as the geometric mean is a better estimate for small samples (*n < 25*) [21].

**Results**

**Information Needs**

The interview with the pharmacists showed that they believed that all drug information was available on the Internet, but that some of the information was difficult to understand without the professional background of a pharmacist. The language, in which the information is to be presented, should be informal and easy to understand by the patient. As an example, none of the participants in the co-design workshops understood the term ‘drug interaction’.

We identified a total of eight themes regarding the information needs: reason for taking a drug, dose and duration of treatment, practical use (when and how the drug should be taken, e.g. without food and with plenty of water), side effects, photos of the drugs, information about generic drugs, combination with vitamins supplements and natural products (herbal medicines), and their interaction. Based on the interview with the pharmacists, we found that information that is given by pharmacists to patients can be misunderstood. For example, one pharmacist told a story about a patient who was given an allergy spray because she was allergic to her cat. Later the same patient returned to the pharmacy because she was dissatisfied with the effect of the allergy spray. The patient explained that she had sprayed the cat every day, but that she was still suffering from allergic reactions. The patient had thus misunderstood and thought that the spray was for the cat and not to be used by her. Therefore, it is necessary to present the method of application or use of medicine and this should include over the counter drugs (OTCs). OTCs could also have side effects, interact with other drugs, including herbal supplements, and can sometimes cause serious health problems, especially in older adults [22; 23].

**Visualizing Drug Information and Functionalities in Prototype**

In the co-design workshops we explored how to present information about the drugs and visualize their interaction in textual description and graphs. We used the information about drug interaction from the web page at www.interaksjoner.no. However, we presented information using simple language than the web page and did not display any anatomic therapeutic chemical (ATC) codes. We also explored how to add additional features and information to the interaction graph, such as zooming, removable nodes, the ability to highlight specific parts of the graph, adding information about side effects, overlapping effects and interactions. We also explored presenting side effects in a word cloud, tiles inspired by VIEVISU [24] and how to use the search function to find side effects. In the visualization we also evaluated presenting information to seniors who often have poor eyesight. Figure 1(a) presents our paper mock-up regarding drug interaction and Figure 1(b) presents the screenshot of the prototype.

The implemented functionalities, based on the co-design workshops and feedback received from pharmacists, patients and users, are: login with high level of security (level 4) in Norway, which requires a national identity number, security token from a bank and a personal password [25]; add and remove drugs (including non-prescribed drugs) in the personal drug list; present possible side effects and indicate how common and how serious they are; present possible drug interactions and indicate how common and how serious they are; present what disease the drugs are intended to treat; present multiple drugs with the same active substances; display warnings for food and beverages that should not be combined with the drug(s); display warnings if the drug affects the ability to operate heavy machinery; present long-term effects of taking drugs; a warning to seek medical advice when necessary; include a photo of the drug; support to report experienced adverse reactions for each user; and display the expiry date of the drugs, customize how much information should be visible to them, and customize the display of information to specific populations (e.g. for elderly patients with poor eyesight). The prototype supports a search function, so it is also possible to search the drug symptoms either by entering the search keyword or by clicking on the body part of a human figure designated in the interface. The drug interactions and symptom interactions are presented in the graph in different colored clickable nodes with details presented in a pop-up window. The prototype supports the automatic updating of the interaction graph and the search results if a new drug is added to or removed from the drug list.

**Comparison between Drug Information Leaflet and Prototype**

People aged 23 to 70 participated in our experiment; the average age in group 1 (PILs) was 37.8 and in group 2 (prototype) 34.5 years old. Based on the pre-test questionnaire, all participants had good computer skills, their educational level was generally high, but was on average slightly higher in group 2. The term ‘drug interaction’ was unclear to the participants. Figure 2(a) presents a comparison of the geometric mean of task completion time between the two groups. Figure 2(b) presents the average SUS score between the two groups. Figure 3 presents the percentage of the task completion rate between the two groups.

We considered two different forms of learning in the evaluation (learning by remembering information linked to the statements and learning that goes beyond the statements). Figure 4 presents the percentage of learning outcome for group 1 and group 2. The learning outcomes were low for both groups, but we could see that users acquired some knowledge about their medicines, both through the PILs and the prototype; however, participants using the prototype seemed to learn more (learning by remembering information) about the drugs compared to the other group. Based on the presented comparison between the two groups, we could see that ‘learning beyond the statements’ was very low in both trials, but it was higher when using the PILs.
Based on the semi-structured interviews, participants stated that the PILs language was difficult to understand, lacked proper structure and contained too much information; it took quite a long time to read through the whole leaflet. They had to skim through the content rather than reading everything in detail. In addition, although some of the participants using the PILs could identify the drug interaction, they did not consider the statements to be correct as they did not understand the presented information. The prototype was described as intuitive, time-saving, easy and effective to use in finding information, logically structured and easy to understand. Several participants emphasized that the interaction graph made it easy to find information about drug interactions and how all the drugs worked together.

**Figure 3— Comparison of task completion between two groups**

![Image](349x580 to 430x668)

**Figure 4— Comparison of learning outcome (in percentage)**

**Discussion**

Based on the results in Figure 2, participants could finish the tasks faster when using the prototype than the PILs. We are aware that faster task completion may have led to more errors and affect the task success rate. Therefore, we compared the task completion time versus task success rate in order to analyze the time spent in relation to the number of correct answers. Figure 5 presents the average time spent for each correct answer for the two groups. As is presented in Figure 5, the time spent (in seconds) was lower per correct answer using the prototype. Taking the participants’ age and education into account and their effect on task completion time, we could not see any correlation between them.

![Image](349x568 to 430x668)

**Figure 5— The average time spent (s) for each correct answer**

We added adjectives to the SUS scores, as suggested by Bangor et al. [26], to better understand the SUS scores. The results of our SUS scores and their mapping to an adjective ranking scale are presented in Figure 6. We could see that the prototype is in the ‘acceptable–excellent’, while the PILs are in the ‘marginal–low’ range. This supports our findings from interviews and the results that are presented in Figure 2 and Figure 3, i.e. that the prototype is more usable than the PILs.

![Image](349x568 to 430x668)

**Figure 6— Adjective rating scale [26] added to SUS scores**

One limitation of this study is that the sample is biased towards 13 participants, who could only access either the PILs or the prototype. Another limitation is that our prototype only supports certain personae and was limited to a certain number of drugs based on the developed personae. We did not evaluate the system in a clinical setting, and patients could have access to the system at home. This will be considered in future work. Conducting a case study in the future on both sources of information for all participants with a different set of tasks is another consideration. A new experiment may be carried out to explore how visualization could be adapted to different patient groups. For example, there is an opportunity to examine whether cancer patients have different needs to stroke patients, or whether women and men prefer different ways to view personal drug information.

Considering the results from the learning outcome, specifically ‘learning that goes beyond the statements’, a detailed study is required to investigate why users learned more from the PILs than the prototype, or to evaluate whether the results from our case study are generalizable or can be different with another set of participants.

**Conclusion**

In this paper we present the process of co-design to identify requirements for developing a prototype system for interactive and visualizing personal drug information. In addition, a case study was conducted to compare the developed prototype to PILs and evaluate users’ task completion success rate, task completion time, learnability and usability. The analysis led to the assertion that using the prototype to find information is faster than using the PILs and the prototype is more usable than the PILs. Participants who used the prototype made fewer
mistakes. Understanding the drug interactions based on the PILs was cumbersome for the users. The results showed that presenting a lot of information in the PILs and using high-level language with no degree of personalization affected the task success rate and the time spent in finding answers. The experiment showed that, using the prototype users were more successful in recalling information related to the assessment of the statements. We conclude that the visual representation makes drug information more accessible and understandable to patients than PILs. The prototype is useful as it provides patients with the ability to assess their own drug use and to answer their concerns.

Mutual Learning and Exchange of Health Informatics Experiences from Around the World - Evaluation of a Massive Open Online Course in eHealth

Sabine Koch, Maria Hägglund

Health Informatics Centre, LIME, Karolinska Institutet, Stockholm, Sweden

Abstract

We report our experiences from the Massive Open Online Course (MOOC), “eHealth – Opportunities and Challenges”, run by Karolinska Institutet using the edx platform both as session-based and self-paced versions between 2015 and 2016. In total, 13,302 students from 162 different countries were enrolled in our courses during the two-year period whereof 573 completed them. 331 students answered an exit survey after finishing the course which was analysed using quantitative and qualitative methods. As positive outcomes of the course, students highlighted set-up and content of the course, the pedagogical approach and the consistent international focus. Students lacked more practical case studies, more interactive discussions and proposed advanced follow-up courses on certain topics. Faculty lacked better functions for management of the discussion forum. Major advantages of the MOOC were mutual learning and exchange of health informatics experiences from around the world that would have been difficult to achieve in traditional learning contexts.

Keywords:
Education, Distance; Medical Informatics; Surveys and Questionnaires

Introduction

Although online education, virtual learning environments and distance learning platforms have been around for many years, it was not until 2008 that Dave Cormier coined the term Massive Open Online Course (MOOC) based on a large online course run by Siemens and Downes [1]. Massive Open Online Courses (MOOCs) offer new possibilities to reach large numbers of students with very different disciplinary and cultural backgrounds. Health informatics as a subject is interdisciplinary by nature. The challenges and opportunities of the field are global. Thus MOOCs may provide a good platform to address the global aspects of health informatics in an international environment.

Motivation to provide a MOOC

Since 2010 we run a global master’s programme in health informatics at Karolinska Institutet as a joint collaboration with Stockholm University [2]. When Karolinska Institutet joined the edx consortium for MOOC-based education [3], we decided to design a basic course for a diverse target group with the aim to reuse parts of the course as a “flipped classroom” model for our own master’s programme, but also to market health informatics at Karolinska Institutet, to raise awareness for our education and to attract highly motivated and competent students for our campus education [4]. We ran different instances of the course, both as session-based and self-paced versions. Without any prior experience in providing MOOCs we offered a course that is broad in content and has an inhomogeneous target group. Thus we were interested in evaluating how students and teachers perceived the course and in how far our initial pedagogical considerations were valid.

Methods

Set-up and content of the course

“eHealth – Opportunities and Challenges” is a six-week introductory course in eHealth and health informatics targeting a broad student group without prior specific knowledge in the field [5]. Some experience with the health sector either as patient, care professional, IT and healthcare manager or policy maker is, however, recommended for following the course. The overall learning objectives of the course are to enable students 1) to describe different eHealth applications and 3) to analyze eHealth strategies and discuss them in relation to the student’s specific context.

The course is divided into six weeks, each covering a distinct topic (table 1). The content is released at the beginning of each week. Each week starts with an introductory video lecture about the topic of the week followed by a series of short videos (5-10 minutes) about sub-topics and by accompanying literature. Smaller learning tasks and quizzes are provided in each of the weeks. Every second week students have to complete a course assignment that covers the content of the preceding two weeks. The estimated workload is 4-6 hours per week. The course was given in three different versions:

1. As session-based course, provided free of charge (April-June 2015).
2. As self-paced course (same content as 1 and free of charge) (Dec 2015 – May 2016)
3. As session-based course with some revised/added content, provided free of charge with the possibility to opt for paid-for-certificates (Oct – Dec 2016)

Quantitative results from the exit survey

331 students filled in the exit survey. 71.6% (n=237) perceived that they achieved all learning outcomes of the course to a large or very large extent. 56.1% (n=186) reported that they achieved their personal goals for taking the course to a large or very large extent.

74.9% (n=248) found to a large or very large extent that there was a common theme running throughout the course. 49.5% (n=164) said that they developed valuable expertise and skills to a large or very large extent.

Regarding the different learning activities during the course students enjoyed the videos most. 83.7% (n=277) found them valuable or very valuable, followed by the quizzes (78.2%; n=259) and the course assignments (73.1%; n=242). The discussion forum was considered valuable or very valuable by only 37.2% (n=123) of the students. 69.8% (n=231) were satisfied or very satisfied with the support offered by the staff and teaching assistants.

87.3% (n=289) agreed or strongly agreed to recommend the course to other students.

Table 2 gives a comparative overview over the quantitative results between the three course instances.

Qualitative results

What did students enjoy most?

Analysis of the open-ended questions of the exit survey, discussion forum entries and open course evaluations on the Internet resulted in the following benefit categories: Comprehensiveness, International Focus and Pedagogical Approach (table 2). Students highlighted set-up and content of the course that was considered to give a holistic, worldwide overview over the eHealth landscape. The global, multidisciplinary perspective of the course and the consistent worldwide aspects in the material were acknowledged by many students. The course was considered very educational and easy to understand. Especially the inclusion of practical knowledge provided through numerous interviews with different stakeholders was highly appreciated.

What can be done better?

Improvement suggestions were related to Content and Interaction and Feedback (table 2). Students lacked more practical examples in form of case studies, requested further deepening of technical issues as well as eHealth implementation and proposed more advanced follow-up courses on these topics. One student also proposed to provide a complete online master program in MOOC format. Students further asked for more interaction in the discussion forums and feedback on their assignments. They proposed less multiple choice quizzes and addition of online conversation.

| Benefits    | Comprehensiveness      | In this category remarks and comments regarding the inclusiveness and understandability of the content as well as the structure of the course were included. | “It [the course] is covering the HIT landscape of whole of the world. I am a volunteer with the state government of [an Asian country] on e-health projects and I have recommended this MOOC to the team for its sheer brilliance and comprehensiveness. Especially the resources and the timeline in which they have been structured. This MOOC is the perfect example of congruence.”
|                          |                        |                                                                                       | “I have been very energized by going through the eHealth online course. From doing piecemeal work on individual eHealth modules starting 10 years ago, we have switched to preparing for the next generation electronic health record system and have gathered a multi-disciplinary team of medical informaticians spending up to 50% of our time in this field. I have encouraged my team members to enroll in this ehealth course and learn together. “It [the course] glued and streamlined different concepts in the perfect big picture.”
|                          |                        |                                                                                       | “I have now the language and knowledge to discuss quality assurance issues at work with senior managers.”                                                                                                                                               |
| International Focus    |                        | In this category remarks and comments concerning the focus on international and global contexts were included. | “I liked the approach of teaching eHealth from different, global perspectives.”
|                          |                        |                                                                                       | “The course showed the power of MOOC not only to reach a lot of students but also get their contributions.”                                                                                                                                          |
| Pedagogical approach   |                        | This category includes remarks and comments regarding the use of interviews, scenario descriptions or other ways of presenting the content. | “The course was very insightful and above all innovative in its presentation by incorporating experiences and challenges from real professionals into the course lectures. This gave a very good contextual richness to the materials taught.”
|                          |                        |                                                                                       | “Care professionals’ experiences add great insight into learning this course. It brings the lectures to life and places topics discussed into proper context and perspectives. Thanks for the innovation in the course presentation.”
|                          |                        |                                                                                       | “Sufficient care was taken to present lectures in a way that even students like myself from a different cultural background could grasp concepts easily.”                                                                                                                   |
| Areas for improvement   | Content                | This category includes remarks and comments regarding additional content.             | “It would be great to have practical case studies from different countries, more examples of IT systems used including screen-dumps.”
|                          |                        |                                                                                       | “Add more references about implementation support and integration guidance in the second version of the course.”
|                          |                        |                                                                                       | “I noted that in Healthcare Informatics Standards FHIR was only named. I strongly recommend one whole week for FHIR standards.”
|                          |                        |                                                                                       | “Please develop an advanced level to this course offering.”
|                          |                        |                                                                                       | “I propose an advanced course where computer skills are a pre-requisite.”                                                                                                                                                                           |
| Interaction and Feedback |                        | In this category comments and remarks about the interaction between students, students and teachers and feedback from teachers or teaching assistants. | “The discussion forum was crowded. Course leaders could identify entries each week and feedback on them.”
|                          |                        |                                                                                       | “Provide a mobile App for course interaction.”
|                          |                        |                                                                                       | “The addition of a peer graded assignment would be an interesting consideration for future courses.”                                                                                                                                         |

### Discussion

We exploited the advantages of a diverse, international student group by highlighting similarities and differences between countries. Many students were inspired by this approach. As an example, one of the most discussed points in the discussion forum in our first course dealt with the question whether electricity is a prerequisite for eHealth or not. Many participants had not even thought about this being a major limitation in low income countries. As also highlighted in the exit survey, interactivity between students and between students and teachers was considered to be an area for improvement. Interestingly, there were no major differences in students’ perceptions between the session-based courses vs. the self-paced one (table 2), except in regard to satisfaction with staff support. Staff support was evaluated better in the self-paced course which might relate to the fact that it was
clearly stated in the instructions that support was not offered. So students were happy when getting some support anyway. Chen et al consider student-faculty interaction and peer-to-peer collaboration essential parts in student engagement which is positively related to the quality of the learning experience [7]. Experiences from this course are that the current edx platform does not sufficiently support such student engaging activities, which is in line with criticism towards xMOOCs [8]. Although the discussion fora were meant to facilitate student-faculty interaction, their cumbersome design hindered this. If the learning platform in use does not meet these requirements, we suggest complementing with tools that support more student-faculty interaction as well as peer-to-peer collaboration. An alternative approach would be to use more interactive online tools, e.g. a combination of live broadcasting via periscope with live chat possibilities in twitter. Online learning is not only a question of having access to content; rather, it should also provide opportunity for social learning through interaction and connectedness [9]. If the learning platform in use does not meet these requirements, we suggest complementing with tools that support more student-faculty interaction as well as peer-to-peer collaboration. Also the integration of tools for adaptive eLearning would be valuable to adapt the learning to individual students’ profiles and behaviors [10].

Today, videos are reused for classroom teaching. Its’ potential impact on student recruitment for our Master’s program is too early to state as we only could monitor one round of admissions so far.

Possible future directions could be to reuse the course material as Small Private Online Course (SPOC) for continuing education and to develop more in-depth courses for certain topics [11]. A major drawback is however the lack of incentives in our current reimbursement system for MOOCs.

Conclusions

Experiences from our MOOC with participants from 162 countries highlighted both challenges and benefits. A difficulty encountered by both students and staff during the course was the poorly designed discussion forum which affected the interaction in the course negatively. A major advantage of the MOOC was the mutual learning and exchange of health informatics experiences from around the world – a learning that would have been difficult to achieve in traditional learning contexts.

Acknowledgements

We thank all guest lecturers, interview persons and teaching assistants as listed in the biography of course staff [5]. The course production was supported by the Centre for Learning and Knowledge at Karolinska Institutet. The rebranding of the third version of the MOOC was funded by EIT Health (www.eithealth.eu).

Abstract

The IMIA History Working Group has as its first goal the editing of a volume of contributions from pioneers and leaders in the field of biomedical and health informatics (BMHI) to commemorate the 50th anniversary of IMIA’s predecessor IFIP-TC4. This paper describes how the IMIA History WG evolved from an earlier Taskforce, and has focused on producing the edited book of original contributions. We describe its proposed outline of objectives for the personal stories, and national and regional society narratives, together with some comments on the evolution of Medinfo meeting contributions over the years, to provide a reference source for the early motivations of the scientific, clinical, educational, and professional changes that have influenced the historical course of our field.

Keywords:
Medical Informatics; Nursing Informatics; Organizations

Introduction

The 16th World Congress of Medical Informatics - Medinfo 2017 in China, will mark the 50th Anniversary since the International Federation of Information Processing (IFIP) Societies approved the formation of the Technical Committee (TC 4) on Medical Information Processing, which was the predecessor of IMIA. The IMIA History Working Group (WG), since 2014, has been working on organizing and writing about the international history of biomedical and health informatics (BMHI), and is editing a book of contributed articles from leaders in the field to commemorate the occasion. This article provides an overview of the work leading up to the book, and describes a preview of the goals, structure and evolution of what it is intended to cover.

Methods

The IMIA History eBook to be published by IOS Press, will contain original autobiographical retrospectives by pioneers and leaders in the field, together with professional organizational histories of the national and regional societies and working groups of IMIA, as well as interpretive commentary on a number of important themes and topics, which have evolved changes as scientific and clinical practices under the influence of new insights, technologies, and the changing socio-economic, cultural and professional circumstances around the globe over the past 50 years.

IMIA History Taskforce

Discussions during IMIA Board meetings during the first decade of the millennium brought up the subject of recording more systematically the history of the organization, and how the structure and functions evolved with changing research and practice trends in the field. A Taskforce on the History of Biomedical and Health Informatics was proposed and approved in 2009, and was composed of representatives from all the major regional associations: Casimir Kulikowski (USA/AMIA-North America, Chair), George Mihalas (Romania/EFMI-Europe), Hyeoun-Ae Park (Korea/APAMI – Asia-Pacific), Sedick Issacs (South Africa/HELINA – Africa), Alvaro Margolis (Uruguay – Latin America). The long-time secretary of IMIA, Diarmuid UaConnaill, was able to provide many original documents of the Association, including minutes from past Board and General Assembly meetings. A Wiki media repository was set up at Rutgers University (http://infohistory.rutgers.edu) by Charles McGrew to make these documents openly accessible, and to index them and summarize the time-lines of IMIA developments graphically, together with thumbnail sketches of past leaders of IMIA. These materials are aimed at chronicling the development and evolution of IMIA, its contributors, its sponsored events, its publications, and its history. The role of the Taskforce was to coordinate and channel the interests of IMIA members related to the history of the organization, to lead the recording of personal and group recollections, and to write about how the field has developed from a wide range of international perspectives. The members of the Taskforce solicited articles for the IMIA Yearbook about the History of the field, and also contributed their own perspectives [1,2,3,4,5,6,7].

Over the past years, the IMIA History Taskforce organized workshops and panels at many conferences, including: Medinfo 2010 in Cape Town, the IMIA-LAC 2011 meeting in Guadalajara [8], many AMIA Annual Meetings and ACM Meetings since that date, the Oslo MIE 2011, APAMI in Beijing in 2012, the Prague Workshop held in conjunction with the EFMI-STM in April 2013, the Medinfo 2013 Congress held in Copenhagen [9], MIE 2014 in Istanbul [10], and APAMI 2014 in New Delhi. A related historical anniversary took place in 2011 in Heidelberg – the 50th year of publication of the first and official IMIA journal of medical informatics: Methods of Information in Medicine (MIM). The IMIA President, Reinhold Haux organized a symposium, which discussed many changes that have taken place in medical and health informatics since the founding of MIM by Gustav Wagner in 1962. The Copenhagen Medinfo 2013 saw important discus-
sions on the systematic elicitation of articles on the history of the field, while at the Prague EFMI-STC, earlier that same year, there had been a special workshop on European History, which led to publications in the proceedings [10, 11, 12, 13] and later a set of books edited by two of the participants, Izet Masic and George Mihalas [14], who compiled papers and biographical materials. In order to recognize the activities of the IMIA History Taskforce, its members proposed to transform themselves into a Working Group, and this was approved by the IMIA General Assembly in August 2014 at the APAMI New Delhi meeting.

**IMIA History Working Group**

Shortly after the IMIA History WG was established, there was an important anniversary in the USA – the 30th anniversary of the American College of Medical Informatics (ACMI). Kulikowski, who also chairs the ACMI Committee of Historians, worked with Alexa McCray to organize two commemorative panels [15] at AMIA 2014: the first with pioneers who were instrumental in the formation of ACMI, and the second with leaders of the field to cover the three decades intervening. After this, the IMIA WG prepared a workshop for Medinfo 2015 in Sao Paulo, where the plans for the 50th Anniversary book were discussed, and prospective contributors identified and invited. At the same time, plans were made to participate in the EFMI-STC to be held in Paris the following April of 2016. This was important because it also included a presentation on the founder of IFIP-TC4, Dr. Francois Gremy, by his daughter Isabelle, and another on Dr. Peter Reichtz, who was a most influential pioneering researcher and teacher in medical informatics from Hannover in Germany, by Rolf Engelbrecht. In the remainder of 2016, three conferences were instrumental in obtaining further commitments from contributors to the proposed History Book from around the world – Nursing Informatics 2016 in Geneva, HEC-MIE 2016 in Munich, and the AMIA 2016 meeting in Chicago. At EFMI, the IMIA General Assembly voted to fund the publication costs of the IMIA History, thus making it possible to proceed with formal invitations and plans for publication with IOS Press. At the AMIA 2016 meeting, there was yet another anniversary to celebrate – the Symposium of Computers in Medical Care (SCAMC), which was the main vehicle for disseminating research in medical informatics in the USA before the creation of AMIA. The meeting brought together leaders in writing the history of nursing, public health, and other clinical informatics to help coordinate their contributions to the IMIA History.

**Some Historical Highlights of IMIA-Related Biomedical and Health Informatics in Asia**

The history of biomedical and health informatics in Asia goes back to the establishment of several national societies, and the decision by IMIA to hold the Third World Congress on Medical Informatics - MEDINFO-80 [17] under the leadership of Dr. Shigekoto Kaihara, a pioneer in medical hospital systems and computer-based decision-making at Tokyo University, who also established the Japan Association for Medical Informatics (JAMI). Many international and Asian participants came to this first Asian MEDINFO, including delegates from China, establishing collaborations which have been ongoing to the present day. The China Medical Informatics Association (CMIA) was founded in 1981 [18], helped organize MEDINFO 89, as did Singapore, which also sponsored the China-Japan Medical Informatics Symposium in 1991, twelve China Medical Informatics Conferences since 1999, and a series of Pacific Health Informatization Summits since 2006 - and it is now hosting MEDINFO 2017 in Xiamen.

KOSMI, the Korean Society for Medical Informatics hosted MEDINFO 98 in Seoul, providing a major impetus for the development of biomedical and health informatics in the Asia-Pacific, which had by then formed its own regional association – APAMI, which held its inaugural conference in Singapore in 1994. Nursing Informatics (NI), which has its own Special Interest Group within IMIA, has flourished in the Asia-Pacific region, where KOSMI-NI hosted the 9th International Congress on Nursing Informatics in Seoul, from which the leadership developed a plan for the future of the field [19]. This is just one notable example of how coordination between IMIA, APAMI, the specialty groups, and national societies ensures the continuing vibrant growth of our interdisciplinary field of biomedical and health informatics throughout Asia, with strong international ties worldwide.

**Results**

**IMIA 50th Anniversary Book Outline**

The result of all the meetings organized or sponsored, in whole or part by the IMIA History WG over the past years, has been the gradual development plans for the publication of the IMIA History in 2017. As of this writing (April 2017), a large number of individual contributions have been already received, and a final set of invitations sent out to cover more comprehensively not only individual members, but also the histories of member societies and groups affiliated with IMIA: regional and national societies, special interest groups, and working groups. A schematic outline of the 50th Anniversary book is as follows:

**PART 1: Collection of Short Personal Narrative or Individual Stories (about 2 to 5 pages in length).** Each story is intended to address questions of how individual researchers and practitioners got started in biomedical and health informatics, and how their own work and engagement in the discipline unfolded from their individual perspective: who inspired them in their work? what were the main ideas? What were challenges and informatics projects that got them started in the field? together with a brief reference to their main changes in direction since then. Summarized current reflections on the outcomes of early work from today’s perspective were encouraged. With the above in mind, and at the request of many contributing authors, templates were developed to suggest questions that the personal stories could address, such as:

- Who inspired you to work in BMHI, or what circumstances determined your choice and how did this happen?
- What motivated you to get started and what were the main ideas or examples of biomedical science, information, and technology that inspired you?
- What were your initial expectations from your first project and what were the challenges you faced in realizing them?
- How did your first experiences in BMHI influence what you did next, and have done since? Summarize briefly your major changes in research, practice, or educational approaches, and their impact on your informatics contributions.
- What have been other experiences and professional position opportunities affecting your life work in BMHI?
- What are the social connections and relationships that were essential to your work, and how have these changed over time and with new technologies?
- How have the international dimensions of your work promoted or contributed to collaborations in research,
practice, education, or professional activities in organization and publications, conferences or other meetings, either locally or nationally? and did they have broader impact at regional and international levels for significant advances in BMHI?

- Other significant individual critical insights on BMHI developments beyond the above.
- From the perspective of 2016, what do you see as key shifts in "grand challenges" that you have dealt with in your discipline, and how have these inspired or challenged your work, and helped your personal and professional development?

Only a few citations to past publications have been requested, focusing on the most essential original and/or most recent summaries or reviews, so as to provide guideposts to any interested reader to pursue further searches online.

PART 2: Summaries of national and regional BMHI organizational short history entries, authored by country or region, from an informatics-related society or publication that authors have participated in – preferably in a leadership position, or with close participation and knowledge of the society.

A suggested template for Part 2 essays a requested by prospective authors suggest addressing the following:

- Briefly list major precursor work in underlying or related disciplines that influenced the emergence of BMHI informatics, and briefly list major people influencing this.
- Which were the first contributors to the field in your country, with their institutions and fields of BMHI activity and major project titles (where known)?
- What were the major topics addressed by early informatics work in your country?
- When and how was informatics organized professionally in your country or region – relation to IMIA (and other national or international societies and institutions when relevant)?
- How did informatics evolved over its first 2-3 decades in your country/region – concentrating on the early days of the field, but bringing the short summary history to the present when possible.
- Short chronological listing of major early professional leaders in your country/region with roles, related to institutional affiliation and major projects.
- Brief listing of major conferences sponsored by professional BMHI informatics societies in your country.
- Compare and contrast very briefly (a long paragraph at most) highlights of early vs. current work in BMHI in your country.

PART 3: Brief IMIA Working Group history entries, and short interpretive entries about publications and major research projects or programs of BMHI. The suggestions for this part of the book are included as a much shortened version of the above for professional societies.

Trends in MedInfo Contributions

A paper in the IMIA Yearbook of Medical Informatics, by one of the present authors [20], summarized the changes in full-paper contributions to MedInfo by broad subject areas and by first author geographic region up to 2004. We have reviewed the trends and how they have changed, by looking at similar statistical breakdowns for the 2007 and 2015 MedInfo, to see if there have been notable differences over the past decade.

The major subject areas were: 1) Health and Clinical Management, 2) Patient Records, 3) Health Information Systems, 4) Sensor, Signal & Imaging Informatics, 5) Decision Support, Knowledge Representation and Management, 6) Educational and Consumer Informatics, and 7) Bioinformatics.

The total of full papers presented at Medinfo International Congresses seen to have grown steadily in the past decade compared to previous decades – for the Medinfo 2015 there were 512, for the 2007 there were 459, in contrast to 302 for the Medinfo 2004, and around mid or upper 200’s or low 300’s for the previous two decades.

The percentage of total for each of the categories is as follows:

2. Patient Records 18.3% vs. 14.8%
3. Health Information Systems: 13% vs. 23.2%
4. Sensors, Signals and Imaging Informatics: 4% vs. 3%
5. Knowledge Representation & Management, NLP, Decision Support: 17.6% vs. 19.3%
6. Education and Consumer Informatics: 21.6% vs. 19.1%
7. Bioinformatics: 1% vs. 1%

We can see from the above list, that the only major changes over the 8 years were between Brisbane and Sao Paulo was that Patient Records (PR), which decreased somewhat, and Health Information Systems (HIS) increased by about the same amount. The latter is largely because the Data Bases category was included in HIS rather than PR, since the DB is more a systems function and can cover all kinds of databases, not just patient records. The jump in NLP is what accounts for the most of the rise in category 5 in 2015. Most of the other areas remain about at the same level.

The breakdown by the six broad subject areas indicated above, as computed by percentage of total papers, indicates certain trends that correlate with recent technological advances in mobile computing, interoperability, and databases, as well as the persistence of emphasis on computer decision support and knowledge representation (ontologies) and management, with a recent (MedInfo 2015) growth in the area of artificial intelligence, which specifically correlates with international trends in applications of machine learning for big data in all kinds of areas, including specifically clinical data. Notable also is the increase of papers contributed in the subarea of natural language processing (NLP), which reflects recent advances in this field.

In health informatics, there continue to be steady contributions in the areas of information systems for clinics and hospitals, and the field of nursing informatics has increased its participation in Medinfos very noticeably in the past couple of decades. The number of papers submitted on electronic patient records grew dramatically in 2007, by over 30% above the 2004 contributions, reflecting initiatives in this direction worldwide, and the especially strong impetus in the USA during this period; however, in 2015, had gone down again.

In education and consumer informatics, there has been a noticeable increase, including, not surprisingly, the new subarea of social media.

On the other hand, Medinfos have seen a continuing, but persistently low participation by authors submitting in the more scientific and technical subjects of sensor, signal and imaging informatics, and also bioinformatics, which reflects the difficulties of attracting these communities to contribute to general biomedical and health informatics, when most of their advanced discussion and research impact comes from presenting and publishing in their own specialty conferences.

The geographical distribution of contributions to Medinfo meetings over the years provides ample support for the early decision of IMIA to rotate the locations around the world, so
that all regions would have a chance to enjoy the hosting in succession, and encourage international participation most amply in the spirit of the Association. An overview of contribution breakdown, by percentage of papers in recent Medinfos, confirms the patterns of contributions that were noted earlier [20]. Looking at the 2007 Brisbane meeting, we see that the Asia-Pacific (AP) region was represented by 23% of contributors of full papers (upon which this comparison is made). This is approximately double the percentages of AP author contributions for Capetown 2010 (13%) and Sao Paulo 2015 (12%), European contributions, which have usually been the most substantial in number to all Medinfos outside those held in North America (NA), when NA attendance has predominated, showed the same for Brisbane (42% vs. 31% for NA) and Cape Town (at 51% vs. 24% for NA contributors), but not for Sao Paulo (29%), where North American authors contributed the most (33%). For the Sao Paulo Medinfo in 2015, Latin American contributions rose to 24%, in contrast to the regional contributions to the Congresses at other locations earlier, where their contributions have usually been between 1% and 6% (in Cape Town), demonstrating not only the rise in medical and health informatics in Latin America, but also the critical importance of rotating the locations. In a somewhat, but even more extreme parallel, the African first-author full paper participation at Cape Town, although still low at 7%, was seven times greater than participation at other Medinfo venues, when it never exceeded 1%, thus reflecting both the very restricted impact of health informatics in the continent, as well as the overwhelming organizational and financial difficulties of travelling for potential participants and practitioners from most of the continent. The Asia-Pacific participation, though reflecting a very different dynamic due to the advanced development of biomedical and health informatics in many of the countries, does, in all likelihood, reflect the factor of cost and convenience of travel to far-off venues, since participation in the Tokyo 1980 meeting was 35%, in Seoul 1998 was 25%, and Brisbane 2007 was 23%, all are predominantly higher than Asian-Pacific contributions to Medinfo meetings held elsewhere, such as Amsterdam 1983 (13%), Washington 1986 (7%), London 2001 (16%), San Francisco 2004 (7%), Cape Town 2010 (13%), and Sao Paulo 2015 (12%). We can therefore reasonably expect that the upcoming Medinfo 2017 in China will confirm this pattern and the importance of the regional rotations, as a wise policy of Medinfo organization for developing a world community of shared research, practice, and education, by encouraging the participation and dissemination of the most recent results in the field of biomedical and health informatics, dating back to its earliest days.

Discussion

For the IMIA History book progress, we can report that, from the contributions received so far, some authors have followed the template suggestions, and providing systematic accounts of the development of their professional lives and contributions to the field. Others have written very reflective and insightful (and sometimes even poetic) stories about the most important inspirations and aspects of their lives, and how they have affected their work in biomedical and health informatics. The present paper provides some preliminary perspective on the activities of the IMIA History WG, from which one can extrapolate for the future, when we expect to continue requesting contributions for further sets of papers on the history of our field for the IMIA Yearbook and other journal publications, for the History MediaWiki, and for potential further collected volumes on more specific topics of research, practice, and education as experienced by those in our field.

Conclusion

The enthusiasm and progress in obtaining contributions from pioneers and leaders in biomedical and health informatics is a good sign that the 50th Anniversary IMIA History will become a unique original reference publication for future historians to study and derive their own conclusions about the very diverse motives, inspirations, and professional journeys of practitioners, technologists, and educational specialists in our field. The essays received so far have excellent original content, and eloquent writing, which reveals patterns of thought and argument that should be of great interest to present practitioners, as well as for future investigators and historians in our field. We look forward to completing this project as a first step in ongoing documentation, archiving, and historical writing about the development of international biomedical and health informatics. It will highlight how IMIA and its constituent societies have played a central role in spanning the global diversity of the field, encouraging scientific and professional collaborations, and providing a framework for international coordination and the development of the friendships that are so essential to this, as we approach the 50th Anniversary of the founding of its predecessor organization IFIP-TC4, to be celebrated in China, on the occasion of Medinfo 2017.

Acknowledgements

The authors gratefully acknowledge the encouragement and support of the IMIA Board and General Assembly and the contributions of their many friends and colleagues from around the world in the preparations for the 50th Anniversary IMIA History of International Biomedical and Health Informatics. They also wish to thank the reviewers for their many helpful suggestions.

Towards a Usability and Error “Safety Net”:
A Multi-Phased Multi-Method Approach to Ensuring System Usability and Safety

Abstract

The usability and safety of health information systems have become major issues in the design and implementation of useful healthcare IT. In this paper, we describe a multi-phased multi-method approach to integrating usability engineering methods into system testing to ensure both usability and safety of healthcare IT upon widespread deployment. The approach involves usability testing followed by clinical simulation (conducted in-situ) and “near-live” recording of user interactions with systems. At key stages in this process, usability problems are identified and rectified forming a usability and technology-induced error “safety net” that catches different types of usability and safety problems prior to releasing systems widely in healthcare settings.

Keywords:
User-Computer Interface; Patient Safety, Health Information Systems

Introduction

Ensuring the usability and safety of healthcare IT is essential in order to lead to successful adoption of healthcare IT. In recent years, the issue of poor usability of many healthcare IT systems has come to the fore \cite{1,2}. Indeed, in healthcare there are continued reports of end-user dissatisfaction with systems and reports of serious usability problems. In addition, implementation failures due to usability issues and negative impacts of some systems on clinical workflow continue to be reported \cite{3}. In recent years, poor usability has also been closely linked with the occurrence of technology-induced error. Technology-induced errors have begun to be studied more widely in health informatics and represent a class of errors that emerge when IT is deployed and used in complex healthcare settings \cite{4}. Such errors are difficult to find using traditional software testing methods (e.g. white- and black-box testing) and in many cases are only detectable (given conventional testing methods) when healthcare IT is operational in real healthcare contexts \cite{4}.

Many different approaches have been proposed and applied for testing the usability of systems and for evaluating their impact on patient safety. Each method has its advantages and disadvantages. For example, basic usability testing can be used to detect surface level usability problems with healthcare IT but may not be sufficient to assess how a system affects clinical workflow (e.g. real patient encounters) or complex clinical decision making and reasoning. In contrast, methods such as clinical simulation may allow for analysis of the impact of systems on clinical work activities but may not detect basic usability problems. Therefore, a multi-method approach may be needed to ensure system usability and safety prior to release. Furthermore, integrating different methods in a multi-phase approach holds promise for obtaining the full benefits of the different methods. In this paper, we will describe a methodological framework for developing a “safety net” approach to detecting and rectifying usability problems and potential technology-induced error prior to widespread release of healthcare IT. It will be argued that the methods described in this paper need to be considered not only in the context of system design (e.g. during one-time design of vendor-based systems), but also in subsequent implementation of commercial systems (e.g. implementation of vendor products, such as electronic health records (EHRs) in hospital settings). As will be described, the methodological approach outlined in this paper has been successfully applied to both improving the design of healthcare IT developed by developers and vendors, as well as assessing the usability and safety of completed healthcare IT deployed in healthcare organizations.

Methods

A process for testing healthcare IT was developed by the authors and involves several phases described below. In the first phase, rapid low-cost usability testing is conducted. Video recording is used to collect data on typical user interactions, where users are recorded while carrying out representative tasks using a system under study \cite{5}. Analysis of the resultant video data is facilitated by using principled coding schemes and computer coding tools. This is followed by a phase of testing under simulated conditions (i.e. by applying clinical simulation methods). Where possible, this is then followed by testing of live, or near-live clinical interactions, where users are observed under close-to-real or real conditions and settings \cite{6}. After fixing errors and problems detected at each of these stages, the system is eventually released for widespread deployment.

The authors have employed the approach described above in the design and development phases of the system life cycle as well as for testing and modifying vendor-based systems that were purchased by healthcare organizations prior to their widespread deployment. The intent is to form in essence a usability and error detection “safety net” that can catch different types of usability problems and errors before a system is released on a widespread basis. Details of our methodological approach are described below.
Phase 1. Low-Cost Rapid Usability Testing

The detection of major surface level usability problems is key to ensuring overall system usability and safety, and although not sufficient on its own to ensure system safety, it is a critical first stage. An approach we have developed and applied is termed “low-cost rapid usability engineering” [5]. Using this approach, free or low-cost screen recording software is installed on computers used in the testing. Participants (e.g. health professionals, patients etc.) are asked to carry out representative tasks using the system under study. The interactions of the study participants are recorded (i.e. screen recording, audio recording and video recording of physical actions) in their entirety. Participants may also be asked to “think aloud” or verbalize their thoughts while interacting with the system. Approaches may include collecting user interaction data (e.g. computer screen interactions as movie files) along with audio of participant verbalizations. This approach to usability testing has been used in many studies and in our approach constitutes the first phase of the “safety net.”

Phase 2. Error Correction from Usability Testing

The data collected in Phase 1 consists of digital screen recordings of one or more users (i.e. study participants) interacting with a system under study while verbalizing their thoughts [7]. One approach to accelerating the process of analyzing this data has been to use predefined coding schemes, such as the one developed by the authors that provides categories of commonly detected usability issues [8]. Such schemes (in conjunction with video coding tools) allow for replay of the video data and coding of that data for key usability problems in close to real-time [5]. Identified usability problems are prioritized and presented to the development or implementation team in the case of vendor-based systems being deployed in healthcare settings. Decisions regarding which issues or problems to rectify at this point are discussed with the IT staff, taking into account the severity of the problems as well as other contingencies such as the release schedule and resources for modifying the system. In a number of our studies, we have found this stage to have a quick turnaround time, but system modifications may need to be restricted to fixing problems considered most urgent or severe. At this stage, issues identified are typically surface level usability problems.

Phase 3. Clinical Simulation

From our early experiences, it was found that Phase 2 usability testing alone is not enough to ensure the usability and safety of healthcare IT. As a consequence, the authors and colleagues have worked on developing low-cost rapidly-conducted clinical simulations [4]. We have defined clinical simulations as an extension of usability testing that includes not only observing representative users doing representative tasks, but also testing in representative or real environments (e.g. clinics with real or realistic workflow) [9-12]. This may involve using real (or realistic) testing scenarios in testing. Clinical simulations in our work have varied from use of actors to development of digital video patients used in testing interactions involving real or highly realistic tasks and workflows. For example, a clinical simulation may involve participants (e.g. physicians) interviewing a simulated patient while using a new electronic health record system or decision support tool to enter and record patient data. Data collection involves video and audio recording of all user interactions with systems under study.

Phase 4. Error Correction from Clinical Simulation

The analysis of the data collected from clinical simulations (e.g. video and audio data) is similar to that of the analysis of usability testing data. However, at this phase, the focus of analysis is typically on assessing the impact of systems on clinical workflow and healthcare activities. Coding schemes we have employed at this phase include categories for assessing impact of systems on decision making, reasoning, physician question asking, and also categories for identifying potentially negative impact such as increased time to complete tasks and workarounds that are potentially dangerous. In addition, from our experience we have found that surface level usability problems not detected from Phase 1 testing may also end up being identified in this stage. Major defects (e.g. negative system impact on clinical workflow) identified from clinical simulation are corrected, where feasible, before moving on to the next phase.

Phase 5. Near-Live Testing

In a number of studies we have conducted, after clinical simulation has been completed, we have moved to observe and record a limited number of user interactions with the system in a live setting, prior to widespread deployment or release [6]. This limited naturalistic testing involves setting up unobtrusive recording equipment (e.g. using free screen recording software installed on systems used) and allows us to collect data on use of the system in real contexts prior to full-scale product release or healthcare organization implementation. Issues at this stage include obtaining institutional review board consent for collecting data that may involve real patients. Whether this additional level of testing is feasible depends on gaining organizational access to settings and contexts in which a system will be ultimately deployed (e.g. a hospital ward, or even an operating room off-hours).

Phase 6. Error Correction from Near-Live Testing

From our work we have found that limited naturalistic testing almost invariably uncovers further issues that could not have been found from usability testing or clinical simulation alone. Major concerns or issues that are identified are brought to the attention of the design/implementation teams, with problems warranting immediate fixing being rectified prior to widespread system release.

Phase 7. Widespread Deployment and Continual Monitoring

Upon completion of the phases described above, the system can be released on a wide scale with greater confidence that major issues have been detected before “going live”. This may involve releasing a healthcare IT software product to the market, or the widespread deployment of a vendor system throughout a hospital or health region. Continual monitoring of system use, in terms of possible usability problems or errors, is recommended. As shown in Figure 1, the safety net approach can be considered a cyclic process, with each phase leading to the correction of different types of errors. Figure 1 also shows the need for continual error monitoring (and correction), once the system is in use.
In Figure 1 we can also see that the approach attempts to identify and rectify as many usability problems and errors as possible before widespread deployment and implementation. At the top of Figure 1, we can see that after initial system design is complete, low-cost rapid usability testing can be employed to correct surface level usability problems. This is followed by clinical simulation and near-live testing. At each stage different types of errors are identified, with surface level usability problems typically detected during low-cost rapid usability, while issues around workflow are more likely to be detected in subsequent phases. The dotted lines in Figure 1 illustrate the “sieve” part of the safety net, which is designed to catch as many errors as possible before a system goes to widespread deployment, as illustrated in the lower part of Figure 1. Once deployed, continual monitoring for usability and feedback from error reports from end-users may need to iteratively trigger further cycles of usability analyses, as indicated by the arrows in the right side of Figure 1.

Results

We have applied the multi-method, multi-phased approach described in this paper in a number of assessments of EHRs, decision support systems (DSSs) and mobile health applications. A finding emerging from our work is that the types of errors and usability problems detected at each phase are different, and that therefore, a multi-phased approach was needed to detect the widest possible range of problems. For example, early phase usability testing (in Phase 1) typically uncovered surface level usability problems, while testing involving clinical simulations (Phase 2) typically detected issues related to impact on clinical workflow, including identifying potentially dangerous workarounds. In Phase 3, near-live testing typically revealed a range of contextual issues that would not have otherwise been predicted by the previous phases. It should also be noted that surface level usability problems (and even software programming errors not caught by traditional white- and black-box testing) were typically detected throughout all phases of the approach (i.e. even during clinical simulations and live or near-live testing, usability problems would still be detected that had not been found in Phase 1). The approach thus provided a usability and technology-induced error “safety net”, without which serious usability problems and errors would have found their way into actual system use and patient care.

In development and refinement of healthcare IT during the design and prototyping phases, our early work employed components of the approach described in this paper, specifically classic usability testing of an EHR was followed by clinical simulation of a commercial EHR system, where actors played the part of a patient while study participants (e.g. physicians) interacted with the system to handle patient cases [13].

In more recent work, we are adapting some of the approaches described in this paper to the testing of a novel, composable user interface designed to allow for near-live testing using remote usability engineering methods [14]. This will take place in two phases, the first being detailed, comparative, in-person, near-live testing in crossover studies of commercial and experimental systems, in which the user is asked to create interfaces in the composable system, and both systems are
evaluated as to user behavior and diagnostic accuracy. Another phase is testing larger numbers of subjects via remote near-live testing, in which software working in the background records user actions and generates a video. The ability to send users a link and have them perform tests at a distance, without in-person meetings, allows for larger numbers of subjects and testing of sharing functionality, which is expected to yield new insights about composable systems and clinician cognitive processes and communication.

The approach described in this paper has also been applied to ensure that the implementation of vendor-based products (e.g., EHRs) as well as their extensions (e.g., addition of decision support capabilities to an EHR) do not inadvertently introduce serious usability or safety issues when implemented in hospitals. Along these lines, we have successfully employed parts of the approach as well as the full approach on a number of projects. In one study, we employed the full multi-phased approach in the implementation of clinical guidelines within a commercial EHR product [6]. In Phase 1 of the approach described in this paper, basic usability testing was conducted. This testing identified a range of surface level usability problems, such as navigational issues, consistency problems and the need for improved layout and wording of alerts. This included the need to relabel alerts that appeared on the screen and to make them more conspicuous to the physician’s eye (these issues were rectified in Phase 2). In Phase 3, a clinical simulation was conducted involving participants (physicians) interviewing a simulated digital patient (from which they could ask for patient information) in order to assess the impact of the system on clinical workflow. Analysis of the video data from these simulations (conducted in Phase 4) indicated the introduction of the guidelines inadvertently changed physician workflow in a number of unexpected ways. For example, some participants found that the alerts were triggered too early, before the participant had a chance to review the patient’s information and data. As a result, alert triggering mechanisms were modified during Phase 4. In Phase 5, limited naturalistic testing was conducted and defects detected from this phase were rectified in Phase 6, prior to widespread release of the guidelines. A subsequent clinical trial showed a high rate of uptake of the guidelines by end-users in the hospital, in large part due to the multi-phased multi-method testing that was conducted prior to system release.

In another application of the approach, we employed these methods in the assessment of a medication administration system in a Japanese hospital. Phase 1 testing involved having 16 physicians and nurses interact with the system to carry out medication tasks while being video recorded. Phase 2 identified a number of specific usability problems, while issues with workflow as a result of the system (as well as potential technology-induced errors) were identified in Phase 3 using clinical simulations. In terms of problems at the workflow level, it was found that the system was inflexible and rigid during emergency situations, when there was a need to override the systems due to time constraints. Results of the phased multi-method approach led to refinement of the system to include emergency overrides, improved workflow and streamlined usability during the defect correction phases of the process [15].

Discussion
In our work we have integrated a number of methods for ensuring system usability and safety. We found that each phase of this method detected different types of problems, starting with surface level usability problems and leading to issues related to workflow, impact on physician cognitive processes, and patient safety. It is argued that such a multi-method phased approach is needed to create a “safety net” to detect and rectify a range of errors and problems prior to widespread system release. The approach described in this paper is beginning to be applied in healthcare organizations where usability and safety have been deemed of utmost importance in system implementations and deployments. Current areas we are working on include streamlining the methods and processes involved to shorten the time taken for analysis (using published coding schemes and computer tools) and increasing dissemination of the approach through demonstration projects at key healthcare organizations worldwide.

Conclusions
The usability of healthcare IT continues to be a problem, with reports of systems that are unusable and in some cases unsafe. One approach has been the development of guidelines and regulations to improve the situation [17-19]. In another direction, to address these issues, the authors have developed a methodological approach that involves several phases of data collection and analyses. This approach begins with low-cost rapid usability testing, followed by a phase of clinical simulation and finally near-live or live testing involving a limited number of participants. Our experiences with this approach has indicated that by applying this “safety net” approach, a wide range of issues and problems can be detected (and rectified) prior to widespread release of healthcare IT systems. Areas of future work include demonstrating the cost-effectiveness of the approach and disseminating information about it more widely. This method can become incorporated in healthcare IT practice as there is a need to enhance patient safety through improving the usability of healthcare IT.

Abstract

Humanism in medicine is defined as health care providers' attitudes and actions that demonstrate respect for patients' values and concerns in relation to their social, psychological and spiritual life domains. Specifically, humanistic clinical medicine involves showing respect for the patient, building a personal connection, and eliciting and addressing a patient's emotional response to illness. Health information technology (IT) often interferes with humanistic clinical practice, potentially disabling these core aspects of the therapeutic patient-physician relationship. Health IT has evolved rapidly in recent years – and the imperative to maintain humanism in practice has never been greater. In this vision paper, we aim to discuss why preserving humanism is imperative in the design and implementation of health IT systems.

Introduction

“Good morning Mr. Jones, it’s great to see you today for your check-up. Tell me, what can I do for you today?” While Dr. Smith is logging in to the in-room workstation, Mr. Jones, who has diabetes and hypertension, begins describing his flu-like symptoms. He is interrupted by a text message from his spouse reminding him to discuss concerns about sexual function during the visit also. After describing his current symptoms, he also is traveling to Florida during the winter months where he has a second home, and plans to travel to Brazil, a lifelong item on his bucket list. He has questions about travel immunizations, and would like to talk about how concerned he should be about Zika virus, which he has heard about on the news for months.

In the meantime, Dr. Smith notes multiple high-importance alerts reminding her to address blood pressure higher than the normal range today, and that Mr. Jones is overdue for his first pneumococcal vaccine, monitoring labs and an eye exam for diabetes. Additionally, his chart still shows he is due for colon cancer screening, which he had previously declined. She also notes high-priority indicators about out-of-range lab values for other patients that just arrived in her in-basket, and receives a repeat page to her smartphone’s secure text messaging app from a radiologist about a critical read from an earlier appointment.

Background

It is no surprise that practicing clinicians are pressured by time constraints and high performance expectations when providing routine patient care. The average practicing primary care physician in the U.S. is limited to spending 15 minutes with each patient [1], yet they and their team may be expected to spend approximately 7.4 hours per working day addressing only preventive services for patients [2] and 3.5 hours per day to provide care for chronic conditions [3], spend on average 2.3 minutes responding to patient questions submitted via electronic messaging [4], perform other in-between visit care management and coordination tasks, and still be required to achieve high patient satisfaction scores. Adding burdensome documentation requirements for billing, quality measurement, and other secondary purposes not directly related to the provision of health care [5;6], and with difficult-to-use health information technology (IT) and electronic health records (EHRs) [7;8], only adds administrative burdens to the already time-consuming responsibilities of care.

Desktop medicine, consisting of activities related to care provision, such as progress note writing, documenting telephone encounters, addressing secure messages and prescription refills, reviewing results and placing orders, is estimated to occupy approximately half of a physician’s time in clinic [9]. The other half of clinic time is face-to-face time in office visits, as estimated by examining physician access logs for a large practice of internists, family medicine physicians, and pediatricians. A recent time-and-motion study of physician practices in multiple specialties was even more concerning, finding that physicians spent 27.0% of time on face-to-face time with patients and 49.2% of time on EHR and clerical work [10]. In another study, estimated face-to-face time may be more optimistic, that is, for every 3 minutes of face-to-face time with patients and 49.2% of time on EHR and clerical work [10]. In the same study, in the exam room with patients, physicians spent 52.9% of that time on face-to-face time and 37.0% on EHR and clerical work. In surveys of physicians who use EHRs, more than one-third of physicians agree that EHRs decrease the quality of face-to-face patient interactions [12;13].
Beyond quantifying and describing in detail the administrative burdens of clinical practice, a call to return to the primary goal of clinical practice must drive the redesign of health information technology and its integration to once again support patient care. Healing and preserving patients’ dignity, core tenets of the sacred Hippocratic Oath, guide the humanistic service of patient care. Over time, as these studies have observed and reported, the human elements of clinical medicine, these sacred oaths, physicians’ ability to practice, and ultimately patients, are endangered by health IT designed in service to the secondary purposes – rather than the primary purpose – of care. In this vision paper, the authors summarize their perspectives on this tension between humanism and health information technology. During two-year sabbatical for E.L., sponsored by Stanford Health Care’s Chief Executive Officer, he established a monthly Clinical Informatics Discussion Forum for Year 1, which included up to 22 faculty and trainees from Stanford University and the Department of Veterans Affairs from September 2013 to September 2015. Forum members included practicing physicians, physician executives in clinical informatics, biomedical and clinical informatics researchers and educators, experts in clinical decision support design, a sociologist, and clinical informatics trainees. Each participant had titles for multiple roles, for example, E.L. is a practicing internist, educator, and clinical and biomedical informatics researcher. Not all participants were able to attend all meetings during Year 1. For some forum meetings, an invited guest from another discipline at Stanford University, including aeronautics, or affective (cognitive) psychology, would also participate in discussion. During the discussion forum, participants drew upon personal knowledge and expertise and identified known sources of literature in order to address key themes raised. Further focused literature searches were performed in a problem-oriented approach. In Year 2, the authors, all participants from the original discussion forum convened in Year 1, formed a subgroup that continued quarterly discussions that culminated in the writing of this vision paper. This vision paper reflects themes derived from the discussion forum and subsequent discussions by the authors.

**Humanism in Medicine**

Health information technology and electronic health records are accelerating the digitization of health care and challenging the practice of medicine to evolve. Vinod Khosla claimed in 2012 that technology “will replace 80 percent of what doctors do” [14]. The transition has only just begun, and growing pains, particularly the painful loss of the human touch or humanism in digital medicine, are rippling through clinical practice. Numerous reports describe disillusionment with wasted time and effort and growing discontent associated with computer-based documentation and clerical tasks. Health information technology, especially EHRs, directly interfere with – rather than enable – patient-physician communication and workflow during visits [7]. Moreover, excessive focus on rapidly developing and implementing IT innovations beyond EHRs may further erode humanism in clinical practice, especially when such innovations are inadequately evaluated. Correspondingly, the role of the physician in technology-enabled modern medicine must evolve to match changing care settings. To meet these needs, the universal guiding principle in designing any health IT system must be humanism. That is, we need human health information technology systems, which are centered on the basic human connection between doctor and patient and less on the novelty of technology alone.

**Humanism in medicine is defined as health care providers’ attitudes and actions that demonstrate respect for patients’ values and concerns in relation to their social, psychological and spiritual life domains [15]. Specifically, humanistic clinical medicine involves showing respect for the patient, building a personal connection, and eliciting and addressing a patient’s emotional response to illness [16]. However, health IT has enabled more interruptions and external requirements on individual encounters, which in turn threaten the quality of the physician-patient connection [17]. To preserve the physician-patient relationship, we as a medical community must prioritize humanism as our central tenet for driving the development of IT that fully supports and enhances – rather than disrupts – the patient-physician relationship. Additionally, the practicing physician must actively preserve the physician-patient relationship, attending primarily to key features of a patient’s life experience without distraction from health IT and also through proficient IT system navigation. Thus, we must act now so that health IT sufficiently evolves into human health IT, intelligently supporting physician’s role in patient care. This evolution towards human health IT is necessary to advance both to scientific and technological innovations while necessarily preserving humanism in clinical practice.

**Why humanism matters**

Social, psychological, and behavioral determinants of health are central to psychiatrist George Engel’s biopsychosocial model of medicine described nearly 50 years ago [18]. These principles remain relevant to clinical practice and medical education today, as precision medicine necessarily incorporates individualized care based upon psychosocial characteristics of each patient [19]. Social and behavioral determinants of health are well-established determinants of patient outcomes [20]. Assessing each individual’s health context is necessary to fully understand a patient’s condition and personalize care recommendations. Currently, social determinants and a comprehensive context of health are not yet systematically collected through health IT, although there is increasing attention to developing frameworks to guide such work [20]. Even more streamlined surveys of health context, for example, the Adverse Childhood Experiences questionnaire, have been suggested as a tool to assist in identifying patients at highest risk for developing certain mental and physical health diagnoses [21], yet largely still remains to be systematically integrated into practice. As a consequence, traditionally, humanistic practices can help elicit this information, and for now should remain a high-priority skill for any practitioner to ensure these relevant features are incorporated into patient-centered care decisions.

Humanistic practice strengthens the continuous patient-physician relationship and facilitates identification of relevant patient features for care. Humanistic practices build patient confidence in the relationship and empower the patient as central stakeholder in the process of care. In principle, continuity settings allow physicians to attend to human dimensions of care, spend less time re-collecting potentially complex histories [22] and more time on addressing the present condition(s), interpret information within the individual’s context of care, and engage in optimal decision making. Such settings facilitate the physician’s motivation to invest the time [22] to build rapport with each patient by actively listening, eliciting patient concerns, and applying excellent communication skills, thus engaging patients as active participants in their health care [15]. While machine learning systems are evolving to identify patient features for decision-making, and data-driven clinical decision support to optimize
decisions, these still remain a goal for the future rather than a reality in real-time shared decision making. Humanistic practice promotes optimal shared decision-making. An in-depth understanding of a patient’s goals, values, and beliefs about their health is essential to informed and shared decision-making. Potentially complex decisions are increasingly common in the primary care setting. For example, more than two-thirds of Medicare beneficiaries in the US have multiple chronic conditions; for these patients, thoughtful attention and time to appropriately consider each condition and resolve conflicting treatment recommendations may be necessary. Strong interpersonal skills are also crucial when discussing goals of care or breaking bad news, such as informing a patient of a new or grave diagnosis [23]; these procedures require careful discussion of appropriate treatment considerations that are both evidence-based yet tailored to the preferences and goals of each patient. An established and trusting patient-physician partnership provides a solid foundation for facilitating difficult conversations and patient-centric decision making. Currently, a health IT system might provide access to useful information and enable such conversations but cannot alone provide such nuanced human dialogue without physician intervention.

How technology compromises humanism

EHRs are ubiquitous, with 78% of practices having implemented EHR by 2013 [24]. Unfortunately, current systems still interfere directly with practice by shifting finite yet vital cognitive resources – physician attention, memory, and time – away from the patient and towards the EHR. In the US, where nearly 50% of visits are performed by family practitioners, general internists, and pediatricians, and in-person visits are often limited to 15-minutes [1], reducing physician attention during an already constrained visit is unacceptable. Evaluation of the unintended consequences of health IT on humanism in practice and medical education is a potential safeguard in support of high-quality health care systems [25;26], including patient safety issues, medical errors, and disruption in clinical workflow, but health IT system implementation and the abundance of new and perhaps proprietary IT innovations outpace such evaluations. Consequently, humanistic practice and care quality are at risk of further erosion.

Technologizing the science of medicine alone threatens humanism. Biomedical knowledge is increasingly able to be represented in a computer system or health IT solution, but humanism cannot. While the technological approach assumes that a biomedical model of disease alone allows for a fully digital representation of a patient, it does not incorporate social determinants of health, patient preferences, or shared decision making. These highly relevant features of a patient and their health context are essential for understanding an individual’s health and life context and for making informed and appropriate health care decisions.

Health IT distracts physicians from practicing humanistic care. Maintaining humanism in clinical practice requires focused time interacting with the patient. Health IT interferes with clinical workflow via inappropriate alerting and time-consuming data entry tasks, often directly contributing to cognitive overload, distraction, and reduced attention to important clinical information. For example, interruptions or multitasking frequently occur as a consequence of health IT implementation. Interruptions require additional cognitive resources and effort to reacquire and then subsequently perform prior tasks, potentially leading to an overreliance on intuitive or heuristic thinking and increasing the risk of systematic and unconscious biases in care. Distractions interfere with rational thinking and clinical judgment when high degrees of uncertainty or many pieces of information require careful synthesis, as is often the cases in clinical encounters, but also for simple tasks such as patient education and counseling.

Health IT excludes humanism from potentially complex shared decision making. Patient preferences, goals of care, and social determinants of health provide a context for making difficult medical decisions. Given the cognitive resources and time to do so, physicians can engage patients in dialogue to elicit their care preferences and provide the necessary clinical context to allow for shared decision making. As noted previously, the digital patient may not sufficiently represent true patient preferences in decision making processes.

Recommendations

We propose guiding principles for the new practice of digital medicine and the design of health IT, towards human health IT, which prioritizes the physician-patient connection above all else.

1. **Physicians must continue to practice with a humanistic approach, with empathy and compassion towards the patient’s condition and care context.** Human health IT also should support and enhance – and never interfere with – the patient-physician connection. Perturbations of thought, affect, time, and other valuable cognitive resources must be minimized to enable patients and physicians to focus on key biopsychosocial aspects of care. This principle is particularly high-priority in situations with a great deal of uncertainty or numerous complex issues to consider in decision making. In particular, patients with multiple chronic conditions or elderly patients, may have particularly inherent complex decision-making required for their care [27;28].

2. **Physicians must adapt to technology-enabled clinical practice by prioritizing humanistic practices and embracing their roles as feature identifiers, where health IT systems alone are insufficient.** The physician has historically performed these roles in the absence of health information technology until recent decades, and the art of medicine, a part of the therapeutic patient-physician relationship, remains one of the core oaths of clinical practice. Nonetheless, the ready quantity, availability and reliability of available health data contributing to decision-making has grown significantly. As health information technologies evolve, the predominant focus of the physician must still be to embody the role of healer, yet also evolve as a health data scientist for each patient, collecting data and identifying vital features of a patient’s life experience in clinical context. Physicians may elicit and incorporate patient preferences into shared care decisions in ways that current health IT cannot. Human health IT innovations should be designed accordingly, thereby enhancing physicians’ ability to focus attention on salient features for the benefit of the patient, especially where vital data cannot be elicited or provided by IT alone.

3. **Human health IT must automate routine or tedious tasks in order to enable high-quality care.** Human health IT should act as a supportive patient care team member, whose role is to facilitate the roles of other team members, and not replace any single entity or relationship on the team. Information systems should automate only the routine or tedious patient care tasks, thereby enabling increased time for dialogue and
essential communication during patient-physician interactions. As human health IT evolves and becomes more intelligent, may acquire additional responsibilities of increasing complexity, yet still maintain a predominantly supportive role that facilitates efficient and high-quality patient-physician interactions.

4. Human health IT must promote only humanistic patient care. Enhanced interpersonal continuity of care improves care outcomes [29] and patient satisfaction [30], and is desired by patients, particularly patients with complex chronic conditions [31]. Alternative technologies newly applied to healthcare offer previously infeasible opportunities for patients to access care, for example, via telehealth platforms, mobile apps, and other modalities. Promising applications for specific patient populations and settings [32-34], but further evaluations are needed to identify optimal clinical circumstances where such technology applications maximize benefits and minimize risks [35;36]. Additionally, there may be significant ethical implications for the patient-physician relationship when technology is misapplied, resulting in a loss of the perceptual richness of face-to-face interactions [37]. This may be a limitation to such applications, particularly if current health IT prioritizes access to care at the expense of continuous patient-physician relationships, similar to other health care delivery models that may fragment and increase costs of care [38]. Human health IT must maintain focus on humanistic, continuous care.

Conclusion

Health information technology has evolved rapidly and will inevitably transform the science of clinical medicine. However, the imperative to maintain humanism, or the art of medicine, in practice has never been greater, and we posit that human health IT, not simply health IT, is necessary during this new age of digital medicine. Human health IT embodies not only health IT, but the core principle that IT must be designed to support and enhance humanism in medicine. Applied human health IT can automate routine patient care tasks, enabling physicians to apply their vital and finite cognitive resources toward high-value and as yet non-computable tasks, such as addressing human dimensions of care, building rapport with patients, maintaining continuity, and developing a rich and valuable understanding of the medical and psychosocial aspects of each patient’s health status. Human health information technology, the next iteration of health IT, must enable humanistic clinical practice and adhere to this high standard, or the digital health revolution dissolve into a biopsychosocial island of future medicine.

Abstract

This paper draws on the vision, mission and experience with the WHO Collaborating Centre on eHealth (WHOCC-eHealth) and Yunus Social Business Health Hub (YSBHH) based at UNSW Australia, and the Asia electronic Health Information Network (AeHIN). Global eHealth aims to provide equitable access to ICT and health care, particularly to the poor, vulnerable and disadvantaged. Social business aims to solve social and economic problem. Its best known product is microcredit financial services for the poor which are small loans that enable them to "produce something, sell something, earn something to develop self-reliance and a life of dignity". Citizen engagement and community participation is integral to both constructs within the context of global partnerships for Integrated People-Centred Health Services (IPCHS) and Sustainable Development Goals (SDGs). The eHealth dimension is consumer health informatics, social media, mHealth and the Internet of Things. The convergence is multidimensional, mutually beneficial and requires good governance and leadership.

Keywords: Commerce; Community Participation; Goals

Introduction

The World Health Organization Collaborating Centre (WHOCC) in eHealth was established in The University of New South Wales (UNSW) Medicine in 2013, with its designated activities being evidence-based evaluation, assessment of eHealth and scoping eHealth solutions[1], including the Internet of Things (IoT) [2]. The Asia eHealth Information Network (AeHIN), a group of eHealth advocates in the Asia-Pacific region with an intent on using the peer learning approach to solve their eHealth challenges, is a longstanding collaborator (http://aehin.org/Home.aspx). The UNSW Yunus Social Business Health Hub (YSBHH) was established in 2015 to establish, conceive, and promote social business eHealth initiatives.

The scope includes implementation and evaluation of integrated information systems and data, mobile health (mHealth) and working towards an IoT for health. The WHO and the International Telecommunication Union (ITU) sponsored National eHealth Strategy Toolkit is a guiding document that promotes seven strategies for successful implementation of eHealth programs [3]. The vision is global partnerships for Integrated People-Centred Health Services (IPCHS) [4]. United Nations Millennium Development Goals (MDGs) [5, 6], Sustainable Development Goals (SDGs) [7] and health and eHealth workforce [8].

With more than 400 million people globally lacking access to essential health care, the SDGs remain aspirational, like the MDGs. To achieve universal health coverage and equitable access to timely health services, the IPCHS Framework proposes five critical shifts that need to happen (Figure 1): Coordinating services within and across sectors; Re-orienting the model of care; Strengthening governance and accountability; Empowering and engaging people; and Creating an enabling environment.

Figure 1 – Five critical shifts required to achieve timely Integrated People Centred Health Services (©WHO 2016)

Developing more integrated people-centred care systems has the potential to generate significant benefits for the health and health care of all people. There is no perfect combination nor a "one size fits all" solution. The right solution will depend on a country’s unique context and needs, as well as local considerations [4].

The MDGs aim to eradicate extreme poverty and hunger, achieve universal primary education, promote gender equality and empower women, reduce child mortality, improve maternal health, combat HIV/AIDS, malaria, and other diseases, ensure environmental sustainability and develop a global partnership for development. The 17 SDGs replaced the MDGs in 2016, with goals relevant to health and well-being:

- SDG#3: Ensure healthy lives and promote well-being for all, at all ages;
Social business aims to alleviate social and economic problems caused by poverty, poor health, unhealthy food, smoking, alcohol, gambling, risky behavior, unemployment, poor literacy and other social determinants of health. Social business is not a charity [9]. It is a non-dividend, non-profit business entity [10], but like for-profit businesses, it has to be sustainable. Costs must be recovered, but with the profit-maximization principle replaced by the social-benefit principle. Social business and SDGs complement each other, the SDG identifies a socioeconomic area for development while the social business model of cost-effective execution works to improve that area sustainably [11].

An application of social business methodology to financial services is the Grameen Bank or “village bank for the poor”, which makes “microcredit” or tiny loans to poor people. It is based on trust, with no collateral required or legal documents involved! Grameen Bank currently has nine million borrowers, who are “owners” of the bank and lends out over one and a half billion US dollars each year. Almost all (97%) of borrowers are women, who usually use the loan start a business to earn a livelihood. As Prof Yunus describes it, ”by producing something, selling something, earning something, she starts to develop self-reliance and a life of dignity” [12].

Successful social businesses in health included selling vegetable seeds at affordable prices to make vegetable growing easy for the citizenry. This business has become the largest seed retailer in Bangladesh and more importantly, is associated with a marked reduction of night blindness, a common disease among the poor children in rural Bangladesh. Malnutrition is being addressed by a joint venture in 2005 with a for-profit global company, Danone, to establish a social business model of cost-effective execution works to improve that area sustainably [11].

A link to eHealth began with the Grameen Village Phone Program. Started in 1997, this provided a good income-earning opportunity to more than 210,000, mostly women, Village Phone operators living in rural Bangladesh through facilitating universal access to telecommunication services by the poor in remote, rural areas. The phone was used mainly for financial discussions and social calls with family and relatives living and working in urban areas, resulting in real savings through avoidance of and reduction in trips to the city [13].

Current social business technologies evolved from adoption of emerging information and communication technologies to affect innovations in social business and the social sector. In 2006, Gramenphone initiated HealthLine 789 for its ten million subscribers, who are charged thirty-eight cents US dollars per call for five minutes. A range of medical information facilities, (e.g., SMS-based laboratory reports), emergency and ambulance services, and real-time medical consultations are provided via mobile phones. A panel of skilled health professionals is available 24/7 through the physician’s interface and support is provided by a back office and network manager [14, 15, 16].

Increasing smartphone penetration [17], strong users and patient demand for mobile phone apps are strong drivers for mHealth [18]. Health professionals may resist this potential power shift to patients and the community. Regulations of the mHealth industry do not appear to be a barrier but, uncertainty exists around the lack of data security and standards. A general barrier is “discoveryability”, where it is difficult to discover the required app from among the 100 thousand plus mHealth apps available online.

Community readiness for eHealth is important globally, as well as in rural Bangladesh[19,20]. Community members, leaders and healthcare providers would use mHealth tools and services. However, awareness of existing services is low, especially among the poor and less educated. While face-to-face consultations are preferred, the community is attracted by the timely access to qualified healthcare providers, time savings and lower costs associated with mHealth. Low literacy, lack of English language proficiency, lack of trust and technological incapability are barriers to mHealth use [21]. However, a sense of ownership, evidence of utility, a positive attitude and intention to use mHealth were drivers of adoption of mHealth services. Implementation strategies must emphasize gaining the trust, training and support of users. This requires citizen engagement to inform and empower consumers and ensure transparency and accountability.

The key construct in citizen engagement is public participation. Unlike public communication to inform the public, public participation is characterized by a two-way flow of communication in an iterative fashion. It involves the public in collaborative ways and emphasises empowerment. However, barriers exist including poverty and a decreased sense of worth, especially among those with disabilities and disadvantages such as extremes of age, female gender and belonging to minority groups [22].

Our key assertion is that global eHealth implementation and evaluation requires social business strategies, targeted at both clinical and population issues, underpinned by citizen engagement if they are to succeed in improving global health through the IPCHS Framework (Figure 1) and National eHealth Strategy Toolkit.

Methods

A literature search, using “social business”, “eHealth”, “electronic health”, and “health” with MEDLINE (1966-2016), EMBASE (1974-2016) and SCOPUS (1960-2016), found only one paper that met all criteria [23] and 44 papers matched on outcome criteria. Only relevant papers were used to guide the critical analysis of the WHOCC-eHealth and YSBHH activities and critical reflection to focus key principles into a conceptual framework for a convergent research and development program on eHealth and social business.

Findings

The dimensions of the sociotechnical framework to converge eHealth [3] and social business [10] concepts and strategies include: 1. integrated infrastructure and building blocks; 2. collaborative eHealth activities with a citizen focus; 3. citizen engagement and collaboration; 4. measurement and evaluation of citizen-centred process and impacts across the relevant SDGs for the individual, family, community at facility, district, regional and national levels.

Transparent governance, management and leadership across the four dimensions is essential to manage the change needed
to achieve the Triple Aim of better health, better care and cost-effectiveness [24].

1. Convergent building blocks and infrastructure

These include standards and benchmarks for data, information systems, software applications, standard operating procedures, clinical and managerial protocols, change management and governance structures to support learning health organizations and networks to achieve the SDGs for the country. Convergent activities with potential benefit include:

- Establishing the infrastructure and tools to support an user-centered Internet of Things [25].
- Collaborative projects with the Australian Collaborative Research Centre on Spatial Information (CRC-SI) to geocode digital data repositories collected in integrated health neighborhoods [26].
- Building a robust and trusted eHealth infrastructure [27, 28] to support the implementation and monitoring of programs to achieve the SDGs and, previously, the MDGs.
- Building the eHealth workforce capacity through professional exchanges, education and training [29, 30].

2. Convergent citizen-centered eHealth tools & things

These include software applications to contribute to the IoT. Legally, "things" should be seen as an "inextricable mixture of hardware, software, data and service" [25]. Examples of "things" may be wireless devices for detecting and/or monitoring of activities and physiological functions, environment quality, food safety, pathogen activity or functioning of smart homes. This IoT framework applies to eHealth activities such as:

- Cloud-based mHealth systems for disaster management in Indonesia [31];
- mHealth for the primary care of cancer patients in Sydney Australia [32];
- Use of tablets for health checks of independent-living elders, within the Silvercare model where a young, retired person supported up to ten elderly people in their neighborhood with the Indian Aboriginal health agencies [33].

3. Citizen engagement, collaboration and convergence

A digital citizen uses information and communication technology (ICT) to engage in society, politics, and government participation. The key concept here is that it is most efficient and effective at the local community and facility levels. However, the governance and accountability needs to link upwards to meso- and macro-organizations at regional, jurisdictional and national levels. Citizen engagement is an evolving dimension of the WHOCC-eHealth and YSBHH. Activities include:

- Assessing community readiness for mHealth with developing countries [19, 20, 34].
- Assessing market adoption, cost, maturity and user acceptance of robotic mHealth services for vulnerable groups with European Union partners [35].
- Education and training of students from high schools, universities and communities [36].

- Collaborative activities with relevant communities and stakeholders organizations,

4. Convergence and integrated health services & information in local neighborhoods

Digital data from electronic health records (EHRs) of health services in local neighborhoods form the core of any eHealth and health services research and development program. The local neighborhood with its local hospital, general practice and primary care services is the most relevant and logical unit of analysis (denominator) for health services and population health research. Data collected as part of routine clinical practice in EHRs and health information systems (HISs) will form the core longitudinal data source, supplemented by more specific quantitative and qualitative data collection methods at specific time points.

We have defined an Integrated Health Neighborhood (IHN) as a referral network of health services across primary and secondary care, supported by an informatics infrastructure and record linkage across clinical and population health information systems, traditional research data sets, social media and personalized appliances [26]. We have developed and validated tools to assess and manage the quality of data collected and stored in HISs during routine clinical or managerial practices [37-40]. We have also conducted research into natural language processing to improve quality of routinely collected health and social data [41-44].

This evaluation methodology, built around networks of IHNs, is the most logical patient and local community centered approach to collecting data to monitor the implementation, progress and impacts of health care interventions. The IHN approach also enables comparative effectiveness research across IHNs and communities to understand variations in quality of data and care, cost-effectiveness of eHealth in improving self-management, equity and access to health care and social capital in local communities.

We have consulted widely and developed models of data quality management and governance needed to ensure ethical and innovative use of the data collected through this informatics infrastructure [39-41,45-48].

This is an invaluable asset to enable ongoing monitoring of safety and quality of care and achieve the Triple Aim [24] of eHealth and health services, i.e., achieving optimal care, cost and health.

Discussion

Global eHealth research and development, with a social business and citizen engagement approach to achieve integrated people centered health services, is logical and sustainable. It gives meaning to eHealth as mechanisms to achieve access, equity, safety, quality and continuity and comprehensiveness of care of both communicable and non-communicable diseases. Individual and community readiness to adopt and use eHealth tools must be assessed within a comprehensive sociotechnical framework and the context in which they work to achieve healthy behavior and patient outcomes. Finally, open and transparent governance, management and leadership is essential. A range of governance structures exist, but the aim is to extend conventional thinking from simply a government-led program to citizen-led and government-enabled eHealth systems.
Citizen engagement is not easy! However, this is exactly where the social business methodology and approach come into its own. Like the Village Phone project, the community can have a stake in the eHealth program as employees or investors through microcredit for eHealth implementation, training and support projects within the local community. The social business paradigm has shown that it can work.

Integrated people centered health care requires integrated data and information systems ( interoperability) to support it and integrated health professionals and services [49, 50] to deliver it to individuals, families and communities. The same data collected during the provision of care should be used to monitor the process and impact on the SDGs [51]. This requires the integration of data from facilities and micro-organizations in health neighborhoods to networks of those managed and governed by meso-organizations at regional levels and macro-organizations further up the hierarchy in the health system.

Most national health systems have this health neighborhood based hierarchical organizational structure. However, the collection, management and stewardship of the data and information is not organized, managed or governed to maximize the benefits of this organizational structure. This need to collect and use meaningful information to monitor progress in the achievement of the SDGs may be a catalyst for developing countries to lead the way for a cost-effective means to organize national HISs to use routinely collected digital data to support health care planning, delivery, evaluation and clinical re-design to iteratively improve the process and impacts of integrated people centered health services.

Finally, mechanisms for countries to share and compare experiences and lessons from the field can trigger and facilitate international learning, which will shorten the transformations in capacity and infrastructure necessary for successful citizen-led relevant social businesses and useful eHealth systems.

P-Care BPJS Acceptance Model in Primary Health Centers

Hosizah Markam

Health Information Management Department, Faculty of Health Sciences, Esa Unggul University Jakarta, Indonesia

Abstract

Electronic Medical Records (EMR) are increasingly adopted in healthcare facilities. Recently, implementation failure of electronic information systems is known to be caused by not only the quality of technical aspects, but also the user’s behavior. It is known as applying the Technology Acceptance Model (TAM). This research aimed to analyze the acceptance model of p-care BPJS in the primary health centers. A total sample of 30 p-care BPJS users was drawn by multistage random sampling in which of these 30 primary health centers participated. Data analysis used both descriptive and inferential statistics. In the phase of structural model, it indicated that p-care BPJS acceptance model in the primary health centers was formed by Perceived Ease of Use (PEOU) and Perceived Usefulness (PU) through Attitude towards use of p-care BPJS and Behavioral Intention to use p-care BPJS.

Keywords:
Electronic Health Records; Hospital Information Systems; Models, Theoretical

Introduction

Information and communication technologies (ICTs) have great potential to improve health in both developed and developing countries by enhancing access to health information and making health services more efficient; they can also contribute to improving the quality of services and reducing their cost. Today, most electronic information systems used in the primary health centers only store data or patient aggregate information at the management level. Based on findings from the global eHealth survey by the WHO and the World Bank, the State of Africa and Southeast Asia were the highest (over 90%) individual patient data usage in paper-based format, whereas electronic medical records (EMR) were mostly adopted in developed and developing countries, such as Brazil, China and India [1-4].

An electronic medical record (EMR) is a real-time patient health record with access to evidence-based decision support tools that can be used to aid clinicians in decision-making. The EMR can automate and streamline a clinician’s workflow, ensuring that all clinical information is communicated. It can also prevent delays in response that result in gaps in care. The EMR can also support the collection of data for uses other than clinical care, such as billing, quality management, outcome reporting, and public health disease surveillance and reporting. Furthermore, an EMR may contain clinical applications that can act on the data contained within its repository, for example, a clinical decision support system (CDSS), a computerized provider order entry system (CPOE), a controlled medical vocabulary, or a results-reporting system. In general, EMRs are clinician-focused in that they enhance or augment the workflow of clinicians or administrators [1, 3, 5, 6]. Currently, the only EMR concept used in primary health centers in Indonesia is p-care BPJS.

P-Care BPJS is Primary-Care BPJS. BPJS is Badan Penyelenggara Kesehatan or National Social Security. In Indonesia, P-Care BPJS is commonly known as p-care BPJS in Healthcare. P-Care BPJS is a web-based patient care application provided by BPJS. It is used for accessing data stored in the BPJS server including patient registration, laboratory, diagnosis, treatment and therapy [7]. Recently, implementation failure of electronic information systems is caused not only by the quality of technical aspects, but also the user’s behavior. Applying the TAM may help reduce implementation failure [8, 9]. TAM is an information system theory that models how users come to accept and use technology: the main dependent constructs are behavior intention to use and system usage. Until now in Indonesia, studies examining the individual acceptance of the use of p-care BPJS have not been done yet. This study aimed to analyze the technology acceptance model of p-care BPJS in the primary health centers.

Methods

This cross-sectional observational study was conducted in February-May 2016. The study population consisted of users of p-care BPJS at primary health centers in the province of East Java. Users of p-care BPJS were responsible to operate the p-care application in primary health center. A sample size of 30 users of p-care BPJS from 30 primary health centers in five districts, namely: Bangkalan; Bondowoso; Lamongan; Malang; Kediri with multistage sampling method, each district was represented by 6 primary health centers and one p-care BPJS user from each were included.

According to TAM, this study posited the following seven hypotheses:

H1: Perceived Ease of Use (PEOU) significantly affects to Perceived Usefulness (PU)
H2: Perceived Ease of Use (PEOU) significantly affects to Attitude towards Use p-care BPJS
H3: Perceived Usefulness (PU) significantly affects to Attitude towards Use p-care BPJS
H4: Perceived Usefulness (PU) significantly affects to Behavioral Intention to Use p-care BPJS
H5: Perceived Usefulness (PU) significantly affects to Actual p-care BPJS Use
H6: Attitude towards Use p-care BPJS significantly affects Behavioral Intention to Use p-care BPJS
H7: Behavioral Intention to Use p-care BPJS significantly affects Actual p-care BPJS Use
The questionnaire has been prepared in accordance to questions in the TAM [8, 9]. The response scale for all TAM items was a six-point scale, ranging from 1 (Extremely Unlikely) to 6 (Extremely likely). The questionnaire was tested for the validity. The result showed that the validity and reliability was good (the Cronbach’s Alpha value was 0.896). A total of 30 questionnaires were distributed with a 100% response rate. Thirty completed questionnaires were obtained and considered valid. Data analysis used both descriptive and inferential statistics. Inferential statistics was performed with Structural Equation Modeling (SEM) by using a SmartPLS 3.0 program consisting of two phases, the measurement model and the structural model [10].

Results

The return rate for the questionnaire was 100%. The characteristics of respondent description in table 1.

</tbody>
</table>

Of the 30 respondents, more than one-half were female (60%), and older than 30 years of age (53.4%). Forty three percent were between the ages of 20-30 years of age and younger than 20 years of age (3.3%). Fifty-seven percent of respondents had obtained a 3-year diploma, with the remaining respondents having completed a four-year bachelor’s degree and senior high school. Eighty percent passed from health education and the remainder having non-health education.

Construct validity test results with the SmartPLS in the measurement model can be seen in the value of convergent validity and reliability tests with value of composite reliability (CR) and Cronbach’s Alpha. In Table 2 the value of the loading factor (convergent validity) was between 0.913-0.949; it can be explained that almost all indicators of loading factor >0.7 and Cronbach’s Alpha > 0.6 (0.855-0.933). Thus all the constructs, Perceived Ease of Use, Perceived Usefulness, Attitude toward Use p-care BPJS, Behavioral Intention Use p-care BPJS Behavioral Intention Use p-care BPJS, Actual p-care BPJS Use have met the acceptable cut-off values of reliability [10, 11].

</tbody>
</table>

Note: *sig=0.05, **sig=0.01
The result of path analysis in Table 3 shows that actual p-care BPJS Use were significantly influenced by Perceived Ease of Use through Perceived Usefulness, Attitude toward Use p-care BPJS, Behavioral Intention Use p-care BPJS. Actual p-care BPJS Use was not significantly influenced directly by Perceived Usefulness and also on Behavioral Intention Use p-care BPJS was not significantly influenced directly by Perceived Usefulness. A coefficient parameter path of Perceived Ease of Use p-care BPJS to Attitude toward Use p-care BPJS is smaller than through Perceived Usefulness p-care BPJS.

<td>0.716</td>
</tr>
<tr>
<td>Actual p-care BPJS Use (AU)</td>
<td>0.790</td>
</tr>
</tbody>
</table>

In table 4, R-squared Actual p-care BPJS Use amounted 0.790, Behavioral Intention to Use p-care BPJS is 0.716 and Perceived Usefulness is 0.793.

- **Perceived Usefulness**

Perceived usefulness as the extent to which a person believes that using a technology will enhance her or his performance. Perceived Usefulness consists of six items: work more quickly, job performance, increase productivity, effectiveness, makes job easier, and useful. Participants responded likely and extremely likely on all of item work more quickly, job performance, increase productivity, effectiveness, makes job easier, and useful more than 75%

Path coefficient of perceived usefulness affected Attitude towards Use p-care BPJS by 0.726 and significant p-value of 0.000 (<0.05). This can be explained that Perceived Usefulness user p-care BPJS positive effect and significantly influenced on Attitude toward Use p-care BPJS. Perceived Usefulness users of p-care BPJS had a positive effect on both Behavioral Intention and Actual p-care BPJS Use but were not significantly significant.

- **Perceived Ease of Use**

Perceived ease of use is the extent to which a person believes that using a technology will be free of effort. Perceived Ease of Use is composed of six items namely easy of learn, controllable, clear and understandable, flexible, easy to become skillful and easy to use. Participants responded likely and extremely likely on all of items easy of learn, controllable, clear and understandable, flexible, easy to become skillful and easy to use more than 79%. Effect of perceived ease of use to the perceived usefulness with path coefficient of 0.892 and significant p-value of 0.000 (<0.05). Perceived Ease of Use positively affected Perceived Usefulness users of p-care BPJS.

- **Attitude Toward Use p-care BPJS**

Attitude toward Use p-care BPJS is an individual’s positive or negative feelings about performing the target behavior. Attitude toward use p-care BPJS is composed of three items have fun, enjoyment and boring. Participants responded likely and extremely likely on all of items have fun, enjoyment and boring more than 82%

Attitude toward use of p-care BPJS positively affected Behavioral Intention Use p-care BPJS with path coefficient of 0.657 and significant p-value of 0.000 (<0.05). Attitude toward use of p-care BPJS of primary health center had a positive effect on Behavioral Intention Use p-care BPJS.

- **Behavioral Intention Use p-care BPJS**

Behavioral intention Use p-care BPJS consists of three items intend, predict and plan. Behavioral intention to use p-care BPJS had positive effect on actual p-care BPJS use with the path coefficient of 0.808 and significant with a p-value of 0.000 (<0.05). Behavioral intention to use p-care BPJS positively affected actual p-care BPJS effect on primary health center.

- **Actual p-care BPJS Use**

Actual p-care BPJS use was significantly influenced by perceived ease of use through perceived usefulness, attitude toward use p-care BPJS, and behavioral intention to use p-care BPJS. Actual p-care BPJS Use was not significantly influenced by perceived usefulness. Behavioral intention to use p-care BPJS was also not significantly influenced by perceived usefulness.

**Discussion**

This study analyzed the technology acceptance model (TAM) factors influencing p-care BPJS users’ actual use in the Primary Health Centers. In particular, the influences of perceived usefulness, perceived ease of use, and attitude towards p-care BPJS on intention to use p-care BPJS are examined. At the same time, hypotheses about the influence among perceived usefulness, perceived ease of use, and attitude towards p-care BPJS use were also tested. The was a strong effect (0.790) of behavioral intention to use p-care BPJS [11]. This showed that the perceived usefulness, attitude toward use of p-care BPJS and behavioral intention to use p-care BPJS could explain the variance of actual p-care BPJS amounted to 79% and the remaining 21% was influenced by other variables.

Perceived usefulness affected attitude toward use of p-care BPJS, which is in line with previous studies of the acceptance on the Clinical Information Systems among medical staff [12], [13], [14].

Perceived usefulness users of p-care BPJS had a positive effect on behavioral intention to use p-care BPJS but was not significant. Perceived usefulness was not affected by behavioral intention to use p-care BPJS, which is in line with previous studies [15]. Perceived usefulness of p-care BPJS had a positive effect on actual p-care BPJS use, but was also not significant. Perceived usefulness affected actual p-care BPJS use. This is in line with previous studies [15].

Perceived ease of use positively affected on perceived usefulness of p-care BPJS users of the primary health center, which is in line with the TAM as proposed by Davis as well as the previous studies [8][16][17]. Perceived ease of use positively affected attitude towards use of p-care BPJS. Perceived ease of use positively affected attitude toward use of p-care BPJS user of the primary health center, this is in line with the previous studies physician’s acceptance of hospital information systems [16], in the Acceptance of Telemedicine Systems [17].

Attitude toward use of p-care BPJS in primary health centers was positively effected by behavioral intention to use p-care BPJS. This research is also consistent with results of previous studies of in the Acceptance of Telemedicine Systems [17], user acceptance of a picture archiving and communication system (PACS) [18].
Behavioral intention to use p-care BPJS affected actual p-care BPJS use. This is in line with previous studies of user satisfaction and technology acceptance [22] and students acceptance of mobile learning for higher education [23].

Perceived usefulness affected actual p-care BPJS use, this is in line with previous studies of end-users’ acceptance and use of hybrid library services [25], electronic medical records: TAM, UTAUT and culture [26].

Goodness of Fit (GoF) index of p-care BPJS acceptance model in the primary health centers was 0.741. It is good or fits the model. There are three categories in GoF index: small=0.1; medium=0.25; and large=0.36. GoF index is crucial for assessing the global validity of a complex model [27].

The R² for the model was 0.790. This means that the diversity of behavioral data of p-care BPJS use in primary health centers can be explained by the construct is 79%, the remaining 21% is explained by other constructs that were not included in the model. The determinant of p-care BPJS acceptance model in the primary health centers is perceived ease of use and perceived usefulness.

Conclusions

Five of seven hypotheses tested here were accepted. There was a difference with the original TAM, but in line with previous studies. Actual p-care BPJS use was significantly influenced by perceived ease of use through perceived usefulness, attitude toward use of p-care BPJS, behavioral intention to use p-care BPJS. Actual p-care BPJS use was not significantly influenced by perceived usefulness or behavioral intention to use p-care BPJS, not was it significantly influenced by perceived usefulness. Effect of perceived ease of use has become a determinant for successful implementation of p-care BPJS in the primary health centers. Thus, users of p-care BPJS need to be trained on an ongoing basis to keep up to date in understanding the latest version of the program. As this is a preliminary attempt to understand how the system is being accepted, a more comprehensive rigorous research approach can be adopted in the future that incorporates a larger model, such as Unified Theory of Acceptance and Use of Technology (UTAUT) and others that are able to capture external influences. It is with a hope that p-care BPJS will evolve and improve to serve the Primary Health Centers as a whole as well as the community through better health care approach using computer based solutions.

Acknowledgements

I would like to thank Esa Unggul University for supporting and funding this study. I also wish to thank to the respondents for the support and help in participating in the study.

The Australian Health Informatics Competencies Framework and Its Role in the Certified Health Informatician Australasia (CHIA) Program

Fernando Martin-Sanchez, David Rowlands, Louise Schaper, David Hansen

Abstract

The Certified Health Informatician Australasia (CHIA) program consists of an online exam, which aims to test whether a candidate has the knowledge and skills that are identified in the competencies framework to perform as a health informatics professional. The CHIA Health Informatics Competencies Framework provides the context in which the questions for the exam have been developed. The core competencies for health informatics that are tested in the exam have been developed with reference to similar programs by the American Medical Informatics Association, the International Medical Informatics Association, and COACH, Canada’s Health Informatics Association, and builds on the previous work done by the Australian Health Informatics Education Council. This paper shows how the development of this competency framework is helping to raise the profile of health informaticians in Australasia, contributing to a wider recognition of the profession, and defining more clearly the body of knowledge underpinning this discipline. This framework can also be used as a set of guidelines for recruiting purposes, definitions of career pathways, or the design of educational and training activities. We discuss here the current status of the program, its results and prospects for the future.

Keywords: Certification, Professional Competence, Medical informatics.

Introduction

In other countries, certification in health informatics is achieved through university degrees. However, in Australia, only a few universities offer studies related to health informatics or a full undergraduate or postgraduate degree in this area [1]. In addition, health informatics lacks formal recognition in the Australian health workforce [2].

To address this, the Health Informatics Society of Australia (HISA), in collaboration with the Australasian College of Health Informatics (ACHI) and the Health Information Management Association of Australia (HIMAA), launched the Certified Health Informatician Australasia (CHIA) certification program in July 2013 at HIC, the major Health Informatics Conference in Australia. The CHIA consists of an online exam, which aims to test whether a candidate has the knowledge and skills that are identified in the competency framework to perform as a health informatics professional.

A competency is the specification of knowledge and skill, and the application of that knowledge and skill, to the standard of performance expected in the workplace. A competency is the smallest unit that can be assessed and recognized [3]. Competencies should be used to set clear expectations for professionals in providing them with direction on what level they need to be performing in the workplace. It also provides professionals with an itinerary for development and continuous education, including closing knowledge gaps. Competencies also provide a framework for career growth and improvement in recruitment processes. Finally, competencies can help establish professional opportunities, including horizontal and vertical moves within an organization [4].

The CHIA Health Informatics Competencies Framework provided the context in which the questions for the exam were developed. It was developed by a committee composed of representatives from HISA, HIMAA and ACHI, and included leaders in health informatics academia and the Health IT sector. The core competencies for health informatics, that are tested in the exam, have been developed with reference to similar programs by the American Medical Informatics Association (AMIA), the International Medical Informatics Association (IMIA) and Canada’s Health Informatics Association (COACH), and builds on the previous work done by the Australian Health Informatics Education Council.

Methods

The Health Informatics Competencies Framework

Health and Biomedical Informatics (HBI) is a discipline with more than 50 years of existence. Along this period, many sub-specializations have emerged. HBI is considered as the core set of information methods, theories and tools, which are relevant to healthcare, biomedical research, and public health. However, depending on the application domain, different sub-specialties can be identified. The original intention by the CHIA governing bodies was to introduce specialization exams based on segmentation by discipline (e.g. CHIA-NI for nurse informaticians). However, given workforce trends across the globe that show the need for transferability of skills and knowledge across disciplines, we are now considering a tiered structure of increasingly advanced health informatics knowledge that is not discipline specific. The decision and subsequent development of ‘CHIA+’ will be occurring from late 2017 onwards. To develop a set of highly regarded competencies in health informatics (HI), we needed firstly to refer to the most relevant existing frameworks:

- AMIA – A leading professional and academic organization in biomedical informatics, published the most recent white paper on core competencies in June 2012 [5];
- IMIA – Peak body at the international level in the area of health and biomedical informatics, published revised education Recommendations in 2010 [6]; and
The eligibility of individuals who don’t meet the above criteria are reviewed by the CHIA Examination Committee on a case by case basis.

Results

The Competencies Framework

Figure 1 provides a representation of the Health Informatics Competency Framework showing the six competency streams as a proportion of the overall. The CHIA exam covers all 6 areas. The list of competencies is provided in Table 1, but the complete information with descriptions and levels of assessment can be accessed at the following URL: http://www.healthinformaticscertification.com/wp-content/uploads/2016/02/CHIA-competencies-Framework_FINAL.pdf

Figure 1 – Health Informatics Competencies Framework

The CHIA Examination Study Guide

An examination study guide entitled “A Practitioner's Guide to Health Informatics in Australia” has been published by the Health Informatics Society of Australia (HISA) as a comprehensive body of knowledge (+1000 pages) covering competencies tested in the CHIA exam. It is the definitive guide for CHIA candidates. The Practitioner's Guide has also been developed with other purposes in mind, including orientation for professionals, such as clinicians or ICT professionals new to health informatics and updates for health informaticians, wishing to maintain the currency of their knowledge, irrespective of certification. It focuses explicitly on the needs of practitioners in the field of health informatics in Australia.

- Covers all of the 52 CHIA competencies at the level of competence required (knowledge, comprehension, application or analysis),
- Aimed at helping candidates achieve certification, and
- Provides a valuable professional and workplace resource.

The Guide is published electronically, into 8 sections and is available for purchase.

Table 1 - CHIA Health Informatics competencies framework
The CHIA Exam

Becoming a CHIA involves sitting and passing the CHIA exam. The exam covers 6 competency areas and 52 competencies, and includes 104 multiple choice questions (2 questions on each competency at various levels of difficulty). The exam is completed online, and the duration is 2.5 hours maximum. Exam questions are selected at random (i.e. students re-sitting the exam will not be given the same questions as the first time they sat the exam). The exam is managed by an Examination Committee comprising of senior Australasian health informaticians.

Periodic Renewal of Certification

Periodic renewal of the certification is required to maintain certified status. Initial certification or renewal of certification is valid for 3 years. Renewal is required to maintain the CHIA certification. The renewal requirements are currently under review and are likely to be: Submit a recertification journal that documents a minimum level of ongoing professional development or take the exam again.

Discussion

Comparative analysis of competencies in health informatics

We provide the comparative analysis of groups and competencies (Table 2) for a breakdown of the different areas of competencies covered.

Results so far

The official program launch took place on July 16, 2013 at the Health Informatics Conference in Adelaide, in conjunction with a workshop and education session. The first exams took place in December 2013, where 415 candidates have registered to sit the exam, 57 have forfeited (not attempted at all), 32 are pending a first attempt, 84 have failed, and 242 have passed. Candidates come from a range of organizational settings. The most popular settings are public hospital (30%, n=126), technology or health IT companies (19%, n=79), and state government (14%, n=60). While this is to be expected due to the significant focus on EMRs within hospitals, we need to examine the applicability of the HI framework and CHIA exam to those in primary and community care, and also to raise awareness amongst this healthcare segment.

CHIA candidates have a range of job roles, the most popular roles are health IT professional (28%, n=118), clinicians, including physicians, nurses, and allied health (20%, n=84), and health information manager (10%, n=43). The majority of CHIA candidates have a clinical educational background (23%). Others include business (10%), IT (10%) and health information management (6%).

In 2017, we are embarking on a survey of all CHIA registrants to gather quantitative data. However, the anecdotal qualitative data we have, indicates that the most common reason for people failing or choosing to forfeit is a lack of adequate preparation for the exam. These people underestimated the amount of time required to prepare. To address this, we are modifying our communication with candidates to emphasize that successful attainment of CHIA requires a thorough knowledge base, which requires study, regardless of the amount of work experience the candidate has. We are also making available the reading materials/study guide for those who wish to purchase it ahead of registering for the exam (at present the reading materials are only made available after registration).

Conclusion

CHIA is a unique credentialing program for health informatics. The CHIA credential demonstrates that candidates meet the Health Informatics Core Competencies to perform safely and effectively as a health informatics professional. Following the early success of CHIA, several Australian universities are currently evaluating how they can include the Australian HI competencies in their training programs, and help prepare graduates to sit to the exam.

The development of this competency framework is helping to raise the profile of health informaticians, contributing to a wider recognition of the profession, and defining more clearly the body of knowledge underpinning this discipline. This framework can also be used as a set of guidelines for recruiting purposes, definitions of career pathways, or the design of educational and training activities. The framework is being re-evaluated in late 2017, and will be re-evaluated every 3 years.

Notes:

1 Degree can be any degree and does not have to be in health informatics.
2 Associated experience includes the following functional areas: health informatics, health administration/management, clinical information systems, e-health, information systems, health information management.

Information and Communication Gaps in Intersectoral Healthcare Processes for Dementia Patients

**Abstract**

In addition to general barriers of information exchange and communication in intersectoral healthcare processes, the healthcare process of dementia patients has unique requirements regarding the communication and information exchange of the various healthcare professionals and non-professional caregivers, such as relatives or their legal caregivers. We conduct a process analysis to determine the status quo of such healthcare processes in the region of Darmstadt, Germany and elicit existing gaps in the information and communication exchange. We identify key processes by performing a document analysis and conducting interviews with seven different healthcare professionals. The results of a weak point analysis based on advanced event driven process chains (EPC) point out 32 information and communication gaps summarized in four categories: “information exchange”, “information transfer” “information provision” and “activity impulse”. Our results show further opportunities regarding the support of caring relatives and primary care physicians.

**Keywords:**

Dementia; Intersectoral Collaboration; Workflow

**Introduction**

Dementia is increasingly affecting people worldwide - in many regions, between five and seven percent of persons over the age of 60 have dementia [1]. Oftentimes, dementia patients suffer from multiple other diseases (multi-morbidity). For example, fractures are a commonly reported co-morbidity of dementia [2] and the resulting increased fall risk [4]. In order to address these different diseases, dementia patients are often in need of healthcare services from different healthcare providers and institutions, such as hospitals, specialists or care facilities.

Furthermore, because dementia patients are often neither able to provide information regarding their general state of health nor provide specific details in acute situations, the barriers of communication and information exchange existing between various professional and non-professional actors involved in healthcare provision, are exacerbated in this setting. This is particularly prevalent in unfamiliar situations, like a hospitalization following a fall or other traumatic experience. Hence, in order to offer optimal patient-centered care, healthcare providers involved should coordinate their services (intersectoral interlinkage). However, because the German Social Security System is divided into two separately organized sectors – inpatient and outpatient care – communicating and cooperating (i.e., sharing information) across these sectoral boundaries is difficult [5]. New care concepts are needed to address these barriers and improve healthcare provision - strategic digital transformation may be instrumental in overcoming these challenges.

The collaborative project “Securing integrated care for multimorbid patients with dementia using an IT-based service concept” (SimiPat) aims to (1) identify key processes (status quo) and deduce information and communication gaps in the care process of dementia patients following a fall experience to solve such problems, (2) determine caregivers needs, (3) develop and implement a resulting IT-supported case management system, and (4) evaluate the effectiveness of the IT-solution.

Even though many projects begin with a number of process analyses, the unique situations surrounding the care of dementia patients such as the limited patient participation and the complex, intersectoral care architecture, and the heightened social relevance of dementia as a healthcare challenge, we think it is important to publish the results of our process analysis at this early stage in the project. Therefore, we present the methods and results of the process analysis (point 1) in this paper.

**Methods**

**Setting**

The process analysis focuses on multi-morbid patients with dementia after a traumatic fall event, e.g., a femur fracture, with subsequent inpatient treatment. The analysis period is defined as the time from hospitalization up to three weeks of post-treatment follow-up. The process data is collected at a local hospital (AGAPELION ELISABETHENSTIFT Darmstadt) and various post-hospital care facilities in the region of Darmstadt.

**Establishment of the status quo of care**

**Data collection**

The data collection took place in two steps. First, we performed a document analysis of hospital-specific documents, geriatric assessments, and required documents from the nursing home. This basic knowledge was used to prepare the subsequent interviews with the different healthcare professionals that are involved in the examined process period.
Second, we conducted semi-structured, open-ended, interactive interviews with various healthcare professionals involved in the target care period. These interviews had an average duration of one hour. One representative (expert) from each category of professional healthcare providers and a self-help organization was interviewed by two researchers during each interviewer, except for the first interview where 2 respondents participated. We conducted a total of six interviews with seven respondents over a period of three months: one outpatient nurse, one hospital-based social worker, one geriatrician, one primary care physician, one nursing home social worker, and one representative from the local Alzheimer’s society.

The interviews started with participants reporting their tasks and activities within the care process without interruption from the interviewers. Meanwhile, the interviewers illustrated this process information as a simple flow chart documenting only activities utilizing a flipchart supplement. This enabled participants to retain a continuous overview of the whole process as they were reporting their tasks and activities. This also facilitated an immediate enquiry on single activities for a more precise documentation of the status quo, especially regarding interfaces to other healthcare professionals.

Upon completion of the interviews, we compared the information of the document analysis with the process data generated from the interviews. In doing so, we were able to supplement any lacking entities, organizational units, and documents used and/or updated in the processes elicited from the document analysis.

**Identification, modelling and description of processes**

The information collected was summarized in an intersectoral care process, integrating the actions of the healthcare providers with those of the non-professional caregivers. Due to the complexity of this (intersectoral) healthcare process, the combined information was modeled as a simplified process flow chart (only activities and responsibilities), and divided into four (main) process-sections:

1. Admission and treatment at the emergency department, including surgery
2. Post-surgery therapy under the leadership of the trauma surgeon
3. Early rehabilitation under the leadership of the geriatrician, discharge management and discharge from hospital
4. Follow-up at home or in a nursing home.

The resulting flow chart provides a general overview of the comprehensive care process and illustrates relevant key processes for each part as well as sub-processes of intersectoral care.

An additional, more detailed visualization was conducted using advanced event driven process chains (EPC) to model the status quo of the key processes as accurately as possible. The model comprises entities, functions, organizational units, supporting systems as well as input and output information, material, or resource objects to conduct the subsequent weak point analysis. We then used those models to conduct the subsequent weak point analysis. Figure 1 exemplifies the depiction of a sub-process, describing the respective key process in more detail.

**Event driven process chain-based process analysis**

The EPC-based process analysis consists of three steps: (1) the establishment of performance indicators, (2) the analysis of the modelled EPCs and (3) the preparation and verification of the analysis results.

**Establishment of performance indicators**

First of all, performance indicators for the process need to be established in order to analyze the EPCs. Generally, a (sub-) process can be considered to be inadequate if it is disrupted or delayed. Depending on the aim of the process analysis to determine information and communication gaps in the care process, the influencing factors considered are the communication and the flow of information between the different healthcare professionals. Consequently, the following performance indicators can be used to analyze the current process in order to detect information and communication gaps: (1) information being unavailable, (2) information being not transferred or not exchanged, or (3) information being disclosed in an untimely manner.

**Analysis of event-driven process chains**

The analysis of the modelled EPCs based on the preassigned performance indicators was performed by three researchers (researcher triangulation). First, all gaps from the EPCs with regards to unavailable, not transferred or exchanged, or untimely disclosed information were extracted. After that, the identified weak points were aggregated and assigned to different problem areas - categories. The definition of categories was performed on the basis of an inductive derivation using the interviews and the overall process representation (open-ended coding). Figure 1 exemplifies the implemented method, detailing the modeled sub-process “initial anamnesis” within the key process “admission and treatment at the emergency department”. The analysis of this EPC-detail highlights the lack of information from the primary care physician at patients’ admission to the hospital.

**Preparation and verification of the analysis results**

The preparation of analysis results implies, amongst other things, a detailed description including reasons and consequences for each identified gap as well as the accompanying process part on which the gap could be identified. Furthermore, the healthcare professionals involved and the related direction of information flow (uni-, bi- or multidirectional) are documented for the assignment to a problem area. Following, the identified and prepared gaps were presented and verified in the project consortium (member checking). This interdisciplinary team of experts is
composed of medical informaticist, economist and different healthcare professionals from the hospital.

Results

Status quo of care

Overall, we identified five key processes, one for each process-section 1 to 3. Process-Section 4, the follow-up, was divided into two processes depending on the follow-up: (1) follow-up at home, or (2) follow-up at a nursing home. Furthermore 16 related sub-processes, as shown in Table 1, were determined.

Table 1 – Identified key processes and related sub-processes

Key process 1 - The care process of dementia patients following a fall event starts with the admission and initial treatment at a hospital, or more precisely, in the emergency department. Depending on the previous care of the patient (treatment at home or in a nursing home) and the type of admission (admission through the primary care physician or as an emergency), varying amounts of information in terms of medication, medical history, and social environment is available for the initial anamnesis (see Table 1 - 1.1). Currently, a short dementia-check takes place in the emergency department to determine, whether the patient needs to have an interdisciplinary treatment due to a manifested dementia. If the patient displays symptoms consistent with dementia, the geriatrician is consulted for a treatment and a risk assessment in the emergency department. Depending on the results of the risk assessment, the patient either undergoes immediate surgical therapy or a conservative, pre-surgical acute geriatric therapy followed by surgery.

Key process 2 - Following the surgery, the patient is transferred to the surgical/geriatric ward for seven days of post-surgery therapy under the care of the trauma surgeon (see Table 1 - 2.1 to 2.2). This is then followed by the inpatient early rehabilitation including nursing and medical treatment as well as physio- and ergotherapy aimed at achieving the best-possible recovery of independence and mobility (see Table 1 - 2.3).

Key process 3 - A continuous social anamnesis is performed by a social worker in the surgical/geriatric ward. Its purpose is to adjust the individual treatment to the patients' needs and to timely plan discharge (see Table 1 - 3.1 to 3.3). Here, information about the patient (e.g., social environment, demands and characteristics) are continuously collected. The collection of information starts with the admission of the patient at the ward. Different sources (e.g., relatives, neighbors, present nurses) are used to gather the necessary information. At the latest, the social anamnesis must be completed before the concrete planning of discharge time and aftercare possibilities starts (see Table 1 - 3.5). To guarantee an adequate and smooth planning of discharge and aftercare at home or in a nursing home, communication and information exchange between relatives and hospital, hospital and follow-up care givers (i.e., outpatient nurse or nursing home) as well as relatives and follow-up care givers is essential (see Table 1 - 3.1 to 3.2). In addition, it is very important to integrate the primary care physician (if known) as soon as possible (see Table 1 - 3.4).

Key process 4 and 5 - Depending on the patient’s situation before admission, the social environment and the condition of the patient, the patient can either be discharged to his or her home or to a nursing home. Should the patient be discharged to a nursing home, care-relevant questions concerning the care level, financing, or necessary health aids, must be settled before admission can take place (see Table 1 - 5.1 to 5.2). Should the patient go home, relatives or legal caregivers must determine whether the support of outpatient hospital services or an in-home nurse is necessary (see Table 1 - 4.1 to 4.2). Regardless of where the aftercare takes place, the primary care physician is responsible for the subsequent therapy, including the prescription of medication and any necessary health aids as well as the suggestion and planning of an elective surgery (see Table 1 - 5.3 to 5.4).

Definition of gap categories

To classify the identified weak points – gaps – into various problem areas, we defined the categories shown in Table 2. Here, the designation does not refer to a possible solution but rather to the existing problem.

Table 2 – Gap classification and definition

<table>
<thead>
<tr>
<th>Designation</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information transfer</td>
<td>Active disclosure of information from one healthcare partner to another (unidirectional).</td>
</tr>
<tr>
<td>Information provision</td>
<td>Passive disclosure, therefore provision of information for one or more healthcare partners.</td>
</tr>
<tr>
<td>Information exchange</td>
<td>Mutual disclosure of information between two healthcare actors (bi-, or multidirectional).</td>
</tr>
<tr>
<td>Activity impulse</td>
<td>Encouragement of an activity which delays the executive process when not or delayed performed.</td>
</tr>
</tbody>
</table>
Identified gaps

In sum, we identify a total of 32 weak points within the four defined categories: 6 in “information transfer”, 13 in “information provision”, 4 in “information exchange” and 8 in “activity impulse”. Tables 3 to 6 show the identified gaps according to the pre-defined categories (Table 2).

Table 3 – Gaps concerning “information transfer”

<table>
<thead>
<tr>
<th>No.</th>
<th>Lack of information transfer…</th>

</tr>
<tr>
<td>1.5</td>
<td>… to outpatient nurse about hospital admission</td>
</tr>
<tr>
<td>1.6</td>
<td>… to primary care physician about patients death</td>
</tr>
</tbody>
</table>

The results show a particular lack of information transfer (Table 3) and information provision (Table 4) from the hospital to the primary care physician during the hospital stay. Commonly, the primary care physician is neither informed of a patients' admission and discharge nor about the treatments undertaken. The primary care physician only receives this information if the hospital has treatment-relevant questions at admission (and the primary care physician is known) or if relatives inform the primary care physician about the admission.

Table 4 – Gaps concerning “information provision”

</tr>
<tr>
<td>2.13</td>
<td>… about existing medical and nursing care of the patient to primary care physician</td>
</tr>
</tbody>
</table>

The results show that the healthcare providers have very little to no joint knowledge about the patient. Information about their medication regimens, social environment, and current treatment is often missing or incomplete. This is usually not an issue as the patient is often able to fill these gaps by transmitting missing information themselves, e.g., to the primary care physician. However, as we describe above, patients with dementia may be highly restricted in their communication and cognitive abilities and as a result, cannot provide the necessary information. For instance, should the hospital change the current treatment and medication plan, this information along with the driving reasons behind the change is lost, so that ultimately, the primary care physician has no knowledge of the change and therefore cannot uphold the new regime, reverting the treatment back to the original regimen. The primary care physician also has difficulty accessing this information. The categories “information provision” (Table 4) and “information exchange” (Table 5) address those problems.

Table 5 – Gaps concerning "information exchange"

<table>
<thead>
<tr>
<th>No.</th>
<th>Lack of information exchange…</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.1</td>

<td>… between hospital and primary care physician about previous medical treatment</td>
</tr>
<tr>
<td>3.4</td>
<td>… between the different healthcare professionals concerning the medication plan (joint access)</td>
</tr>
</tbody>
</table>

Occasionally, some parts of the healthcare process are interrupted or delayed by the failure to complete preceding activities on time. This is not only attributable to a lack of information exchange and communication, but rather to a missing impulse that must be given automatically or from one actor to another to initiate the activity. As seen in Table 6, caregiving relatives are affected in a number of ways. During the hospitalization, they must complete many tasks in order to ensure an appropriate follow-up at home or at nursing home. However, they are often not aware of when and where information can be accessed, or at which time certain information needs to be transmitted. Especially, tasks such as 4.3, 4.5 and 4.8 are neglected by the caregiving relatives due to the growing work load as well as the physiological burden.

Discussion

This process analysis attempts to describe the status quo of the intersectoral healthcare processes of dementia patients after a traumatic event in the region of Darmstadt. To achieve this objective, we determined the intersectoral care processes and identified information and communication gaps between healthcare professionals and non-professional caregivers. Using EPCs and an EPC-based weak point analysis, we illustrate the identified key and sub-processes, and classified information and communication gaps. These modelling methods enable a simplified depiction of complex processes with parallel and alternative activities [6]. Furthermore EPCs can be used “[…] to find parts of the process that are never
used or find parts where users deviate from the prescribed procedure" [7], and are thus instrumental in also identifying weak points or gaps.

The results show that significant gaps exist in the process concerning the transfer, provision, and exchange of information. The gaps often occur when coordination or communication between the healthcare sectors is necessary for a seamless process, such as the transfer and provision of information between a hospital and a primary care physician. Moreover, contrary to healthcare professionals, non-professional caregivers are often unfamiliar with typical activities in the care process, and are unaware of the activities expected of them. For example, when a loved one suffering from dementia is admitted to the hospital due to a fall, caregiving relatives may be unaware that the hospital needs basic information such as patient history and a medication plan in order to optimally plan further treatment steps. Reminders or information requests, or other activity impulses, may or may not be in place to collect this information from external parties. Impulses, given by the healthcare professionals, may in fact initiate those activities. Our analysis lead us to deduce that the care process may be disturbed when those impulses are missing.

There are, however, some limitations to our study. In order to identify the key processes, we conducted an extensive document analysis. The document analysis refers to the documents of one hospital in the region of Darmstadt. The hospital, previous to our study, established a structure promoting a tight cooperation between the surgery and geriatric ward, placing special attention to the care of patients with dementia. During the interviews, some respondents emphasized the fact that the communication with this hospital is better than the communication with other hospitals in the region. On the one hand, this must be considered when interpreting the results (transferability). On the other hand, we were still able to identify gaps that represent general requirements for a functioning intersectoral care process. We also interviewed a limited number of healthcare professionals. However, although the perception of the care process might differ between individuals, the activities within the process remain similar. The key processes were described in a very similar manner and respondents also supplemented the key processes reported by defining the sub-processes.

Finally, limitations of the method implemented are manifest in the modeling of processes. Due to the limited number of modelling components and modelling rules, an intersectoral modeling of processes is better than the communication with other hospitals in the region. On the one hand, this must be considered when interpreting the results (transferability). On the other hand, we were still able to identify gaps that represent general requirements for a functioning intersectoral care process. We also interviewed a limited number of healthcare professionals. However, although the perception of the care process might differ between individuals, the activities within the process remain similar. The key processes were described in a very similar manner and respondents also supplemented the key processes reported by defining the sub-processes.

Conclusion

In order to provide optimal patient-centered care, healthcare providers involved in the care process should coordinate their services (intersectoral interlinkage). However, because the German Social Security System is divided into two separately organized sectors – inpatient and outpatient care – communicating and cooperating across these sectoral boundaries is difficult. Dementia patients are especially in need of integrated care, because they are often neither able to provide information regarding their general state of health nor provide specific details in acute situations. Because of the unusual demands caring for dementia patients in acute medical situations places on professional and non-professional actors, as well as on the patients themselves, we publish the results of our process analysis to further the field and encourage discussion on important developments in this field.

In this paper, we analyze the intersectoral care process of multimorbid dementia patients that have suffered a traumatic event with a subsequent hospital admission to identify key processes and weaknesses in the care process. We determine the existence of five key processes in the care process and identify and describe 32 gaps in the information and communication exchange of the care process that have the potential to significantly impact the quality and efficiency of care provision. We also find that healthcare professionals may be in a unique position to generate activity impulses in order to overcome these communication and information deficiencies, thereby securing optimal care for the patients.

To solve such identified problems, further steps involve the establishment of functional and non-functional requirements as well as the development and implementation of an IT-supported case management system supporting the communication and information exchange beyond the sectoral boundaries via a holistic view at the patient.

Equality Challenges in the Use of eHealth: Selected Results from a Danish Citizens Survey

Lone Stub Petersen, Pernille Bertelsen

Department of Development and Planning, Aalborg University, Aalborg, Denmark

Abstract

The increased focus on and use of citizen/patient generated health data has spurred a wide range of personal health technology projects within digital intervention in health, e.g. telehealth. These developments are focused on objectives of improving health, but also claiming to provide health services at a lower cost. However, the question is: do the ways health care technologies are designed and developed support and improve health care services for those who need it the most?

Survey data from our study point toward health informatics challenges in reaching the people who are considered in ‘health risk’ group, who, in this study, are interpreted as people with low level of education. The study shows that this group is less likely to use and communicate through health information technologies (HIT) and is generally more sceptical towards the benefits of HIT.

We conclude that there is a need to pay specific attention to the patient groups that are socio-economically and health wise weakest during HIT design and development. It would also provide equality and equity in digital health intervention and access to healthcare for them in the future.

Introduction

Today we see an increased focus on the use of patient-generated health data (PGHD) both developed for consumers interested in improving their own health, and for use in the healthcare sector [1], where many healthcare professionals and health care managers see an enormous potential in HIT to improve service and reduce costs. The potential usefulness is seen as enormous but we know little about a) who uses the technologies and b) how these data can benefit/support health care services [2].

The two perspectives on PGHD presented in Table 1 have data generated by patients as common ground but differ when it comes to the objective or purpose of why patient data is collected and also when it comes to purpose of its use. The commonly used terms, when it comes to framing the intersection between citizen or consumer generated data and the use or non-use of these data by health care professionals are patient or person generated data (PGD) and/or patient generated health data (PGHD). Person or patient generated health data (PGHD) can be defined as health-related data created, recorded, or gathered by patients (or by their family members or other care givers) for own use or to be shared with their health care providers [3]. We will go into depth first with the citizen/patient perspective and then the health care professional perspective in the following section.

Citizens perspective in HIT and patient generated health data. (C-PGHD)

Citizens and patients are beginning to use a range of health information technologies (HIT) to track and generate personal health data outside the clinic. Today, numerous types of HIT and more contemporary consumer health technology are migrating from being expensive “first movers” toys to becoming inexpensive and generally available to the more average consumers. These technologies provide patients the ability to track their own health data [1]. Some of the best known platforms supporting and encouraging people with smartphones to track their own health are Apple's HealthKit [4] and Google’s Google Fit [5]. The potential of using PGHD data are seen as enormous but it still remains to be seen how best to integrate these data into contemporary clinical work, and to make sure those in most need also are those being encouraged to collect own health data and thus benefit from the use of the health data.

Market developments predict that consumer technology for health management will continue to increase – it has been estimated that wearable health technology will become the eighth largest revenue driver within consumer and mobile devices in 2018 [6]. This increase shows strong indications on citizens’ interest in everyday health management. Simultaneously, this has sparked increased interest from health professionals to explore how to include patient generated health data as part of clinical practice and electronic health records [3].

This development, often framed as Quantified self or life logging, enables patients to capture, measure, track, and analyse data from and within their daily life (e.g. physical activity, food consumption, mood). Availability of relatively inexpensive wearable technologies and availability of digital storage of personal data offline and on-line has made personal HIT a research topic [7]. Now citizens are able to gather and store

</table>
large volumes of personal data in a very cheap manner, e.g., by using their smartphones.

This availability of data put pressure on the health professionals to include these technologies in their treatment. How the challenge materializes in the clinical setting depends, among other things, strongly on the type of national health care system governance, for example, the degree of public, private, and health insurance financed health interventions. The healthcare sector will need to meet the challenge by developing and implementing digital health interventions (DHI) [8] and by enrolling patients.

**Healthcare Professionals, eHealth and patient generated health data (HP-PGHD).**

Citizens and patients are still in the upstart of exploiting HIT to either support their own management of health and diseases at home or to supplement the service provided by their health care provider [8]. DHI aimed at the public or citizens in general have a wide span from telehealth and telecare systems to mobile health applications and devices [9, 10]. As a result, new HIT tools are becoming available for clinical practices to potentially be integrated in their health interventions, and are also available at the market for citizens to buy and use in their private sphere. Mobile technologies for self-monitoring of wide-ranging variables such as blood pressure, physical activity, blood glucose, daily weights, sleep etc. are available and question the traditional patient-physician relationship [11].

Challenges of PGHD when used in the clinical context of healthcare professionals include the reliability and accuracy of the data collected, forgetfulness of patients, e-health literacy, attitudes towards technology, and patients’ self-bias [12]. However, the innovative technologies and the change of culture related to Quantified Self have opened up the potential for patients to collect more accurate and reliable health data [3].

In addition to DHI, another form of PGHD used in clinical settings are Patient reported outcomes (PRO) and Patient Reported Outcome measures (PROM). PRO is information on patients’ health and quality of life, reported directly from the patient to be used by health provider organizations as a feedback and quality assurance measurement system on local as well as national levels. PROM is information about a patient’s health, including physical and mental health, symptoms, health related quality of life, and functional level [12, 13, 14]. Patient reported data could inform different aspects of patient experience, from their encounter with the healthcare sector, for example, the structure, processes and results [16]. Patient Reported Outcome measures (PROM) may be seen as a sub-category of PRO where the systematic collection of data on patient experiences are measured at, for example a national level, as is seen with NHS in England [13], and the Danish Cancer Association [14].

PRO and PGHD are both concepts that feed into a debate on who uses and how to make use of and learn from, the data that patients generate in different health care provider settings and while developing DHI. PRO and PROM, as well as tele health information are structured by and feed into clinical practice in a format that clinicians have control over. This is not the case with C-PGHD. These data are not formally structured but have the same quality assurance issues as the HP-PGHD. This makes it difficult for clinicians to agree on their usefulness in daily clinical practice and therefore to integrate these data into the existing healthcare services.

**Health inequality – The Socio-technical challenge of HIT**

In this context of C- and HP-PGHD, we like to argue for the importance of a social investigation of who the users of the HIT are, and when doing so keep an eye on whether the increased use of HIT in healthcare is decreasing or increasing health inequality in society. The World Health Organisation (WHO) defines health inequalities as “avoidable inequalities in health between groups of people within countries and between countries” and describes health inequality as significantly influenced by social determinants [15]. It is paradoxical that despite a long tradition as a welfare country, and a relatively low income gap between rich and poor, Denmark is a country that within the last 25 years has doubled health inequality (measured on mortality) [16]. This inequality does not only need to be handled through healthcare governance, but needs to be addressed when developing HIT.

Showell and Turner from an Australian context [17] argue that most HIT claiming to be of use for patients, are designed and developed, and therefore being used, by “people like us” (PLU). ‘People like us’; that is, “people who believe to understand healthcare and health issues, take care of their own health, are literate, well to do, tech-savvy, and hold a tertiary qualification” [17]. On the other hand, those citizens who really are in strong need of better health, care, and support are the disempowered, disengaged and disconnected, the DDD’s. If this is indeed the case and most health promoting IT used in DHI reinforces health inequality, there should be a motivation for understanding and contributing to change in development of HIT.

In this paper we report on selected findings from the 2015 survey based on data from eight questions (20A, 20I, 20B, 22A, 21A, 23, 24) [18] that explore the citizens’ experiences with accessing and using a) the national health portal Sundhed.dk, b) consumer apps and internet and c) mobile health apps and services. Educational background data have been analysed to investigate if a difference in use of IT correlate with respondent’s educational background. Education is free for all citizens in Denmark, and has been so for more than a century. Therefore, all citizens have at least a primary school education. Further, educational level, socio-economic status, and health are strongly related in a Danish context. This is the reason education is used as an indicator of socio-economic and health status in this analysis of inequality. We acknowledge that this might not be the case in all countries, however, we are confident that similar challenges of the reproduction of inequality in eHealth can be found in other countries.

**Methods**

The survey reported from in this paper is the second in a biannual series of National surveys on Danish citizens’ expectations and perspectives on eHealth. The first was done in 2013, inspired by Canadian and Australian studies of consumer experience with eHealth [18,19]. The second survey in 2015 was further inspired by questions posed in national surveys from Norway and Finland. The survey is supported by Danish eHealth Observatory and The Danish Center for Health Informatics who have monitored eHealth implementation in Denmark for many years such as the national implementation of the Electronic Health Record (EHR) and the national monitoring of clinicians’ use of health informatics in their daily practices. A Danish market research agency (Megafon) was commissioned to carry out the surveys with a population sample of n=1,059 in 2015 and n=1,058 in 2013. The questionnaires were tested twice. The surveys are combination of using both email and telephone. The selected respondents are part of a citizens’ panel reflecting the Danish adult population with respect to age, education, and geographic distribution.
Results

People with only primary school education are less likely to use the Danish national health portal than those with higher education (Sundhed.dk in Figure 1). Only 21% of people with only primary school education have used the portal while 60% of people with a high education have used it.

![Figure 1 - Cross Table: Educational Level and Expected Impact of Health IT](image1)

Citizens with only primary school education have less experience with using applications developed for health purposes (8% vs 26% in Figure 2).

![Figure 2 - Cross Table: Educational Level and Expected Impact of Health IT](image2)

Few citizens used Internet or fitness trackers to log information about training and food (30% n=1,059 in Figure 3). Also, here citizen with high education are more likely (22%) to use these services than people with low or only primary school education (3%).

The same is the case when asked about the use of Internet based self-help health services (6% low vs. 25% higher education in Figure 4).

![Figure 3 - Cross Table: Educational Level and Expected Impact of Health IT](image3)

![Figure 4 - Cross Table: Educational Level and Expected Impact of Health IT](image4)
When asked if they generally agree or disagree to the statement "I have difficulties navigating within health IT systems", 26% with only primary school education agreed while only 14% of people with high education agreed (Figure 6).

Danish citizens are generally positive towards the use of IT in healthcare. However, the study shows that the higher the educational level, the more positive they are. As shown in Figure 7, there is high scepticism among respondents with low education when questioned whether they expected health IT to improve or impair the quality of the healthcare services they expect to receive within the next three years.

Discussion

The study shows a significant difference between citizens with low and high educational level, when it comes to opinion on, knowledge of, and experience with the use of HIT and other Internet, apps or mobile services. In the answers, there was a significant tendency that people with low educational background are more sceptical, not so familiar with HIT and find it difficult to use the technologies and systems.

This indicates a strong need to target and support the socio-economically weak population in getting access to technology that can assist in accessing HIT and enrolling in DHI. The findings of the study empirically support the concern and conceptual framing of DDDs and PLU of Showell and Turner [17]. To address the findings, concerns as well as the challenges of health inequality in Denmark, attention needs to be placed on the role of the DDDs in HIT design, development, and use.

DHIs need to be specifically targeted at those citizens with the greatest needs if the digital and health divide is not to grow even larger. If the socio-economically challenged DDDs are to be given access to live a healthier life, it may have a positive impact on the health outcome and thus provide an economic benefit to the health care system.

To summarize this view, we propose (Table 2), that the problem be addressed both in relation to HIT developed to provide citizens with health data (C-PGHD) and DHI providing healthcare professionals with citizen and patient data (HP-PGHD).

Provide special support to engage and involve socio-economically disadvantaged patients in design and use of HIT

Involves socio-economically disadvantaged users in Design (or re-design) of DHIT-technology

The HIT technologies used to support such change need to be understood as not only technical but also socio-technical and therefore, designed and targeted with attention to the context of use and their future users. To point at what can be done to increase the equality, user centered design (where designers investigate what users need) [20] is believed not to be an adequate or sufficient approach to overcome the dominating PLU problem. Instead, we—knowing that this does not follow directly from the data in this paper—suggest technology designers to use a User Innovation Approach (UIM) [21]. Here users are motivated and encouraged by facilitators to develop design concepts that meet their specific needs (e.g. the DDDs specific needs). The designers of HIT and DHH need to hand over the stick to the socio-economically disadvantaged people (the DDDs) and by doing so for some time reduce their own professional role to (1) plan and facilitate, and (2) draft design concepts and draft prototypes to be validated and changed by the participants [22, 23, 6].

Conclusion

On the basis of an examination of the educational inequality detected in perspective on and use of HIT in a national Danish survey, we propose an increased focus on inequality in the use and development of HIT and involvement of citizens and patients from the socio-economically disadvantaged groups in HIT design and development. It will be of benefit to technology developers and the healthcare providers to improve the use of appropriate consumer HIT for this group, in both health care services and preventive health initiatives as well as general health monitoring and management in everyday life. Engaging with and involving this group of citizens and patients is important in levelling out inequality in health which is a key concern in a Danish healthcare context.

Acknowledgements

We are appreciative of the Danish Center for Health informatics (DaCHI) for making the survey possible.

Analysis of the Updated Swedish Regulatory Framework of the Patient Accessible Electronic Health Record in Relation to Usage Experience

Isabella Scandurra\textsuperscript{a}, Maria Pettersson\textsuperscript{b}, Benny Eklund\textsuperscript{a}, Leif Lyttkens\textsuperscript{c}

\textsuperscript{a}Informatics, School of Business, Örebro University, Örebro, Sweden

\textsuperscript{c}Uppsala County Council, Uppsala, Sweden

Abstract

In Sweden, all citizens can (in 2017) access their health data online from all county councils using one national eHealth service. However, depending on where the patient lives, different information is provided as care providers have assessed differently how to apply the National Regulatory Framework (NRF). The NRF recently was updated and this paper analyses version 2.0 should now serve as the guideline for all county councils. Potential improvements are analyzed in relation to patient experiences of using the service, and the rationale for each change in the NRF is discussed. Two real case quotations are used to illustrate potential implications for the patient when the new version is placed into operation. Results indicate that this NRF allows for opportunities to create a national eHealth service that better supports patient-centered care and improves health information outcome.

Keywords:
Patient Portals; Electronic Health Records; Health Information Exchange

Introduction

The number of eHealth services for patients is rapidly increasing, as many countries are launching these services as a means to manage an ageing population, to increase efficiency in healthcare, and to empower patients. Although aiming to improve patient outcomes and satisfaction [1], the adoption of these services has often not been as successful as anticipated by politicians and vendors [2, 3]. Many healthcare professionals are concerned about how, e.g., the information will be understood by patients when reading without any medical support [4]. Patients, on the other hand, often strive to manage their own health and illnesses and want their electronic health record (EHR) [1, 5, 6]. In short, deployment of such a service is controversial for healthcare professionals and the establishment of an asset of rules regulating how the eHealth service should be used has been much discussed in Sweden, since the first region-wide deployment of the eHealth service enabling patients’ access to their EHR in 2012 [7]. Sweden has recently (in 2017) extended the Patient Accessible Electronic Health Record (PAEHR) service to cover all county councils and to include its 10 million citizens.

Also, internationally, similar services have been provided to large groups of patients, such as in the UK, the US, and Norway [2, 6, 8, 9]. The strive towards providing PAEHRs has been limited in part by professional resistance and concerns about security and privacy [10], legal constraints [11] and the need for interoperable solutions [12]. Little has been studied regarding implementation of policies for PAEHR services [2], although policies form the basis for such services, and their use is ultimately dependent on how they are implemented.

Sweden has a decentralized healthcare system, and a National Regulatory Framework (NRF) was developed to support the deployment of the PAEHR in the 21 county councils. From the point of view of the patient, the first version of the NRF was less successful as it contained electable paragraphs that were applied differently across counties [13]. This resulted in a national eHealth service that displayed health data differently depending on where, when and why a patient sought treatment [13].

This paper analyses the recently updated version (October 15, 2016) of the NRF in relation to the previous one, and the rationale for each change is discussed. The analysis was performed in the light of a service still considered controversial, county councils that act autonomously, and a national development and deployment that are ongoing. As many countries are facing an introduction to eHealth services providing health information to patients, not only the NRF, lessons learned from Sweden may be of interest to policy makers and developers in order to improve deployment and use of PAEHRs and similar eHealth services elsewhere.

Current status of the national PAEHR ‘Journalen’

The PAEHR is currently (April 2017) accessible by the citizens of 18 out of 21 healthcare regions or county councils. They access it via a national patient portal www.1177.se, which contains several services and functionalities. Sweden has approximately 10 million inhabitants, where 37.9 % have created their own account for the 1177.se portal in order to reach these services. Statistics of the month of January 2017 show almost 2 million logins. Each user has, per year, logged in 10.7 sessions (~ services) of 1177.se. The PAEHR currently has over 1 million users. The numbers are increasing, as the PAEHR accounts for 10000-13000 users per day [14].

Methods

Based on the hypothesis that the new version better supports patient-centered care, this study qualitatively analyzed the first (v.1.0) and the second version (v.2.0) of the NRF, and the functionality of the PAEHR. Data collection regarding the NRF was performed via Inera.se website, the owner of Swedish eHealth services [14], whereas data collection of the PAEHR version 2.6.2 was through 1177.se, the national portal
of all public eHealth services in Sweden. The analysis started off with retrospective reviews (managed by IS) based on experiences and knowledge of the other authors (MP, BE, LL). Subsequently, key concepts of the NRFs were thematically analyzed [15] with regard to the following patient-centered care: children; relatives; information handling; harm; and secrecy. Focus was on eliciting the rationale of the changes in the NRF. All the authors (BE, LL, MP) have extensive experience with the PAEHR and the NRF. They developed the service in Uppsala County Council (UCC), the first region to deploy the eHealth service regionally, as well as its preceding pilots since 1997 [16]. They also designed the framework of rules valid for UCC, and acted as consultants for the creation of the first national framework [17]. The analysis of the current PAEHR and the NRF 2.0 (in operation since October 2016) was, therefore, based on user data as well as experiences regarding usage during the deployment of the service and NRF v.1.0 [7, 13, 14, 16].

This analysis is limited to the NRF; thus, the analysis of which type of information is displayed in the respective county is not presented here, although sets of information shown still differ between various counties which affects the usage. Decisions from the 18 connected regions were compiled by Inera AB and can be found on their web site [14], whether displaying or not displaying the following sets of information: medical notes; diagnoses; forms; log report; prescriptions; maternity care; lab results; referrals; blocked parts of the record; growth curves; cave and medical alerts; vaccinations; care contacts; and psychiatry notes.

Results

National Regulatory Framework Version 1.0

The previous NRF (v.1.0) was established by the National Board of Health and Welfare in 2014 after referral to all county councils and stakeholders in Sweden. It was based on the asset of rules developed by UCC to support its deployment of PAEHR, which at the time had been used by over 115 000 users [13]. Thus, the regulation developed for UCC was adopted by the national development of the service, with the aim to create the basis for the NRF. For example, it stated with ‘Healthcare providers allowing direct access to an individual’s patient data will also be responsible for the existence of an assessment system of the parts that require special protection in relation to the individual and shall not be disclosed by direct access’ [13]. That statement, among others, opened up discussions within and between the other counties. Such information entities are per se delicate, and by tradition and culture handled differently by various care providers. Due to the self-governance of the county councils, the NRF 1.0 resulted in a set of both mandatory paragraphs and paragraphs where some content was optional, and where each health authority made decisions for their regional development of the service.

Mandatory paragraphs

1. The individual must be identified by secure login.
2. The individual should be informed about where to turn for help to understand what is written in the EHR, as well as to which extent information in the EHR is not presented in the PAEHR.
3. Adults from 18 years should have direct access to their own PAEHR.
4. Guardians have access to their child’s information until the child turns 13 years.
5. Adults shall be able to appoint other adults as being their representatives and give them direct access to the proper PAEHR.
6. Children up to 17 years shall not have direct access to their own health data.
7. Individuals shall be able to seal their PAEHR and shall thereafter not have direct access to their health data.
8. Individuals must be able to read the access log, and thereby, obtain information on healthcare professionals who have opened their EHR and representatives who have opened their PAEHR.

Electable paragraphs

Application of the electable paragraphs was decided by each health authority and, consequently, the content of the PAEHR currently varies between the county councils.

9. The individual should opt for the EHR to be available for direct access, regardless if signed/authenticated – or to be given direct access only if it is signed/authenticated.
10. The individual should opt for the EHR to be immediately available for direct access – or to be given direct access with the delay of 14 days.
11. Medical notes categorized by keyword “Early hypothesis” should not be accessible to the individual by direct access.
12. Medical notes categorized by keyword “Exposure to violence in close relationships” should not be accessible to the individual by direct access.
13. Health data not available for direct access: from care units where the health authority, through a policy decision, has determined that manual audit should precede extradition.
14. Health data not available for direct access: from care professions who the health authority, through a policy decision, has determined that manual audit should precede extradition.
15. The individual must receive direct access to all information in the EHR that is electronically available (with exceptions given above) [14]

Proposed rules 11 to 15 could be either accepted or rejected by the various county councils.

National Regulatory Framework Version 2.0

Although connected regions accepted the use of the NRF v 1.0 and submitted their decisions regarding the electable paragraphs, there was a debate on how to apply certain functionality with respect to the optional rules of the NRF. As stated in the analysis of NRF v. 1.0 [13], there was a need to revise the NRF to provide less electable paragraphs, and to require an adherence to the next NRF by all county councils.

On 22 September 2016, the Board of Inera took the decision on a new framework for the PAEHR that all counties and regions should be able to endorse. The new framework has been developed together with the Swedish Association of Local Authorities and Regions (SALAR) and replaces the previous regulations [14]. Based on the goals of the National Action Plan of eHealth [18] and subsequent updates, “all residents from 16 years should by 2020 have access to all information
documented in county-funded health and dental care through the PAEHR ‘Journalen’. Using PAEHR, every individual can reach all information about themselves and actively participate in the healthcare. Care providers take responsibility for the information related to their organizational business, but the individual should have full access to it; anywhere, anyhow and anytime” [14].

The next step is to establish this NRF at the political level of management in counties and regions to underpin the continued development and implementation of the PAEHR.

**Principles regarding information to be made available:**
1a. All digital health records, in the county-funded health and dental care, which may be disclosed to the individual, shall be made available through direct access.
2a. The information shall be made available as soon as it is inserted in the EHR.
3a. The individual shall be able to choose what information he/she wants to see, and whether a selected individual should be invited to read information and to what extent.
4a. Guardians have access to their child’s information until the child turns 13 years.
5a. Depending on the situation of the child, in individual cases, it shall be possible to extend or shorten the access of a guardian, as well as to advance the child’s own access to his/her information.

The five Available-principles (1a-5a) apply throughout county-funded health and dental care. Individual rules are referred to as people from 16 years and all digital medical records are referred to as information supported by Inera’s service platform, also historically.

**Principles regarding information not to be made available**

In exceptional cases and with regard to the law of Public Access and Secrecy, information can be hidden from direct access of an individual. The four principles of exception (1e-4e) concern:
1e. Details of a respondent (third person) in a record entry.
2e. Details of the patient, if it is of particular importance with regard to the purpose of ongoing care and treatment that the information shall not be disclosed to the patient.*
3e. If information may harm a person in exposure to violence.
4e. If information is subject to investigation secrecy at the request of the Police or prosecutors.

*This provision shall apply only in exceptional cases and applies only to patients undergoing care and treatment. A patient with a completed treatment cannot be denied access to the PAEHR.

**Analysis and Discussion: Rationale for Change and Implications for the Patient**

Compared to the NRF v. 1.0, the second version is based on the national and European action plan of eHealth [18, 19] and, thus, the aim is to deliver more general principles; whereas the first version aimed to support practical implementation of the PAEHR in the Swedish regions based on experiences of the first county to deploy the service. Therefore, the paragraphs were quite hands-on and on a detailed level.

**Goal-oriented principles**

The major change in the NRF is that it clearly marks that all digital health information shall be made available for direct access of the patient.

Moreover, the first version of the NRF resulted in 21 different interpretations, as each region is autonomous and had the opportunity to select among the electable paragraphs which rules should apply in their region. In the second version, the goals of the European and national eHealth strategies are used to create a number of principles, thereby giving the citizens the same opportunities regardless of where you live, where and when you seek care. Further, it should be possible for the regions to update their solutions to adhere to version 2.0 by 2020, and to incorporate the new goals. One is to include dental care, and another is to show all information that may be disclosed to the individual, via the Inera service platform, using standardized service contracts. The service contracts support municipality data as well as historical data.

**Unified principles replace mandatory and electable rules**

The 15 paragraphs of version 1.0 are unified into five principles regarding information to be made available, and four exceptions when information should not be exposed to the patient directly (figure 1).

![Figure 1- 9 Principles of v.2.0 replace 15 paragraphs of v.1.0](image)

In a wide interpretation of the rules it is possible to group the paragraphs of NRF 1.0 and the principles of NRF 2.0. The ones that explicitly handle children and adults (from 16 years) are now described in 4a and 5a. 3a states that individuals should choose what to read and who should be able to read the information. Mandatory paragraphs of v.1.0 regarded technical requirements and information about the service, such as what type of data was not available for direct access, as well as logs of who accessed the EHR or the PAEHR. They are now replaced by the 1a, 2a and 3a principles, which also rule out the electable paragraphs 9, 10, 11 and 15. In the same way, the exceptions 2e and 3e that address potential harm to the patient in different circumstances, rule out electable paragraphs 13 and 14. The mandatory paragraph number 7 addresses the action of sealing the PAEHR, which has no direct equivalent in the new NRF. Alike the old paragraphs 1 (secure log in) and 2 (information and help), paragraph 7 is now handled as a functional requirement. Electable paragraph 12 is replaced with exception 3e. A more clear connection to the law of secrecy is made by adding the exceptions 1e and 4e.
Rationale for Change

The new principles aim to support an alignment and a joint adherence of all county councils and regions in Sweden. Version 2.0 states, in short, that health information should be made available directly regardless of what the healthcare authority previously had decided, as long as the information with regard to the law of secrecy does not risk harming the patient or other persons. Individual rules may apply to children and their guardians.

Principle 1a: The rules for using the service should take into account the patient’s demands of the greatest possible access to data. The NRF should not contain options that lead to different accessibility in different parts of the country.

 Provision regarding the patients’ direct access can be found in Chapter 5. §5 of the Patient Data Act (PDA) [20]: a healthcare provider may allow an individual direct access to data on the individual himself, as may be disclosed to him or her, and treated for purposes specified in Chapter 2. §4 in the PDA. The government justified the provision on direct access as follows: “Giving patients direct access to their medical health data contributes to their ability to a better way to actively participate in their care” (Prop. 2007/08: 126 p. 158). Further, disclosure on different terms gives rise to unequal healthcare and should be avoided.

Principle 2a: In general, the opinion of patients and their representatives has been to show all information immediately, while medical professions have argued that patients should be allowed to have direct access only after a 14 days window [4, 7], as the example of the electable paragraph 10. Principle 2a also refers to electable rule 9: whether the patient should be able to read only signed notes, or get access also to unsigned notes. This issue was settled by the Supreme Administrative Court (HDF 2013 ref. 33). For a public caregiver, record entries are always public documents. This means that such notes are considered established and public before “the ink dries”. It is irrelevant according to the court if they are signed or not.

Principle 3a: A person acknowledged by the patient, e.g. a relative or an agent, has the right to take part of the patient’s health records through direct access. The Agent functionality in the PAEHR has been tested by the Administrative Court (judgment 2016-06-10, Case No. 5402-15). The court considers the operation legal in accordance with the individual consent under Chapter 2. §3 PDA; the conditions are the same for the agents as for the individual. The judgment has been appealed.

Principle 4a, 5a: A big change is that the age of majority for accessing health data is now set to 16 years, compared to the previous 18 years. This decision was preceded by discussions with representatives of children, pediatricians and SALAR based on an increasing pressure to lower the majority age for health data, with respect to children’s rights not to be excluded. Previously, it was not possible for a 16 years old person to get an e-Identification, as the age of majority in general is 18, and that age seemed reasonable to keep. Now, Sweden follows the example of Norway [6] of trying out the new age of 16 years for accessing health data (prop. 2007/08:126 s. 153).

Currently, there is no law that supports this decision as the Parental Code refers to a “degree of maturity”, which does not apply for a technical system. However, both the Data Inspection Board and the European Data Protection Regulation (art 8.1) acknowledge that at the age of 16, children can prevail over questions of confidentiality and consent to the processing of personal data. The guardians lose the possibility to read their child’s health information when the child turns 13 years, unless there are individual needs (see 4a, 5a).

Exceptions 1e-4e: The starting point, under current law, is that the patient has the right to take part in all care documentation. In exceptional cases, information can be hidden from direct access of an individual. Compared to NRF v. 1.0, this does not regard information from specific organizations, care facilities or professional groups. The exception addresses confidentiality in relation to the patient pursuant to Chapter 25. §§ 6 and 7 of the law of Public Access and Secrecy.

The NRF v 2.0 in relation to patients’ own stories

Introducing PAEHR in Sweden has been a success from the patients’ perspective. The PAEHR allows for users to send feedback via email, and the mailbox receives 10 emails a day. Also, the patient portal 1177.se receives feedback from patients and, approximately, 400 phone calls a day, where some are in regards to the PAEHR. A brief overview of the feedback content revealed that patients most often had difficulties in understanding the different interpretations of the NRF and the different filtering of the care providers, as a result of that some information is displayed from certain regions while the same information is not displayed from other regions. The most frequent question was the fact that patients want direct access to all information. One user quote illustrated that the PAEHR is not only appreciated by the patients, but also a benefit for the patient in terms of improved health information outcome:

“I have used the eService “Journalen” a few times now, and thanks to the ability to continuously follow up clinic visits, with notes nobody can dispute, after two years, I finally received the referral I was promised already in 2014 and I have taken the tests for the disease that doctors speculated on. I think your service can save healthcare in this country. You deserve a medal and hero status!”.

Here the patient benefits from principles 1a, 2a and 3a from NRF v. 2.0, as well as the provision stating that “all digital medical records are referred to as information supported by Inera’s service platform, also historically”.

Another written remark from a patient illustrated the need of the 4a and 5a principles:

“Hi Journalen! =) I am writing from two completely different angles, firstly as myself as a patient. When will more regions be connected to the different parts of the PAEHR? It is amazingly annoying to wait for important test results, to log in, and to see that my region (Skåne) does not report test results. Furthermore, I am a geek (and many with me), and would have had a benefit of arranging the values in, for example in a graph! It is a pity that not everyone uses the great technology that is available. AND: I am the mother of a son who will turn 14 and have a lot of chronic diseases I need to relate to. In the past, I could, before a doctor’s appointment log in and read, check the values from last month, remind myself of which preparation he received in his last vaccination etc. From the day he turned 13 there is not this possibility anymore. WHY?
Above all: Why is there no agent system for one’s own children? My dad can share his medical records – but the one of my son, I cannot have access to? How did you think? I was answered by your support that he can order his records on paper – but that is not at all what we want. This is the WORST I have ever been through, and besides, I think that 13 is a very low age limit. Now it sounded like I am not satisfied with your product, but I am, as a whole. Thanks for letting me leave my comments.”
One of the most common complaints of patients is that the latest information cannot be read when the provider has chosen to show only information that is signed or authenticated. Experience shows that positive effects related to direct access outweigh the negative effects [7].

Data analysis of the UCC implementation presented that a majority of patients (98%) chose immediate access to health record information. A window of two weeks is experienced as too long for patients who want to be involved in their care [7]. This is in line with the Swedish eHealth Strategy [18] and the European eHealth Action Plan [19] promoting personalized service and interactive eServices to exercise participation and self-determination on their own terms.

If this transformation of healthcare is going to take place, there is a need to consider development and deployment from a real patient-centered perspective. Although the NRF and the PAEHR now follow the strategy objectives, there is still much work to do to reach a service addressing patient needs to follow his/her care and treatment.

Conclusion

To date, care providers have assessed differently how to apply the NRF v.1.0. The framework of v.2.0 shows potential as it indicates a clear direction towards all information to be made available to the patient. It is more equitable for all patients to get access to and share all their health information regardless of where they live or receive care. The exemption is valid only in specific cases, and will apply only during ongoing care, which means that limits are neither static nor valid forever.

All county councils have endorsed the new framework, and regional decisions to adopt the framework are expected in the near future. The county councils now have a few years to work to get all pieces in place by 2020. However, the increasing usage reveals that citizens probably do not want to wait until 2020 to get involved, and the authors anticipate that the work needs to be intensified, once the ball is set rolling.

Abstract

Being able to design information systems to an untouched domain, without the burden of existing information systems, especially legacy systems, is often seen as a dream of most information system professionals. Uncharted domains are anyway scarce, and often such greenfield projects turn into brownfield projects, also to projects where existing structures severely constrain the development of new systems. In this article we discuss the concepts of greenfield and brownfield domain engineering and software development, and reflect their possible messages to the re-engineering of the Finnish health- and social care ecosystem currently under way. In our fieldwork we could identify a lot of need and wish for greenfield domain engineering in the Finnish health and social services delivery. As well we found a lot of brownfield elements inhibiting change. Our proposal for the future is a ecosystem approach, where new and established elements could live together in a self-governed balance.

Keywords:
Knowledge Management; Information Systems; Decision Making

Introduction

Health and social care are under restructuring in many countries [1], including well-known programs like Obamacare in the US [2] and reform of National Health Service in UK [3] and Sweden [4]. In Finland, the renewal of health and social services (the Finnish SOTE-reform) is currently under way, and it will demand a lot of new governance structures, processes and supporting ICT infrastructure to become a reality, the whole health and social care ecosystem will deeply reinvent itself in Finland. This puts heavy pressures on many domains, including, and not to the least, information systems in the industry. Whereas all would like to see this new ecosystem as a greenfield design, also a design without restrictions from the past, in reality we talk of a brownfield design: old structures must be taken into account, and they often inhibit the implementation of the best available solutions. Greenfield and brownfield terminology is eagerly used in land usage planning [5; 6], but the metaphors of greenfield and brownfield have also found their way to the field of organizational context [7; 8] and information systems [9].

In this article, we review based on academic literature what brownfield and greenfield development means in organizational and industry context, and what it specifically means in the design of information systems. We look for insights that could be used when redesigning information systems in health and social care domain.

Total rework of a large entity can be called domain engineering. Domain engineering is often seen as focusing on software. Domain engineering is relevant to the work required to establish a set of software artifacts that can be reused by the software engineer. The purpose of domain engineering is to identify, model, construct, catalog and disseminate a set of software artifacts that can be applied to existing and future software in a particular application domain [10]. There is anyway evidence that domain engineering is more than just software work: Domain engineering aims to support systematic reuse, focusing on modeling common knowledge in a problem domain [11].

The major alternatives for domain engineering are greenfield and brownfield engineering.

Most of the system and software requirements literature assume development of system from scratch i.e. Green Field Systems [12]. New product development or greenfield process (which does not include constraints for development work like brownfield process) has higher risks. Markets usually have dominant designs, which affect the customer behaviour. When a new product has been developed, there is a risk that the customers do not accept it. Investments to infrastructure of the organization and existing resources have an effect on the selection of whether to develop current products to higher level or to develop completely new products [13].

Lehtonen et al. [13] define that the brownfield (process) stands for the reusing of available assets and it includes notions that there are limitations to designing and solutions because of existing structures. Old product solutions, product structures or customer requirements limit designing of new products. Because of this, the brownfield process is not the preferred solution from the designer point of view. Most organizations in this era have existing large-scale or medium-scale operational systems. With the evolution of new business requirements arise for change in existing systems to meet evolving business demands and needs. In general, the challenges faced by industries are mainly the capture of requirements for changes and re-engineering in operational systems. Unfortunately, there are very limited approaches defined for re-engineering and changes in existing Brownfield operational systems because most of the system & software requirements in the literature assume the development of system from scratch i.e. Green Field Systems [12].

Infrastructure building is a key task in domain engineering: a domain engineering process should encompasses at least three main activities: domain analysis, infrastructure specification and infrastructure implementation [14].
A common scenario of brownfield system development can be a major upgrade in current operational system in terms of the following requirements [12]:

- Incorporation of new business rules in existing system
- Adding up new feature in existing system
- Up-gradation of existing feature
- Adoption of new technology
- Legalization/Certification of product or specific feature

Today and increasingly in the future, most large software-intensive system (SIS) developments will be constrained by the need to provide continuity of service while migrating their services away from poorly structured and documented legacy software applications. Yet most SIS process models contain underlying assumptions that an application project starts from scratch in an unconstrained Greenfield approach [15]. We feel that this is a more than core description of health and social care projects in most countries – including Finland.

A health and social care system reform has been on the agenda of several Finnish governments. Prime Minister Sipilä’s current government has a plan to put the new health and social care system into operation by 2019. One of the main targets of the ongoing healthcare system reform is to reorganize service providers into larger units called health and social care provider regions. The aim is a full horizontal and vertical integration of health and social care and the primary and secondary levels of services. [16]

New key actors in the new ecosystem will be regions, that will order the health and social care services from the markets, where public, private and third sector service providers compete in equal terms as much as possible. These new regions are yet inextistent, and so are their information systems. They need a totally new ICT infrastructure that is related to and built on the currently available one, but especially systems to manage contracts with service providers, and systems to foresee and plan for service demands, so that they can purchase the right amount and quality of services from the markets. Similar systems are rather unseen in the Finnish context at least; here we are not speaking of ordinary procurement systems [17]. One of the domains where public authorities have most experience of purchasing services might be logistics [18; 19].

**Messages from Brown/Greenfield development to health- and social care work**

The problem area of Brownfield system development seems to be rather sparsely understood in health and social care information systems field. Much more understanding needs to be gained on how existing structures inhibit the implementation of best new practices. In healthcare, especially the ponderous patient records systems are a core element, to which all new systems must adjust. As well different other systems, such as different coding systems and terminologies inhibit change. On top of everything else, the industry is heavily regulated.

As said, domain engineering is about modelling common knowledge in a domain. Knowledge in the area of medicine especially is extremely extensive, and there is very little room for greenfield engineering or modelling. Yet new ecosystem functions might necessitate a fresh view on knowledge too.

As a reprieve to the problems, IS projects meet with brownfield elements Boehm [15] proposes incremental commitment building. All decisions concerning the new systems are not done at once, and they are not done by just one party. In order to rapidly and successfully adapt to the increasing rates of change, projects need to be able to concurrently, rather than sequentially, assess and manage (1) opportunities and risks; (2) requirements, solutions, plans, and business cases; and (3) hardware, software and human factors [15]. This kind of approach is clearly needed and to a great extend also visible in the Finnish renewal of health and social care.

Brownfield development means that there are established structures, experts and solid knowledge of the domain area already available. Careful listening to experts and taking their ideas into attention and production is a key success factor for brownfield projects. It is important to remember that customers and ordinary staff members are often the best experts in details, even when they are not always able to structure the total picture. The chance of success for Brownfield domain engineering is greatly enhanced if the people working together are effective communicators, like working in teams, are humble, and enjoy learning from others. All of these are important to help create a “no blame” culture, where people aren’t afraid to help one another and do what is right for the project [9].

Infrastructure development is a key action in domain engineering. Again, infrastructure in health and social care might in many cases not be the most sophisticated one, but it is usually deeply rooted and difficult to change. Different standards of healthcare message exchange are at the core of infrastructure development in health and social services [20].

Table 1 summarizes our main findings from the literature on brown/greenfield engineering.

**Methods**

Our fieldwork took four months in December 2016 - March 2017 in Southwest Finland. During that time we held 12 expert interviews with Finnish experts in social and healthcare information systems, and one workshop. The theoretical background of green or brownfield domain engineering was not present in the empirical discussions. Our study approach was explorative [21].
Results

In our fieldwork we could identify a lot of pressures and change in agents to the current situation. Genuine interest to design the whole information governance in Finnish health- and social care clearly exists. The main identified factors are summarized in Table 1.

The most clear brownfield element in Finnish health and social care domain of health and social care information governance is the established portfolio of many clinical healthcare information systems. While the amount of different system brands can be counted in thousands, a few main systems – especially patient record systems – account for the main part of current system portfolio. The new and central Finnish main database for health and social care customer information Kanta is on the edge – it can be interpreted as a new building block in an old brownfield landscape.

The current situation in health and social care IS can be described in Finland as waiting. A lot of planning work goes on, but real investments into new systems are few, because of the unclear situation of the upcoming new health and social care governance. It is still widely unclear, what kind of organizations will operate in the new domain, and with which kind of processes and business models, and which kind of incentives are given to different players by government and market forces.

In Finland, there is already a lot of hefty discussion on the future of the fixed property, which will be most likely deserted in the new market environment – especially facilities in rural areas are in danger. Less discussion has been on the same possible fate of heavy investments in current information systems and infrastructure.

Finally, making Greenfield domain engineering is made difficult because of very traditional reasons: lack of finance, lack of vision and direction, and lack of market or other new alternatives that would really look like superior ones as compared to current status.

</tr>
</tbody>
</table>

Political agenda setting in Finnish health and social care field has been ambitious. However the situation that there would be a lot of fresh resources and areas to untap, which is a key idea in greenfield domain engineering, is missing.

There also seems to be going on some rich and ambitious work on new IS architectures for the health and social care domain. Unfortunately, however, the work seems to form an archipelago; the bridges joining the work items are few and far.

The new regions should act as main change agents. Their capacity and capability to do so is still under speculation, as they are not established yet. The goal is to have strong and wisely led regions as a major change agents for Finnish health and social care domain and its information systems.

There seems to be a strong consensus that especially decision making in the new health and social care domain needs strengthening. Decision makers at all levels should be fed with relevant and fresh information. The same holds true for secondary use of information in research and development domains.

We can also see some new initiatives in the main system portfolio. The nationwide Kanta-service was already mentioned. In addition, some regions plan for ambitious fresh patient record systems and related functionalities. IBM seems to enter the field strongly with its artificial intelligence Watson concepts, that it seems to utilize as a Trojan Horse to more strongly access the Finnish health and social care IS market.

Discussion

A promising approach for governance and management of the complexity, wide scope and brown/greenfield development of the social and healthcare system is the ecosystem approach. An eHealth ecosystem is composed of healthcare organizations, both public and private, service provider professionals, customers, citizens and patients, industrial companies providing their products and services, and technology-mediated communication and infrastructures that in collaboration provide add-on value for both service consumers and other service providers. Infrastructures and networks are needed both for knowledge sharing and management, and for exchanging and communicating information and data. In an ecosystem, services and products are developed and delivered to fulfill the customers’ needs, or regulation-stated needs, and the role of marketing and commercialization is minor [22]. Customers are both health professionals and patients, citizens, and service providers are healthcare organizations and various suppliers and industrial companies to offer systems and services to be used by healthcare organizations and patients. This approach supports very well the regional model of the Finnish social and healthcare reform. Good examples of ecosystem applications and services are electronic health records, personal health records, patient portals and health information systems including health knowledge management and e-learning for healthcare professionals. Further, these systems include clinical decision support systems and remote patient monitoring and management applications to be used at home and on-move by patients and citizens. Wellness and fitness applications should also be mentioned.

An eHealth ecosystem is very dynamic system that incorporates a varying number of stakeholders. Ecosystem requires enabling information, communication, and empowerment mechanisms, which make it possible for information and expertise to be accessed quickly and
accurately to inform and guide the ecosystem activities and performance. An eHealth ecosystem is very specific in the sense that political decision making has strong effects on how the healthcare services are organized and funded, and also, there is strong legal and normative regulation on how the services can be delivered, accessed, disclosed, charged and funded [23]. Typical for an eHealth ecosystem today is that the services, e.g., electronic health records, need to be delivered online, across distinct organizational, regional or even national borders. This requires that an ecosystem is composed of interconnected stakeholders, each one with a mission to improve the quality of care. In this situation, in order to ensure the patient safety and quality care, the stakeholders build new relationships, often outside the healthcare organization, e.g., develop new types of public-private partnerships [24].

The ecosystem approach on eHealth systems and applications, especially in this new nation-wide social and healthcare reform context, helps healthcare organizations and e-health stakeholders to create business models based on collaborative service production and thus improve collaboration and communication between the stakeholders. The actors, partners of the ecosystem need to share the common objectives of the system and benefit from collaboration, create shared value, and when they have adequate tools and means for communication, collaboration will be active and support the ecosystem sustainability.

eHealth ecosystem can provide many potential benefits for the healthcare professionals and organizations and patients and citizens and for industrial suppliers. However, creating sustainable eHealth ecosystems requires that all stakeholders’ opinions and needs are taken into account for ecosystem success and sustainability. Sustainability is important because the benefits often can be achieved only over a period of time. This kind of approach is very relevant, essential, and necessary for the successful governance and management of our planned social and healthcare reform.

Conclusions

Our explorative journey confirmed that terminology and thinking on greenfield and brownfield domain engineering fits well even to the social and healthcare domain information systems development. This to a great amount in health and social care, IS development untapped theoretical construction, and stream of literature and research offers new avenues and insights to research in health and social care IS.

In reality healthcare is plagued with brownfield elements that hamper new openings of IS in the domain. Social care is having less past burden, especially in IS governance, but even there old traditions might heavily hamper new development ideas.

A lot of long-term IS planning in the form of architectures is taking place in the Finnish health- and social care domain. We can easily see that the development initiatives are forming an archipelago, with few bridges between the different plans and a lot of overlapping work.

Incremental commitment building is a key to success in brownfield domain engineering projects. Listening to different stakeholders and allowing them to make their real input to the future IS governance arrangements is an enabler of success, but of course not yet a silver bullet. The cost of this approach is most likely a lot of superimposed work, but this is the cost that has to be paid for consensus. Allowing wide groups of stakeholders to co-produce the plans also serves educational and learning purposes.

Our proposal for a fresh approach is more underlining the nature of an ecosystems of the health and social care domain. Rational top-down planning will never harness the realities of the domain – even not in a small country like Finland. Rather we need more focus on the understanding on how the health and social care ecosystem works, and how IS as a sub-ecosystem in the area works.

Abstract

Accurate, complete, and timely disease surveillance data are vital for disease control. We report a national scale effort to automatically extract information from electronic medical records as well as electronic laboratory systems. The extracted information is then transferred to the Centers of Disease Control after a proper confirmation process. The coverage rates of the automated reporting systems are over 50%. Not only is the workload of surveillance greatly reduced, but also reporting is completed in near-real-time. From our experiences, a system sustainable strategy, well-defined working plan, and multifaceted team coordination work effectively. Knowledge management reduces the cost to maintain the system. Training courses with hands-on practice and reference documents are useful for LOINC adoption.

Public Health Surveillance; Electronic Health Records; Logical Observation Identifiers Names and Codes

Introduction

Infectious disease surveillance has been a cornerstone of disease control. In order to have effective surveillance systems, we need to obtain timely, accurate, and complete data. In the past, data collection process used to rely on the physicians and Infection Control Nurses (ICNs) to manually report via telephone or faxing to the health authorities. The manual reporting process is not only time-consuming and labor-intensive, but also error-prone. With the adoption of web-based information systems, reporting time has greatly reduced and data quality has significantly improved. Information systems have transformed from a supportive role for public health to a proactive one in the last two decades. In 1995, the first syndromic surveillance systems were established to detect outbreaks of waterborne illness [1]. In addition, the US government started promoting a National Electronic Disease Surveillance System (NEDSS) in 2000. Hospitals were encouraged to develop electronic reporting systems to achieve stage 1 of Meaningful Use [2]. In 2004, the Public Health Information Network (PHIN) integrated the information systems to meet public health functional needs [3]. These all improved case detection and lead to prompt responses to an outbreak.

Currently, the major surveillance systems in Taiwan are the notifiable disease reporting system, laboratory surveillance system, school surveillance system, populous institutions surveillance system, and Taiwan Real-time Outbreak and Disease Surveillance (Taiwan RODS) system [4]. Among them, the notifiable disease system is the most important one. Physicians and ICNs are mandated to report notifiable diseases through this web-based system. That is to say, they need to look up all the information from hospital information systems and then type information into the notifiable reporting system. According to Taiwan’s regulations, there are more than seventy notifiable diseases. For each disease, plenty of data needs to be collected. Thus, collecting surveillance data comprises heavy workloads for physicians and ICNs. In addition to the notifiable disease system, Taiwan RODS is also important for infectious disease surveillance. Taiwan was severely struck by the SARS epidemic, and subsequently, the government has made a lot of progress in disease surveillance. Taiwan RODS was launched to automatically monitor several syndromes through emergency departments since 2004. Taiwan RODS was easily adapted to monitor an outbreak of red eye syndrome and has shown its effectiveness in situational awareness [4]. Now, it monitors influenza-like illnesses, enterovirus infections, red eye syndrome, and diarrhea. However, before conducting this project, Taiwan had not yet implemented any electronic laboratory reporting (ELR) system. We could only obtain pathogen information from sentinel physicians through the laboratory surveillance system to characterize the subtypes of influenza virus and enterovirus infections.

In the past decade, the Taiwanese government has aggressively promoted Electronic Medical Record (EMR) systems and Health Information Exchanges (HIE). There are 406 out of 501 hospitals that have implemented EMR systems and are capable of interchanging EMRs among institutions [5]. Given this basis, Taiwan Centers for Disease Control (TCDC) launched the National Epidemic Prevention and Control (NEPC) project to improve the efficiency and effectiveness of surveillance in 2014 [6]. This project comprises two programs. One is the “automated reporting via EMR” program (EMR program for short), which aims to accomplish the automatic machine-to-machine reporting of notifiable diseases from hospitals’ EMR systems to TCDC. The other is the ELR program, the goal of which is to report positive laboratory test results of 20 selected pathogens from hospitals (directly from the laboratory information system). In this article, we report Taiwan’s experiences of its implementation strategies and current achievements in promoting the NEPC project.

Methods

Implementation strategies

The initial step of the NEPC project was amending the regulation by the authority to make automatic extraction and reporting acceptable. A committee was formed to design the system architecture and establish program workbooks that
contain all the necessary information to implement such systems. The data format as well as the semantics of required data elements of each notifiable disease and an accompanying specification using HL7 [7] Green Clinical Document Architecture (GCDA) [8] were also included.

The three-year NEPC project took an expanding-and-maintaining strategy in three rounds. For each round, which took one year, there were three stages: the recruitment stage, development stage, and evaluation stage. The first two months were the recruitment stage. TCDC announced the latest program workbooks and recruited hospitals. The incentives for hospitals to join the project included funding for system construction and bonus points for hospital accreditation. The recruitment stage ended with a signed contract, and the seven-month development stage began. During this stage, the participating hospitals followed the program workbooks to develop the reporting system and had to pass the system testing at the end. The last three months were evaluation stage. Data completeness and system stability were evaluated at this stage. In order to encourage the participating hospitals to report complete data and maintain system stability, an extra bonus was given based on the results of the evaluation stage. It is worth mentioning that hospitals joining in earlier rounds were actively engaged and this was the maintenance art of the strategy.

In order to run the project smoothly, TCDC organized a multifaceted team, which consisted of a policy instruction committee, an information technology (IT) support group, and a project coordination office. The team meeting was held weekly to monitor the progress and to assist all the hospitals for implementation issues. The details of the development and evaluation stages for the EMR and ELR programs are as follows.

**EMR program**

The EMR reporting system is designed to utilize hospital EMR to report notifiable diseases. A schematic view of the EMR reporting system is shown in Figure 1. We selected participating hospitals according to the reporting quantity. The participating hospitals have to develop a reporting module, XML generation module, and digital signature module. The reporting module extracts cases from EMR systems; the XML generation module creates reports conform to the defined XML schema; the electronic signature module adds digital signatures to the reports. After physicians or ICNs review the data, the hospitals report the cases to TCDC. For each hospital, we compute a weighted sum of the ratios of all notifiable diseases cases reported by that hospital divided by the national total and this is the coverage rate of the hospital. We can then add all the coverage rates of all participating hospitals as the coverage rate of the project. Furthermore, system maintenance is estimated by the EMR reporting rates and successful reporting rates. The reporting rates of each participating hospital have been monitored since the systems were launched. We also surveyed how frequently the participating hospitals send the reports.

**ELR program**

The Laboratory Automated Reporting System (LARS) is designed to monitor trends in 20 selected pathogens such as hepatitis virus, influenza virus, and Salmonella, to name a few. A schematic view of the LARS is shown in Figure 2. There are two objectives when selecting participating hospitals: the reporting quantity, and balance of area. The participating hospitals were asked to send positive laboratory test results to TCDC. There are three steps for system development, including gateway setup, Logical Observation Identifiers Names and Codes (LOINC) [9] mapping, and data transmission. The IT support group assisted the hospitals to setup the gateway. The positive laboratory test results were then sent to TCDC. Because there is no reference data for LARS, we used the notifiable disease reporting rates of all hospitals participating in the ELR program in 2015 as a proxy for the coverage rate. The total coverage rate and the district coverage rates were calculated. (Taiwan is divided into six districts according to geographic location.) We adopted the international standards for the laboratory test results, LOINC, as well as the coding system for LARS. Therefore, the first step is to map the hospital local codes to LOINC codes. When the project was initiated, LOINC was not commonly known in Taiwan. Medical technologists (MTs) were not familiar with LOINC. TCDC provided LOINC mapping training courses to all the participating hospitals on the second month of the development stage in each round. The courses contain the introduction of basic knowledge of LOINC, mapping procedure demonstration, and hands-on practice. RELMA® [10] was chosen as the mapping tool.

In addition to the training courses, TCDC keeps auditing data to ensure the data quality and the auditing results are fed back to the hospitals. The six parts of LOINC are compared with the mapped LOINC codes to see whether they are matched to each other. The LOINC mapping rates are then calculated. LOINC mapping rate is also one of the items in auditing.

**Results**

There are now a total of 47 and 53 participating hospitals in the EMR and ELR programs and the coverage rates are 52% and 59%, respectively. The characteristics of the participating hospitals are shown in Table 1. In the first year, medical centers had higher priority. In the end, all the medical centers in Taiwan joined this project.

EMR program

The implementation strategies of all the EMR program participating hospitals can be categorized into self-developing and outsourcing. Most medical centers (84%) developed their own EMR reporting systems. On the contrary, 75% of the regional hospitals tended to outsource to vendors (Table 2). We conducted a chi-square test with Yates’ continuity correction to compare the implementation methods between the two groups and the finding revealed a significant difference with $p < 0.001$. These regional hospitals are served by four health information companies, which is an advantage to the project because the vendors can serve many hospitals.

From our experience, we found that self-developing hospitals were more likely to fall behind schedule. Every year, there are always 1 or 2 hospitals having trouble keeping up with the schedule. Thus, we set up milestones for program progress and carefully monitored the progress of every hospital. Any hospital that was 30 days behind schedule was arranged to be met by the project coordination office. Moreover, it takes a longer time for the self-developed systems to revise the program. This April, the case definition of syphilis was amended; it took about one month to update the program for the self-developed systems, whereas less than two weeks was enough for the outsourced, developed systems to update the program.

The EMR program has achieved three marked effects: high reporting rates, near real-time reporting, and decreased workloads.

1. High reporting rates:

All the EMR program participating hospitals were monitored for the EMR reporting rates and successful EMR reporting rates. The average EMR reporting rates were constantly maintained around 93%. Some hospitals had a reporting rate below 60% because they did not develop a reporting module for diseases that rarely occur there. Hospital 41 (H41) is a small hospital. It missed one case, and had only one reporting failure after the system was launched at the end of this September.

2. Near real-time reporting:

The EMR reporting system can automatically extract data from EMR systems. After ICNs examine the reporting data, the data can be sent. Among these participating hospitals, 25 out of 47 hospitals can send data in real-time. The others send data via a scheduled program. The reporting intervals are shown in Table 3. In the future, with enough evidence, the workflow can be further streamlined; the confirmation of the ICNs can be a parallel process with the machine-to-machine reporting. Undoubtedly, the status data will be further streamlined; the confirmation of the ICNs can be a parallel process with the machine-to-machine reporting. Undoubtedly, the status data will be classified as to-be-confirmed and confirmed. This modification can partially mitigate the potential issue that ICNs become the bottleneck in the process.

3. Decreased workloads:

The most important benefit of the EMR reporting system is the reduction of ICNs’ workloads. Because the ICNs’ role changes from entering the data to reviewing them for confirmation only, it reduces the reporting time from 8 minutes per case to 3 minutes, as mentioned by a senior ICN from a medical center [11].

ELR program

Compared with the traditional laboratory surveillance system, which collects data from only a few contracted laboratories, LARS gathers data directly from hospital laboratory information systems. On average, TCDC received around 13,000 positive laboratory tests of the 20 selected pathogens per week from the 53 participating hospitals. The coverage rates of LARS for each of the six districts ranged from 44%-69%.

From our experience, with the help of knowledge management, LOINC mapping training courses are the most effective way to promote LOINC adoption. The average LOINC mapping rate was about 50% in 2014, and has improved steadily since. It has now reached 82% in 2016. In the first year, only basic knowledge and RELMA demonstration were provided in the training courses and the average mapping rates were low. More efforts were made to correct the data. Therefore, we added hands-on practice in the second year and the average LOINC mapping rates increased to 72%. In addition, we extracted knowledge from data auditing and reached a consensus for LOINC mapping rules from expert panel discussions. The knowledge was documented as LOINC mapping rules, the LOINC mapping FAQ, and the most frequent LOINC combinations. These documents became the teaching materials in the third year.

Here, we used the influenza virus data as an example to represent the system effects of LARS. Figure 4 shows the number of positive influenza virus tests during the period from the 40th week, 2015 to the 48th week, 2016. In this figure, it
Discussion

The NEPC project was successfully executed under a limited funding budget. TCDC has made the coverage rates of both programs reach more than 50%. Besides, the implementation of the EMR reporting systems has greatly reduced the workloads of ICNs. Thus, the reporting rates have been constantly maintained above 90%. The LARS collects positive test results of the selected pathogens and provides further information for infection control efficiently. The experience of the NEPC project provides an operational roadmap for implementing a surveillance system in their member hospitals without any funding.

1. System sustainability:

TCDC makes a tremendous effort to make the operation sustainable. From a policy perspective, the first step is to have a legal basis and then bring in incentives. Hence, the Infectious Disease Control Act and Implementation Regulation for Epidemic Surveillance and Alert System were amended. Thereafter, a one-year grant jumpstarted the program. Further, the maintenance strategy included providing feedback to the hospital and awarding outstanding hospitals. Hospitals also can earn extra bonus points during hospital accreditation. From an implementation perspective, knowledge management is an effective way to maintain the system with limited resources. In this case, we documented each of the issues encountered during the project. As for TCDC, it helps them to provide continuous support to the hospitals. As for the participating hospitals, it is also useful when the personnel change. In addition, the EMR reporting system directly benefits ICNs by reducing their workloads. This makes hospitals more than willing to participate in this project. We have heard that several hospitals were actually persuaded by their infection control departments. Some of the healthcare networks even voluntarily implemented the EMR reporting system in their member hospitals without any funding.

2. Project implementation:

A well-defined working plan and schedule management help the project run on schedule. A full-year detailed working plan and schedule were determined at the beginning with a thorough communication process. The project coordination office monitors the progress in accordance with this plan closely, in order that any delay can be detected earlier. The noted delay triggers a coordinated effort to speed up the progress. Therefore, all of the participating hospitals can finish system construction, testing, and evaluation on schedule.

Furthermore, keeping the project running smoothly requires multifaceted team coordination. There are multiple stakeholders in the project: the hospital, IT support group, project management office, and TCDC. We note that when hospitals need help, the best approach is to have all stakeholders work together to resolve issues. We note that cases in which only IT support group is involved may focus on technical details regardless of administrative support issues, and thus, delay the progress. It seems to be a trivial observation, but when there are several hospitals asking for help, it soon becomes a daunting effort. Furthermore, bilateral efforts soon become the norm if multilateral collaboration is not mandatory. Besides, we note that the needs of the hospitals vary dramatically. For example, medical centers usually have their own in-house software development teams, and the trouble usually comes from inter-departmental communication, especially between the infection control departments/laboratory departments and software teams. The project also has to compete with other projects in the hospital; therefore, an early warning to the project leader, usually the deputy director of the hospital, is very important. For hospitals that do not have in-house software teams, the trouble usually stems from the interaction between two IT vendors, one from the hospital and one from the CDC. The detection of early warning signs and timely intervention from the project office are vital.

3. LOINC adoption:

Although training courses are an effective method to introduce LOINC, only teaching basic knowledge of LOINC is not enough. Hence, we held two expert panel discussions and reached a consensus for LOINC mapping. Thus, overall LOINC mapping rules have been created and incorporated into teaching materials for the next training courses. Online videos for LOINC mapping were also provided. Given the clear instructions and online videos, MTs are able to map LOINC effectively. Because laboratory data change with time, continuous auditing is important. We extracted knowledge from data auditing, and documented the mapping FAQ and the most frequent combinations of LOINC parts.

Conclusion

The NEPC project’s success is two-fold: 1) the EMR reporting system greatly reduces the workloads of ICNs and shortens the reporting time of notifiable diseases; 2) LARS collects positive test results of 20 selected pathogens to complement the existing surveillance systems. These achievements have made the surveillance more efficient and effective. From our
experiences, we have learned lessons for system sustainable strategy, project implementation, and LOINC adoption. A system sustainable strategy includes having a legal basis and adequate incentives. Knowledge management reduces the cost to maintain the system. Further, a well-defined working plan, schedule management, and multifaceted team coordination work effectively for project implementation. Training courses with hands-on practice and reference documents are useful for LOINC adoption. Reference documents include the overall mapping rules, mapping FAQ, and the most frequent combinations of LOINC parts.

Change Management Strategies: Transforming a Difficult Implementation into a Successful One

Giussi María Victoria, Baum Analía, Plazzotta Fernando, Muguerza Pablo, González Bernaldo de Quirós Fernán

Clinical Informatics Office, Ministry of Health, Buenos Aires city, Argentine
IT department, Ministry of Health, Buenos Aires city, Argentine
Government Health Advisor, Buenos Aires city, Argentine

Abstract
The implementation of health Information Technologies (IT) contributes to improve quality of care and management processes. In spite, evidence shows that the rates of IT adoption are not the expected ones. Since 2004, Public Healthcare System of Buenos Aires city has been implementing a Healthcare Information System with a difficult adoption in clinical setting. In December 2015, the Government made some changes that allowed the implementation of an Electronic Health Record in 20 Primary Care Centers. This paper describes the change management strategies that were designed in order to transform a difficult implementation into a successful one. The combination of timely approach to change management, good governance and specialized human resources were keys to achieve this goal.

Keywords:
Electronic health record, Healthcare system, Change management

Introduction
Implementation of health Information Technologies (IT) contributes to improve quality of care and management processes. Provision of quality information for health care decision making, optimization of resources, contribution to the healthcare system giving timely and equitable care, are some of the benefits that can be achieved. Although IT benefits are clear and well described, evidence shows that the adoption of new information systems is not an easy task, and the utilization rates are not the expected for the current times [1].

There are many issues that can become barriers in the implementation of a health IT project, if they are not timely taken into account. For example: political and economical support to ensure governance, the design of a strategic plan with clear objectives in short, medium and long term, the lack of external regulations and internal processes that provides a legal framework according to the needs, the definition and adoption of interoperability standards, and change management strategies to transform the organizational status quo [2]. Evidence has shown that more than a half of IT projects result in failure [3]. Despite inevitable failures, medical informatics leads to many successes. Implementing information systems into complex healthcare organizations requires an effective blend of technical and organizational skills [4]. Therefore, the technology field offers challenging possibilities and new tools that demand new approaches, without disregarding the human factor [5].

Since 2004, the Public Healthcare System of Buenos Aires city has implemented a Health Information System (HIS) called SIGEHOS (Sistema de Gestión Hospitalaria -Hospital Management System-). SIGEHOS was mainly adopted in hospitals for administrative purposes such as patient identification, manage medical appointments and billing services according to patient insurance. In 2012, SIGEHOS was provided with clinical record capabilities and tried to implement in Primary Care centers; however, all approaches and strategies to accomplish significant results were unsuccessful. The arrival of a new Government in December 2015 brought in different policies on health IT and the possibility of another chance.

This paper describes the new approach and strategies designed after 2015 in order to transform a difficult implementation into a successful one.

Methods

Setting

Health Care Network
Buenos Aires is the capital city of Argentina and its largest and most important one. According to the 2010 census, the city’s population is 2,890,151 inhabitants [6].

The Argentine’s Public Healthcare System provides free services to its entire population but much different insurance models often coexist on the same patient. According to 2014 statistical data, the average of the population residing in Buenos Aires city is insured only by the public system is 17.8%. This percentage reaches 31.2% in the south of the city, which is the more unprivileged [7].

The healthcare network is formed by 33 Hospitals and 43 Community and Primary Care Centers (Centros de Salud y Acción Comunitaria - CESAC). The city is structured into 12 areas in order to organize health care delivery (Figure 1). In 2015, the Buenos Aires’ Public Healthcare System provided approximately 9,600,000 of consultations in ambulatory setting [8].
Software

SIGEHOS is web-based and in-house developed software (Figure 2). From 2004 to 2012, the first version of SIGEHOS was implemented in 20 hospitals, including modules that allowed patient identification, schedules management, hospital admission and billing, pharmacy stock management, registry of corpses and management reports. In 2012, an electronic health record (EHR) was developed and incorporated into SIGEHOS with the aim of replacing paper clinical records and getting the benefits of the electronic format.

First EHR implementation

Since 2012, the Government intended to implement an EHR and develop initiatives to improve the infrastructure of the healthcare institutions.

It was not until 2014 that said implementation started in Primary Care Centers, but by October 2015 it was adopted only in 1 of the 43 CESAC.

The following problems were encountered:

- Difficult negotiations with each CESAC due to lack of governance, and project management were in hands of a technical department with few healthcare professionals participating
- Lack of a multidisciplinary team which understands how to deal with healthcare professional’s resistance to change.
- The definition of standards was inappropriate to represent the different domains of clinical knowledge

Study design

This is a descriptive paper about the strategies implemented in the primary healthcare network in Buenos Aires city since December 2015. These strategies were based on a better health care strategic planning and on the redesign of the primary care network [9].

Results

Change management strategies

The strategic plan comprises 7 fields related to Health IT projects [10].

1. Change of project leadership: The Clinical Informatics (CI) Office was created and coordinated by a physician specialized in health informatics. Thirty professionals from different disciplines such as medicine, nursing, health informatics, systems analysis and engineering, sociology, psychology, anthropology, social communication and education sciences, were incorporated to the implementation team (Figure 3). All these professionals set up a great interdisciplinary workforce along with the IT department.

2. Organizational Policies and Procedures: The standardization of key processes, such as patient identification, was needed. In this regard, a special area for internal policies and procedures was created with the purpose of redesigning, documenting and publishing processes and workflows along with the implementation of the EHR.

3. Standards for interoperability

- **Person Identification Services**: The patient identification module was strengthened with rules for unique and unequivocal identification. A Master Patient Index (MPI) with an audit module was developed based on Person Identification Services (PIDS) and CORBAmend standard [11].
- **Clinical Terminology Services**: Several SIGEHOS EHR modifications were requested to the development team, taking into account physicians complaints and recommendations before extending the implementation. One of these complaints was the ICD-10 codification drop-down menu. Clinical Terminology Services (CTS) based on SNOMED CT as reference vocabulary were included to
automatically coding diagnoses and problems list [12].

4. User Centered Design (UCD): One of the major modification from the first EHR version was the shift to a problem oriented EHR. The new version allowed professionals to record clinical notes, anthropometric values, vital signs and vaccination (Figure 4). The developing team worked with UCD techniques in new functionalities like: family clinical record, pregnancy registry sheet, a computerized physician order entry (CPOE) module, recording and visualizing social, environmental, community and epidemiological data, all of which are keys for Primary Care and Public Health [13].

5. Training, Communication and Support
   - Training characteristics: The implementation team committed to train the final users of the system (software) in situ with a theoretical-practical approach. A team of 4 people performed the training 7 hours a day during a period of 4 weeks.
   - Communication and Support: A web-based portal for Primary Care was developed; this webpage was the entrance door for access the EHR and its support system. This web page allowed unifying communication between clinical staff and delivering news about health care to final users.

6. Qualified human resources for continuity: In November 2016, a multidisciplinary residency program on health information systems was created. This program is oriented to professionals from different disciplines and based on a similar training program already in practiced in Argentina with more than 10 years of experience [14, 15]. Once residents finish the program, they should be capable of:
   - Analyze Health Information Systems (HIS) and detect opportunities for improvement in healthcare organizations.
   - Design HIS to accompany healthcare processes and contribute with quality information for continuity of patient care.
   - Implement HIS that allows obtaining quality data for the management of public health policies

7. External Rules, Regulations, and Pressures
   - Legal framework: In October 2016, Buenos Aires legislature passed the EHR law [16]. This law provided an important legal framework to support the implementation of the project and help to overcome the natural resistance to change. It also guaranteed the rules to carry out standardized implementations between public and private health care providers.
   - Specialist Advisory: To develop the project, the Government received advice from a specialized physician with almost 20 years of healthcare management experience and a pioneer in health information system implementation in the region [17].

Implementation results

Implementation results are described before and after applying the strategies described above as parameters of implementation success.

Goals
At the beginning of the project the goal was to implement the EHR in 14 CESAC by the end of 2016, taking into account that 6 months were needed for setting up the team, gather processes and change the SIGEHOS software. The first implementation was in June 2016, and after applying new strategies the team was able to increase the initial target until 20 CESAC were fully implemented by December 2016.

Users
The adoption of the EHR increased from 27 users in 2015 to 1200 on December 2016, 90% of them was healthcare professionals and 10% administrative staff.

Among the healthcare professionals users, most frequent specialties were pediatrics, nursing, general medicine, psychology, obstetrics, internal medicine and social service (Figure 5).

Identifying patients
In a similar way, the new approach helped to increase more than 10x times the number of patient registered in the MPI in a 6 months period reaching a total of 52,580 patients by December 2016 (Figure 6).
Progress of Clinical Notes
The more professionals used the EHR the more clinical notes were registered, going from 10,000 notes to a total of 75,281 by December 2016 (Figure 7).

Discussion
The governance model implemented since December 2015 allowed the successful implementation of a health information system in Buenos Aires city. The implementation was carried out within the framework of a strategic ministerial aim consisting of strengthening primary care network and achieving an integrated and efficient healthcare system that provides timely, equitable and progressive care to people.

A key issue was the standardization of processes and the incorporation of interoperability standards for unequivocal patient identification. Primary clinical data capture should be as expressive as possible, then semantic coding and control should be transparent to the user. First EHR version considered mandatory the ICD-10 codifying by professionals and it caused resistance. Terminology services were incorporated in second EHR version and users could write free text overcoming barriers. This is one of the most recognized interventions and ensures the scalability of the project [21].

Another key aspect was the careful building and shaping of the implementation team. A blend of IT professionals and clinicians cannot become a team of health informatics specialists. There was a need for specialists in health informatics to be a "bridge" between the two disciplines and to be the guide through the changes of the organizational culture. The incorporation of healthcare professionals specialized in health informatics helped to reduce the time needed to implement the software and overcome preexisting barriers [5]. Moreover, in order to maintain the project beyond any political changes, an educational program was built to train an ongoing qualified workforce.

Healthcare professionals usually have little resistance to change unless the change is beyond their control or is intended to modify existing work conditions. In order to decrease healthcare professional resistance to change it was necessary to consider healthcare workflow in the redesign of processes and the EHR. This approach avoided the misuse of the systems and the poor quality of the recorded information by professionals [4, 22, 23].

Lack of regulations and legislation about eHealth is an important barrier to a HIS adoption. Working together with a group of lawyers, lawmakers and other professionals made it possible to define a legal framework for the implementation of the EHR.

The development and implementation of a robust and scalable health information system involves the detailed knowledge of the business rules of each healthcare organization. Despite the fact that good software solutions can be imported, the strategies of implementation and the "peopleware" are proper of each institution [24].

It is hoped that this document will be useful for similar experiences. It is necessary to continue working on the implementation of this project and to achieve an evaluation through a validated instrument.

Conclusion
Implementing Health Information Systems in Public Health faces a major challenge that requires political good governance, human resources with specific skills and a health information system able to adapt to the culture and organizational context.

This paper describes first months of an EHR implementation in Primary Care in Buenos Aires city. Good governance, a strategic implementation plan and the conformation of an interdisciplinary work team with human resources trained in health informatics, were key components for carrying out a large-scale project and handling adequately the resistance to change.

Abstract

Purpose: Instant messaging (IM) is one kind of online chat that provides real-time text transmission over the Internet. It becomes one of the popular communication tools. Even it is currently an era of smartphones, it still a great challenge to teach and promote the elderly to use smart phone. Besides, the acceptance of the elderly to use IM remains unknown. This study describes the usability and evaluates the acceptance of the IM in the elderly, who use the smartphone for the first time. This study is a quasi-experimental design study. The study period started from October, 2012 to December, 2013. There were totally 41 elderly recruited in the study. All of them were the first time to use LINE app on the smartphones. The usability was evaluated by using the Technology Acceptance Model which consisted of four constructs: cognitive usability, cognitive ease of use, attitude and willingness to use. Overall, the elderly had the best “attitude” for LINE APP communication software, with the highest rating averaging 4.07 points on four constructs, followed by an average of 4 points on “cognitive usefulness”. The scores of “cognitive ease of use” and “willingness to use” scores were equal which are an average score of 3.86. It can be interpreted that (1) the elders thought that the LINE APP as an excellent communication tool for them; (2) they found the software is useful (3) it was convenient for them to communicate. However, it was necessary to additionally assist and explain the certain functions such as the options. It would play a great role in the “willingness to use”. The positive acceptance of LINE APP in elderly refer to the probable similar acceptance for them to use other communication software. Encouraging the willingness the elderly to explore more technology products and understanding their behavior will be the basic knowledge to develop further software.

Keywords:
Technology; Instant messaging (IM); Technology Acceptance Model

Introduction

Aging of the population is an irreversible change. The effective promotion of using the technologic product in the elderly can enhance the “active ageing”. In the past studies have shown the dependence of an elderly person relied on the several factors which were recognized as primarily functional and cognitive impairment, chronic diseases, a diminishing social network, and a low level of physical activity. However, effectively using the IM can make their lives more abundant and enhance their interpersonal relationships.

The alleviation of the chronic diseases and enhancement of the subjective happiness result in higher self-appraisal in health condition. By the contrast, it is not prone to develop into depressive mood and the related symptoms. [2]

The effective use of mobile communication software for the elderly will reduce the social isolation, conversely, make them confident and be willing to participate in the community activities and their interests. [3] [4]. Therefore, it is a solution for the most elderly people to get positive attitudes towards technology [5] [6].

In the past, many studies have explored the use of technology acceptance patterns to compare the acceptance of application-related technologies such as Mobile Health, Telehealth, and Telecare for the elderly.

The Technology Acceptance Model (TAM) was developed by Davis (1989) on the basis of rational behavioral theory TRA. This model to predict and explain a person's adoption of information technology. It consists of (1) the usefulness awareness (2) the easy of the use (3) the use of attitude (attitude toward use) (4) the use of the behavioral (actual use) [7]. In TAM, usefulness awareness and ease of use cognition are considered to directly affect the use of attitude [8]. When a technology is easy to use, it is easier for the user to think that it is useful [9] [10].

Therefore, the concept of technology acceptance model was applied to develop the the certain questionnaire which will clarify the relationship between cognitive use, cognitive usefulness, use attitude and willingness to use communication software in the elderly. The feasibility of this model-based study will be the blueprint and reference of the further system construction.

Methods

This study is a quasi-experimental design study. The study period started from October, 2012 to December, 2013. The program was held at a regional urban hospital in Taipei City. Each participant was provided with an android-based smart phone including a charger, a memory card, and a mobile phone number. There are two lectures during the study period.
The first lecture was held to instruct the participants to use the basic function of the mobile phone. The second lecture in one month later was held to instruct the participants to operate the IM app “LINE” and its group chatting. The feedback from the participants was collected in the same lectures. Three months after the first lecture, the participant completed the TAM-based questionnaire. The feedback and trouble analysis were also done.

The reliability and validity of the questionnaire

In order to ensure the validity of the contents of the questionnaire, a seven-experts panel meeting was held to assess the relevance and the completeness. The four experienced experts devoted themselves to geriatric researches and the other three engineering background experts dedicated to the programming on the mobile devices. The experts provided suggestion of the relevance, comprehensiveness of the content and the grammar. The questionnaire contains four constructs as the cognitive usefulness, cognitive ease of use, the use of attitude and the use of will. Besides, the troubles while using LINE all were also collected and analyzed. Acceptance were measured on a Likert scale of five points, with 1 being strongly disagreeable, 2 being disagree, 3 being no opinion, 4 being consent, and 5 being very agreeable. The expert evaluates the validity of the scale according to the item, content and description of the questionnaire. Content validity index (CVI) was 0.63 and the internal consistency (Cronbach’s alpha) was 0.824.

Data processing and analysis

The results were analyzed with SPSS 23 statistical software to describe the distribution of variables. Descriptive t-test and one-way ANOVA were used to analyzed the effects of the four constructs from the individual factors such as gender, age, educational level, the experience of using traditional mobile phones or smartphone and the understanding of LINE APP and other attributes.

Results

There were 49 participants initially recruited, and only 41 participants completed the survey. The (Figure 1).

The basic properties of the study object

There were 61% female and 39% male participants. The majority of age was 60-69 years old (60.90%). There were 34.1% college-educated participants. The majority of the monthly family income was the group less than USD$940.97 were family income (39%). Most of the participants (68.3%) had the limited experience of using traditional mobile phones and smart phones less than five years. However, 28 of 41 (68.3%) participants tried to download LINE app during the study period. (Table 1)

The technology acceptance of the LINE app

The questionnaire construct is divided into "cognitive usefulness", "cognitive ease of use", "use attitude" and "use will" totally four major aspects consisting of 17 questions. Overall, the elderly had the best "attitude" for LINE APP communication software, with the highest rating averaging 4.07 points on four constructs, followed by an average of 4 points on "cognitive usefulness". The scores of "cognitive ease of use" and "willingness to use" scores were equal which are an average score of 3.86. It can be interpreted that (1) the elders thought that the LINE APP as an excellent communication tool for them; (2) they found the software is useful (3) it was convenient for them to communicate. However, it was necessary to additionally assist and explain the certain functions such as the options. It would play a great role in the "willingness to use".

I think it is useful to communicate through the LINE APP communication software (4.1), and to use the voice communication function (4) for a score of 4 or above. (4.02), C1 "I think it is wise to use the LINE APP communication software" (4.07), D2 "I think this tool is worth promoting" and D3 "I am willing to Recommend this tool to friends and family to use "average score is 4.05 points. There were six items in the "percentage" of the distribution, with "consent" and "very much agree". More than 60% of the total, respectively, were "using the LINE APP communication software to meet my mobile communication needs" (63.4%), (65.9%), B1 "LINE APP communication software is very easy to operate" (63.4%), B2 "LINE APP to graphic display of each function project, so that the use of operation (65.9%), B4 "Limitation of using LINE APP will be less than traditional SMS, 61% of mobile phone calls", and B6 "Communicate through LINE APP, I think it is simpler than traditional mobile phones" (63.4%). Can explain the majority of the elderly that LINE APP in the use of communication is very useful for them, and the ease of use on the operation can have a certain understanding. This means that the elders have some acceptable usability for LINE APP acceptance (Table 2).

The impact of different attributes on four dimensions of LINE APP technology acceptance

\( t = 2.51, \ p < 0.05 \), which indicated that the educational level of LINE APP was significantly different (\( P <0.05 \)), which indicated that there were significant differences in LINE APP between different educational backgrounds. The willingness of the use of the difference in the higher level of education for the elderly have a higher LINE APP use. Other attributes were not statistically significant (Table 3).

The elderly for the use of LINE APP troubled analysis

In the study of elderly people to use LINE APP during the troubled items are three items are "1. when passed chat messages too noisy", "2. For not familiar with, not more convenient to talk about." The first item "When passed chat messages too noisy" average score accounted for a maximum of 3.46 points; followed by the second item "For not familiar with, not More convenient to talk about." "Average score 3.41 points; the third item" Chat interface complex, do not know how to click "average score 3.39 points. If you get chat messages too noisy (46.3%), you get the "Consent" and "Strongly Agree" options from a distribution percentage of more than 40%. It can be explained that there are still some elderly people who think that the use of LINE APP for them, we chat when the message may cause their distress, (Table 4).

Discussion

From this study, the use of the LINE for the elderly to accept the degree is good, not only that this is a useful communication software, for them more feel is an easy to use tool. But in the use of the operation must still be someone to help guide the various buttons between the various functions, so to promote the elderly more convenient operation.

In Davis's (1989) theory of technology acceptance, cognitive usability tends to influence cognitive usability, and both factors directly influence attitudes toward use. In the present study, the elders had the highest ratings on the "attitude" of the LINE APP communication software, followed by the "cognitive usefulness" and the "ease of use" and the "willingness to use" scores. It can be explained that the elderly in the software that can be used for the software, but also in use that it is useful and easy to use, the relative will be willing to use. The higher the education level of the elderly for LINE APP have a higher use of will. So for the elderly in terms of LINE APP communication software is acceptable.

In addition, this study explores the use of LINE APP communication software for the elderly, showing that the use of communication software chat rooms of the message transmission is a higher problem for them; secondly, if you are unfamiliar with the people in the LINE APP communication software chat room chat is a bit embarrassing situation, do not know what to talk about? Finally, LINE APP communication software button complex, so that the elderly do not know how to press the button. From this it can be seen that if they further instruct the elders to confirm the accuracy of each step of their keys and to confirm their intention for each key, they can self-mute the voice of the message or reduce the sound, To complete. In addition to between the elderly in the LINE APP communication software chat room do not know what to talk about? If researchers are able to deliver a thematic message in this group, leading the elders to the topic, it may be possible for the elders to participate in the discussion.

Conclusions

This study is an experimental study, the technology acceptance questionnaire for data collection, for the elderly> 50-year-old home for the recipient to investigate the results, if you want to apply the results to other age levels of scientific and technological acceptance, has its inference limits. Suggested that the future can do the investigation of different age groups, in-depth understanding of different age groups for the use of communication software habits and recommendations.

Augmented Reality in Nursing: Designing a Framework for a Technology Assessment

Hanna Wüllera, Marcus Garthausa, Hartmut Remmersa

*School of Human Sciences, Osnabrück University, Osnabrück, Lower Saxony, Germany

Abstract

During the last decade, research emphasized the wide range of possibilities of augmented reality (AR). At the same time, Information Technology usage in nursing increased. The question occurs if AR can have reasonable fields of application in nursing. Nursing hinges strongly on the emotional and physical relationship between patients and their nurses. This may lead to ethical conflicts while implementing AR leading to special challenges. Therefore the realization of a technology assessment (TA) seems to be reasonable. We designed a framework for a TA of AR in nursing through workshops with nursing scientists and practical partners. The framework is designed to address ethical aspects of AR in nursing through techno-ethical scenarios, a plausibility assessment, and a participatory approach.

Keywords:
Nursing; Technology Assessment; Ethics

Introduction

Usage of Information Technology (IT) in nursing is constantly increasing [1]. While technology in nursing may have some positive effects on nursing processes, the special characteristics of nursing should be considered when designing technology for nurses. These characteristics are: high emotionality, physical contact, and the importance of the relationship between the patients and their nurses. Within these characteristics the nurse has to take the specific situation of the patient into account and act on an individual basis [2].

The special characterization of nursing, the nursing environment, and the developments and trends in nursing technology shall be taken into account when designing the framework for Technology Assessment (TA) in nursing.

During the past decade technological advancements in augmented reality (AR) have been significant. Thus, AR received a lot of attention, e.g. in the field of architecture, construction, and engineering [3]. No consistent definition of AR exists [4; 5], however, the definition by Azuma et al. is most established [6]. Azuma defines AR as any system that has the following three characteristics:

1. Combines real and virtual
2. Is interactive in real time
3. Is registered in three dimensions

Milgram and Kushino described the virtuality continuum which reaches from the real environment to the virtual environment. AR as part of mixed reality is placed closer to the real environment, whereas augmented reality is closer to the virtual environment [7]. Although that definition is conceived as too generic [4], for the goal of our approach we used it because it includes the widest range of possible applications.

Both definitions share a common concept, they are independent of any technology. They do not refer to special input and output methods as well as tracking procedures. Research in the field of healthcare focuses on the usage of smart glasses without using the term “augmented reality” [8; 9]. In this paper, possibilities of augmented reality are taken into account without limitation to any device such as smart glasses. Whereas, a broad field of prototyped applications exists and a high potential is assumed in different areas. In healthcare most of the implemented use cases are in the field of surgery [10]. For example, anatomic information can be visualized during surgery without interrupting the procedure [9].

Nursing AR research focuses on implementing and evaluating prototypes. For example the implementation and evaluation of a system for hands-free image capture [8] or a system for organizing tasks and monitoring vital signs [11]. These and other studies focus on specific applications without considering the future perspective and ethical aspects. To our knowledge no research on AR in nursing in general exists.

As part of this project, the possibilities and limitations of AR in nursing will be examined. This paper presents a framework for realizing a TA. TAs take intended and unintended consequences of technology into account [12]. One of the challenges of realizing a TA with the aim of influencing technology development is to find the right starting point. If you start the TA in the early stage of an emerging technology, the shape of the technology is very unspecific. In contrast, a TA on a completed technology offers no influence on the technology. The challenge to find the right time to start the assessment is called the Collingridge dilemma [12; 13]. Whereas von Gleich claims that this should not be a problem, he argues that it is most important to find a good way to deal with the lack of information [14]. One way to deal with this lack of information is the usage of appropriate methods.

For conducting a TA, multiple methods may be appropriate. As an example, Grunwald describes two ways just to get prospective results. One way is the exploration of trends and the other is the model based simulation [12]. Djanatliev and German describe a model based simulation supporting prospective healthcare decision making by using an agent-based simulation [15]. Exploration of trends as well as model based simulation rely on available data and allow a quantitative perspective on future trends. For the case of AR in nursing, only prototypes and short-term data exist [16]. Using applications in real life is necessary to produce data, which can be used in model based simulations. Therefore these methods cannot be used.
In contrast, the construction of scenarios allows for the exploration of ethical concerns without the need of previous data. Furthermore, with this approach certain patterns of moral argumentation about new and emerging technology may be included, which are missed in other types of TAs. These aspects are called ethics of new & emerging science and technology (NEST-ethics) [17]. In addition, there is a mutual change of technology and society [18], which Boenink et al. includes in their framework of techno-ethical scenarios [19]. This framework will be described later on.

In the construction of scenarios, one challenge is to assess the plausibility of the technological change. To address this issue Lucivero constructed a plausibility assessment [20]. The single step of the plausibility assessment are described in the construction of our framework. First, exploratory results for the construction of the framework were figured out in workshops. Based on these workshops, we designed a framework for a TA for AR in nursing to address the wide range of possible consequences of using TA in nursing.

Parts of the framework are techno-moral scenarios. The advantage of scenarios is the possibility to take morality change into account [19]. In combination with a plausibility assessment and a participatory approach, these scenarios serve as starting points for future research.

The paper contains four sections: Section one describes the design and the results of the workshops. Section two presents the framework for a TA of AR in nursing. Section three discusses limitations and possible next steps. Finally, section four summarizes the results.

Methods

As shown, many approaches for TAs already exist. All these approaches take different aspects into account. In order to get insights to which kind of TA is needed for AR in nursing, three workshops were designed. As part of the workshops, use cases for AR in nursing were developed. Designing use cases allows us to estimate expectations according to the usage of AR in nursing.

As an introduction to a diversity of perspectives, the workshops had different participants, scientists (workshop I) and practical partners (workshop II and workshop III). All three workshops started with the explanation of AR. The participants and the use cases are described in detail in the following sections.

Workshop I - Scientific Approach

Workshop participants included researchers in the field of nursing and related scientists skilled in nursing practice (n=8). The first part of this workshop was designing a nursing process landscape. The second part discussed use cases in the context of the most relevant nursing processes.

The researchers discussed the characteristics and special aspects of nursing, and confirmed the results of the literature review. They emphasized communication, emotional, physical contact, and priorities of nursing being dependent on the setting. In addition, they identified ethical aspects and privacy concerns as possible obstacles to AR in nursing. Furthermore, hygiene was identified to be an important aspect to take into account when developing an AR application.

Wound care management, food and liquid management as well as drug management were identified as processes with the highest potential for AR in nursing. Furthermore, a possible reminder function was seen as an advantage. In addition, the possibility of getting legal security was questioned.

Possible use cases of AR in wound care management and drug management will be described later on, as they were part of the other workshops as well. For food and liquid management, AR systems should take into account special diets, give advice if a patient has some intolerance, and measure how much has already been eaten and drunk.

Workshop II and III – Practical Approach

The participants of workshop II (n=7) and III (n=5) had a variety of different backgrounds in the field of nursing (nursing director, IT specialist in a nursing home and operative nurses), IT, and science. The nurses’ workplaces involved a nursing home as well as an ambulatory care unit.

In the two workshops of the practical approach, use cases were designed based on the experiences of the participants as well as on advice of the IT experts.

The workshops identified potential processes where AR could offer support. Processes included documentation, contact with experts, physicians and patients’ relatives, drug management, handover for the next shift, wound care management, inclusion of new residents, training new employees, reminder function, medical prescriptions, knowledge transfer and care sequences. We further describe the use cases, shift handover, wound care management, and drug management.

Supporting the process of the shift handover is especially relevant for nurses working in ambulatory care units. There is no personal handover as nurses from different shifts do not meet on a daily basis.

Currently, the nurses write down relevant information for the next shift into a book, which does not belong to the regular documentation system. This book should be replaced by a tablet. In addition, the important information should be readable on smart glasses. One of the advantages of this application is the organization of the entries. It should be possible to view entries of one specific shift as well as entries according to one patient. In addition, it should be possible to search within the entries. Furthermore, the tablet offers the possibility of a speech-to-text transcription and of taking pictures. The application on the glasses should allow observing relevant information in the field of view. Which entries are relevant has to be marked at the time of making the entry. Another feature of the digitalized version for the handover should be the possibility of making entries, which are relevant in the future and appear as an entry for the relevant day.

For wound care management, the first documentation of the wound requires nurses to describe the reason for the wound, , the kind of wound, the location of the wound, additional actions, and information for other professionals regarding relevant patient data. In addition, the progression of the wound care has to be documented. Relevant aspects are length, width, depth, etc. In addition, it is necessary to take a picture of the wound. With the help of the wound management application it could be possible to take care of the patient and perform wound documentation at the same time.

Furthermore, possible features of an AR application for wound care management could be the serving of therapy proposals and the availability of these proposals at the time of care. In addition, depth and length of the wound should be calculated automatically and be compared to earlier documentation.
The third use case is drug management. AR could assist nurses in preparing drugs for every patient by showing a picture of the correct sample of medicine for every patient. In addition, the system could offer information about where to find the relevant drug. It would no longer be necessary to change view for medication plans while searching for the drug because all relevant information could be provided directly.

Results

The described use cases are diverse. Applications like shift handover, wound care management, and drug management would be needed in specific situations. In contrast, applications to support the whole process of documentation as well as applications for reminder functions need to be used the whole working day.

To examine the relationship between type of application and consequences, a good assessment is needed. According to Halloran et al. ethical aspects will be expressed as soon as stakeholders are working with prototypes and models [21]. According to the wide range of possible applications for AR in nursing using prototypes and models to assess all of them does not seem to be reasonable. As a result this approach is not preferred here.

However, ethical aspects are important for integrating AR in nursing, especially because of the special features of this field, and were explicitly mentioned in workshop I but were not discussed further. In addition, the workshops showed how difficult an imagination of AR technologies can be.

In order to take ethical aspects into account, a framework for a TA to AR in nursing was designed. As the research on AR in nursing is just in its beginnings and no data according to usage of AR in nursing is known, it is necessary to start the research with a prospective method. To shape the future development of the technology it is necessary to conduct a TA in an early stage of the process.

1) Will expected artifact promote expected values?
2) Are promised values desirable?
3) How likely will the technology bring the desirable consequence?

Figure 1 -Framework for a TA to AR in nursing

This framework is a consolidation of three approaches. These are the framework for constructing techno-moral scenarios [19], the plausibility assessment [20] and a participatory approach [12]. Whereas Boenink et al.[19] describe the approach to design techno-moral scenarios in three steps, we integrated a plausibility assessment into the second step and claimed that the development of the scenarios should take place in participatory workshops.

Techno-Moral Scenarios

As previously noted, TAs often miss ethical aspects. One method to address ethical aspects in an emerging technology are scenarios [22; 23]. As a prospective method, using scenarios allows addressing ethical aspects at an early stage of the development.

To assess ethical aspects of a nascent technology, techno-ethical scenarios are a useful tool because they allow the inclusion of morality change into the considerations [20; 22]. Scenarios can lead to a more reflexive co-evolutionary process and create openings for responsible innovation [22]. Furthermore, scenarios allow reflection on long-term-changes. This is important because “morality normally evolves on the long term” [19].

Boenink et al. describe a framework for developing techno-moral scenarios [19]. Their special focus is on the interaction between technology and morality. In contrast to other scenarios and ethical TAs, their framework takes this interaction into account [19]. The framework consists of three steps. Firstly, the current moral landscape is identified. Secondly, the technological development and its potential interaction with the moral landscape are introduced. Thirdly, a preliminary closure of the controversies based on a historical and sociological analysis is constructed. According to requirements and to evolve the scenarios further step two and three can be repeated [19].

The scenarios describe possible usages of AR in nursing. One possible controversy, which was discussed in the conducted workshops, is the usage of AR in direct contact with the patient. Whereas AR may have the highest usage in this situation, in the current moral landscape the privacy of the patient would have to be protected and AR cannot be used to its full potential. To close this controversy technological developments, which allow data protection or a change of the value of privacy, has to be considered.

Plausibility Assessment

Detailed research is recommended for the construction of scenarios to be able to design plausible scenarios [20; 22]. In addition to the plausibility Rip and Te Kulve consider an informed moderator to be important for being able to intervene in the discussion and offer reasonable arguments [22]. In contrast, Lucivero focuses on plausibility and designed a plausibility assessment. Lucivero argues that following the plausibility assessment allows a grounded construction of scenarios [20]. Scenarios are controlled or grounded through empirical research, they also have a speculative aspect as they explore a potential future in order to trigger imagination [20].

The plausibility assessment consists of three steps. According to Lucivero these steps can be summarized in the following questions:

“How likely is it that the expected artifact will promote the expected values?”

To what extend are the promised values desirable for society?

How likely is it that a technology will instrumentally bring about a desirable consequence?” [20]

To answer these questions, relevant data has to be collected. The methods of collecting data in this case are described later on. As one important point Lucivero recommends to describe the technology in detail to reject implausible scenarios and describe two possibilities where appropriate [20].

Participatory Approach

Defining the development of a scenario includes a description of the data resources [24]. In this case, the scenario should be
developed during a workshop. For the preparation of the workshop results from the earlier workshops can be used. Based on these workshops in combination with the literature an overview about the current moral landscape will be handed to the participants. The first step of the workshop is to develop a technological application and potential interaction with it.

To yield ideal results, a participatory approach is used. Nursing IT experts, nursing scientists, ethical experts, elderly people/patients, relatives, nurses and nursing directors shall have the necessary experience for this assessment. In this stage ethical controversies can be detected and discussed. Possible closures have to be included. If AR is able to promote expected values, if these values are desirable, and how likely the technology will bring the desired consequence needs to be discussed when the last controversies could be solved.

The design of scenarios in workshops is a participatory approach which allows the inclusion of stakeholders in the process. For responsible innovation this approach is recommended [25]. Furthermore, a participatory approach is recommended for requirements engineering in general [26].

**Discussion**

This paper presents a framework for a TA in nursing with the goal of assessing intended and unintended consequences of using AR in nursing. In contrast to existing approaches to ethical aspects in software engineering, this framework shall consider changes in morality and take the plausibility of technological developments into account.

Our empirical results show the necessity of conducting a TA for using AR in nursing. One of the main results was the diversity of imaginable use cases. The early stage of the considerations make it hard to examine ethical controversies. By using a participatory approach in the constructed framework we follow a widely approved method.

**Implications for Research and Practice**

Due to the growing possibilities of AR and the actual challenges in the field of nursing, the application of AR technologies in nursing seems to be reasonable. The constructed framework provides a starting point to assess intended and unintended consequences of using AR in nursing. The results can be used to shape AR technology in nursing and may serve as a starting point for further research.

The development of AR nursing applications is just in its beginnings. Conducting a TA with the described framework at an early stage of the process may influence the development of the technology positively. Constructed scenarios may be useful for everyone who wants to develop AR applications for the field of nursing. Furthermore, they may lead to interesting results for continued development of AR in other areas.

**Directions for Future Research**

As a next step the framework has to be implemented and evaluated. An improvement of the framework as well as an examination of ethical controversies shall be the result. Furthermore, this framework may be used to evaluate AR applications in other fields and with other emerging technologies.

The framework has no specific elements for the domain of augmented reality or nursing. Other researchers can therefore adapt and use it for any software development if the development of the software is in an early stage and the field of application has a high ethical relevance.

**Limitations**

As the conducted workshops were not evaluated systematically, the presented results have limited impact. Furthermore, due to the small number of participants in the workshops generalization may be limited. Nevertheless, the presented workshops are a first exploratory approach to get knowledge about the complex field of nursing and AR. As nursing and technology follow different logics, the usage of technology may influence the work of nurses negatively [2]. Hülken-Giesler considers objective information as an obstacle to perceive subjective recognized data which is claimed to be very important to take the specific situation of the patient into account [27]. Whereas this aspect was not directly mentioned in the empirical setting, it was pointed out from the participants with describing communication, emotionality and physical contact as important aspects of nursing. The unspoken question was if technology can support nursing in these aspects.

Furthermore, the proposed TA may require additional methodological steps in order to be applicable to AR that has undergone further development beyond the early stages. This method may be the construction of vignettes based on the scenarios. In contrast to scenarios, vignettes describe not a story but a picture of one possible situation. Vignettes may enhance the discussion about a wide range of ethical concerns. They are more useful if the usage of the technology is already more defined [20]. The vignettes could again be discussed in workshops. The additional usage of vignettes would meet the statement of the Association of German Engineers that a good TA consists of different methods which are used together [28].

**Conclusions**

The conducted workshops show a need for TA of AR in nursing. The complex topic addresses the need of a framework for a TA which has to take different aspects into account. These are the techno-moral development, the plausibility of expected advantages and disadvantages and the participation of stakeholders. As a next step the TA framework should be evaluated.

Design a Learning-Oriented Fall Event Reporting System Based on Kirkpatrick Model

Sicheng Zhou, Hong Kang, Yang Gong

School of Biomedical Informatics, The University of Texas Health Science Center, Houston, Texas, USA

Abstract

Patient fall has been a severe problem in healthcare facilities around the world due to its prevalence and cost. Routine fall prevention training programs are not as effective as expected. Using event reporting systems is the trend for reducing patient safety events such as falls, although some limitations of the systems exist at current stage. We summarized these limitations through literature review, and developed an improved web-based fall event reporting system. The Kirkpatrick model, widely used in the business area for training program evaluation, has been integrated during the design of our system. Different from traditional event reporting systems that only collect and store the reports, our system automatically annotates and analyzes the reported events, and provides users with timely knowledge support specific to the reported event. The paper illustrates the design of our system and how its features are intended to reduce patient falls by learning from previous errors.

Keywords: Incidental Findings; Accidental Falls; Patient Safety

Introduction

Patient fall has been a prevalent and significant problem in healthcare facilities across the world. The fall rate in acute-care hospitals is between 1.3 and 8.9, mainly ranging from 3-5 per 1,000 occupied bed days [1]. Fall risks are pervasive that not only elderly people are vulnerable to falls, but any patient can be at risk for falls due to medical conditions or procedures, such as taking various types of medications, surgeries, or diagnostic tests that can make the patients weak or unstable [2]. A fall with injury adds in average 6.3 days to the hospital stay and costs around $14,000, which is a huge waste of time and money for both patients and healthcare facilities [3; 4].

To improve this situation, a variety of toolkits for fall prevention have been developed by major agencies and institutes, such as the Agency for Healthcare Research and Quality (AHRQ), Institute for Healthcare Improvement (IHI), Emergency Care Research Institute (ECRI), European Innovation Partnership on Active and Healthy Ageing (EIP-AHA), Institute for Clinical Systems Improvement (ICSI), the Joint Commission, and VA National Center for Patient Safety [2]. Even though these comprehensive toolkits provide systematic introductions and guidelines for building fall prevention programs, a huge gap between these guidelines and practice still exists. First, the actionable solutions are not always applicable and indicative to the conditions where they should apply. This is especially true for less experienced staff. Second, evaluation strategies are inadequately introduced in these toolkits. Third, the compliance over time as directed in the toolkits may gradually reduce. Reinforcement for learning may compete with other clinical priorities and staff often have difficulties in recalling toolkit contents. Efforts have been made on the fall prevention training programs, yet the expected outcome for reducing patient fall rate remains difficult to achieve[2]. Hereby, how to execute, supervise, and evaluate the fall prevention program in the healthcare settings becomes a major challenge in the patient safety community.

In 1999, the Institute of Medicine’s seminal report, To Err is Human [5] specifically recommended to establish the event reporting systems within healthcare organizations. Although numerous event reporting systems have been developed since the IOM’s report, most of the systems just function as a primary data repository of the reported events. The evidence is very limited to show that event reporting can improve patient safety, and how much influence it can make remains unclear[6]. Nonetheless, learning from errors is still an intuitive way to avoid the recurrence of errors. The reason is that root cause analysis (RCA) can be carried out only when an occurrence of safety event has been reported in details, based on which further actions of improvement will become possible. The event reporting system has great potential to manage the fall cases and provide training for clinicians in long term. Studies on event reporting systems have been limited and fragmented. Most of them were based on the qualitative studies[7-9]. Thus, it has been vague regarding how to build an effective event reporting system and to overcome the technical barriers, the informatics research questions for researchers to explore. The barriers identified are worth an extensive discussion so that timely knowledge support and reporting motivation could be enhanced. In addition, it has been unclear in terms of effective long-term evaluation strategies based on the event reporting systems, triggering the uncertainty about the real effect of the systems. To mitigate or toward removing these issues, the goal of our project is to design a set of learning-oriented and user-centered features to enhance reporting motivation and introduced the Kirkpatrick model into our system toward effective long-term evaluation.

The Kirkpatrick Model

The Kirkpatrick model, is frequently used for training and performance evaluation in various areas, such as business companies, universities and government agencies [11]. It is...
reported that the Kirkpatrick model provides the technique for appraisal of the evidence for any reported training program and could be used to evaluate whether a training program meets the expected outcomes of both organizations and the staff [12]. Figure 1 explains an overall structure of the model. Basically, it has four levels, and each level addresses the sub-goals that are necessary to achieve. The four levels will be explained in following sessions in conjunction with the designed features of our system. The model presents the training program in a way that enables the participants not only to learn what they need to know but also to react favorably to the program [13]. No matter in the business area or in the healthcare setting, the training activities have commonality regarding their core challenge, which is how to reach the expected outcomes through improving the staff’s learning effect and application of what they have learned in daily work. Thus, in our case, the model has great potential to improve the patient safety event reporting and prevention systems.

The paper summarizes current barriers of event reporting systems, and describes how the Kirkpatrick model serves as a framework in developing a learning-oriented fall event reporting system. Important features including how the system provides instant and specific feedback to the clinicians and builds a reporting and shared-learning culture in healthcare facilities are introduced. The system holds promise in overcoming current barriers of event reporting systems and improving patient safety.

Methods

Identifying barriers of patient safety event reports in healthcare literature

Seven MeSH terms including ‘incident’, ‘reporting’, ‘system’, ‘feedback’, ‘patient safety’, ‘barrier’ and ‘challenge’ were identified and used to search in the PubMed database with Boolean algebra. Papers published prior to 2004, and not discussing the barriers or challenges of patient safety event reporting systems were excluded. The challenges, barriers and defects of current event reporting systems mentioned in the selected papers were extracted, classified and summarized by two reviewers separately. Then the discrepancies were solved by group discussion, the final results are shown in Table 1.

Building a knowledge base for reporting system

A key component in developing the system is a knowledge base that can provide timely knowledge support to clinicians. The knowledge base contains solutions and classic fall cases. Solutions were extracted and summarized from the patient falls prevention guidelines published by authoritative institutes, including AHRQ, Joint Committee, VA National Center for Patient Safety, Pennsylvania Patient Safety Authority, IHI, EIP-AHA, ICSI and ECRI [2]. Classic fall cases with experts’ comments were extracted from AHRQ WebM&M [14], an authoritative peer-reviewed online journal and forum related to patient safety that provides expert analysis of all kinds anonymously reported medical errors cases. The extracted contents were reviewed and modified by domain experts in a Patient Safety Organization (PSO) institute [15].

Applying the Kirkpatrick model in system design

As shown in Figure 1, the model has four levels: reaction, learning, behavior and results. Each level has its own goals that guide the event reporting system design. We designed a set of learning-oriented and user-centered features for the reporting system that aim to achieve all the goals in each level. The developed features will be elaborated in results.

Developing the structure of the fall event reporting system

Our web-based reporting system is mainly comprised of four modules: 1) Data collection module. The AHRQ Common Formats [16] is used as the template for event reporting. 2) A knowledge base used for providing feedback to the users. 3) Data repository module that stores the reported cases. 4) Data analysis module, a key for RCA and long-term evaluation of the outcomes.

Results

Current barriers of patient safety event reporting systems

Eight literature regarding the barriers, challenges and benefits for the patient safety event reporting systems were identified and reviewed. The main barriers of current reporting systems and their occurring frequencies in the literature are summarized in Table 1. All the findings are based on the qualitative studies among front-line staff in healthcare facilities. The barriers can be roughly divided into three types. First and the most important type is that the reporters’ doubt about whether the reporting systems can improve patient safety in real practice. Typical examples include “lack of effective feedback” and “no follow up”, which indicate the issue and status usefulness. The second type of barrier is the designing flaws of the systems, such as “poorly designed reporting form”, “lack of necessary fields in the system”, which make reporters feel unsatisfactory during reporting processes. The third is that cultural factors or working atmospheres in many healthcare facilities do not encourage event reporting. It can be caused by the heavy workload or concerns of taking additional responsibilities. These barriers, all together, negatively impact the utilization and expected outcomes of the reporting systems. Thus, an enhancement in design and implementation of the systems is urgently needed.

Growing a knowledge base for the event reporting system

The knowledge base developed in the system by far has a collection of 137 specific solutions, 45 general solutions, and 29 classic cases for fall prevention. The specific solutions are provided to users when reported events matching the categories of Common Formats. General solutions are provided to reporters as general principles and basic learning materials regardless of the event categories. In addition, classic fall cases with experts’ comments from WebM&M are provided as supplementary leaning materials for reporters.

Overall design of the reporting system based on Kirkpatrick model

To overcome the barriers of patient safety event reporting systems and evaluate the effect, our system has integrated the following features in correspondence to every level of the Kirkpatrick model.
Level 1: Reaction

Reaction is defined as the degree to which participants react favorably to the learning event [10]. Whether a training program is favorable and engaging is mainly based on to what degree the staff like the training program and are actively involved with the learning experience. Relevance measures whether the participants will have the opportunity to use or apply what they have learned in training on the job [10]. How the system can be favorable, engaging and relevant were carefully considered during the design of the system. We put the concept of user-centered design into first place, which means what users may need and want from the system were always prioritized in all the design processes. Users may use the product as intended and with minimum effort to learn how to use it. The targeted users, including nurses and staff from our institute and our collaborative PSO were involved in the design, gave us suggestions about what functions they feel necessary for event reporting based on their experience. It is fundamental to address visibility and accessibility in the design which require the elements of the system to be visible and easy for users to determine the potential actions and to evaluate the current status of the system [23]. In the web page design, we adopted a straightforward style with a concise menu and navigation bar to each function and module. A text prediction function was added to facilitate users’ text entry and searching in the system. For reporting fall cases, a logic branching was implemented based on the Common Formats [16] to guarantee the completeness of the reports and prevent irrelevant sub-questions. The thirteen multiple-choice questions make the reporting much easier for reporters to understand what is expected in a report. To collect new pieces of knowledge beyond the pre-defined options, feedback boxes were also provided at the end of each question. In summary, all these features were designed to increase the engagement and satisfaction of reporters.

Relevance determines ultimate training value since even the best training could be a waste of resources if the participants fail to practice in their everyday work [10]. To ensure the supported knowledge is useful and practical, the knowledge base of our system was established on evidence-based solutions. We matched the actionable solutions to according question options in the Common Formats. Once a reporter chooses a certain option, the corresponding solutions to this option will be provided, which makes the provided knowledge support highly relevant to the reported cases. For example, if a knowledge reporter chose “No” for the question asks if fall risk knowledge and skills, and thus repeatedly and costly trainings were required. In fact, it is highly possible that the poor performance is due to a lack of motivation or other environmental factors in reality. In order to achieve the goals in the learning level, our system provides authoritative and relevant solutions from the knowledge base to the reporters. The solutions are targeted and practical since they are provided according to the specific reported event as previously mentioned. This mechanism also solves the most common barrier for current event reporting system, which is lack of effective feedback. The ultimate goal of our system was to make the learning become a continuous process as part of the workflow in healthcare facilities. Traditional training, which often requires the staff to be involved away from their job, may not be as effective as it is supposed to be. About 70% of learning happens during the job [13]. Thus, the learning efficiency is estimated to be greatly improved since our system integrated the training into the healthcare providers’ daily work. Moreover, a similarity-searching module is under development and will be embedded into our system. Classic fall cases summarized in AHRQ WebM&M were annotated by PSNet topics [14] through text mining and integrated into the system. Once a new case is reported, it will be automatically annotated by PSNet topics. Then the system will provide the reporter with previous cases that have similar annotations and their associated solutions, which may help reporters learn more about how to deal with similar situations. The similarity-searching module will also facilitate to build a “shared learning” atmosphere where the reporters can learn from each other based on the accumulation of reported cases.

Level 3: Behavior

This level focuses on monitoring and evaluating whether and how much the participants apply what they have learned after they return to work [10]. This stage aims to fill the gap between knowledge and practice. It overlaps with the learning level, since the improvement of attitude, confidence and commitment can directly increase the consistency between what staff has learned and their behaviors at their routine job. Identifying and critical behaviors of staff are addressed in this stage. Critical behaviors are the few and specific actions that will have the significant impact on the desired results if performed consistently during the job [10]. In our research, the critical behaviors can be regarded as the most important actions that can reduce the occurrence of patient safety events. In order to highlight the critical behaviors, the solutions in our system are not provided randomly. Instead, they have inherent priorities based on several factors. The most important is the contributing factors, once a case is reported, the system will label the contributing factors to the case. The solutions related to similar contributing factors will be prioritized. Moreover, the solutions from authoritative organizations will be arranged on top of the list. We also categorized all solutions into three subtypes: principle solutions, specific actions for staff, and specific actions for patients. In general, the principle solutions are listed first, followed by the specific actions. Thus, the solutions provided to the reporters are supposed to be the most helpful and actionable ones based on the reporting case. This strategy is expected to maximize the transformation from knowledge to real actions and the efficacy of the final actions.

Monitoring is to ensure the right actions are executed. Direct monitoring is hard to be accomplished without human labors, thus, a specialized group with an elected leader should be set up. The responsibilities of the group are inspecting the omissions and mistakes made by the healthcare providers, and building the rewards mechanism to make sure the learning knowledge has been applied. Patient interview is also an effective method since patients have the intuitive sense about
whether they have been protected from patient safety events. On the other hand, indirect monitoring can be done by the system through supervising and analyzing the reporting history and results. Each reporter should have an independent account under which the behavior of reporters can be analyzed based on a long-term reporting history. More discussion is available in the Results level. The aim of monitoring is to improve the performance of users through identifying their mistakes, increasing the reporting quality, and facilitating users apply what they learned during work rather than punishing the users or their colleagues when they make mistakes.

**Level 4: Results**

Results are defined as to what degree the targeted outcomes occur as a result of learning from events and subsequent reinforcement [13]. Measuring the results simply by counting the number of the reported cases can be an initial step. Ultimately, an overall evaluation is needed to determine the change of outcomes, i.e. patient fall rate, is due to the application of event reporting system. The Targeted Solutions Tool (TST)® [2], developed by Joint Committee Center for Transforming Healthcare contains features in fall events analysis and strategic planning. Through TST, the accumulated fall cases will be analyzed to create a summary, including top contributing factors for fall cases, primary causes, injury levels, fall locations, etc. And different presentation forms like tables, pie chart, and column chart are given to enhance the clarity and explicitness of the summary.

**Figure 2 – System features and corresponding aims within four levels of the Kirkpatrick model**

To integrate event reporting with TST analysis, a similar module has been designed in our reporting system. The module will track and analyze the rates of all solutions offered as feedback to reporters. An obviously declining frequency of a certain solution over time may indicate that this solution is well executed; otherwise, the solution may need special attention or modification. Then, a connection between the rate of events and rates of provided solutions is expected to be established. By such a design, the influence of our event reporting system can be quantitatively measured. The limitation of this method is that the evaluation can be processed only when the tracking records reach a sufficient amount. Nevertheless, the data will increase significantly as processed only when the tracking records reach a sufficient limitation of this method is that the evaluation can be established. By such a design, the influence of our event module has been designed in our reporting system. The interactions between the system and users will form a loop of “reporting, feedback, improving and evaluation”. Both the system and users will keep learning from each other and improving themselves.

**Discussion**

Patient fall events in healthcare settings have been a major concern for years. Applications such as guidelines, training programs, and solution kits have been developed to tackle down this problem, but the effects of these applications are still far away from the expectations. The main problems reside in the low training quality for healthcare providers and the lack of consistency between guidelines and practices in daily work.

In order to improve this situation, we have designed and been developing an enhanced patient fall event reporting system with timely knowledge support based on the Kirkpatrick model. The Kirkpatrick model is applicable in healthcare areas since all the trainings have common features needing to be addressed. A successful training should fulfill at least two conditions: the training should teach the right contents; and the training should set mechanisms to ensure people correctly apply what they learned in real work. The Kirkpatrick model is well suited in accomplishing these conditions with the help of the four highly integrated stages defined by the model.

Following the principles from all stages of the model, the design of the knowledge-based reporting system would support basic conditions and maximize the training effect through three key aspects: 1) ensuring the contents in the knowledge base are correct and relevant to fall prevention practice; 2) fostering the positive attitudes among staff, making them confident and willing to apply what they have learned; 3) monitoring and analyzing the outcomes such as the behavior changing of the users, to improve the knowledge base.
Our event reporting system was designed for the prevention of patient fall, but not limited to it. The design framework can be generalized to other types of patient safety events in healthcare facilities. The core idea is to provide a user-friendly platform to facilitate clinicians to timely report the patient safety events and integrate the process of learning from errors into their daily workflow. The whole design framework of the event reporting system was abstracted in Figure 3. Overall, reporting is merely an initial step toward shared learning. The four levels are interlocked with each other. The first two levels aim to make the system easy to use, and let users learn what they need. They are the foundations for the remaining two levels, which aim to facilitate and monitor the behavior change of users and measure the final outcomes. The improved outcomes, will in turn, encourage the reporting and learning. A virtuous cycle is expected to be established.

Future work will mainly focus on solving the limitations of our event reporting system at current stage. The limitations include: 1) It is difficult to keep updating the knowledge base without human labors over time. 2) Some advanced functions for data storage and analysis have not been fully built into the system yet. These functions are important for the RCA of patient falls but not limited to it. The design framework can be generalized to other types of patient safety events in healthcare facilities. The core idea is to provide a user-friendly platform to facilitate clinicians to timely report the patient safety events and integrate the process of learning from errors into their daily workflow. The whole design framework of the event reporting system was abstracted in Figure 3. Overall, reporting is merely an initial step toward shared learning. The four levels are interlocked with each other. 3) The experts of patient safety may have divergent views during the evaluation of our knowledge base. Further evaluation involving diverse expert groups has been planned. 5) The solutions in our knowledge base may not be applicable to all healthcare facilities, since the facilities may have different scales, financial budgets, and types of patients, etc. We plan to set individual accounts for different users to grow a personalized knowledge base. This mechanism could encourage the reporters to interact with the system instead of passively accepting the learning materials, thus both staff and the system are always in the “personalized” learning process. Also, the usability and field tests are necessary, which let target users to use the system to figure out potential problems and evaluate the system’s effects on them.

Conclusion

The functions and designed features of our fall event reporting system satisfy the needs of fall management and healthcare staff training. The integration of the Kirkpatrick model makes the system promising to fix the gap between knowledge and practice, thus can better improve the severe fall situations in healthcare organizations. In the future, we will continue improving our system to overcome the current inadequacy and limitations.

Abstract

Enablement, guidance, and proactive preparation for a new IT system implementation has proven to be a smart way to prepare people to embrace change. These activities are closely related to change management approaches which seek to help people understand and adopt specific behaviors. That being said, investing in such activities becomes the cornerstone of the success of the project. Leading IT companies around the world include in their strategy for new services and offering deployments, a proactive HelpDesk service. This not only helps build long lasting/trusted relationships between end users and IT sectors but also helps reduce cost and maximizes the Return of Investment. A streamlined process and easy to use/fluent communication channel between parties are powerful risk management/Quality Assurance and Continuous Improvement tools. In this paper, we address the example of a HelpDesk support team implementation of a city-scaled Electronic Health Records implementation.

Keywords

Health Information Systems; Workflow; Argentina

Introduction

HelpDesk support is key to set in motion a successful implementation of any IT system. Not only does it help with User Experience and Satisfaction it also helps with the Return of Investment (ROI) associated with the funds allocated to the IT system. A well-qualified HelpDesk would be not only fix technical issues, but would also ensure root causes are tackled accordingly and prevented from reoccurring in the future. HelpDesk employees perform these tasks working side by side with developers. An IT system implementation is not just a junction of applications. There is consensus among the private and public sectors a successful implementation depends on organizational factors [1,2], including the ability to answer to the needs of users directly or indirectly involved in the implementation process.

An information system attempts to accurately reflect and streamline processes and, also, bring them to life as they are executed. The IT system is meant to prove it’s worth by adding value to the process, positively impacting the overall Organization [3-6]. Implementation reports and practices show there is a continuous life cycle adaptive evolution between work processes and the applications of an information system, requiring appropriate change management in the first as well as the establishment of continuous improvement cycles [2, 7]. In this context, Helpdesk implementations - understood as a tool leveraged to support the operational line - is part of the Organizational Strategy. A Helpdesk combines technologic and human resources, providing services to manage and solve incidents/scenarios and/or requirements related to Information and Communication Technologies (ICT). Clinical Information Systems (SCI) involve several ICTs as well as different types of users, who need adequate support and training to ensure the successful use of such systems [8].

In addition to the HelpDesk’s benefits to supporting the operational aspects through a fluid communication with the central-level and by contributing to increase user experience/satisfaction, HelpDesks also act as management tools. It allows management to gather feedback from end users regarding areas of improvement, recurrent scenarios, automation opportunities, etc. empowering management to to sort/label problems and allow through reporting, accurate and up-to-date information to be available for leadership’s smart decision making, both for corrective and preventive actions [9].

This paper’s objective is to describe a HelpDesk implementation process and its benefits to operational management and excellence applied to the primary care level of Buenos Aires’ public health system.

Design

This is a cross-sectional study. A secondary analysis of HelpDesk’s database was performed.

Setting

The Autonomous City of Buenos Aires (CABA) is Argentina’s capital city. According to the 2010’s national census, the population of the city is 2,890,151, and the population of its urban cluster/outskirts, locally named Greater Buenos Aires, is around 12,801,364 making Buenos Aires the largest urban area of the country and the second largest one from South America [10].

Health Care Network and Public Health System in CABA

Three sub-systems coexist in Argentina’s Health System. In addition to the Public sub-system, there is health care coverage derived from Social Security, which assists the population with formal jobs and, lastly, private health coverage, funded with contributions from its users. The public health sub-system is funded by the government (i.e., local, provincial or national) and provides health care for free to the population. The CABA health network has 33 Hospitals, 44 primary and community health centers (CeSAC) and neighborhood medical centers which are divided into four regions. Each health region is subdivided into areas which include a general hospital and the local CeSAC. The CeSACs are part of the city’s primary health care network (APS), which provides services to approximately 500,000 medical queries per year, 50% of them correspond to...
the pediatricians’ specialty and the other half are carried out by primary care physicians and OBGYNs. In addition, CeSAC provides services to approximately 260,000 non-medical specialization queries, including nutrition, social work, psychology, obstetrics, and dentistry. Based on data from 2014, 17.8% of the population living within CABA receive assistance only from this system. This percentage rises to 31.2% in areas South of the City. The network also takes care of people residing in the outskirts of Buenos Aires metropolitan area and in other provinces, although to a lesser extent [11].

Implementation Process and Management

Fifty-two days passed from the first to the last link between CeSAC and the HelpDesk (4/21-6/13). The tickets were labeled based on: problems (Category) and priority (low, medium, high, and critical). Given some tickets could not be included within existing categories, HelpDesk managers had ownership of the generation of new categories, making them available for future similar scenarios.

Results

Until November 14th, the final cut-off date for this study, 1400 requests were made to the HelpDesk, coming from the 44 primary care centers of the City of Buenos Aires. The overall analysis of these orders is shown in Table 1, which lists the total number and percentage of tickets sorted by the main categories.

Table 1 – Generated Tickets to November 2016

<td>1.64%</td>
</tr>
</tbody>
</table>

Considering the context of progressive implementation, we also analyzed the qualitative difference in terms of ticket categories and the rate of ticket generation, adjusted by business days in the month. This analysis shows the fluctuation of the requests, motivating the ticket generation routed to the central level, quickly change. Regarding the labeling of the reported problems, in the first two months of implementation, the root cause of tickets generated was related to legacy issues (e.g., supply orders and maintenance issues), a trend that changed from the third month onwards to issues related to operational support of the actual implementations (Patient Indexing and electronic scheduling represent almost 40% of orders). Figure 1 illustrates the counts of the most used categories in the first 3 months compared to the 7th month.

As for the number of tickets generated per day, the value accounts for a mildly increasing trend during the initial months with a steep increase in September, keeping the increased rate until the cut-off date. This trend is best observed when adjusting the number of orders per working days of the month (Table 2), going from an average of 7-8 orders/day in August to 23 orders/day in November. This phenomenon correlates with computerized processes enabling remote support.

Discussion

As previously mentioned, a help desk has different capabilities and purposes, depending on the kind of users under consideration within scope. Analyzed in the context of the present implementation, the HelpDesk is used as a change management tool. In addition to serving as a sensor of operational needs, the HelpDesk also becomes an indirect tool to satisfy, totally or partially, the most pressing needs of health centers.

From a management point of view, the central level represented by the Ministry could quickly diagnosis the needs in the first level of care. This led to operational decisions aimed at formalizing the processes to resolve these problems, outlining specific responsibilities where applicable, and establishing supervision over external third party vendors (i.e. outsourced). With regards to historical problems, most were reported in the first few months; action was triggered by the central level focusing on their resolution, especially on maintenance issues, which were addressed mostly through regular follow-up meetings with the office accountable for the third parties’ supervision. We then proceeded to standardize response times for the most frequently incoming tickets (i.e., supply chain and basic maintenance issues), which allowed the generation of continuous improvement cycles of issue resolution quality assurance processes.

In alignment with the progress of the overall implementation, the HelpDesk also becomes the channel for reporting errors that require corrective actions as well as suggestions for procedural or computer improvements as a result of user empowerment.
The present work has several limitations. Because of being a cross-sectional study, the results should be interpreted as being potentially impacted by factors not being considered within the scope of this study. On the other hand, although all the CeSACs have the HelpDesk implemented, half of them have not implemented HCE applications and electronic scheduling. The mentioned scope corresponds to the 2017 agenda. Finally, the user satisfaction was not measured with a qualitative methodology. This could have enriched the work presented in this paper.

Conclusion

As the Health Informatics Project for Buenos Aires City advances, we conclude that the HelpDesk is a valuable tool, not only for management, but also for change facilitators. Results in our study will be used to plan further implementations as we move forward throughout different settings.

Abstract

We report on a study of our custom Hootation software for the purposes of assessing its ability to produce clear and accurate natural language phrases from axioms embedded in three biomedical ontologies. Using multiple domain experts and three discrete rating scales, we evaluated the tool on clarity of the natural language produced, fidelity of the natural language produced from the ontology to the axiom, and the fidelity of the domain knowledge represented by the axioms. Results show that Hootation provided relatively clear natural language equivalents for a select set of OWL axioms, although the clarity of statements hinges on the accuracy and representation of axioms in the ontology.

Keywords:
Natural Language Processing; Biomedical Ontologies; Knowledge Management

Introduction

Ontologies are artifacts of encoded knowledge that represent pieces of information in a subject > predicate > object format (e.g., HPV virus > increases risk for > cervical cancer) known as triples. Ontologies aim to represent a defined domain space using interlinked triples, harnessed by machines for further processing or machine intelligence tasks. For ontologies to be machine-readable, special syntax is utilized to encode the interlinked triples. For example, the Web Ontology Language (OWL)1, or Resource Description Language (RDF)2 / Terse RDF Triple Language (Turtle)3 are commonly used to encode the interlinked triples.

As a data-source, ontologies are not immune to errors or inconsistencies. Reasons for the errors and inconsistencies are beyond the discussion of this paper, but the importance of this area of ontology work has been highlighted recently in [1] and [2]. Additionally, most biomedical ontologies on the National Center for Biomedical Ontologies (NCBO) Bioportal do not report any evidence of any evaluation [3].

Background

Evaluation frameworks are invaluable to knowledge engineers constructing or refining an ontology, and when assessing if a given ontology is fit for use. According to Gómez-Pérez, ontology evaluation falls under two categories: validation and verification [4]. Validation examines the purposeful, extrinsic aspect of the ontology while verification examines the internal aspects (e.g., the quality of terms, graphical structure, etc.).

Evaluation of ontologies typically involves assessment along three axes: Syntax, Semantics, Pragmatics. Both qualitative [5-7] and quantitative [8] assessment of the three axes are possible [9]; a common approach is to enlist subject matter experts to review the ontology artifact. Our focus is on the veracity of ontologies, which we ascribe as a verification-based evaluation. We presume that Subject Matter Experts (SMEs) are integral to the quality of the ontology during development phases. However, for an SME to review and assess an ontology, specifically those with little to no knowledge engineering background, we need to present it in a format that is accessible.

Among the challenges when engaging subject matter experts is the substantial learning curve to help these experts interpret the knowledge representation in the ontology [10, 11], and their lack of familiarity with ontology construction and visualization tools such as those in the commonly used ontology editor Protégé. This is unfortunate as many experts could provide significant input in improving the quality of the ontology. One possible solution is to translate the knowledge in the ontology to human-readable natural language statements. Below, we discuss details of our approach.

We propose that expressing an ontology in natural language is likely to provide a more readily understandable approach to interpret the interlinked triples, and thereby provide a valuable resource when engaging domain experts in working with the ontology. The natural language sentences produced by the Hootation tool (described below) can be used to assess ontologies along all three axes. Syntax can be assessed by determining if statements constructed from the model and expressed in natural language are correct when compared to used cases and other artifacts of importance within the domain. Semantics can subsequently be assessed by determining if the definitions of labels expressed in the sentences convey an accurate and complete meaning in the context of their intended use, and if the classes, association, attributes and relationships in the sentences are understandable and relevant. Finally, close examination of the sentences produced can reveal pragmatic issues with the ontology such as formal completeness i.e., what may be missing from the ontology, and what cognitive effort on domain experts is needed in understanding the ontology. The latter is sometimes used as a proxy measure for consistency of the ontology.

“Hootation” Java Library

Related Studies

Natural Language Generation (NLG) is an expansive topic that has been the focus of considerable previous research. NLG is one of the two main topics of natural language processing – the other centers on natural language understanding (NLU), which is the focus of much biomedical
informatics research. While NLU centers on interpreting free text into data for machines to understand, NLG focuses on interpreting data from the machines into free text or documents for humans to understand. In the context of this study, the emphasis is on transforming triples from ontological models to natural language statements that would help evaluate the knowledge contained in biomedical ontologies. The merits of NLG applications for biomedical ontologies include question-answering, document creation and summarization from datasets, concealing the complexity of the syntax, and ontology evaluation.

An early work in this area was ModelExplorer [12] that generated lines of text from object-oriented models. Other relevant work for authoring and NLG applications involved the use of bi-directional Controlled Natural Language (CNL) for OWL 1.1 such as Attempto Controlled English (ACE) [13], Sydney OWL Syntax (SOS) [14], Rabbit [15] etc. However, CNL are compounded by the issues of NLU (ambiguity of text) and NLG (difficult to comprehend for users and limitations the label’s nomenclature). None of what has been described provides a dedicated OWL2-to-NL engine that is portable for application use. However, NaturalOWL employs a basic template approach, but it depends on a separate authoring tool for domain dependent generation [16; 17].

**Hootation**

Our Hootation software library is derived from the natural language generation work by Agile Knowledge Engineering and Semantic Web (AKSW) Research Group [18; 19] developed initially for a semantic web application. The NLG layer harnesses the OWL-API; as initially developed, it supported the translation of 12 logical axioms for OWL2. We added support for 6 additional logical axioms, with plans to add more translation for the remaining axioms. Hootation also utilizes SimpleNLG [20], a state of the art NLG engine that provides flexible APIs to manipulate morphological and syntactical aspects of a generated statement. SimpleNLG also allows the use of the NIH Specialist Lexicon [21] for expanded coverage for medical lexicon, which we have yet to exploit, but an added benefit for biomedical ontologies.

While many NLG applications focus on producing documents or other large bodies of text, an immediate goal is proper translation of each individual axiom to NL statements, so that biomedical experts can rate the veracity of the information and then report on the content quality of the ontology. We intend to integrate the Hootation API library into our continued work to provide a web-based tool for comprehensive ontology evaluation (see Future Direction section for details). Source code and a Java binary library will be available for open source distribution.

**Methods**

Our primary objective was to determine whether Hootation could accurately produce natural language from biomedical ontologies in a way that is understandable for subject matter experts. We also wanted to evaluate factors that contribute to or hinder the clarity of the natural language. Java code was developed to interface with the Hootation API library, and output for each of the ontologies was exported in CSV format including, for each natural language statement, the corresponding axiom in OWL Manchester format and the type of logical axiom.

**Sample**

Because most ontologies do not use every axiom type available by OWL, three ontologies were used to capture the NL translation for diverse axioms. The "People" Ontology represents knowledge on the types of people based mostly on familial information. The People ontology is a teaching tool for University of Texas Health Science Center students, used as an introduction to the development OWL-based ontologies and as an introduction to the descriptive logic power of OWL. This ontology is based on descriptive definitions from California Polytechnic State University, in San Luis Obispo, California [22]. The ontology used for this study contained 13 classes, 8 properties, 9 instances (90 total) and a variety of axiom types. This ontology was included because of the simple and universal nature of the encoded information as well as its utilization of various axiom types.

The “Informed Consent Ontology” (ICO) [23] is a preliminary ontology based on the analysis of informed consent templates and blank informed consent forms obtained from two separate Institutional Review Boards (IRB) at the University of Michigan. In its current iteration, ICO focuses on informed consent documents and processes. Consequently, the concepts represented by classes and relations in the work are in the context of informed consent documents, and recommendations for addressing concepts of risk, privacy, and other notions of precepts laid out in US Common Law and medical ethics. ICO is based on the Basic Formal Ontology (BFO) [24], represented in the Web Ontology Language (OWL2), was built on Open Biomedical Ontologies (OBO) Foundry principles [25], and inherits the classes, relations, and axioms from the Ontology of Biomedical Investigations (OBI)[26]. ICO contains 375 classes, including 163 ICO-specific classes and 86 properties. The ontology contains 677 axioms, however many of these axioms are inherited directly from the OBI framework, leaving 183 ICO-specific axioms that are studied in this paper.

The Time Event Ontology (TEO) is a derivative of the Clinical Narrative Temporal Relation Ontology (CNTRO) by the Ontology Research Group at the School of Biomedical Informatics (University of Texas Health Science Center) [27]. TEO contains entities and definitions relating to temporal information and their semantic relationships between them. Its intention is to “provide a formal conceptualization of temporal structures in both structured data and textual narratives” and “core semantic components for representing temporal events and relations to enable reasoning capacities in temporal relations.” TEO (version 1.7) contains 156 classes, 51 properties, 8 instances, and 1026 axioms. Similar to ICO, TEO is based on BFO.

**Evaluation Procedures**

For each ontology, two persons familiar with the logic of the ontology evaluated the NL expression along three dimensions. First, Clarity was scored from 1-3, where 1 indicates the natural language expression of the axiom is clear, unlikely to cause confusion or ambiguity, 2 indicates the natural language expression of the axiom is clear, but there may be ambiguity attributable to the axiom, and 3 indicates the natural language expression is not interpretable. NL Fidelity to Axiom, addressed whether the natural language expression demonstrated fidelity to the underlying axiom (i.e. logic was accurately expressed in the natural expression). If this dimension was scored as “yes”, the natural language expression is an accurate reflection of axiom; if “no”, the tool appears to have misinterpreted the logic. Axiom Fidelity to Domain, addressed the fidelity of the axiom itself to domain

---

4 https://goo.gl/sGkYIi
knowledge. Although an evaluation of the fidelity of the axiom to domain knowledge is an assessment of the ontology and not an evaluation of the expression generated by the Hootation tool, it addresses this dimension because both syntactic and semantic issues within the ontology itself sometimes confounded assessments of the clarity of the NL expression. A score of 1 indicated that the reviewer agrees with axiom, 2 that the reviewer disagrees or is uncertain about concepts or relationships in axiom, and 3 that the reviewer disagrees or is uncertain about concepts and relationships indicated by the axiom. Overall, familiarity with the ontology is important as it yields direct expertise of the intention and construction of the axioms, and adeptness in assessing the translation based on the three dimensions.

Evaluators used online, shareable spreadsheets to record their assessments of each dimension. The first three columns of the spreadsheet presented the axiom type (e.g., SubClassOf, EquivalentClasses), the axiom logic expressed in description logic notation, and the natural language expression generated by the Hootation tool (See Table 1). After reviewing the content of each row, each of the evaluators assigned to the specific ontology recorded their assessment of each of the three dimensions in separate columns. Reviewers were not blinded to each other’s assessments because the goal was informed critique and convergence on evaluations of each natural language expression. Disagreements were recorded if scoring decisions could not be reconciled between reviewers.

Table 1 - Sample output

<table>

<th>NL Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>SubClassOf</td>
<td>ICO_0000062C</td>
<td>every human subject unable to give informed consent is a human subject</td>
</tr>
</tbody>
</table>

In order to explore relationship when the NL statement may be clear but the axiom is incorrect, we utilized IBM SPSS (v23) to calculate Spearman’s rho correlation between the Clarity values and Axiom Fidelity to Domain knowledge values.

Results

Interrater agreement was calculated among the raters, and the overall agreement for the aforementioned metrics were 86% for Clarity, 91% for Fidelity to Natural Language, and 90% for Fidelity to Domain. For the People ontology, the agreement was 83% for Clarity and Fidelity of Natural Language to Axioms, and 98% for Axiom Fidelity to Domain. Likewise, for Time Event and Informed Consent the agreements were 82%, 96%, 88%; and 92%, 93%, 85%, respectively. Overall, there was high agreement with the results of the assessment. We caution that each ontology was independently assessed and consequently, the results do not yield normalized quality data of the underlying ontologies.

The data in Table 2 and Table 3 were aggregated and segmented to comprehensively evaluate the evaluators assessment of Hootation’s results.

Table 2 provides a summary of the overall averages for each of the assessment described earlier. Across the three ontologies, the People ontology demonstrated the best rating for Clarity and Fidelity to Domain knowledge; the Clarity metric rating was 1.19, and Axiom Fidelity to Domain was 1.01. The ICO ontology demonstrated the best NL Fidelity for the axioms (95%). For the Time Event ontology, the average assessment scores were 1.32 for Clarity, 92% for NL Fidelity to Axiom, and 1.13 Axiom Fidelity to Domain. The Informed Consent ontology average assessment scores were 1.28 for Clarity, 95% for NL Fidelity to Axiom, and 1.36 for Axiom Fidelity to Domain. Altogether, the three ontologies yielded an average Clarity of 1.26, 92% (yes) for NL Fidelity to Axiom, and 1.17 for Axiom Fidelity to Domain. The correlation between clarity and fidelity to domain knowledge reveals a positive, strong linear relationship that was statistically significant (r= 0.76, p<0.01).

Table 3 presents data segmented by 14 OWL axioms supported by Hootation. Because of space constraints, below we show only the two examples demonstrating the range of metrics observed related to axioms. See https://goo.gl/Br3qQU for full table. The majority of the axioms the types were SubClassOf, and others appearing in two or more ontologies were ClassAssertion, EquivalentClasses, ObjectPropertyDomain, ObjectPropertyRange, DataPropertyDomain, DomainPropertyRange, DisjointClasses, and SymmetricalObjectProperty. Five axiom types, FunctionalDataProperty, FunctionalObjectProperty, DataPropertyAssertion, DifferentIndividuals, and ObjectPropertyAssertion, only appeared in the People Ontology. Not all ontologies used every axiom types, and variations in Clarity, NL Fidelity to Axiom, and Axiom Fidelity to Domain are noted across axiom types. For example, across all three ontologies, more complex axiom types such as ObjectPropertyRange scored much worse on clarity than less complex axioms such as SubClassOf.

Discussion

The results of this study are encouraging with respect to NLG generation for use in ontology evaluation. Overall, Hootation appears to generate natural language statements with clarity, and fidelity to the axiom. Problems in clarity included the introduction of mid-level noun phrases that would not be typical in a purely natural discourse between domain experts. For example, the ICO axiom:

\[ \text{ICO}_0000171 \subseteq \exists \text{IAO}_0000136.\text{ICO}_0000064 \]

produced the text “every answer option text entity is something that is about a study requiring informed consent”. While technically correct, a more natural English discourse might have been written as “every answer option text entity is about a study requiring informed consent”. In general, the introduction of the phrase “is something that” in descriptive logic axioms containing an existential restriction of the form “∃ R.C” caused considerable discussion among the reviewers as to the clarity of the produced phrases.

Another factor we noted during our evaluation that clearly impacts the usefulness of the produced natural language are the class and object property labels of the source ontology. The choice of appropriate labels agreed on by domain experts during the construction of an ontology is generally considered good practice. Iterative use of Hootation during ontology construction and refinement can assist with this.

While not the primary focus of this paper, the fidelity of the axiom to underlying domain knowledge was noted by reviewers of ICO as an issue. Reviewers noted approximately 41 axioms (the number varied slightly between the two reviewers) were not accurate representations of the underlying domain knowledge. ICO developers intend to target these axioms for review and correction. This is strong evidence that tools such as Hootation are useful and effective at improving the quality of ontologies.

Also, the majority of the axiom NL translations were of the SubClassOf type, which intuitively, should be “easy” to translate. However, due to nomenclature of the labels, the translation was not straightforward, and the results point to some lack of clarity and fidelity to domain knowledge. The finding of a positive correlation between clarity and fidelity of the axiom to domain knowledge merits further investigation, and suggests that when the axiom fidelity to domain knowledge is less accurate, the clarity of the NL statement also diminishes. For example, the TEO axiom, TEO_0000048 \(\subseteq\) TEO_0000084, which produced “every Saturday is a week day” is technically correct within the context of TEO axioms (Saturday is modeled as subclass of weekday entity), but as a generated statement it could be misleading to human evaluators because Saturday is typically discussed as a weekend day, not a weekday. Future work on this relationship needs to account for the complexity of the axiom as well as the fidelity of the axiom to domain knowledge. For example, an axiom of the general form \(A \subseteq \exists \text{B (C.D)}\) is more complex than an axiom of the form \(A \subseteq \text{B}\). We also intend to add an option to the program to address discourse type as typified by the “is something that” issue discussed above, allowing production of text more suited to a domain expert.

Software

Other factors that influenced evaluator ratings were software bugs and the stemming algorithm. The tool does not yet support import of external ontologies, so some NLG statements included unresolved names of entities from external ontologies that were not merged into the ontology file, e.g., “every duration measurement is an iao 0000032”, where the iao 0000032 is associated to an entity from the external Information Artifact Ontology. Future work may require that the API automatically downloads and resolves references to external ontologies at runtime. Another problem we noticed was introduced by our utilization of the Porter-Stemmer algorithm, which sometimes unnecessarily decomposed a word to a form that is unrecognizable (Ex: “date” became “da”). WordNet API software packages offer lemmatization that might be an alternative.

Limitations and Future Direction

The Hootation software library was limited to 14 OWL axioms that can be translated to natural language statements, most of which were carried over from the work of previous developers. In the future, we plan on supporting the translation of the full set of axiom types to provide comprehensive translation of OWL axioms to natural language statements.

Also, we did not separately examine the impact on clarity of BFO-based axioms for those ontologies using BFO as upper level ontology. BFO uses a specific realism-based model to provide a framework for building other ontologies against. Evaluation of ontologies based on the BFO framework demands some familiarity of the underlying BFO model and the precise terms used by BFO for representing terms, classes, and relationships. Finally, we recognize the need to consider complexity of axiom types in future studies.

One of the ongoing projects we are engaged in is to develop a web-based tool (“OntoKeeper”\(^5\)) to evaluate published ontologies according to various metrics influenced by \([8]\). One of the metrics include evaluating the veracity of the ontology from subject matter expert review through an online user interface. To do this, we need to translate the logical axioms to natural language statements to be more “readable” for the experts with little knowledge on how to navigate through an ontology or no knowledge of complexities of the OWL/RDF syntax. The finalization of this work will be to integrate the NL translation component to the web-based tool and publish the API library for future research on biomedical ontology evaluation research.

An impending study will perform an extensive evaluation of specific biomedical ontologies with accomplished biomedical ontology experts to review the NL axioms. That study will also include details on implementation of Hootation and near complete support for majority of the axiom types.

Conclusion

To address the specific need of generating human-friendly interpretation of ontology axioms in natural language, we introduce Hootation. This software library utilizes a combination of the OWL-API and SimpleNLG, as architected by AKSW, to produce basic natural language statements for 14 axiom types. By translating the axioms into natural language statements, we can enlist the participation of domain subject matter experts who can therefore easily review an ontology without the barrier of learning the complexity of knowledge engineering. In the future, we plan on incorporating this library into our prototype software tool OntoKeeper to add a subject matter expert review component. Overall, this work has potential implications for bridging the gap between the expertise of domain experts and encoded knowledge in machine encoded syntax.

Abstract

Value sets (VSs) used in electronic clinical quality measures are lists of codes from standard terminologies (“extensional” VSs), whose purpose (“intension”) is not always explicitly stated. We elicited the intension for the 09/01/2014 release of external medication value sets by comparison to drug classes from the October 2014 release of RxClass. Value sets matched drug classes if they shared common ingredients, as evidenced by Jaccard similarity score. We elicited the intension of 80 external value sets. The average Jaccard similarity was 0.65 for single classes and 0.80 for combination classes, with 34% (27/80) of the value sets having high similarity scores. Manual review by a pharmacist indicated 51% (41/80) of the drug classes selected as the best mapping for a value set matched the intension reflected in that value set name. This approach has the potential for facilitating the development and maintenance of medication value sets.

Vocabulary, Controlled; RxNorm; Algorithms

Introduction

Clinical quality measures and value sets

Healthcare professionals and hospitals must report clinical quality measures (CQMs) in order to qualify for additional payments under the Electronic Health Records (EHR) Incentive Programs [1]. CQMs define proportion, ratio, or continuous variables that help track the quality of services provided within the healthcare system [2]. To calculate CQMs, healthcare organizations must use codes from standard terminologies to identify concepts and that these concepts represent the intension.

Intensional definitions are critical for the maintenance of value sets. For example, when a new beta-blocker becomes available on the market, it should be added to the beta-blockers value set. If the value set is defined in reference to the drug class (i.e., intensional definition), the new drug will be added to the value set automatically. In contrast, if the list of beta-blockers is established by a pharmacist (i.e., extensional definition), it will need to be periodically revisited to reflect new drugs.

For most value sets currently in use to support CQMs, value set developers have created sets of codes from standard terminologies (e.g., RxNorm for drugs), without explicit documentation of why specific codes were selected. These extensional value sets pose a challenge for validation and maintenance.

Objectives

The objective of this work is to elicit the intension of medication value sets in reference to drug classes. More specifically, we have observed that the value set names generally correspond to: 1) a single drug class, like Statin; 2) a drug class in the context of a given disease, like Antibiotic Medications for Pharyngitis; and 3) multiple drug classes, like ACE Inhibitor or ARB Ingredient. Based on this observation, we propose to use single drug classes, as well as combinations (i.e., intersections and unions) of drug classes to specify an explicit structured intension for medication value sets. A secondary objective is to evaluate the quality of medication value sets by comparison to drug classes. We investigated the 09/01/2014 release of medication value sets for eligible practitioners and hospitals, from the NLM Value Set Authority Center (VSAC), located at https://vsac.nlm.nih.gov/. These value sets were created against the October 2014 release of RxNorm.

Related work

Most work on clinical quality measures (CQMs) has focused on their potential for electronically tracking and improving delivery of care [3], issues in validating results from CQMs [4], and accuracy and completeness issues of some CQMs [5; 6]. In this investigation, we specifically focus on the quality of value sets used in CQMs.

In previous work, Winnenburg and Bodenreider [7] assessed the quality of disease value sets by comparing them to the disease classes in the source from which they were derived (e.g., SNOMED CT or ICD10-CM). They hypothesized that concepts in the value set were rooted in one or more ancestor concepts and that these ancestor concepts represent the intension.

The extension for a reference value set could then be constructed as the root concepts along with their descendant concepts. For example, the value set left ventricular systolic dysfunction would ideally include the concept left ventricular
systolic dysfunction and its descendants in SNOMED CT. These techniques provided a framework for evaluating the quality of a value set from a known, structured intensen.

We take a similar approach for medication value sets. Of note, while disease value sets can be analyzed in reference to the disease hierarchy provided by SNOMED CT or ICD10-CM, medication value sets require drug classification systems external to RxNorm, namely ATC, MeSH, NDF-RT and DailyMed (described below). Moreover, drug classification systems organize drugs according to various dimensions (e.g., indications, mechanism of action) and multiple combined criteria may be needed to fully characterize a medication value set.

RxNorm and drug classification systems

RxNorm [8] is a standardized nomenclature for medications produced and maintained by the NLM. It provides drug concepts and relations among them. RxNorm concepts are also linked to various drug classification systems through RxNorm’s companion resource, RxClass. In this investigation, we leveraged the RxNorm and RxClass application programming interfaces (APIs), available at https://rxnav.nlm.nih.gov/. More specifically, we used the RxNorm API, to map various kinds of drug entities to ingredients (e.g., the brand name Lipitor to Atorvastatin), as drug classification systems generally reference ingredients. We used the RxClass API to associate ingredients with drug classes.

The following drug classification systems were used as a source of drug classes. The Anatomical Therapeutic Chemical (ATC) [9] classification system is maintained by the World Health Organization (WHO) for pharmaco-epidemiology purposes. Each ingredient is associated with one or more ATC class. For example, Atorvastatin is a member of the class HMG CoA reductase inhibitors.

The Medical Subject Headings (MeSH) [10] is a controlled vocabulary produced and maintained by the NLM for indexing and retrieval of the biomedical literature. Its descriptors are linked to Pharmacologic Action (PA) descriptors which describe mechanisms of action and therapeutic uses. For example Atorvastatin has the following pharmacologic actions: anticholesteremic agents and hydromethylglutaryl-CoA reductase inhibitors.

The National Drug File Reference Terminology (NDF-RT) [11] is developed by the Department of Veterans Affairs (VA) Veterans Health Administration and associates ingredients with different pharmacological classes, including chemical structure and diseases for which the drug is indicated. For example, Atorvastatin is a member of the disease class Hypercholersterolemia (among others).

Finally, DailyMed [12] associates ingredients with different pharmacological classes, including the Food Drug Administration’s Established Pharmacological Classes (EPC), mechanism of action (MoA), and physiologic effect (PE). Although these associations are also defined in NDF-RT, we used DailyMed because it represents a more authoritative source. For example, Atorvastatin is a member of the EPC class HMG-CoA Reductase Inhibitor, and the MoA class Hydroxymethylglutaryl-CoA Reductase Inhibitors.

Methods

Our approach to eliciting the intension of medication value sets can be summarized as follows (Figure 1). We establish sets of ingredients from drug value sets and from drug classes, and we compare lists of ingredients between value sets and drug classes. Finally, we perform a quantitative and qualitative evaluation of the elicited intensions.

Establishing sets of ingredients from drug value sets

Medication value sets from VSAC can contain various kinds of RxNorm drug entities, including ingredients (e.g., Carvedilol) and clinical drugs (e.g., Carvedilol 25 MG Oral Tablet), as well as brand names (e.g., Coreg), specific salts and esters (e.g., carvedilol phosphate) and other kinds of drug entities. We leveraged the RxNorm API to map the various kinds of drug entities to their corresponding ingredient to simplify the analysis. We excluded multi-ingredient drugs, because the corresponding single-ingredient drugs tend to be listed in the value sets and also because multi-ingredient drugs are not represented consistently across drug classification systems.

Establishing sets of ingredients from drug classes

We leveraged the RxClass API to find the list of RxNorm drug members for drug classes from ATC, MeSH, NDF-RT, and DailyMed. As was done for drug entities from the value sets, we ignored multi-ingredient drugs and mapped the various kinds of drug entities to their corresponding ingredient.

In addition to the (single) classes found in drug classification systems, we created combination classes to represent the sets of drugs reflected in value sets. Namely, we created two types of combination classes: 1) intersection classes, where each single class is intersected with each of the disease classes (attempting to approximate value sets, such as Antibiotic Medications for Pharyngitis); 2) union classes, where multiple single classes are merged (attempting to approximate value sets, such as Ace Inhibitor or ARB Ingredients). We created the intersection classes systematically for each single class. In contrast, we created union classes corresponding to the best match for each value set (by finding the single class that is most similar to a given value set, and then the best single class that is most similar to the drugs not covered at earlier steps).

Comparing ingredients between value sets and drug classes

We used the Jaccard coefficient to measure the similarity between value sets and (single or combination) drug classes based on their normalized ingredients. The Jaccard coefficient for a value set and a drug class, \(J(V, C)\), computes similarity as the ratio between the number of ingredients common to the value set and the drug class, \(|V \cap C|\), over the total number of ingredients in the value set and the drug class, \(|V \cup C|\). The Jaccard coefficient ranges from 0 (no similarity) to 1 (exact match). The (single or combination) drug class with the highest Jaccard score is considered to best reflect the intension of the value set.
Figure 2 - The Jaccard metric is used to assess the equivalence between value sets and drug classes. The Beta Blocker Therapy value set has an initial match with Adrenergic beta-Antagonists from MeSH. This match is further refined by intersecting the MeSH class with the NDF-RT disease class Hypertension.

Figure 2 presents an example, in which the value set Beta Blocker Therapy is evaluated against the MeSH class Adrenergic beta-Antagonists intersected with the NDF-RT disease class Hypertension. The red dotted line indicates that there are 14 ingredients in the combination class. The white circle indicates that 12 ingredients are in both the value set and combination class. This results in a Jaccard score of 0.86 (12/14). The intension for Beta Blocker Therapy value set could then be interpreted as Adrenergic beta-Antagonists used for Hypertension.

Evaluation

We performed a quantitative and qualitative evaluation to assess the fit and validity of elicited intensions.

Quantitative. The quantitative evaluation assesses the overall similarity between value sets and (single or combination) drug classes. More specifically, we simply compute the average of the best Jaccard score for each value set-drug class pair. To assess the contribution of the combination classes (intersection and union classes defined earlier), we compared the averages obtained under the following strategies:

1. When using only single classes
2. When using single classes and intersection classes
3. When using single classes, intersection classes and union classes

We conducted a one-way ANOVA (with repeated measures) to compare the effect of these different strategies on eliciting the intension based on the Jaccard score. A Tukey post hoc analysis was performed to identify which strategies were significantly different (pairwise). The statistical analysis was completed using STATA 13 (StataCorp. 2013. College Station, TX).

Qualitative. The qualitative evaluation assesses the extent to which the (single or combination) drug class matches the intension reflected in the value set name. An expert pharmacist (SDN), who had not been involved with the development of the methods, analyzed the drugs listed in the class and in the value set for the class identified as the best match for each value set. More specifically, the pharmacist was asked to answer two main questions for each value set-drug class pair:

1. Do the drugs listed in the value set correspond to the intension reflected in the value set name?
2. Do the drugs listed in the (single or combination) class correspond to the intension reflected in the value set name?

Additionally, the pharmacist was asked whether there were missing or extraneous drugs in the value set, in the best-matching class, or in both.

Results

Establishing sets of ingredients from drug value sets

As shown in Figure 1, there were 183 extensional medication value sets. Ninety-seven were excluded because they contained only one ingredient and could be trivially mapped to the Chemical structure drug class restricted to this ingredient. Five were excluded because their extensions were composed entirely of multi-ingredient drugs. One contained one ingredient that could not be mapped to a drug class. The remaining 80 value sets were analyzed and contained 468 distinct ingredients after mapping to RxNorm.

Establishing sets of ingredients from drug classes

Table 1 shows the number of single and combination classes for each source. The NDF-RT disease classes (reflecting drug indications) were combined with other drug classes resulting in approximately 4 million intersections. We iteratively generated the union of classes that had some equivalence to value sets based on the Jaccard score. This resulted in approximately 100 union candidates. The 6519 single classes contained 2957 distinct ingredients after mapping to RxNorm.

Comparing ingredients between value sets and drug classes

We compared each of the 80 value sets to all single drug classes, resulting in 521,520 comparisons, from which we selected the best value set-drug class pair match. We found that there was no single source that best described all value sets. However, many of the top matches appear to come from ATC and DailyMed EPC, followed by NDF-RT Physiologic effect and NDF-RT Mechanism of action.

Similarly, we identified the best match for each value set and all intersection drug classes (over 320 million comparisons). Here again, intersections between Disease classes and classes from ATC and DailyMed EPC provided most of the best matches. The intersection of Disease classes and classes from NDF-RT Chemical structure also contributed many of the best matches. Finally, we determined the best union classes for each value set.

Evaluation

Quantitative. We examined the distribution of the Jaccard scores for best matches between the 80 value sets and drug
classes, using three mapping strategies: single classes only; single classes or intersection classes; single classes or intersection classes or union classes. A larger proportion of the value sets obtain better Jaccard scores under the last two strategies compared to single classes.

More specifically, the average Jaccard score of single classes was 0.65, with 23% (18/80) of the value sets having high similarity (0.9-1) with a drug class. Adding disease intersections increased the average Jaccard score to 0.79 with 34% (27/80) of the value sets having high similarity with a single drug class or a drug class intersected with a disease class. Adding union classes provided a very small performance gain, only increasing the average Jaccard score to 0.80. The union mostly affected value sets that did not have a good match to a single drug class or single drug class intersected with a disease class.

The one-way ANOVA test showed that the different strategies resulted in statistically significant differences in mean Jaccard scores, F(2, 158) = 30.02, p < 0.005. The post hoc Tukey test indicated that both types of combination classes performed significantly better than single classes only (p = 0.024 and p = 0.009). However, there was no significant difference between the two types of combination classes (p=0.934).

Table 2 - Examples of elicited intensions (original value set, single or combination drug class, Jaccard score, and pharmacist comments).

<table>
<thead>

<td>0.40</td>
</tr>
<tr>
<td>Beta-Lactams for Allergy Determination</td>
<td>beta-Lactams OR other beta-lactum antibacterials OR Beta-lactamase sensitive penicillins</td>
<td>[Value set had a lot of missing SCs. Drugs that are not antibiotics, but inhibit beta-lactams not in ingredients.]</td>
<td>0.80</td>
</tr>
<tr>
<td>BH Mood Stabilizer Medication RxClass</td>
<td>Phenothiazines with piperazine structure OR Dibenzazepines OR Fructose OR Other antipsychotics</td>
<td>[Value set is poorly defined and has a lot of missing drugs.]</td>
<td>0.27</td>
</tr>
</tbody>
</table>

Qualitative. Table 2 shows examples of value sets with elicited intensions.

Value set extension vs. value set name. Eighty percent (64/80) of the value sets had ingredients that were consistent with the intention reflected in the value set name. Sixteen percent (13/80) of the value sets had extraneous ingredients and 46% (37/80) had missing ingredients.

Drug class extension vs. value set name. Fifty-one percent (41/80) of the single or combination drug classes selected as the best mapping for a value set matched the intention reflected in that value set name. Twenty-eight percent (22/80) of the best-matching drug classes had extraneous ingredients and 43% (35/80) had missing ingredients. In thirty-one percent (25/80) of the cases, there were missing ingredients in both the drug class and value sets.

Other issues. We found several duplicate value sets, such as BH Antidepressant Medication - SSRI Antidepressants RxNorm and SSRI_Antidepressants. The issue of duplicate value sets had already been reported by Winnenburg et al [7] for disease and procedure value sets, so it was not surprising to find duplicates in medication value sets. We also found some naming inconsistencies, such as with the qualifiers used to refer to injectable drugs in value set names, which included IV, parenteral, Injectable, and for IV Administration.

Discussion

Applications

This work presents a framework for eliciting an explicit form of the intention in reference to a normative drug source, such as the ATC, MeSH, NDF-RT and DailyMed drug classification systems. The drug classes from these sources allow us to compare logical groupings of drugs and derive a reference extension that can be used to validate the ingredients in the value set.

There are two main applications for this framework. The primary application is to derive operational intensional definitions for medication value sets in order to facilitate their maintenance. Once a value set has been associated with a single or combination class, value set developers can rely on the corresponding drug classification systems for the maintenance of the value set. In practice, instead of relying on experts for checking whether drugs should be added to or removed from a given value set, value set developers would only need to check the members of the drug class the value set has been mapped to when new versions of the drug classification system become available. Operational intensional definitions greatly facilitate the maintenance and reliability of drug value sets. We discussed our findings with representatives of the NLM Value Set Authority Center (VSAC), where these techniques could be implemented to facilitate the development and ongoing maintenance of the value sets.

A secondary benefit of comparing value sets to drug classes is that it provides an opportunity for quality assurance. Our expert pharmacist identified potential errors, specifically missing drugs and extraneous drugs, in almost two thirds of the value sets. Here again, the availability of such a framework will likely benefit the quality assurance of medication value sets in VSAC. Of note, similar errors were identified in drug classes and could be reported to the developers of the corresponding drug classification systems.

Finally, this work informed the visualization of drug classes in RxClass (https://mor.nlm.nih.gov/RxClass/), the tool we developed for browsing and comparing drug classes associated with RxNorm.

Failure analysis

We were able to elicit an appropriate intention for about half of the value sets, while the other half corresponded to value sets with a mixture of drugs belonging to many different, but similar classes. For example, the value set IV Quinolones Used For Prophylaxis for Hysterectomy and Colon Surgery best matched the intersection between two drug classes, Quinolone Antimicrobial and Sinusitis. Antimicrobial drugs have many therapeutic uses, so in this case, we elicited the wrong intention that provided a good match (treatment of sinusitis vs. prophylaxis for hysterectomy and colon surgery).

In other cases, the value sets contained a complicated mixture of drugs. For example, the Anti-Hypertensive Pharmacologic Therapy value set contained 67 distinct ingredients. The best match consisted of a combination class resulting from the intersection of Hypertension with the top-level class Established Pharmacologic Class (EPC), i.e., all drugs with any EPC class. Interestingly here, the expected best match was to the single
class **Hypertension** itself, not an intersection class. However, this occurred because several drugs used to treat hypertension were missing from the value set, such as **Methyldopa**, **Guanethidine**, and **Bumetanide**. This case illustrates not so much a failure of our approach to associating value sets with drugs classes than a quality issue with the value set.

We observed that some of these value sets were restricted by dose form (e.g., **IV Quinolones**, which restricts antibiotics from the quinolone class to their intra-venous forms). Because drug classes list ingredients as their members, a drug class, such as **QUINOLONE ANTIBACTERIALS** in ATC would retrieve the appropriate ingredients, but would not distinguish between intra-venous and other forms of these ingredients. For these classes, RxNorm could be used to filter ingredients for which there exist clinical drugs for specific dose forms. Failure to implement this feature in our framework resulted in extraneous ingredients in some value sets. For example,** QUINOLONE ANTIBACTERIALS** in ATC lists the ingredient **Ofloxacin** as a member, for which there exist no injectable forms. Similarly, the dose of the drug often had contextual implications. For example, some value sets only listed heparin flushes, rather than the therapeutic dose. This suggests that value set developers created some value sets with specific dose form groups in mind.

Finally, there were a few cases, where we were unable to achieve a good match because the requisite information was often outside the scope of the terminology. For example, certain drugs or doses listed in the terminology are not legally prescribed in the U.S., such as **Phenprocoumon** and **Dicumarol**.

**Limitations and future work**

There are a few limitations regarding the materials used in this study. First, multi-ingredient drugs were not included in the analysis, because the corresponding single-ingredient drugs tend to be listed in the value sets and also because multi-ingredient drugs are not represented consistently across drug classification systems. However, this restriction resulted in eliminating five value sets composed entirely of multi-ingredient drugs. Second, the therapeutic intent of medications is often dependent on medication route and dose. As discussed in the failure analysis, we could easily restrict ingredients based on intended route, when a route restriction was expressed in the value set name. However, we would probably not be able to account for specific doses (such as heparin flushes), because this information was not made explicit in value set names. Third, this study is based on older versions of the value sets, RxNorm and drug classification systems, because the qualitative analysis was performed against these specific versions. Nevertheless, the methods are generalizable to newer versions.

**Conclusion**

We proposed an approach for eliciting the intention of medication value sets by comparing the list of ingredients in these value sets to single or combination drug classes derived from drug classification systems, such as ATC, MeSH, NDF-RT and DailyMed. With this approach, we were able to find drugs classes that match the value sets with 0.79 Jaccard similarity on average. This approach has the potential for facilitating the development and maintenance of medication value sets. We also discussed its benefits in terms of quality assurance.

Abstract

Dutch interface terminologies are needed to use SNOMED CT in the Netherlands. Machine translation may support in their creation. The aim of our study is to compare different machine translations of procedures in SNOMED CT. Procedures were translated using Google Translate, Matecat, and Thot. Google Translate and Matecat are tools with large but general translation memories. The translation memory of Thot was trained and tuned with various configurations of a Dutch translation of parts of SNOMED CT, a medical dictionary and parts of the UMLS Metathesaurus. The configuration with the highest BLEU score, representing closeness to human translation, was selected. Similarity was determined between Thot translations and those by Google and Matecat. The validity of translations was assessed through random samples. Google and Matecat translated similarly in 85.4\% of the cases and generally better than Thot. Whereas the quality of translations was considered acceptable, machine translations alone are yet insufficient.

Introduction

The use of SNOMED CT in electronic health systems is growing \[1\]. Recording clinical data using SNOMED CT helps to uniformly describe medical data, which enables data reuse such as data analysis, auditing quality of care and decision support.

SNOMED CT is officially released in English and Spanish. Before SNOMED CT can be used in clinical practice in other languages, a translation needs to be made, or interface terminologies need to be created. SNOMED CT has been fully translated in Denmark and in Sweden. A Canadian French translation is ongoing. Similar to other countries \[2\], in the Netherlands a partial translation of SNOMED CT is undertaken. Such translations generally provide one term for each concept, adhering to the strict translation guidelines of SNOMED International\[3\]. However, they do not necessarily contain the synonyms used in clinical practice, and these synonyms may not adhere to the translation guidelines. Interface terminologies provide a close-to-user description for concepts, generally covering a part of SNOMED CT, e.g., diagnoses or procedures. Also for Dutch healthcare, one or more Dutch interface terminologies for SNOMED CT need to be made available. Descriptions for a part of the diagnoses form the Dutch interface terminology "Diagnoses thesaurus", which is maintained by Dutch Hospital Data (DHD) \[2\]. The next step is to start creation of an interface terminology for procedures. Recording of procedures is an essential part of clinical documentation and serves, once standardized, many data reuse purposes. These include calculation of quality indicators and reimbursement.

SNOMED CT contains more than 55,000 procedures, each described by one or more English descriptions. Manual translation of these descriptions requires a lot of time and resources. If computers are used to make initial translations, terms only have to be validated, which may save a lot of time. Machine translation has already been used for translating SNOMED CT in Spanish, Swedish and French. To make the Spanish version, prefixes, suffixes and roots of terms were used to make an automated proposal \[3\]. In Sweden, mappings to other already translated terminologies were used \[4\]. In France, lexical methods and mapping to the Unified Medical Language System Metathesaurus (UMLS Metathesaurus) were used \[5\].

Above methods were well evaluated, but not much research has been performed on already available translation tools. Hence, in this study, we assess the quality of the translation of descriptions of concepts in the procedures hierarchy of SNOMED CT from English to Dutch. We compare generic translation tools and a tool with a translation memory that was specifically trained and tuned for this purpose.

The first generic tool is Google Translate\[1\], the second generic tool is Matecat\[4\] \[6\], and the third tool is Thot\[7\], a toolkit for statistical machine translation, which requires training and tuning of the translation memory.

The hypothesis is that translations that are the same among the three methods are of better quality, because three different translation systems have found the same result. We furthermore hypothesize to get less but better translations with Thot as this tool is trained with terms from a medical background.

Materials & Methods

Tools

Machine translation was performed using Google Translate, Matecat, and Thot.

Google Translate is a widely used translation tool. The translator is a black box with a large translation memory. It

\[1\] \url{http://www.ihtsdо.org/resource/resource/9}

\[2\] \url{https://www.dhd.nl/klanten/producten-diens\te/diensten/diagnosesaurus/Pagina/Diagnosesaurus.aspx}

\[3\] \url{https://translate.google.com/}

\[4\] \url{https://www.matecat.com/}

\[5\] \url{http://daormar.github.io/thot/}
has previously been used for translation of SNOMED CT, e.g., in the research of Schulz et al. [2].

Matecat [6], is a tool that has its own translation memory. One difference with Google Translate is that one can select the subject of the text to translate. This context might help with choosing the right translation for a term. We selected ‘Medical/Pharmaceutical’ as the subject of the Matecat translation.

Thot is a phrase-based tool [7], i.e., it is usually trained by providing pairs of translations of phrases. In this research, these pairs consisted of Dutch and English phrases, predominantly noun phrases. Apart from providing the basic functionality for preparing, training and translating files, this tool also provides interactive translation possibilities. This means the system provides functionality for the user to have an influence on the final translations. For training, incremental learning is used to result in better language models.

Sources for Training, Tuning and Testing Thot

We used three resources to train, tune and test Thot. First, we used Dutch-English translation pairs from the UMLS Metathesaurus. Second, an existing but partial Dutch translation of SNOMED CT that has been developed in the joint Dutch-Belgian efforts to develop Dutch interface terminologies. Third, a Dutch-English medical dictionary, Springer Groot Medisch Woordenboek [8].

Thot tests were compared by means of the BLEU (bilingual evaluation understudy) score generated by Thot [9]. This score measures the closeness to a human translation in a range from zero to one, with one being a perfect human translation. The configuration that gave the best test result after training and tuning was used for the final translation of the SNOMED CT descriptions. This resulted in the Thot translation, which was compared to the Google Translate and Matecat translations.

Filtering non-translations

The fully specified names of all procedure concepts of the January 2016 release of SNOMED CT were selected. Each tool created a translation for each of the fully specified names, after removal of the semantic tags (‘(procedure)’ and ‘(regime/therapy)’).

Tools may fail to translate some words, resulting in untranslated English words in a “Dutch” translation. For example, if “Urinary undiversion” is translated as “urine undiversion,” the second word is not a Dutch word. However, if “Open drainage of liver” is translated as “Open drainage van de lever,” this is perfectly correct.

Hence, before comparing the three translations the amount of remaining English words was assessed. This was done by a Java program that checked if the words were in a Dutch list of words. This list consisted of generic Dutch words merged with the words from the Dutch file we used to train Thot for domain-specific words. Translations containing more non-Dutch words than Dutch words were deleted. The amounts and percentages of included terms were calculated for each of the three tools, and the results were compared with McNemar tests.

Validity of translations

For each SNOMED CT concept we constructed a set of translations, as shown in Table 1. Sets with three equal translations, two equal translations and all different translations were created. We calculated the percentage of sets with at least one exactly similar translation by another method.

From each of the sets, a sample of 100 English terms was selected, with one, two and three different Dutch translations respectively. These samples of the translations were checked on validity: two reviewers (RC & CH) assessed whether the translations were well-formed Dutch noun-phrases reflecting the meaning of the English description. The meaning of the translation could be different, for example due to translation of an English homonym in the wrong context, such as vessels as ships (“scheep”) (see Table 1), or stool as furniture (“krui”). The reviewers graded using marks from zero to three, with zero and one being not acceptable and two and three being acceptable as a good translation. If an English word is recognizable as a Dutch word, the term will get 2 points, otherwise not more than 1 point. Determiners are not considered; wrong spacing costs a point, as Dutch is a language in which words are combined, e.g., “Mouth reconstruction” is “mondreconstructie”, not “mond reconstructie”.

A translation was considered acceptable when it was recognizable as a translation that covers the meaning of the English term. Average marks and 95% confidence intervals (CI) were calculated for the different samples and reviewers. Also, total weighted averages were calculated for the three tools. The percentages of the translations that were considered acceptable were calculated. For the samples containing two or three different translations, the reviewers assessed which translation they considered the best.

Results

Training Thot

Table 2 shows the results of the different Thot translations with their BLEU scores. The configuration with the highest score was used to compare to the general translation tools. This turned out to be a combination of Dutch terms (coming from other thesauri like ICD, ICPC) that UMLS relates to SNOMED CT concepts, terms from a Dutch-English medical dictionary, and terms from a Dutch translation of parts of SNOMED CT.

Filtering non-translations

SNOMED CT contained 54419 procedure concepts. Sets of translations (i.e., all translations for a concept) were excluded if any of their translation contained more English words than Dutch words. Table 3 shows the number and percentage of included translations for each of the tools used.

There was no practical difference in the number of translated terms, whereas Thot translated (p < 0.001) significantly more terms into Dutch than Google and Matecat, which were not significantly different (p = 0.535). In all translations, less than 4% of the translations were rejected. Excluding all preferred terms for which one or more of the tools didn’t provide a translation resulted in a set of 50838 terms. This set was used for further analysis.

For these terms we compared whether one or more of the tools provide the same translation. The results of this analysis are shown in Table 4.

Table 4 shows that full agreement between the three tools is much less common than full disagreement, and that Google and Matecat agree most of the time, in 43413 (85.4%) of the cases.

Validity of translations

We selected 100 sets from 1548 with all translations equal, i.e., 100 translated terms; 100 sets from 41865 where Google and Matecat agreed, but Thot did not, hence 200 translated terms, and 100 sets from 7158 that had 3 different translations each, hence 300 translated terms.

Table 5 presents the results of the analysis on the mean acceptability score of each translation, the percentage of acceptable translations, and the agreement between the two raters on this judgement.

The total mean translation score for Google Translate was 2.15. The total mean translation score of Matecat was 2.11 and of Thot 1.91. Taking 0 and 1 (regarded as not acceptable) and 2 and 3 (regarded as acceptable) together resulted in acceptability percentages between 45% and 93%.

Finally, in those cases where there was more than one translation for a term, the reviewers determined which tool they considered to provide the best translation. This is shown in Table 6.

Kappa’s for acceptability were 0.623 and 0.577, meaning a fair level of agreement. Both were significant with p<0.001. The weighted average of the percentages from Table 5, based on the number of terms from Table 4, results in an overall percentage of acceptable terms of 61%. The translations by Matecat and Google Translate were considered better than those of Thot.

Discussion

In this research the quality of translations by three machine translation engines was tested. To our knowledge, this is among the first studies in which different automated translations were compared.

The Thot translation improved when it was tuned with procedures. The big step to making a translation that resembled human translation was training with the available parts of Dutch SNOMED CT. This training set already contained some translations for terms that had to be translated by Thot.

Even though Thot used existing translations for SNOMED CT descriptions, it could not outperform the tools with a generic translation memory.

Translations that are the same among the three methods are generally of better quality. Ninety-three percent of those translations are acceptable, a number which is only approached by the Google translations in the case that all tools provide different translations. We expected to get less but better translations using Thot, as it was trained for this purpose. However, it has a much smaller translation memory than Google and Matecat, and the contrary has been the case. The number of translations, after filtering non-translations, was higher for Thot than for Google and Matecat, but the validity of the translations was lower.

A Java program checked the translations for non-Dutch words, and we were surprised by the large amount of terms that could be translated. This does not directly mean the translations are of good quality, but it does mean that most terms have been translated to Dutch terms.

In the comparison Matecat and Google translated many terms the same, and Thot translated very differently. This emphasizes the difference between generic and specific tools. The real quality was measured by manually assessing the validity of three samples of 100 terms. Average scores show the terms are on average considered acceptable. However, we did see that the Thot translations were the only ones to score under 2.00 on average, and under 60% in acceptable translations. This means the Thot translations were considered inferior to the other translations. There is also a difference in the total average score. The terms that were all translated the same were considered better than the other terms. The reviewers could see that these terms were shorter than other terms. This might mean there was less possibility for making different or wrong translations. When the two different translations were compared, Matecat and Google scored a bit better than Thot. When comparing the three different translations, the Google translation was considered the best most of the time. Most of the translations were considered acceptable, but not perfect. The translations made by Google, Matecat and Thot can give an idea of the translation of a term, but most of the time they will not give a translation that is ready to use. In this research, Google Translate scored the best in comparison with Matecat and Thot. Thot scored worst.

Limitations of this study were the fact that only two reviewers rated the terms, and the small size of the samples that were judged for validation of the translations. Furthermore, the analysis of acceptability of translations could be further systematized. Additionally, the types of errors in translations could be further specified. For example, the generic tools occasionally used synonyms from a non-medical domain, leading for example to translations of “blood vessels” as “blood ships.” Regarding Thot, the high inclusion rate (i.e., relatively few English terms in a translation) seems to be explained by the fact that Thot simply leaves out fragments it cannot adequately translate. This may lead to close-to-human translation, but lacks the full semantics of the English term that has to be expressed. Further analysis of such mechanisms and types of error is needed.

Creating translations with machine translation tools has the potential to help make good translations, but the translations are not made according to the translation rules for SNOMED CT from SNOMED International. This means making a translation with machine translation tools will only provide reference terms, and not official translations. This makes machine translation not suitable for making an official translation of SNOMED CT, as stated in the research of Schulz [2].

Our research contributes to the field of machine translation, in which efforts are undertaken for various languages. The distinguishing features are the application to SNOMED CT, and the translation to Dutch. In earlier research [10], we showed that Dutch is among the languages with a scarcity of resources for language processing in medicine. It similarly lacks corpora, especially bilingual medical corpora, that could contribute to improving the quality of machine translation. This poses challenges and gives need to the use of alternative approaches, such as lexical and morphosemantic approaches [11].

Our study is similar to the one described in [12], which compared three approaches for translating the Gene Ontology from English to German. They used Wikipedia, Google API with context and Google API without context. The average scores for adequacy (the extent to which a translation represents the meaning) and for fluency (the extent to which a translation is proper German) were over 4.0 on a 5-point Likert scale. This seems higher than the scores we found in our study, which may be explained by the fact that we combined adequacy and fluency in our scores, and the existence of a larger corpus of German terms, as German is the second-most represented language in PubMed/MEDLINE, after English [12].

Further research should be performed on using machine translation tools in a full translation process. This could determine whether using machine translation tools will be beneficial for translation. Training Thot using only validated translations that conform to SNOMED International’s translation guidelines may eventually lead to higher translation quality. Research could be done on building a good translation memory to train a tool such as Thot. This might result in translations of better quality. Furthermore, this may prove useful for maintenance, i.e., for providing translations for concepts that are added to new releases of SNOMED CT.

Further research is also needed to point out the impact that translations, translation quality, and adequacy of synonymy have when actually using a translation of SNOMED CT in clinical practice, for example, on impacting the inter-coder agreement, which is considered to be low when using SNOMED CT in English [13].
Conclusion

Overall quality of the three different tools was considered acceptable, but not good enough for use in clinical practice. The Thot translations were considered worse than the Google and Matecat translations. Shorter terms were more often translated the same by the three tools, and these translations were considered better. The translations made by the tools could be used in a translation process, but cannot be used directly. The translation tools cannot translate the terms according to the translation rules for SNOMED CT. This means the tools are of limited help for making an official translation of SNOMED CT.

Trends in Fetal Medicine: A 10-Year Bibliometric Analysis of Prenatal Diagnosis

Ferdinand Dhombres, Olivier Bodenreider

National Library of Medicine, National Institutes of Health, Bethesda, MD, USA

Abstract
The objective is to automatically identify trends in Fetal Medicine over the past 10 years through a bibliometric analysis of articles published in Prenatal Diagnosis, using text mining techniques. We processed 2,423 full-text articles published in Prenatal Diagnosis between 2006 and 2015. We extracted salient terms, calculated their frequencies over time, and established evolution profiles for terms from which we derived falling, stable, and rising trends. We identified 618 terms with a falling trend, 2,142 stable terms, and 839 terms with a rising trend. Terms with increasing frequencies include those related to statistics and medical study design. The most recent of these terms reflect the new opportunities of next-generation sequencing. Many terms related to cytogenetics exhibit a falling trend. A bibliometric analysis based on text mining effectively supports identification of trends over time. This scalable approach is complementary to analyses based on metadata or expert opinion.

Keywords:
Bibliometrics, Prenatal Diagnosis

Introduction
The availability of new genomic analysis techniques is transforming research and practice in Medicine. This is especially true of Fetal Medicine with the emergence of non-invasive prenatal testing (NIPT) procedures enabled by sequencing of circulating cell-free DNA (cfDNA) from a simple maternal blood sample [14]. This evolution is expected to be reflected through manuscripts published in Prenatal Diagnosis, the official journal of International Society for Prenatal Diagnosis. In fact, such advances in Fetal Medicine are regularly screened by members of the editorial board and summarized in a yearly editorial “In case you missed it” [2,6,7]. For example, cfDNA was discussed in the editorial presenting trends of the year 2015 [5].

Trend analysis often relies on manual review and expert opinion. For example, significant trends have been identified in medical literature, including increase in frequency and complexity of statistical reporting [1] and increase in computerized tomography and magnetic resonance imaging in Radiology research [12]. Bibliometric techniques have also proved useful for identifying trends in scientific disciplines [15,21], and could be used for capturing an unbiased evolution of major themes in Fetal Medicine over a longer period of time. In context of trend analysis, bibliometric techniques of choice are not citation metrics [4,20,26] (e.g., impact factor and h-index), rather those techniques used for analyzing metadata associated with scientific articles [9,11,13,16] (e.g., indexing terms) and the text of these articles [10]. Surprisingly, use of text mining techniques on full-text articles has not been reported for trend analysis purposes.

The objective of this investigation is to automatically identify trends in Fetal Medicine over the past 10 years through a bibliometric analysis of articles published in Prenatal Diagnosis, using text-mining techniques.

Methods
We conducted a bibliometric analysis of 2,423 full-text articles published in Prenatal Diagnosis over a 10-year period, from January 1, 2006 to December 31, 2015. Our approach can be summarized as follows. We extracted salient terms from the articles; calculated their frequencies over time; and established evolution profiles for most frequent terms, from which we derived falling, stable, and rising trends.

Extracting salient Fetal Medicine terms
We processed the full-text articles to extract all sequences of consecutive words (“n-grams”) of 5 words or less, most likely corresponding to medical terms. Let us consider the sentence “Currently, commercial applications of cell-free fetal DNA testing include RhD blood group typing” [19]. Examples of n-grams extracted from this sentence include “fetal” and “DNA” (N=1); “fetal DNA” and “testing include” (N=2); “cell-free fetal DNA” (N=3); “RhD blood group typing” (N=4); and “testing include RhD blood group” (N=5). Not all n-grams are expected to correspond to medical terms, let alone to salient Fetal Medicine terms. We used Apache Solr (http://lucene.apache.org/solr/) to extract n-grams.

Intuitively, common English words (i.e., non-medical words) or expressions and general medical terms are unlikely to be terms of interest. In contrast, terms frequently occurring in Prenatal Diagnosis are more likely to be salient terms. Therefore, as shown in Figure 1 we filtered out all n-grams entirely composed of common English words, e.g., “commercial applications” (filter #1); selected N-grams present in more than 10 articles in at least one year (filter #2); selected N-grams present in UMLS Metathesaurus [3], a large medical dictionary (filter #3); but excluded N-grams corresponding to general medical terms (isolated adjectives and terms categorized as “Concepts & Ideas” in UMLS Semantic Network), e.g. “mmol” and “arterial” (filter #4). Finally, one author (FD) manually reviewed terms excluded by these filters and rescued salient Fetal Medicine terms that were not covered by the medical dictionary (e.g., “cell-free fetal DNA”).

Calculating term frequencies
For each medical term, we recorded the number of articles in which it appears, for each year of the decade 2006-2015, and for the whole decade. Additionally, we determined the cumulative proportion of occurrences for each term in each year.
Establishing evolution profiles

Intuition here is that terms used mostly at the beginning of the 10-year period under investigation are becoming less popular (denoting a falling trend). In contrast, terms used mostly at the end of the decade have become more popular recently (denoting a rising trend). In practice, we used cumulative frequency over time to determine when terms were used most. We divided the decade into 3 periods, namely 2006-2009, 2010-2011, and 2012-2015. For a given term, if 50% or more of all occurrences were observed during 2006-2009, its overall frequency is decreasing (falling trend). In contrast, if 50% or more of all occurrences were observed during 2012-2015, its overall frequency is increasing (rising trend). Otherwise, the term was deemed “stable”. We extracted 30 most frequent terms in each trend group for visualization and further analysis. Additionally, we extracted 200 most recent terms among those exhibiting a rising trend, as they are likely to denote “hot terms”. Finally, we surveyed frequency evolution for a selection of terms, including those identified by editors of *Prenatal Diagnosis* as reflecting advances in Fetal Medicine for 2015[6].

To produce the evolution profiles, we used the R Foundation Computing environment [17] along with packages for text and data management [24,25] and for data visualization [22,23]. Excluding manual review of terms, it took about four hours to process the documents and compute evolution profiles.

Results

Extracting salient Fetal Medicine terms

From the 2,423 articles, we identified 3,598 salient medical terms. On average, the terms occurred in 101.9 articles over the decade. Our manual review rescued 231 (2.7%) of the 8,637 terms that had been inappropriately filtered out, including “prenatal ultrasound”, “maternal plasma”, “fetal nuchal translucency” and “cell-free DNA”. These terms were present in 178.5 articles on average, ranging from 33 (for “fetoscopic laser photocoagulation”) to 883 articles (for “fetal medicine”).

Establishing evolution profiles

Distribution of terms according to year in which their cumulative frequency reaches 50% of their total document frequency is presented in Figure 2. We identified 618 terms with decreasing frequencies over time (falling trend), 2,142 stable terms, and 839 terms with increasing frequencies (rising trend). Not surprisingly, while stable terms occur in a large number of articles, terms with decreasing or increasing frequencies occur in fewer articles.

![Figure 2 - Distribution of terms according to the year in which their cumulative frequency reaches 50% of their total document frequency.](image)

**Falling trend.** Among the most frequent terms with decreasing frequencies, we found many terms related to Cytogenetics (e.g., “FISH”, “cytogenetic analysis”, “molecular cytogenetic”, “cytogenetic studies”). Of note, the term “case report” is the term whose frequency decreased most dramatically, dropping from 121 articles in 2006 to 58 articles in 2015. The top 30 terms exhibiting a falling trend are shown in Figure 3a. These terms reached 50% of their total document frequency before 2010.

**Stable trend.** Not surprisingly, many common terms in Fetal Medicine have relatively stable frequencies (Figure 3b). For example, the terms “pregnancy”, “fetus”, “ultrasound” were present in over 2,000 articles, and the terms “gestational age”, “karyotype”, “maternal age” and “amniocentesis” in over 1,000 articles. The terms “chorionic villus sampling” and “placenta”, present in over 500 articles are also stable over the decade. These terms reached 50% of their total document frequency in 2010 or 2011.
Figure 3 - Evolution of term frequency (coloured lines) over time for the top 30 terms exhibiting a falling trend (a), a stable trend (b) and a rising trend (c). (The font size in the term cloud is proportional to term frequency.)

</table>

Rising trend. Terms with increasing frequencies include those related to statistics (e.g., “statistical analysis”, “p-value”, “significant difference”), medical study design and methods (e.g., “cohort study”, “systematic review”, “meta-analysis”, “ethics committee”, “institutional review board”), and clinical practice documents (e.g., “guidelines”, “recommendations”) (Figure 3c). These terms reached 50% of their total document frequency after 2011. Of particular interest, “hot terms” (i.e., the most recent terms exhibiting a rising trend) generally reflect the new opportunities of next-generation sequencing (“cell-free DNA”, “non-invasive prenatal testing”, “microarray analysis”). The list of the 20 most frequent hot terms is provided in Table 1; these terms exhibit a document frequency ranging from 377 to 123 over the decade.

Trend for specific terms. As expected, many terms identified by editors of Prenatal Diagnosis as reflecting advances in Fetal
Medicine for 2015 [6] were also captured by our approach among the recent terms exhibiting a rising trend (e.g., “fetoscopic laser surgery”, “monochorionic diamniotic twin pregnancies”, “placental insufficiency”, “placental function”). Further analysis of these terms is presented in the discussion section. We also surveyed specific terms for invasive diagnostic procedures, imaging procedures, fetal therapy procedures and next-generation genetics. As shown in Table 2, terms in two of these categories, namely invasive diagnostic procedures and imaging procedures, are generally stable. In contrast fetal therapy procedures and next-generation genetics tend to exhibit a rising trend, some of these terms having appeared very recently (“hot terms”).

Discussion

Trends in Fetal Medicine

Through a bibliometric analysis of articles published in Prenatal Diagnosis, using text mining techniques, we were able to identify trends in Fetal Medicine over the past 10 years.

Trends for diagnostic techniques. As expected, terms related to noninvasive prenatal testing exhibit a rising trend. More generally, terms denoting new genetic methods (e.g., “next generation sequencing”, “whole genome sequencing”, “single nucleotide polymorphism” or “microarray analysis”) are on the rise. In contrast, terms related to Cytogenetics (e.g., “molecular cytogenetic” or “FISH”) were highly used at the beginning of the decade, but are now less popular, reflecting a paradigm shift in Fetal Medicine. Interestingly, terms denoting invasive sampling techniques (“amniocentesis”, “choriocentesis”) remain stable in Fetal Medicine discourse, with a high number of occurrences across the decade, possibly because they continue to be mentioned as a reference when discussing newer techniques.

Trends in study design. In addition to trends for diagnostic techniques, our analysis identified trends in study design, namely an evolution toward structured studies reflected by a falling trend for “case report”, as well as a rising trend for “retrorospective study” and for “meta-analysis”. The most recent terms (“hot terms”) include “prospective cohort study” and “systematic review”. Case reports are still given consideration for publication as research letters in Prenatal Diagnosis. However, a partnership with the journal Clinical Case Reports since 2013 may be the reason why fewer case reports end up being published in Prenatal Diagnosis nowadays. The rising trend for statistical methods, tests and variables is consistent with the observed evolution of study design towards structured epidemiological and clinical studies reported in the general medical literature [1].

Text mining vs. expert opinion

While our analysis is generally consistent with the trends identified by the editors of Prenatal Diagnosis as reflecting advances in Fetal Medicine over the past few years [2,6,7], some terms related to fetal surgery do not appear in our lists of terms exhibiting a rising trend, simply because their frequency is below that of top terms in this group. For example, although it exhibits a rising trend, the term “fetoscopic laser surgery” occurs only in 40 articles during the decade. Similarly, the terms “fetal therapy”, “in utero treatment”, “fetoscopy”, “fetal surgery”, “diaphragmatic hernia”, “spina bifida” or “twin-twin transfusion syndrome” are stable but occur in less than 210 articles. Evaluation of placental function was also deemed as a major advance in 2015 [6], and our analysis also finds a rising trend (but limited frequencies) for “placental function”, “placental dysfunction” and “placental insufficiency”. Interestingly, although clearly identified in our analysis, trends in study design discussed above were not reported in editorials of the journal (probably because they do not reflect advances in diagnostic techniques per se). Moreover, stable and falling trends are not reported in editorials, but they are identified by our bibliometric analysis.

Text mining vs. metadata analysis

The medical literature referenced in PubMed/MEDLINE is indexed with Medical Subject Heading (MeSH) thesaurus. Therefore, an analysis of the indexing terms (MeSH descriptors) assigned to Prenatal Diagnosis articles could also help identify trends in Fetal Medicine. However, MeSH descriptors have limited granularity and there is often a delay between publication and indexing.

Limited granularity. MeSH has a limited number of descriptors for indexing Prenatal Diagnosis articles. In addition to the descriptor “Prenatal Diagnosis”, there are 7 more specific descriptors, namely “Amniocentesis”, “Chorionic Villi Sampling”, “Fetoscopy”, “Maternal Serum Screening Tests”, “Ultrasoundography. Prenatal”, “Cervical Length Measurement”, and “Nuchal Translucency Measurement”. Arguably, this granularity is insufficient for specific bibliometric analyses and cannot match granularity resulting from text mining techniques.

Delay between publication and indexing. There is a delay between time of publication and indexing. For example, in May 2016, 53% of articles published by Prenatal Diagnosis in 2015 were still awaiting indexing. Moreover, MeSH thesaurus is updated on a yearly basis, with some exceptions for public health emergencies (e.g., the term “Zika Virus Infection” was added to MeSH ahead of normal maintenance cycle). There is usually a delay between emergence of a new phenomenon and its availability as a MeSH descriptor. For example the term “Maternal Serum Screening Tests” was introduced in MeSH in 2013, whereas the first articles on the subject were published over 30 years ago [5]. (Of note, a specific term for “cell-free DNA” is currently under consideration for introduction in MeSH.) Therefore, our approach based on text mining is better suited for identifying trends in a timely fashion.

Limitations and perspectives

For text mining purposes, we had to extract text of articles from PDF documents, which are optimized for human readability, rather than automatic text processing. For example, we had to eliminate text of headers and footers to avoid extracting the name of the publisher present on each article as a “frequent term”. Similarly, we had to ignore words containing digits, which resulted in absence of potentially important terms, such as “h2-microglobulin”, “CRISPR/Cas9”, and many gene names (e.g. “CHD7” or “FGFR3”). Availability of Prenatal Diagnosis corpus in computer-friendly formats, such as XML, would make text mining analyses simpler and more reliable.

As mentioned earlier, we had to manually review terms excluded by our medical term filter and rescue 2.7% of them for analysis, including “fetal mchula translucency” and “cell-free DNA”. This is a consequence of limited coverage of Fetal Medicine terms in standard terminologies integrated in UMLS. Recent inclusion of Human Phenotype Ontology [18] into UMLS (version 2015AB) brought some important terms for postnatal phenotypes, but coverage of Fetal Medicine remains limited [8].
Conclusion

Through a bibliometric analysis of articles published in *Prenatal Diagnosis*, using text-mining techniques, we were able to identify trends in Fetal Medicine over the past 10 years. These trends are related to diagnostic techniques (Cytogenetics is progressively replaced by non-invasive techniques based on Genomics) and to study design (Fetal Medicine increasingly relies on scientific methods, including statistics and bioinformatics).

Our bibliometric analysis identified trends that are consistent with those identified by experts (about recent diagnostic techniques), but also identified other interesting trends (about study design), and provided an account for terms exhibiting falling trends and stable terms. In practice, bibliographic analysis and expert opinion are complementary approaches to identifying trends in Fetal Medicine.

PubMed/MEDLINE indexing based on MeSH offers limited granularity and a delay that is not compatible with identification of trends in a rapidly evolving domain, such as Fetal Medicine. We observed that coverage of Fetal Medicine, in MeSH, and standard terminologies integrated in UMLS is limited. List of terms identified through our text mining analysis could be basis for developing a terminology for Fetal Medicine. The list of terms and their evolution profiles are available up to request to the authors.

In summary, a bibliometric analysis based on text mining effectively supports identification of trends over time. This scalable approach is complementary to analyses based on metadata or expert opinion.

Abstract

To address current key problems of medical documentation: lack of transparency, overwhelming amount of medical contents to be documented and missing interoperability, the Portal of Medical Data Models (http://medical-data-models.org) was established in 2012. Constantly evolving, four years later, the portal displays more than 8900 medical data models with more than 250000 items, of which 84% have been semantically annotated with UMLS codes to support interoperability. Giving an update on new functions and contents of the portal, two additional export formats have been implemented, allowing the reuse of forms such as HL7’s framework Fast Health Interoperability Resources (FHIR) Questionnaires, as well as the OpenDataKit format. Future projects include the implementation of an ODMtoOpenClinica converter, as well as supporting the reuse of forms with Apple’s ResearchKit and Android’s ResearchStack.

Keywords:
Surveys and Questionnaires, Semantics, Clinical Trial

Introduction

The Portal of Medical Data Models (MDM), established in 2012, is a constantly evolving and fast-growing German and European information infrastructure for medical research and healthcare [1,2]. The multilingual platform allows the upload, download, discussion, ranking and reuse of medical questionnaires or documentation forms. These “medical data models” are created in Operational Data Model (ODM) format, developed by the Clinical Data Interchange Standards Consortium (CDISC) [3]. ODM is XML-based and represents the standard exchange format for research metadata in order to facilitate interoperability amongst various software systems [4]. Apart from ODM, the portal offers various download formats, enabling the import of metadata into different medical information systems. To improve interoperability and data integration, medical concepts are semantically annotated with Concept Unique Identifiers (CUIs) from the Unified Medical Language System (UMLS), developed by the U.S. National Library of Medicine [5]. The identification and coding of medical concepts is manually performed by medical experts respecting the published coding principles [6]. The creation of medical data models has been standardized, allowing uniform semantic annotation, using ODMedit [7]. The integrated editor ODMedit proposes possibly matching data elements, which have been defined and semantically annotated before and may be reused.

The value of interoperability in the United States was evaluated in 2005, showing that the fully standardized exchange and interoperability of health care information between various providers has the potential to save 77.8 billion dollars per year [8]. The German Federal Ministry of Education and Research has launched a funding initiative to establish data integration centers, for which the portal provides an infrastructure for a standardized exchange of medical data models between participating consortia in order to analyze their medical (meta-) data landscapes [9].

The overwhelming amount of data documented in medicine, as well as the number of distinct medical concepts in a clinical terminology, such as Systematized Nomenclature of Medicine (SNOMED CT) [10], indicate the “astronomical” number of potential medical data models used by health professionals [11]. Up to now, most of the medical forms and data from clinical trials remain unpublished. This leads to a cost and time intensive process of re-developing and re-implementing case report forms (CRFs) for clinical studies and documentation forms in EHR systems. Researchers, practicing physicians and their patients are calling for “open (meta-) data”, starting to consider clinical trial data as a public good [12]. Unpublished data hampers the systematic review and reproduction of published results leading to redundancies in clinical research as well as uncertainties in patients and treating physicians. MDM addresses the lack of transparency by granting open access to all of its contents. Furthermore its contents may be downloaded under different Creative Commons Licenses, allowing sharing and adapting the material for different purposes.

In this paper we will analyze the current contents and describe new functions of the portal. Further research objectives give an overview of the user’s activities, planned additional download formats, functions and further research based on MDM. The research questions of this paper can be summarized as followed:

1. What kind of medical contents and functionalities are available in the system and how did it evolve over time?
2. Who is using the system and what export formats are selected most frequently?

Methods

Architecture of the Portal and its contents

The technical background of the portal and the editor have been described before [7,13]. To summarize, the portal has been implemented in Ruby on Rails. The data models are stored on a web server. After uploading an ODM file, its structure is additionally stored in a MySQL database on the server [7,13].

The medical data models are sustainably archived by the University Library of Muenster [14].

Designing medical data models with ODMedit

As data models represent an “interoperable image” of actual medical forms, they are created in the CDISC ODM format using original templates from clinical trials, registries, routine
documentation forms, common data elements (CDEs) , data standards or patient-reported outcomes. Medical experts, such as physicians, medical documentalists and medical students, create and semantically annotate forms with UMLS codes using ODMedit [7]. Currently 14 medical experts with more than 120 hours per week are creating and annotating medical data models manually. The UMLS CUI of a medical concept is stored as an alias property of the items or codelist items. If a medical concept can be described by a single CUI, it is called a pre-coordinated concept. If a medical concept needs more than one CUI to represent its full meaning, the process is called post-coordination. Uploaded medical data models are reviewed and verified for accuracy before being released for public use.

Analysis of the contents

Database queries were performed using the MySQL Workbench 6.3. To determine the time course of items and medical data models offered by the portal, the cumulative number of items and data models from November 2011 until November 2016 were analyzed. Furthermore, the UMLS codes mapped to the items and the Medical Subject Headings (MeSH) descriptors of the category C for diseases mapped as keywords to the medical data models were analyzed to display the medical contents of the portal.

To display the portal’s user distribution, a world map was configured using Leaflet, OpenStreetMap and Mapbox. The retrieval of geolocations of the users’ most recently used IP addresses was conducted using freegeoip.net. To analyze the geolocation of potential users who didn’t register but visited the portal and accessed forms, Apache Log-Files of the previous eight months were assessed, ignoring Internet bots.

An online user survey was conducted in February 2016 using LimeSurvey. The online questionnaire, available in English and German, contained questions on missing functions and further export formats requested by users.

The new functions of the portal were reviewed: the table of contents was expanded and modified after reviewing and analyzing the contents of the portal. By choosing a subentry of the table of contents, the search function is called with predefined terms, similar to a manual search. Two additional export formats were implemented.

Results

Contents of the Portal of Medical Data Models

As of November 2016 the Portal of Medical Data Models contains 8948 active forms, 16794 forms in total, with a total of 256751 items. The analysis of the time course of medical data models shows that the number of medical data models as well as the number of items are continuously growing (see Figure 1). Since December 2015, about 400 new medical data models per month were uploaded to the portal. As for the number of items, approximately 10000 are added per month. 84 % of the items are semantically annotated with UMLS codes, representing their medical concepts. The amount of semantically annotated items totals to 216586 items. The three most common UMLS codes tagged to items, representing medical concepts, are “C0022885” for “Laboratory Procedures”, “C0031809” for “Physical Examination” and “C0006826” for “Malignant Neoplasms”.

Other UMLS codes that were assigned most frequently are mainly administrative concepts, such as “C0011008” – “Date in time” or “C2348585” – “Clinical Trial Subject Identifier”.

Figure 1 - Time course of items in active medical data models represented in the Portal of Medical Data Models

The results of the analysis of MeSH descriptors is presented in a logarithmic scale in figure 2. A total of 13747 assigned descriptors were identified. The prevailing majority of medical data models is related to oncology. More than 4300 medical data models have been tagged with a MeSH descriptor of the category C04 for neoplasms. The second most used MeSH terms are branches of the category C20 for Immune System Diseases, including diseases such as multiple sclerosis and asthma. The third most represented category is C17 for Skin and Connective Tissue Diseases.

The portal offers contents in multiple languages. Though most 7731 forms (86 %) are monolingual, either in English or German, 1199 forms (13 %) are available in two languages, mainly in English and German. A total of 14 forms (0,16 %) are available in more than two languages, ranging from 3 languages up to 30 languages. The most common language is English with 8414 forms, followed by German with 1858 forms, French with 13 forms and Spanish, Italian and Polish with 5 forms.

Online Survey and User’s distribution

The analysis of the users requests for further export formats revealed the demand for HL7’s framework Fast Health Interoperability Resources (FHIR) Questionnaires, combining the most advantageous features of HL7 v2, v3 and CDA for exchanging health data [15]. Other export requests were OpenClinica, an electronic data capture system, using Excel templates to import metadata and OpenDataKit (ODK), a toolset for mobile data collection.
Currently the Portal has 611 registered and active users, distributed worldwide (Figure 3, green pins). Analyses of users visiting the portal without registration showed the distribution as presented in Figure 3 by the blue pins. The majority of users are located in Central Europe and the United States.

The total numbers of users, registered and potential are displayed in Table 1, grouped by their geographical origin.

Table 1 - Total number potential users’ page views, grouped by their geographical origin

In response to the users’ requests, two new export formats were implemented. A converter, transforming forms from ODM to FHIR Questionnaire Resources was implemented in Java and integrated into the portal. This included identifying equivalent elements and mapping these ODM elements to the elements of the FHIR Questionnaire Resources [16]. A similar approach was conducted implementing the requested converter ODM to ODK.

Table 2 gives an overview of the most frequently downloaded formats. Since the implementation of the ODM to FHIR converter in February 2016, the FHIR questionnaire format is at 5% for FHIR-XML and 4% for FHIR-JSON as one of the six most common download formats. Most forms were downloaded in ODM (35%), PDF (14%) and REDCap (12%). The least downloaded formats were ADL [17] and R with 1%.

The table of contents (see Figure 4) was modified and adapted to the medical contents of the portal. It contains 7 main categories, arranging the contents by type of documentation within the medical data model, such as “Clinical Trial”, “Routine Documentation” or “Patient-Reported Outcomes”. Furthermore the contents are indexed by specialty under...
“Specialty-related forms”, containing 16 subitems, such as “Internal Medicine”, “Neurology” and “Surgery”.

In November 2015 the portal contained about 4300 models. Models show major progress over the past year. The analysis of the contents of the Portal of Medical Data “Internal Medicine”, “Neurology” and “Surgery”. “Specialty-related forms”, containing 16 subitems, such as “clinical trials. It has to be mentioned that semantic annotation is not a trivial task. From our experience, manual review by medical experts is highly required. Even respecting coding principles, mapped UMLS codes still differ between independent coders. When generating CDEs, this still represents an issue, leading to the inevitable, time-consuming process of “code-cleaning”. Steps towards uniform semantic annotation are being conducted using the integrated editor ODMEdit [7]. Furthermore, the impact of coding principles and ODMEdit on inter-coder reliability are being evaluated.

With regards to the representation of disease entities in the portal, we are able to show that a wide range of disease entities is already represented. The majority of contents are related to oncology, explaining the third most frequent semantic code assigned (“Malignant Neoplasms”). This is in line with the contents of ClinicalTrials.gov, a registry for clinical studies, maintained by the U.S. National Institutes of Health [19]. It currently lists a total of more than 231,900 studies, 25% of which are associated with “Neoplasms”. The European Clinical Trials Register currently displays more than 29,300 studies [20]. In accordance with the worldwide registry ClinicalTrials.gov, the amount of clinical trials related to oncology represents, with more than 7,000 studies, about 24% of the contents. A great amount of medical data models in the portal have been created based on the trial inclusion and exclusion criteria, indicated in the study record details of studies on ClinicalTrials.gov. With a focus on oncologic, neurologic and cardiovascular diseases, this resembles the numerical distribution of contents. So far, the portal does not contain medical data models, mapped with a MeSH descriptor of the tree branches C21 for disorders of environmental origin and C03 for parasitic diseases. Only one medical data model from the tree branch C22 for animal disease was found.

Another medical research repository is the National Institute of Health’s (NIH) Common Data Element Repository, maintained by the U.S. National Library of Medicine. It currently offers 2,175 case report forms in four export formats (OMM, two NIH/CDE schemata and SDC). The main research domain focus is on neurological disorders (NINDS) with 140,900 elements, as well as on PhenX measures, a consented amount of 627 “standard measures of phenotypes and exposures for use in research” [21]. This is only a small subset of medical forms, compared to the amount of forms offered by our portal. Nevertheless, one must note, that the contents of the NIH CDE Repository consist mainly of previously consented CDEs. Considering the costly and time-consuming task, the creation of CDEs poses, involving the close cooperation of various research communities, the NIH CDE Repository contains already a substantial number of reusable forms. By presenting an image of the current state of documentation in various medical backgrounds, the Portal of Medical Data Models may contribute to a faster, more efficient and effective way to create CDEs, serving as the infrastructure used to identify and generate CDEs. In course of their doctoral thesis, six medical students are currently doing research on various disease entities. To identify CDEs used in myeloid leukemia, the portal already presents a solid and feasible foundation [22].

By adapting the table of contents, clinicians may be able to get a quick overview over the topics of their specialty. To approach the needs of users, we are constantly implementing further export possibilities. As the user survey showed, there is a great need for an export of medical forms to the OpenClinica metadata import format. The converter is currently being developed and will be available in the short term.

Furthermore we soon will offer an export to Apple’s ResearchKit, in order to support the reuse of our contents in studies conducted by mobile devices via mobile applications. We are planning the implementation of an export “OMDtoResearchStack” as it represents the equivalent to Apple’s ResearchKit for surveys conducted by Android users.

Figure 4 - Table of contents of the Portal of Medical Data Models. The subentry “Routine Documentation” is expanded, showing the contents of the medical documentation in clinical routine. The subitems are chronologically arranged, following the patients path through the clinic from admission to discharge.

Discussion

The analysis of the contents of the Portal of Medical Data Models show major progress over the past year.

In November 2015 the portal contained about 4300 models with about 136,500 items. One year later, the number of medical data models more than doubled to the amount of over 8900, increasing by about 400 data models per month. The amount of items also almost doubled to 256,751 items, reaching an upload rate of about 10,000 items per month. Our goal is to reach an upload rate of 600 medical data models per month in order to ensure the availability of data models in a timely manner. Furthermore the portal shall cover most contents in medical research and clinical practice. Difficulties concerning the open access to metadata in routine patient care and clinical and epidemiological research are still far from being resolved. Small steps in the right direction are being made, as journals like the New England Journal of Medicine have committed to data sharing [18].

To enable semantic interoperability of medical data models, they are semantically annotated. With an annotation coverage of 84%, the portal provides the possibility to access more than 246,500 semantically annotated items for reuse. The most frequently assigned UMLS codes with medical content, “laboratory procedures” and “physical examination” represent very well two of the most common medical items documented and examined in clinical trials. It has to be mentioned that semantic annotation is not a trivial task. From our experience, manual review by medical experts is highly required. Even respecting coding principles, mapped UMLS codes still differ between independent coders. When generating CDEs, this still represents an issue, leading to the inevitable, time-consuming process of “code-cleaning”. Steps towards uniform semantic annotation are being conducted using the integrated editor ODMEdit [7]. Furthermore, the impact of coding principles and ODMEdit on inter-coder reliability are being evaluated.

With regards to the representation of disease entities in the portal, we are able to show that a wide range of disease entities is already represented. The majority of contents are related to oncology, explaining the third most frequent semantic code assigned (“Malignant Neoplasms”). This is in line with the contents of ClinicalTrials.gov, a registry for clinical studies, maintained by the U.S. National Institutes of Health [19]. Considering the costly and time-consuming task, the creation of CDEs poses, involving the close cooperation of various research communities, the NIH CDE Repository contains already a substantial number of reusable forms. By presenting an image of the current state of documentation in various medical backgrounds, the Portal of Medical Data Models may contribute to a faster, more efficient and effective way to create CDEs, serving as the infrastructure used to identify and generate CDEs. In course of their doctoral thesis, six medical students are currently doing research on various disease entities. To identify CDEs used in myeloid leukemia, the portal already presents a solid and feasible foundation [22].

By adapting the table of contents, clinicians may be able to get a quick overview over the topics of their specialty. To approach the needs of users, we are constantly implementing further export possibilities. As the user survey showed, there is a great need for an export of medical forms to the OpenClinica metadata import format. The converter is currently being developed and will be available in the short term.

Furthermore we soon will offer an export to Apple’s ResearchKit, in order to support the reuse of our contents in studies conducted by mobile devices via mobile applications. We are planning the implementation of an export “OMDtoResearchStack” as it represents the equivalent to Apple’s ResearchKit for surveys conducted by Android users.
A problem with the current implementation in Ruby on Rails is the lack of scalability and easiness of maintenance. To face these problems the system is currently being re-developed in Java EE, which is planned to go online in the course of 2017.

Once the contents of the portal represent most of the currently used medical data models, the transnational creation of data standards and CDEs may be accelerated and will support the interoperability of clinical data, leading to harmonized documentation, improving cross study comparisons and meta-analyses.

Conclusion

Transparency, interoperability and huge amounts of data and metadata are crucial issues in medical research, approached by the Portal of Medical Data Models. This paper gives an overview of the new contents of the portal, such as the representation of an increasing amount of medical data models and items as well as new functions such as converters from ODM to FHIR or ODK. Additionally, the presentation of content is now structured according to the origin and specialty that the medical data models are related to. The user survey revealed the demand for further export features, which will be developed in the near future.

Abstract

The National Cancer Institute Thesaurus (NCIt), developed and maintained by the National Cancer Institute, is an important reference terminology in the cancer domain. As a controlled terminology needs to continuously incorporate new concepts to enrich its conceptual content, automated and semi-automated methods for identifying potential new concepts are in high demand. We have previously developed a topological-pattern-based method for identifying new concepts in a controlled terminology to enrich another terminology, using the UMLS Metathesaurus. In this work, we utilize this method with the National Cancer Institute Metathesaurus to identify new concepts for NCIt. While previous work was only oriented towards identifying candidate import concepts for human review, we are now also adding an algorithmic method to evaluate candidate concepts and reject a well defined group of them.

Keywords: Biomedical Ontologies; Vocabulary; Quality Assurance

Introduction

Biomedical ontologies, terminologies and controlled vocabularies are widely used in a variety of healthcare information systems for encoding healthcare data such as diagnoses, laboratory test results, patient-reported problem lists, and billing statements. They are also used to facilitate knowledge management, data integration, decision support, and biomedical natural language processing. The development and curation of biomedical ontologies are mostly driven by ontology engineers and subject matter experts. As domain completeness is one of the key properties of a biomedical ontology [1], new concepts need to be included as they are needed by the users. As manual curation is costly and time consuming, automated or semi-automated methods for identifying new concepts that are relevant to the domain of an ontology are therefore in high demand.

The National Cancer Institute (NCI) Thesaurus (NCIt) is an important reference terminology in the cancer domain. It currently contains over 100,000 concepts that are hierarchically organized into 19 distinct hierarchies relevant to cancer research, such as neoplastic diseases and molecular abnormalities. NCIt is a central reference terminology of NCI’s Enterprise Vocabulary Services (EVS) [2]. The EVS leverages both an internal quality assurance (QA) team and external participation in the development and QA of NCIt. Outside contributors can suggest new concepts or terms for NCIt, which will be reviewed, validated, and incorporated into it, based on NCI’s content development and editing guidelines.

In previous work [3; 4], we have developed a topological-pattern-based method to demonstrate the vertical density differences across pairs of source terminologies in the Unified Medical Language System (UMLS), the most comprehensive biomedical terminological system in existence, developed by the U.S. National Library of Medicine [5]. Leveraging the topological patterns in the UMLS, we have identified potential new concepts for SNOMED CT [3; 4]. Figure 1 illustrates the simplest case of a topological pattern, called a 1:1 trapezoid where \( k = 2 \). In this case, both Terminology 1 (T1) and Terminology 2 (T2) contain Concept A and Concept B. In other words, Concept A and Concept B in T1 and T2 have the same UMLS Concept Unique Identifier (CUI). There is one intermediate concept X between Concept A and Concept B in T1 but no intermediate concept in T2. Upward pointing arrows indicate IS-A links.

One can argue that Concept X may be missing in T2. However, the intermediate concept(s) from T1 may not be needed in T2 according to human judgment. If \( k > 2 \), there is more than one intermediate concept in T1. In this paper, T2 is always NCIt. The final decision whether the intermediate concepts should be included in NCIt or not always has to be made by its curators.

Recently, we applied this method to identify concepts in the UMLS that could enrich NCIt [6]. The National Cancer Institute Metathesaurus (NCIm) is a terminological system with the same structure as the UMLS, but with more cancer related content [7]. Therefore, a natural question arises – “Is NCIm a better source for utilizing topological patterns to identify new concepts for NCIt than the UMLS Metathesaurus?” Because NCIm and UMLS have much overlap, we were especially interested in concepts suggested for import by topological patterns that exist only in the UMLS.
but not in the NCIm and vice versa. The latter case would indicate a new source for candidate concepts compared to previous research.

One difficulty with our previous approach is that all evaluations of candidate concepts have to be performed by a human expert. In this paper, we were investigating ideas for algorithmically rejecting some of the candidates, reducing the work load for the human expert. We formulated the following hypotheses about reasons for missing intermediate concepts in k:1 trapezoids in NCIt:

- The parent concept (A in Figure 1) has only one child (B in Figure 1) in NCIt. Therefore, an intermediate concept is not needed to organize the conceptual content.
- The intermediate concept is a synonym of the parent concept (A in Figure 1) or the child (B in Figure 1) in NCIt.
- The curators of T1 and NCIt made different modeling decisions.

The contributions of this work are twofold: 1) We compare the usefulness of the NCIm and UMLS Metathesaurus as data sources for using topological-pattern-based methods to identify new concepts for NCIt; 2) We propose a practical method to algorithmically reject some concepts for import, thereby reducing the work load of the human expert.

Background

UMLS Metathesaurus (Meta)

The UMLS Metathesaurus (Meta), which integrates over 190 biomedical terminologies, is the most comprehensive biomedical terminological system in existence [5]. It maps over 12 million terms into over 3.2 million concepts.

NCI Metathesaurus (NCIm)

The NCI Metathesaurus (NCIm) is a wide-ranging biomedical terminological system that covers most terminologies used by NCI for clinical care, translational and basic research, public information and administrative activities [7]. It maps about four million terms from more than 75 source vocabularies into two million concepts that represent their meaning. Importantly, it has a monthly update cycle, ensuring the timely update of its core terminology, NCIt. It covers most of the public domain terminologies of the NLM’s UMLS Metathesaurus as well as many other biomedical terminologies created by or of interest to NCI and its partners such as RadLex. Some vocabularies such as SNOMED CT were also shrunk in the NCIm.

Methods

Identifying Candidate Terminologies

In this work, we compared the effectiveness of using NCIm versus UMLS Meta to identify potentially useful concepts for enriching the conceptual content of NCIt. We used the August 2015 version of the NCIm and the 2015AA version of the UMLS Meta. Both NCIm and UMLS 2015AA contain SNOMED CT US (March 31, 2015 version). The NCIt version in NCIm is 2015 08E, whereas the NCIt version in the UMLS is 2014 03E. The main criteria for selecting a candidate terminology for this research include: 1) the terminology must be in English; 2) the terminology must be organized with an IS-A hierarchy backbone; 3) the terminology must exhibit sufficient overlap in content with NCIt; and 4) the terminology must exist in both UMLS Meta and NCIm. We first identified seven English source terminologies with “PAR” (parent-child) relationships and “INVERSE IS_A” relationship attributes, including SNOMED CT, Foundational Model of Anatomy Ontology (FMA), Universal Medical Device Nomenclature System (UMD), RadLex (a radiology lexicon), University of Washington Digital Anatomist (UWDA), MGED Ontology (MGED), and Gene Ontology (GO). Out of these seven terminologies, RadLex and MGED are not in the UMLS Meta. UWDA is part of FMA and was therefore excluded.

Identifying and Analyzing k:1 Trapezoids

We first identified all the k:1 trapezoids in NCIm and UMLS. The NCIm, which is based on the UMLS, may contain cycles of IS-A relationships [8]. We eliminated the cycles in the trapezoid by detecting repeating Concept Unique Identifier (CUIs) in the IS-A paths.

After we identified all the k:1 trapezoids in the NCIm and the UMLS, we calculated the number of trapezoids for each kind and the number of intermediate concepts in T1. Note that multiple parents may lead to overlapping trapezoids with the same intermediate concept. We eliminated duplicate intermediate concepts in the results.

Manual Review of the 2:1 Trapezoid Samples

To compare the utility of the topological patterns in the NCIm and the UMLS Meta for identifying new concepts for enriching NCIt, we took a random sample of 50 2:1 trapezoids between SNOMED CT and NCIt that can be found in the UMLS but not in the NCIm (Sample 1), as well as a random sample of 50 2:1 trapezoids between SNOMED CT and NCIt that can be found in the NCIm but not in the UMLS (Sample 2). We combined the two samples and randomized the order.

The terminology expert (YC) investigated the content of both SNOMED CT and NCIt using the Neighborhood Auditing Tool (NAT) for the UMLS [9], and assessed whether the intermediate concepts in SNOMED CT should be suggested for inclusion in NCIt or not. The terminology expert chose one of the following three options: 1) the intermediate concept (Concept X in Figure 1) in T1 should be imported into NCIt; 2) the intermediate concept should not be imported into NCIt; and 3) the intermediate concept may be imported into NCIt. For the options 2) and 3), the terminology expert was also asked to give rationales for making such a choice. The NAT tool (http://nat.nijit.edu/) allows an auditor to concentrate on a single focus concept and its neighborhood (i.e., parents, children, siblings), thereby well meeting the need of this study. We will report the manual review results and the reasons for options 2) and 3) in the Results section.

Identifying More Complex Topological Patterns

There could also be one or more intermediate concepts in T2 in a topological pattern. We therefore defined MN trapezoids as topological patterns in which both T1 and T2 have both Concept A and Concept B, but there are M-1 intermediate concepts between A and B in T1 and N-1 intermediate concepts between A and B in T2. The intermediate concepts in T1 do not appear anywhere in T2 and vice versa. MN trapezoids are a generalization of k:1 trapezoids. The relationships among intermediate concepts in MN can be categorized into the following three types: 1) an intermediate concept in T1 can be a parent/child of an intermediate concept
in T2; 2) an intermediate concept in T1 can be a synonym of an intermediate concept in T2; 3) T1 and T2 have alternative classifications, indicating two different ways of conceptualizing a domain that are both valid but not immediately compatible [3]. A trapezoid may also indicate an error in one of the two terminologies. In a recent publication [10], we provided an estimate of the difficulty faced by a domain expert in a concept import task. In this paper, we merely identified the M:N trapezoids (M >= 2, N >= 2) in both the NCIm and the UMLS. The analysis of the relationships among intermediate concepts in M:N trapezoids is beyond the scope of this work.

Results

2:1 Trapezoids in the NCIm and the UMLS Meta

Table 1 shows the number of 2:1 trapezoids identified in the NCIm and the UMLS Meta. As shown in Table 1, notably fewer 2:1 trapezoids between SNOMED CT and NCIt were identified in NCIm than in the UMLS. In these 2:1 trapezoids, 1,019 distinct intermediate concepts can be found in both NCIm and the UMLS; 890 distinct intermediate concepts were found in the UMLS but not in the NCIm; and 174 intermediate concepts in the NCIm were not in the UMLS. This may be due to the fact that the NCIm contains a newer version of NCIt than the UMLS Meta. Only a small number of trapezoids could be found between terminologies other than SNOMED CT and NCIt. In the subsequent analysis, we will focus on the trapezoids between SNOMED CT and NCIt.

Table 1 – Number of 2:1 Trapezoids Identified in NCIm and UMLS Meta

Figure 2 shows the histogram of semantic types of 890 intermediate SNOMED CT concepts that were identified in the 2:1 trapezoids in the UMLS Meta but not in the NCIm. Semantic types with fewer than 10 concepts are not shown in the figure.

Figure 3 shows the histogram of semantic types of 174 intermediate SNOMED CT concepts that were identified in the 2:1 trapezoids in the NCIm but not in the UMLS. All the semantic types except for ENZYME also appear in Figure 2.

K:1 Trapezoids in NCIm and the UMLS Meta

Table 2 shows the number of trapezoids and the number of unique intermediate concepts identified in k:1 (k > 2) trapezoids between SNOMED CT and NCIt in both NCIm and the UMLS Meta. As the value of k increases, the difference between NCIm and UMLS becomes larger, indicating that NCIm has significantly downsized SNOMED CT and removed concepts that are unnecessarily granular for the cancer domain.

Manual Review of the Samples of 2:1 Trapezoids

According to the review results of YC, in Sample 1 (2:1 trapezoids found in the UMLS but not in the NCIm), 20 intermediate concepts (40%) should be imported into NCIt, 23 intermediate concepts (46%) should not be imported into NCIt, and 7 intermediate concepts (14%) may be imported into NCIt. In Sample 2 (2:1 trapezoids found in the NCIm but not in the UMLS), 20 intermediate concepts (40%) should be imported into NCIt, 23 intermediate concepts (46%) should not be imported into NCIt, and 7 intermediate concepts (14%) may be imported into NCIt. For the cases in which the intermediate concepts should not be imported, the major reasons for rejecting the import are: 1) The term of the intermediate concept is a synonym of the parent/child concept in NCIt; 2) the parent concept has a single child in NCIt; it was felt that creating a structure of one child with one grandchild contradicts the idea of hierarchically organizing concepts in an ontology into groups of similar concepts; and 3) NCIt and SNOMED CT are using two different categorizations. For example, SNOMED CT models the concepts by sites but NCIt does not.
For the cases of possible import, the rationale is that SNOMED CT is more granular than NCIt, i.e., the parent concept has more children/descendants in SNOMED CT than in NCIt. We list the review results of the mixed sample in Table 3. Even though both samples have the same percentage of trapezoids that can contribute concepts to NCIt, Sample 2 has a higher percentage of intermediate concepts that may be imported into NCIt than Sample 1 (14% vs. 6%).

Figure 4 illustrates a case of reason 1). In this case, the term of the intermediate concept Complete Blood Count (C0009555) in NCIt. Therefore, there is no need to add the intermediate concept in SNOMED CT to NCIt.

Figure 5 illustrates a case of reason 2) in which the parent concept Retinitis (C0035333) has only one child - Cytomegaloviral Retinitis (C0206178) in NCIt. It is therefore not recommended to add an intermediate concept in NCIt.

SNOMED CT

Automatic Rejection of Import from K:1 Trapezoids

As discussed in the manual review section, one of the major reasons why an intermediate concept in a 2:1 trapezoid should not be imported into NCIt is that the parent concept in the trapezoid has only one child in NCIt. To assess the scale of this problem, we investigated all the k:1 trapezoids between SNOMED CT and NCIt in both the UMLS and NCIm to find the percentage of parent concepts in the k:1 trapezoids with only one child in NCIt. As can be seen in Table 4, 8.7% of parent concepts in 2:1 trapezoids in the UMLS have only one child in NCIt, whereas 7.5% of parent concepts in 2:1 trapezoids in the NCIm have only one child in NCIt. As k increases, the percentage drops fast. About 5% of intermediate concepts identified in 2:1 trapezoids with such a structure can be automatically rejected for import. Another reason for rejecting an import is that the term of the intermediate concept is a synonym of the parent/child concept in NCIt. However, it is not easy to fully automate the detection of such cases because certain judgments of synonymy need to be made by human experts.

M:N Trapezoids in NCIm and the UMLS Meta

Table 5 shows the number of M:N trapezoids (M, N >= 2) between SNOMED CT and NCIt in the NCIm and the UMLS, respectively. Due to the space limit, we only show the

Z. He et al. / Perceiving the Usefulness of the National Cancer Institute Metathesaurus
numbers of 2:N and 3:N trapezoids. A smaller number of M:N trapezoids was found in the NCIm than in the UMLS. Whether a higher percentage of trapezoids is useful for concept enrichment or not warrants further investigation.

For the k:1 trapezoid cases where the intermediate concepts were deemed to be possible imports into NCIt, the final decision will depend on the NCIt curators at two levels. First the curators will have to decide whether this topic area in NCIt is sparse on purpose, or whether it is only sparse because of lack of time and budget. Then the curators will have to decide about each concept individually whether it is desirable for import into NCIt.

A few limitations need to be noted. The version of NCIt in NCIm (2015 08E) is different from the one in the UMLS. Because the NCIt version in the UMLS always falls behind the NCIt version in the NCIm, we were not able to find NCIm and UMLS Metathesaurus releases with the same version of NCIt and SNOMED CT. Nevertheless, both the 2015AA release of the UMLS and the August 2015 version of NCIt contain the SNOMED CT US March 31, 2015 version. In future work, we plan to develop a more robust method that leverages more sophisticated topological patterns to recommend new concepts for NCIt and reject inappropriate ones.

Shiny FHIR: An Integrated Framework Leveraging Shiny R and HL7 FHIR to Empower Standards-Based Clinical Data Applications

Na Hong, Naresh Prodduturi, Chen Wang, Guoqian Jiang
Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA

Abstract

In this study, we describe our efforts in building a clinical statistics and analysis application platform using an emerging clinical data standard, HL7 FHIR, and an open source web application framework, Shiny. We designed two primary workflows that integrate a series of R packages to enable both patient-centered and cohort-based interactive analyses. We leveraged Shiny with R to develop interactive interfaces on FHIR-based data and used ovarian cancer study datasets as a use case to implement a prototype. Specifically, we implemented patient index, patient-centered data report and analysis, and cohort analysis. The evaluation of our study was performed by testing the adaptability of the framework on two public FHIR servers. We identify common research requirements and current outstanding issues, and discuss future enhancement work of the current studies. Overall, our study demonstrated that it is feasible to use Shiny for implementing interactive analysis on FHIR-based standardized clinical data.

Keywords:
Data Interpretation, Statistical; Health Level Seven; Reference Standards

Introduction

Great attention has been paid recently on the need for interoperability in healthcare information systems and healthcare solutions to facilitate the meaningful use of healthcare data. However, current healthcare application practices have been greatly limited by data heterogeneity and data model diversity. Component reuse, service sharing, and data exchange have become common challenges in the development of healthcare applications.

On the one hand, data standardization plays a very important role in clinical and translational data analysis systems, especially when large-scale data are accumulated. On the other hand, applications for clinical statistics and analysis could advance healthcare by connecting clinical data with analytic tools that can support data analysis, and engage clinicians in the process of analysis. This study is motivated by the need for open solutions to support clinical statistics and analysis with scalable standards-based data model.

Over the last decade, a number of organizations have been targeting the development of clinical data standards to improve medical research, such as Health Level Seven (HL7), the Clinical Data Interchange Standards Consortium (CDISC), the Observational Health Data Sciences and Informatics (OHDSI) and the Patient-Centered Outcomes Research Institute (PCORI). Meanwhile, a number of data models have been developed to support the needs of clinical data standardization [1, 2]. Some of the data models are:

1. The Operational Data Model (ODM), developed by CDISC, is a vendor-neutral, platform-independent format for exchanging and archiving clinical study data [3]. As a specification, ODM supports interchange of data, metadata or updates of both between clinical systems.

2. The HL7 Clinical Document Architecture (CDA) is a document markup standard that specifies the structure and semantics of “clinical documents” for the purpose of exchange between healthcare providers and patients. The most popular use of CDA is for inter-enterprise information exchange, such as that envisioned for a US Health Information Exchange (HIE) [4].

3. The Observational Health Data Sciences and Informatics (OHDSI) Common Data Model (CDM) specifies a data model that enables the transformation of data contained within different observational databases into a common format (data model) as well as a common representation (terminologies, vocabularies, coding schemes). It also enables systematic data analysis and characterization using a library of standard analytic routines that are written based on the common format. The purpose of the CDM is to standardize the format and content of the observational data, so standardized applications, tools and methods can be applied to them [5].

4. The PCORnet CDM is based on many CDMs of other large national research consortia. PCORnet is an innovative initiative of the PCORI. Each PCORnet partner network maps and transforms data to the PCORnet CDM using the same consistent format (i.e., the same variable names, attributes, and other metadata) [6].

5. The Fast Healthcare Interoperability Resources (FHIR) is an emerging clinical data standard developed at HL7 [7], which enables the representation and exchange of the electronic health records (EHR) data in a standard structure. Others clinical related data standard, such as HL7 Reference Information Model (RIM) [8] and OpenEHR [9] also define common data models that provide a way of organizing data into a standard structure.

Comparing the usability and clinical concepts coverage, we chose FHIR as our practicing data model in this study as FHIR has strong executability based on a RESTful service architecture and multiple flexible data exchange formats. As an emerging executable HL7 standard, the implementations of FHIR have already attracted a lot of interests from healthcare
practitioners, such as SMART on FHIR [10], characterized by its simplicity for implementation and its rigorous mechanism for exchanging data.

R is a functional language and environment for statistical and graphical exploration of data sets, which is widely utilized in clinical and biomedical statistics and research. Shiny is a web application framework with a simplified web deployment mechanism requiring no HTML or JavaScript knowledge [11]. Shiny also includes the ability to integrate R functions for graphical and interactive analysis.

Therefore, with the goal of building reusable and extensible clinical statistics and analysis applications, we aim to design, implement and evaluate an integrated framework called Shiny FHIR using the HL7 FHIR standard and the R-powered web application Shiny.

Materials

In total, four major materials are used in this study, comprising FHIR resources for the data modeling, Shiny and R packages for clinical data analysis functions implementation, and ovarian cancer clinical data for the use case implementation.

FHIR Resources

The FHIR specification defines a set of resources and an infrastructure for handling those resources [12]. The core FHIR resources represent a wide range of healthcare related concepts, both clinical and administrative. The extension FHIR resources represent customized clinical concepts. By aggregating (“bundling”) granular clinical concepts, the resources can support a complex clinical data report and data exchange.

The base FHIR Specification is a platform specification—a specification on which a variety of different solutions are built. The FHIR Specification has 3 versions in its developing timeline, which are the Draft Standard for Trial Use (DSTU1), DSTU2 and the final non-draft version STU3. We currently use the officially released version DSTU2.

HAPI FHIR

HAPI FHIR is an open-source implementation of the FHIR specification in Java [13]. It is based on the easy-to-execute principle, but applied to the Java implementation. HAPI FHIR APIs are designed based on the JAXB and JAX-WS APIs. HAPI FHIR defines model classes for every resource type and datatype defined by the FHIR specification. FhirContext acts as a factory for most other parts of the API as well as a runtime cache of information that HAPI needs to operate. Under the FhirContext, HAPI FHIR APIs support the data model operations with the FHIR resources, and the RESTful client interacts with the FHIR server.

Shiny & R

Shiny contains two components: a user-interface script (ui.R) and a server script (server.R). The ui.R script controls the layout and appearance of the Shiny app. The server.R script contains the instructions of the programming logic about how to build the Shiny app.

Ovarian Cancer Clinical Data

Ovarian cancer (OC) is the most lethal gynecological cancer. Most OC patients undergo radical surgery to maximize reduction of initial tumor volume, and then receive at least six cycles of platinum-based chemo-treatments to eliminate remaining tumors. Although most patients are initially highly responsive to chemotherapy, the majority of them succumb to recurrent disease [14]. In a pilot study at Mayo Clinic, we are particularly interested in identifying the potentially prognostic importance of preoperative complete blood count (CBC) parameters and derived inflammation markers such as neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and monocyte-to-lymphocyte ratio (MLR), as well as a tumor marker named CA125 [15, 16]. To enable such studies, we collected the ovarian cancer clinical data from three clinical databases: Ovarian cancer registry database, Lab-test database and Clinical document management (CDM) system.

Methods

In our study, we designed an integrated framework known as Shiny FHIR for enabling standards-based, interactive clinical data applications (Figure 1). The framework comprises three modules: 1) a FHIR server module that represents the clinical data (here, ovarian cancer data) from different sources with unified FHIR specification; 2) a workflow module focusing on patient-centered data analysis and cohort-based data analysis; and 3) an interactive user interface module using the Shiny web framework and the established FHIR server. The overall goal of the integrated framework is to enable a library of Shiny Apps with extensible and reusable tools to support clinical statistics and analysis leveraging standardized data exchange and access services based on FHIR.

FHIR Data Modeling and Populating

In order to use FHIR for modeling ovarian cancer clinical data to meet the data analysis requirements, we mapped ovarian cancer data to the different types of FHIR resources (Figure 2). We first extracted demographics, diagnosis, and survival outcomes data from the three databases. 1) Ovarian cancer registry database: Upon diagnosis, the demographic and diagnosis data (e.g. histological types) were manually retrieved, curated and loaded into an ovarian cancer registry database. Clinical outcome data such as survival and recurrence were also routinely updated in the registry. 2) Lab-test database: The CA125 and CBC (e.g., red/white-blood cell counts) test values were retrieved from an institutional lab-test database using the clinical IDs of patients in the OC registry, and returned as time-stamped records with actual test values and additional test-related details. 3) Clinical document management (CDM) system: The chemo-treatment data of
identified OC patients were extracted from chemo-treatment documents in an institutional system named CDM, which stores all patients’ data regarding clinical visits and the medical services they received. Since the patient data from the different databases are generated during different steps of ovarian cancer diagnosis and treatment, the original data are heterogeneous and describe the patient in different dimensions. In addition, the data formats are also diverse, such as CSV, XML, or combined. However, all the extracted data need to be merged from content to format to support integrative analysis. Since the patient’s unique clinic number is the one key guaranteed to connect these objects, we used that number to merge the data into a group of tables in a relational database to support further query and analysis.

Second, we performed basic data cleaning and standardization processes. The data cleaning includes checking and cleaning up redundant data, null-value data, and wrong data generated by data extraction from local databases. In addition, we focused on standardizing the term, code, and value set, and mapping local code to standard code. According to the FHIR resource terminology binding definition, we allocated the Logical Observation Identifiers Names and Codes (LOINC) [17] codes for resource “Observation”, and mapped local ovarian cancer related lab test codes manually to LOINC codes. For the chemo-treatment data and diagnosis data, the SNOMED CT is suggested as the binding terminology of “Procedure” and the value set code defined in FHIR is suggested as the code of “Condition”. Our methods support assigning of multiple codes for each FHIR resource, therefore, we kept the original codes the Current Procedural Terminology (CPT) [18] for “Procedure”, and the International Classification of Diseases (ICD) [19] for “Condition”. The purpose of the data preprocessing in this step is to ensure high quality and interoperability of clinical study data.

Third, we analyzed the FHIR data model resources (core resources and extension resources), single resource representations, data elements, data types, terminologies, codes, resource references, search parameters, and data exchange formats (XML and JSON). For example, the FHIR Patient resource structure is shown in Figure 3 [20]. We invoked an open source HAPI FHIR API to populate the ovarian cancer clinical data into the FHIR resources Patient, Observation, Condition, and Procedure.

The next step was to enable secondary use of the ovarian cancer data while simultaneously protecting patient privacy via deidentification. Identifiers were removed from the patient data, and replaced with a set of randomly-generated patient IDs and other privacy objects IDs. We also maintained a mapping table between the local identifiers and FHIR resource identifiers. Thereby, protected health information could be safely utilized for testing and analysis.

Finally, we established a local FHIR server to manage the ovarian cancer clinical data and uploaded the structured FHIR data objects into the FHIR server through HAPI FHIR client API.

The Clinical Data Analysis Workflow Design

Guided by the common clinical data analysis requirements, we designed two general analysis workflows: patient-centered data analysis and cohort-based data analysis (Figure 4).

The patient-centered data analysis workflow provides faceted browsing of all kinds of information oriented to the individual. Patient-specific data derived from different sources are integrated to a single identifier. In the FHIR data model, Patient is an independent resource and other resources such as Observation and Procedure have a property “subject” that is linked to a particular Patient object for representing the patient-centered relations.
The cohort-based analysis workflow reflects more common data analysis needs of clinical statistics and studies. In this workflow, the condition/procedure/observation/medication of a cohort is largely measured by the distribution of patient characteristics from different dimensions. The workflow is designed to support a variety of clinical data analysis tasks, including patient observation timeline analysis, patient cohort gender/age distribution statistics, and survival analysis.

The Shiny Implementation on FHIR data

In the prototype implementation step, we adopted the Shiny web framework and developed a prototype platform called Shiny FHIR. The designed workflows and established FHIR server with ovarian cancer data were used to implement the prototype. Shiny FHIR follows a typical structure of Shiny, as shown in Figure 5. The server.R script contains all the workflow functions, and supports the data exchange between Shiny server and FHIR server by using the FHIR RESTful API; the ui.R script controls the layout, appearance and user interactions of the Shiny FHIR in web browser.

![Figure 5 - The System Architecture of Shiny FHIR](image)

From the technical perspective, a series of R packages are aggregated in the workflows to facilitate accessing, parsing, analyzing and visualizing the FHIR data. For example, the ‘jsonlite’ package supports FHIR JSON structure parsing, the ‘dygraph’ package is used for the timeline display of observation data values for any particular patient, and survival analysis is supported by the ‘survival’ package. By drawing on independent contributions from the active R community, the Shiny FHIR platform can facilitate a great number of extensible clinical data analysis applications building on FHIR data. Ideally, as clinical analysis tasks are modularized and the Shiny Apps library matured, a nearly unlimited number of R packages will become available to researchers via FHIR.

Evaluation Methods

We evaluated the feasibility of our framework and prototype by using a number of public FHIR data servers. Our evaluation mainly focused on the adaptability of the framework and the platform to other clinical data following the FHIR standard.

Results

Using the framework described above, we transformed the ovarian cancer clinical data from local EMR into the FHIR-based representations. A total of 61 patient records, 3400 observation rec-ords, 66 condition records and 900 procedure rec-ords and the relations among them were populated into a FHIR server for testing. A total of 4366 “subject” relations were created between the Patient data objects and other data objects (Table 1).

<table>

<tr>
<td>Total</td>
<td>4427</td>
<td>4366</td>
</tr>
</tbody>
</table>

For the patient-centered analysis, we designed and implemented a workflow to support the display and discovery of all the clinical data around individual patient, including diagnosis, examination, laboratory test, treatment, etc.

For the cohort-based analysis, we designed and implemented a workflow that measures patient distribution from 11 patient characteristics, comprising age at diagnosis, race, origin of cancer, stage, histology, grade, preoperative CA125 level, ascites at surgery, residual disease, recurrence, and vital status. In addition, the workflow supports a survival analysis task to analyze the prognostic importance of pre-operative lab test values in patients with ovarian cancer. Overall survival rates were estimated via the univariate Cox proportional hazards analysis method. Based on the parameters of observation (for example, red blood cell distribution width), age at diagnosis, deceased time, and the overall survival rates were calculated as the time from the date of diagnosis to the time of death. The prototype and its interactive analysis workflows are displayed as Figures 6 and 7.

![Figure 7 - Cohort-based data analysis](image)
Currently, there are a number of FHIR servers that are publicly available for testing [21]. On the grounds of server stability and data quality, we chose two as testing servers for our system evaluation: the HAPI FHIR server and Michigan Health Information Network Shared Services server. The data published from the two servers were both successfully requested through the FHIR RESTful API. The JSON parsing interface was invoked according to each FHIR resource structure template, and data elements of each type of FHIR resource were successfully parsed and imported into our workflows. The testing demonstrated that our framework and workflow could be generalizable to other clinical data represented in FHIR specification. On the other hand, we encountered some unsatisfying testing results. For example, a number of requests to these servers had issues in terms of the response speed. More critically, data from the test servers contained a FHIR extension representation that was not defined in our FHIR model. Nevertheless, the overall results of the experiment showed that the Shiny FHIR integration approach offers the feasibility of web-based interactive statistical analysis on FHIR-based standardized clinical data.

Discussion

In this study, we developed an integrated framework leveraging Shiny and FHIR, with a prototype implementation and evaluation, aiming to empower standardized clinical statistics and analysis applications. There are two main contributions in this study. First, all the framework and workflow design follows the FHIR data standard, which could be reused in other clinical data domains and enable extensive support for any clinical data that follows the FHIR specification. Second, the data analysis workflow and tools incorporate the experience of clinical statisticians and researchers, and leverage powerful R analytics. Our inte-grated Shiny FHIR framework could greatly facilitate interactive, user-friendly, and web-accessible data analysis.

One limitation of this research is that the ovarian cancer research use case is currently designed only to test the Shiny FHIR framework, and as such only replicates common clinical research scenarios. Other possible data analysis workflows and customized research discovery scenarios could be performed upon FHIR-specified data, but are not currently supported by our framework.

In addition, there are several technical challenges in our study:

1. When the target data are represented using the FHIR extensions, our framework and APIs need to be enhanced to support the handling of the extensions.

2. Although we developed a records combination algorithm to overcome the access records limitation problem when requesting FHIR data through the RESTful APIs, the system performance needs to be improved when handling large datasets.

3. Our interfaces are currently developed under FHIR DSTU2 and need to be upgraded to the official FHIR STU3 when it gets finalized and released by HL7.

In the future, we plan to refine the Shiny FHIR Apps and testing datasets in terms of their modularity and reusability, and perform more rigorous evaluations including usability studies for the future development of the Shiny FHIR Apps. We plan to adopt the FHIR STU3 with particular genomic related resource definitions to represent genomic data in our framework. We also plan to build a robust mechanism handling the FHIR extensions. Furthermore, we will continue to enhance our framework leveraging FHIR terminology service resources to the optimal and meaningful use of standard codes, code systems and value sets.

Conclusion

In this study, we demonstrated that Shiny FHIR is a feasible framework for facilitating interactive analysis on FHIR-based clinical data. We implemented two workflows based on an ovarian cancer analysis use case to enable both patient-centered and cohort-based analyses, and identified common clinical research requirements, outstanding issues, and challenges. The framework can be generalized and applied to other EHR data that follow the FHIR standard. With more and more healthcare data being accessible using the FHIR standard, we believe that our Shiny FHIR framework, with ongoing enhancements and subject to rigorous evaluations, will empower future clinical data applications for statistics and analytics, ultimately advancing clinical and translational discovery.

Abstract

Within the large body of biomedical knowledge, recent findings and discoveries are most often presented as research articles. Their number has been increasing sharply since the turn of the century, presenting ever-growing challenges for search and discovery of knowledge and information related to specific topics of interest, even with the help of advanced online search tools. This is especially true when the goal of a search is to find or discover key relations between important concepts or topic words. We have developed an innovative method for extracting key relations between concepts from abstracts of articles. The method focuses on relations between keywords or topic words in the articles. Early experiments with the method on PubMed publications have shown promising results in searching and discovering keywords and their relationships that are strongly related to the main topic of an article.

Keywords:
Data Mining; Algorithms; PubMed

Introduction

Searching effectively and efficiently for topics within the rapidly growing biomedical literature is an unprecedented challenge for researchers in the field, even with the help of advanced online search tools. The task becomes even more difficult when we try to find relationships between concepts or topics, which represent potentially more interesting and important information than what concepts alone describe. If concept relationships related to the topic can be extracted from the abstract of an article without going through the main body of the article, the results can be organized and presented for quick review based on which more focused further searches can be carried out, with the additional advantage of also increasing the number of articles covered in the search. More importantly, relations extracted from abstracts can be quickly integrated into a knowledge network [1, 2] for ontology-based discovery. Topic mining and relation extraction from unstructured publications such as research papers and case reports has become more feasible and productive over the past decade [3-5]. Most existing methods follow one of two different approaches: pre-specified pattern-based vs more general machine learning.

- Pattern-based relation extraction [6-8] typically relies on syntactically or grammatically pre-specified patterns of sentence components designed to extract one type of relation. To improve specificity and accuracy, generalization of these patterns is needed to cover most or all expressions likely to be found in a text. These approaches typically suffer from being tightly domain- and even problem-dependent because of customization or over-fitting to the particular characteristics of language used in interpreting a particular class of problems. For different domains, the issues are even more daunting: what works in, for example, financial text retrieval will not be generalizable to biomedical domains, and vice versa.

- Machine learning based relation extraction [9, 10] tackles the topic extraction differently but suffers from related problems of overfitting, in this case, to whatever training set of data is used, which will completely constrain the generalizability of results as in all such learning approaches. If abstracts of all publications in PubMed is of interest, then specifying and obtaining a suitable training set will be an extremely difficult task. Different subfields or subjects in biomedicine usually require models to be trained separately in order to improve performance. However, the cost of this is unavoidably high and strategies of partitioning the datasets are themselves a factor in biasing the results.

- A hybrid method combining the approaches has been developed recently which relaxes the need for a large number of pre-specified patterns of the first approach while reducing the need for large training sets with the goal of achieving results with similar or better accuracies for problems that are general, but expertly circumscribed so as to present a reasonable challenge to how automatic extraction plays off against expert pre-specification.

Most relation extraction methods are developed to extract relations from massive unstructured texts, such as research papers and case reports. Topic mining [11] methods are developed to classify topics for text classification. One main group of topic mining algorithms extract topics from texts, and another group of algorithms labels a body of text with one or more topic words selected from a pre-specified topic list. Topic mining methods discover topic-related words within the text, but do not provide more or deeper information contained in an article.

Relation extraction methods and topic mining methods produce different types of summarizations of an article. The former returns a list of relations, while the latter returns a set of words. Most relation extraction methods are designed to extract all relations in the article, but are not concerned with
whether the relations are linked to the topic of the article. Since these methods process the entire text of each article, the computational load for implementing the algorithms is usually extremely heavy. In addition, it is up to human users to interpret and filter the relevance or significance of the large number of relations returned by these methods, which is usually time consuming and inefficient, since most extracted relations will simply not be related to the main topic of the articles. In contrast, many topic mining methods are reported to achieve impressive accuracies, but fail when the topic of a paper is not clearly described by the set of keywords in the paper. Furthermore, most existing topic mining methods are limited to analyses of single or individual concepts in an article, and do not address important issues of finding relations between key biomedical concepts across all the relevant literature within a large publication repository such as PubMed. To overcome these limitations, we have focused our work on improving key relation extraction using an innovative approach based on a novel combination of topic mining and relation extraction methods. We consider relations of an article connected to its substantive contribution to a topic, as key relations. Key relations are structured, and are composed of a specific relation and the concepts connected to this relation which are the substance of an article.

Our Key Relations Extraction Method (KREM) presented in this paper extracts key topic-related relations from the abstract including the title of an article. KREM processes each article individually and returns key relations in the article that are related to the main topic of the article. A key relation is one that is related to the topic of the article, or is a part of the subject or theme discussed in the article. Key relations together can be viewed as a structured summarization of the article. Our method has been tested using the PubMed repository.

Method

The basic framework of our approach combines both topic mining and relation extraction. For topic mining, a structural statistical model is developed based on which a topic classifier is built. For key relation extraction, we propose and implement a pattern-based algorithm to compute relations between key concepts generated by the relation extraction method and by topic mining.

Combining the Methods of Relation Extraction and Topic Mining
