ABBREVIATIONS

AA	arachidonic acid
AMPK	5'adenosine monophosphate-activated protein kinase
AP-1	activator protein 1
Apaf-1	apoptotic protease-activating factor-1
Atg5	autophagy protein 5
ATP	adenosine triphosphate
Bak	Bcl-2 homologous antagonist/killer
Bax	Bcl-2-associated X protein
Bcl-2	B-cell lymphoma 2
Bid	BH3 interacting-domain death agonist
COPD	chronic obstructive pulmonary disease
COX	cyclooxygenase
cPLA ₂	cytosolic phospholipase A ₂
CYP	cytochrome P
cysLT	cysteinyl leukotrienes
DAMP	danger associated molecular patterns
DAO	dehydroarmillylorsellinate
DISC	death initiation signaling complex
DNA	deoxyribonucleic acid
EA	ethanolamine
EET	epoxyeicosatrienoic acid
e.g.	for example (lat. <i>exempli gratia</i>)
ER	endoplasmic reticulum
e(t)-LTB ₄	LTB ₄ isomers: 6-trans-LTB ₄ , 6-trans-12-epi-LTB ₄
FLAP	5-lipoxygenase activating protein
fMLP	N-formyl-methionyl-leucyl-phenylalanine
Golgi	Golgi apparatus
GPCR	G-protein coupled receptor
GSH	glutathione
HEK	human embryonic kidney cell line
H(p)ETE	hydroxy(peroxy)eicosatetraenoic acid
IA	invasive aspergillosis
IC ₅₀	half maximal inhibitory concentration

ABBREVIATIONS

IL	interleukin
JNK	c-Jun N-terminal kinase
LDH	lactate dehydrogenase
LM	lipid mediators
LOX	lipoxygenase
LPS	lipopolysaccharide
LT	leukotriene(s)
LTA ₄ H	leukotriene A ₄ hydrolase
LTC ₄ S	leukotriene C ₄ synthase
MAPEG	membrane-associated proteins in eicosanoid and GSH metabolism
MAPK	mitogen-activated protein kinase
MCP-1	monocyte chemoattractant protein 1
mPGES-1	microsomal prostaglandin E synthase 1
mRNA	messenger RNA
mTOR	mammalian target of rapamycin
MTT	3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide
NFκB	nuclear factor “kappa-light-chain-enhancer” of activated B-cells
NO	nitric oxide
PAF	platelet activating factor
PAMP	pathogen-associated molecular patterns
PARP	poly(ADP-ribose)-polymerase 1
PC	phosphatidylcholine
PE	phosphatidylethanolamine
PGP	proline-glycine-proline (tripeptide)
PK	protein kinase
PMA	phorbol-12 myristate 13-acetate
PMNL	polymorph nuclear leukocytes
PS	phosphatidylserine
RNA	ribonucleic acid
ROS	reactive oxygen species
sEH	soluble epoxide hydrolase
TLR	Toll-like receptor
TNF(R)	tumor necrosis factor (receptor)
UPLC-MS/MS	ultra performance liquid chromatography tandem mass spectrometry

SUMMARY

In the present thesis, the mode of action of three different natural secondary metabolites was clarified in human cancer cells and primary immune cells. The investigated compounds of this work were (I) the mycotoxin gliotoxin from *Aspergillus fumigatus* targeting leukotriene A₄ hydrolase (LTA₄H), identifying thereby the cause of neutropenia during invasive aspergillosis (IA), (II) the melleolide dehydroarmillylorsellinate (DAO) and several structural analogs exhibiting, on the one hand, anti-inflammatory features by abrogating 5-lipoxygenase (5-LOX) product formation, and on the other hand, manipulate monocyte functions by covalent binding of the cellular membrane constituent phosphatidylethanolamine (PE), and finally (III), the myxobacterial compound myxochelin A hampering 5-LOX activity by iron chelation. Over the last decades, the link between inflammation and cancer gains relevance. Hence, it is important to investigate new anti-inflammatory drugs to prevent chronic diseases, and to elucidate the mechanism of action of cytotoxic compounds to develop new strategies of action for anti-cancer drugs. Both approaches are the basis of this work.

Gliotoxin is known as important virulence factor of *A. fumigatus* [1] causing IA by affecting neutrophils [2, 3], but the underlying molecular mechanism is still elusive. Our data revealed that gliotoxin inhibits the biosynthesis of the important neutrophil chemoattractant leukotriene B₄ (LTB₄) [4, 5] *in vivo* using the zymosan-induced peritonitis model in mice and the carrageenan-induced pleurisy model in rats. Furthermore, gliotoxin caused a reduced neutrophil infiltration into the peritoneal or thoracic cavity. Interestingly, gliotoxin suppressed solely LTB₄ formation without compromising other eicosanoids. The well-known 5-LOX inhibitor zileuton [6] was deployed as reference drug reducing all 5-LOX products. Similar results were reached *in vitro* in human primary monocytes and neutrophils in comparison to zileuton and the selective LTA₄H inhibitor SC-57461A [7, 8]. In addition, we confirmed gliotoxin as virulence factor of *A. fumigatus* by using an *A. fumigatus* strain containing a deletion of the *gliP* gene, which is responsible for gliotoxin biosynthesis (Δ *gliP*) [9]. Supernatants of this strain failed to inhibit LTB₄ production in neutrophils, and in line with this finding, histopathological investigations confirmed our hypothesis. Leukotrienes (LT) are formed by 5-LOX, which convert arachidonic acid (AA) in a two-step reaction to LTA₄ followed by a hydrolysis to LTB₄ performed by LTA₄H [10]. Interestingly, gliotoxin failed to impede LTA₄H activity in non-cellular systems but pre-incubation with GSH enables inhibition of LTA₄H activity by gliotoxin indicating that reducing conditions were crucial to cleave the intramolecular disulfide bond. The formed free thiol groups chelated the zinc ion in the active epoxide hydrolase center of the bifunctional enzyme [11] causing covalent and irreversible inhibition of LTA₄H. Beside epoxide hydrolase activity, LTA₄H exhibits also an aminopeptidase function involved in the resolution of inflammation by hydrolysis and inactivation of the tripeptide matrikine proline-glycine-proline (PGP) [12, 13]. We measured the enzymatic degradation of PGP in gliotoxin-treated

neutrophils by UPLC-MS/MS resulting in an exclusively abrogation of the epoxide hydrolase activity by gliotoxin. Additional, we excluded an inhibition of other bifunctional enzymes containing an epoxide hydrolase activity by investigating sEH activity [14] after treatment with gliotoxin.

In contrast to gliotoxin, we identified myxochelin A biosynthesized by *Pyxidicoccus fallax* as direct 5-LOX inhibitor in cell-free assays ($IC_{50}=1.9\ \mu M \pm 0.2\ \mu M$), correlating with its anti-proliferative effects in leukemic cells. As expected, the catechol basic structure was crucial for hampering LT biosynthesis, whereas methylation of aromatic hydroxyl residues caused detrimental effects on 5-LOX inhibition. Structure-activity relationships formed a basis for further investigations and structural modifications.

Besides myxochelins, also DAO act as direct and irreversible 5-LOX inhibitor in cellular ($IC_{50}=0.3\ \mu M \pm 0.1\ \mu M$) and non-cellular ($IC_{50}=2.8\ \mu M \pm 0.9\ \mu M$) experimental settings. Furthermore, DAO hampered the interaction between 5-LOX and its helper protein 5-LOX activating protein (FLAP) determined by a proximity ligation assay, and DAO inhibited solely the 5-LOX pathway without targeting other enzymes of the AA cascade. Screening of various melleolides for 5-LOX inhibition provided detailed information on the underlying structure-activity relationships. Especially the α,β -unsaturated aldehyde turned out to be crucial for potent 5-LOX inhibition. This structural element is also known as Michael acceptor. Compounds containing a Michael acceptor structure showed interactions with cysteines located at the entrance to the catalytic center of 5-LOX [15, 16]. Using stable transfected HEK cells with 5-LOX cysteine mutants, we showed that cysteines are catalytically relevant causing reduced 5-LOX activity and mediated diminished product formation. 5-LOX translocation was not affected by DAO, but the interaction with FLAP at the nuclear membrane was hampered, especially by the 5-LOX_C¹⁵⁹ mutant. Interestingly, DAO interacted with C¹⁵⁹ triggering abrogated 5-LOX/FLAP interaction and impaired 5-LOX activity resulting in reduced LT formation.

Besides its anti-inflammatory effects, DAO displayed remarkable cytotoxic properties towards human primary monocytes and cancer cells. DAO induced cell death in an unusual rapid onset, characterized by apoptotic and necrotic features. The apoptosis marker PARP was cleaved within 15 min with preceding a slight activation of caspases, whereas the potent cytotoxic compound staurosporine [17, 18] triggered PARP cleavage only after 5 hrs. Furthermore, DAO affected also the membrane integrity after 15 min measured by an LDH assay indicating an untypical mode of action for its cytotoxicity. We clarified the cytotoxic mode of action of DAO, which is seemingly due to a covalent binding of its α,β -unsaturated aldehyde group to the ethanolamine residue of membrane PE by UPLC-MS/MS. Furthermore, we excluded an effect on serine or choline residues of other phospholipids. With the help of subcellular fractionation, we identified that DAO interacted primarily with plasma and lysosomal

membrane parts of cells causing an abrogation of PE in the membrane fraction. Hence, destabilization of lysosomes and the related decreased intracellular pH might be induced by a DAO-PE interaction on lysosomal membranes mediating necrotic features of cell death.

In conclusion, the results of this thesis clarified the mode of action and targets of two fungal toxins and of the myxobacterial compound myxochelin A in human cells. Inhibition of LTA₄H activity in case of gliotoxin seems to be the reason for neutropenia during IA, providing the basis for new therapeutic approaches of this disorder. Myxochelin A and its derivatives represent an interesting substance class for new 5-LOX inhibitors, but further investigations are essential, e.g., the *in vivo* confirmation of the anti-inflammatory efficiency. Finally, the melleolide DAO influences 5-LOX activity, but it exhibits also potent cytotoxic activity in human cells due to its unusual rapid onset of cell death induction by covalent binding to membrane PE.

ZUSAMMENFASSUNG

In der vorliegenden Arbeit wurde der Wirkmechanismus von drei verschiedenen natürlich vorkommenden Sekundärmetaboliten in Krebszellen und primären Immunzellen aufgeklärt. Die untersuchten Substanzen sind (I) Gliotoxin aus *Aspergillus fumigatus*, welches mit LTA₄H interagiert und damit ein potentieller Auslöser für die Neutropenie während einer IA festgestellt werden konnte, (II) das Melleolid DAO und verwandte Strukturanaloga, welche aufgrund einer 5-LOX-Hemmung anti-inflammatorische Eigenschaften besitzen, aber auch kovalent an das Membranlipid PE binden und damit wichtige monozytäre Funktionen manipulieren, und zu guter Letzt (III) Myxochelin A aus Myxobakterien, welches die 5-LOX Aktivität durch eine Chelatisierung des zentralen Eisen-Atoms beeinflusst. Innerhalb der letzten Jahrzehnte verfestigte sich der bestehende Zusammenhang zwischen Entzündung und Krebsgeschehen. Deshalb ist es von großer Bedeutung neue Wirkstoffe zu identifizieren und weiterzuentwickeln, die eine chronische Entzündung verhindern und Wirkmechanismen zytotoxischer Substanzen zu untersuchen, um neue Ansatzpunkte für die Krebsmedikation finden zu können. Beide Aspekte werden mit dieser Arbeit angesprochen und behandelt.

Gliotoxin ist bekannt als bedeutender Virulenzfaktor von *A. fumigatus* [1], der durch gezielte Beeinflussung von Neutrophilen eine IA auslöst [2, 3]. Unsere Untersuchungen ergaben, dass Gliotoxin die Biosynthese von LTB₄, welches ein wichtiger Signalstoff für die Chemotaxis von Neutrophilen ist [4, 5], *in vivo* und *in vitro* hemmt. LTB₄ entsteht durch die von LTA₄H ausgelöste Hydrolyse aus LTA₄, welches durch 5-LOX aus Arachidonsäure (AA) gebildet wird [10]. Für die Untersuchungen *in vivo* nutzten wir zwei Entzündungsmodelle: (1) eine durch Zymosan ausgelöste Bauchfellentzündung (Peritonitis) in Mäusen und (2) eine durch Carrageen ausgelöste Brustfellentzündung (Pleuritis) in Ratten. In den Tiermodellen reduzierte Gliotoxin die Einwanderung von Neutrophilen in die spezifischen Gewebe und hemmte selektiv die LTA₄H. Als Kontrollsubstanz diente der klinisch relevante 5-LOX Inhibitor Zileuton [6]. Diese Ergebnisse konnten ebenso *in vitro* in primären Monozyten und Neutrophilen im Vergleich zu Zileuton und dem LTA₄H Inhibitor SC-57461A [7, 8] nachgewiesen werden. Zusätzlich wurde die Bedeutung von Gliotoxin als Virulenzfaktor mit Hilfe eines *A. fumigatus* Stammes, bei dem das verantwortliche Enzym gliP für die Gliotoxin Biosynthese eliminiert worden ist (Δ gliP) [9], bestätigt. Kulturüberstände dieses Stammes zeigten keine Reduktion von LTB₄ in behandelten Neutrophilen. Interessanterweise konnte eine Aktivität von Gliotoxin nur intrazellulär nachgewiesen werden, da ein reduzierendes Milieu notwendig ist, um die intramolekulare Disulfidbrücke zu spalten. Die entstehenden freien Thiolgruppen bilden einen Chelatkomplex mit dem zentralen Zink-Ion in der Epoxidhydrolase Bindungstasche [11], was eine kovalente und irreversible Hemmung der LTA₄H bewirkt. LTA₄H ist ein bifunktionales Enzym, welches neben der Epoxidhydrolaseaktivität noch eine Aminopeptidaseaktivität aufweist [12, 13]. Diese ist an der Resolution einer Entzündung durch die Hydrolyse und

Inaktivierung des Matrikins PGP beteiligt. Mittels UPLC-MS/MS konnten wir nachweisen, dass Gliotoxin die Degradation von PGP und damit die Aminopeptidaseaktivität nicht beeinflusst. Des Weiteren wurde eine Beeinflussung anderer bifunktionaler Enzyme wie die sEH, welche ebenso eine Epoxidhydrolase Aktivität besitzt [14], ausgeschlossen.

Im Gegensatz zu Gliotoxin, identifizierten wir Myxochelin A, welches von dem Myxobakterium *Pyxidicoccus fallax* gebildet wird, als direkten 5-LOX Inhibitor ($IC_{50}=1,9 \pm 0,2 \mu M$) aufgrund einer Komplexbildung des zentralen Eisenions [19] im zellfreien Milieu, was mit seinen anti-proliferativen Eigenschaften in Leukämie-Zellen korreliert. Wie zu erwarten war, ist die Catechol-Grundstruktur verantwortlich für die verringerte LT-Bildung, da O-Methylierungen zu einem gravierenden Wirkungsverlust führen. Struktur-Wirkungsbeziehungen bilden die Grundlage für Strukturmodifikationen und weitere Untersuchungen.

Des Weiteren hemmt das Melleolid DAO selektiv die 5-LOX Aktivität und verhindert damit auch die Biosynthese pro-inflammatorischer LT. DAO ist ein direkter und irreversibler 5-LOX Inhibitor unter zellulären ($IC_{50}=0,3 \mu M \pm 0,1 \mu M$) oder zellfreien ($IC_{50}=2,8 \mu M \pm 0,9 \mu M$) Bedingungen. DAO verhindert die Interaktion zwischen 5-LOX und dem Helferprotein FLAP an der nukleären Membran, was wir mittels eines Proximity Ligation Assays analysiert haben. Neben DAO untersuchten wir auch andere Melleolide auf eine potentielle 5-LOX-Hemmung, um Informationen über Struktur-Wirkungsbeziehungen zu erhalten. Dabei ergab sich, dass das α,β -ungesättigte Aldehyd essentiell für die Interaktion mit 5-LOX ist. Dieses Strukturelement kann auch als Michael-Akzeptor bezeichnet werden und interagiert unter anderem mit Cysteinen, welche am Eingang zum katalytischen Zentrum der 5-LOX angeordnet sind [15, 16]. Wir nutzten stabil transfizierte HEK Zellen mit verschiedenen 5-LOX Cysteinmutanten und bestätigten aufgrund einer verminderten 5-LOX-Produktbildung, dass diese Cysteine katalytisch relevant für die LT-Biosynthese sind. Interessanterweise beeinflussten die Cysteinmutanten nicht die 5-LOX-Translokation, sondern die Interaktion mit FLAP, welche vorrangig über C^{159} gesteuert wird. DAO interagierte mit C^{159} und verursachte damit die gestörte 5-LOX/FLAP Interaktion, was eine verringerte 5-LOX Aktivität zur Folge hatte.

Neben seinen anti-inflammatorischen Eigenschaften weist DAO auch zytotoxische Charakteristika in humanen Monozyten und Krebszellen auf. DAO induzierte untypisch schnell den Zelltod, welcher sowohl apoptotische als auch nekrotische Merkmale aufweist. So aktiviert DAO den Apoptosemarker PARP innerhalb von 15 min, wofür Staurosporin, ein bekannter Apoptose auslösender Pan-Kinase Inhibitor [17, 18], mindestens 5 h benötigt. Des Weiteren schädigt DAO auch innerhalb von 15 min die Membranintegrität von Zellen, was wir mittels LDH Assay nachweisen konnten. Diese Aspekte lassen einen eher untypischen Wirkmechanismus für die Zytotoxizität vermuten. Wir zeigten, dass die α,β -ungesättigte Aldehydgruppe von DAO kovalent an die Ethanolamin-Kopfgruppe von membranständigen

Phospholipiden bindet, während Phosphatidylcholin und –serin nicht betroffen waren. Aufgrund einer durchgeführten subzellulären Fraktionierung stellten wir fest, dass DAO vorrangig mit PE aus der Plasmamembran/Lysosomen-Fraktion interagiert, welches die Reduktion des PE-Gehaltes in diesen Fraktionen erklärte. Gleichzeitig könnten damit die zu beobachtende Degradierung von Lysosomen und der sinkende intrazelluläre pH-Wert erklärt werden.

Zusammenfassend identifizierten wir den Wirkmechanismus und die Zielstrukturen der beiden Pilzgifte Gliotoxin und DAO und der myxobakteriellen Substanz Myxochelin A. Gliotoxin hemmt die LTA₄H Aktivität, was die Neutropenie während einer IA verursacht. Myxochelin A und Strukturanaloga stellen eine vielversprechende Substanzklasse für neue 5-LOX Inhibitoren dar, wofür allerdings weitere Untersuchungen wie zum Beispiel die Bestätigung der Wirksamkeit *in vivo* notwendig sind. DAO hemmt ebenfalls die 5-LOX-Aktivität und weist ein interessantes Wirkprofil nicht zuletzt wegen seiner untypisch schnellen zytotoxischen Wirkung durch die kovalente Bindung von PE an humanen Zellmembranen auf.

1. INTRODUCTION

1.1 Inflammatory response and cancer

Acute inflammation is a self-limiting innate immune response to internal or external harmful stimuli aiming to restore the homeostatic balance and to protect the organism against infection or any tissue damage. Inflammation is characterized by five major symptoms: (I) redness, (II) swelling, (III) pain, (IV) heating, and (V) loss of function. Classical initiators of acute inflammation are tissue injury or infection by pathogens [20]. During acute inflammation, various pro-inflammatory mediators, e.g., cytokines, chemokines, and eicosanoids are released by macrophages or mast cells initiating the recruitment of leukocytes and plasma proteins to the site of infection or injury. Due to the direct contact with pathogens or pro-inflammatory mediators, neutrophils are activated leading in a release of detoxifying agents, e.g., reactive oxygen species (ROS), to eliminate infectious agents. In a second step, monocytes and macrophages access the inflammatory site, where alternatively activated macrophages promote the resolution phase of inflammation [20, 21]. Thus, the recruitment of neutrophils is interrupted, and an alteration in lipid mediator (LM) biosynthesis occurs from pro-inflammatory prostaglandins and leukotrienes (LT) to anti-inflammatory lipoxins, protectins, maresins, and resolvins, mainly produced by macrophages [22, 23]. Macrophages initiate tissue repair and phagocytosis of apoptotic neutrophils and other dead cells. In the case that the acute inflammatory response fails to remedy the infection or injury, inflammation becomes chronic [20, 21]. Dysregulated inflammation leads to a homeostatic imbalance and can promote several diseases, e.g., rheumatoid arthritis, cardiovascular diseases, and ultimately also cancer. Several pro-inflammatory mediators and enzymes, e.g., cytokines, chemokines, matrix metalloproteinases, vascular endothelial growth factors, cyclooxygenase-2 (COX-2), and 5-lipoxygenase (5-LOX) are involved in inflammation but play also an important role in tumorigenesis as part of a pro-tumorigenic tissue microenvironment [24, 25]. This tumor microenvironment arises during persistent inflammatory states surrounding tumor cells and triggering tumor growth via the above-mentioned released mediators of infiltrating immune cells. Beside innate immune cells and cancer cells, the microenvironment consists of adaptive immune cells and surrounding stroma containing blood vessels, fibroblasts, and extracellular matrix [26-28]. Furthermore, two transcription factors are mainly involved in (inflammation-triggered) tumor development: (I) signal transducer and activator of transcription 3 (STAT3) inducible by interleukin (IL)-6, and (II) nuclear factor κ B (NF κ B). NF κ B is responsible for pro-inflammatory, proliferative, and pro-survival gene expression leading to suppression of apoptosis and support of cell cycle progression in cancer cells [29-31]. As mentioned before, neutrophils release ROS, inter alia, to eliminate injuring agents, but excessive formation of ROS can also initiate tumorigenesis by subsequent DNA damage. Considering, that 20% of cancers are associated with chronic inflammation [32], and that the tumorigenesis process is

biased by inflammation, it is concluded that inflammation is one key regulator of tumor development through various pathophysiological processes.

1.1.1 Arachidonic acid pathway

Arachidonic acid (AA) is a notable polyunsaturated fatty acid (20:4 ω -6) in mammalian cells. Due to its esterification within membrane phospholipids, AA is a marked component of human cellular membranes and affects membrane fluidity and flexibility [33, 34]. Furthermore, as essential precursor of pro- and anti-inflammatory bioactive LM, AA plays an important biochemical role in the initiation and resolution of inflammation [34, 35]. Three various types of oxygenases convert AA to bioactive LM in mammals: (I) cyclooxygenases (COX), (II) lipoxygenases (LOX), and cytochrome P450 (CYP450) enzymes. Initially, AA can be released from cellular membranes by the cytosolic phospholipase A₂ (cPLA₂) [4]. Free AA may then be metabolized by COX-1 or COX-2 to pro-inflammatory prostanoids, that encompass prostaglandins and thromboxanes, which are crucial mediators of inflammation [36]. But also LOX, including 5-LOX, 8-LOX, 12-LOX, and 15-LOX, generate pro-inflammatory LT and anti-inflammatory lipoxins from AA [4, 37, 38], and CYP450 isoenzymes form epoxyeicosatrienoic acid (EET) [39]. In the last decades, many chemically synthesized or natural compounds have been investigated, that interfere with the AA pathway and possess a promising potential as anti-inflammatory drugs, but only a few compounds reached the pharmaceutical market until now [40-42].

Fig. 1 The arachidonic acid pathway.

AA – arachidonic acid, cPLA₂ – cytosolic phospholipase A₂, COX – cyclooxygenase, EET – epoxyeicosatrienoic acid, FLAP – 5-lipoxygenase activating protein, LOX – lipoxygenase, LT – leukotriene, LTA₄H – leukotriene A₄ hydrolase, LTC₄S – leukotriene C₄ synthase

1.1.1.1 5-Lipoxygenase and its helper protein FLAP

5-LOX is one of the six known LOX in humans and was first discovered in the year 1976 [43-45]. 5-LOX is a soluble, 78 kDa protein expressed in the cytosol or inside the nucleoplasm of leukocytes (neutrophils, eosinophils, monocytes/macrophages, dendritic cells, mast cells, and B-lymphocytes) [46]. Mammalian 5-LOX exhibits a monomeric structure with 672 or 673 amino acids possessing two different functional domains: (I) an N-terminal C2-like domain (residues 1-112), and (II) an α -helical C-terminal domain (residues 126-673) [19, 47]. The regulatory C2-like domain consists of β -sheets and is responsible for Ca^{2+} , membrane, and coactosin-like protein (CLP) binding. In contrast, the C-terminal domain represents the catalytic center of 5-LOX with a non-hem iron [19]. This non-hem iron functions during the 5-LOX reaction mechanism as electron acceptor or donor forming a redox cycle between the inactive ferrous (Fe^{2+}) and the active ferric (Fe^{3+}) form promoted by lipid hydroxyperoxides [48]. Three conserved histidines (His^{367} , His^{372} , His^{550}) and the carboxylate of the C-terminal Ile^{673} coordinate the iron [10, 19]. The crystal structure reveals additionally a unique variation of small helix $\alpha 2$ in the catalytic domain controlling the entrance to the iron like a mobile lid [49], and the side chain of Phe^{177} and Tyr^{181} seals access to the catalytic domain, thereby called “FY cork” [19]. Usually, 5-LOX is described as monomeric protein, but also a homodimer formation of two monomers is reported [50, 51]. Dimer formation is caused by four cysteines (C^{159} , C^{300} , C^{416} , C^{418}) located at the region around the entrance to the catalytic center generating disulfide bonds by cross linking among each other [50, 51]. As monomer, 5-LOX exhibits an increased enzyme activity but after dimerization, the catalytic activity is reduced [51]. The C2- and the catalytic domain interact by a salt bridge between Arg^{101} of the β -sandwich and Asp^{166} located at the catalytic domain [49].

FLAP

The 5-LOX activating protein (FLAP) is an 18 kDa integral membrane protein embedded in the inner and outer leaflet of nuclear and endoplasmic membranes. FLAP belongs to the membrane-associated proteins in eicosanoid and glutathione metabolism (MAPEG) family and shows contrarily to other MAPEG family members no catalytic activity or GSH binding site [52, 53]. FLAP was firstly discovered in the late 1980s as target of MK-886 that was found to inhibit LT biosynthesis devoid of targeting other enzymes of the AA cascade [54, 55]. In 2007, the crystal structure of FLAP in complex with the inhibitor MK-591 was determined [56]. This study demonstrated by X-ray crystallography a formed homotrimer anchored in the nuclear membrane, whereby each monomer consists of four transmembrane helices linked by two cytosolic and one luminal loop [56]. During LT biosynthesis, FLAP interacts as 5-LOX helper protein to transfer AA to 5-LOX by a so far unknown mechanism [57] and thus stimulating conversion of exogenous AA to 5-HpETE and additionally triggering dehydration of AA to LTA_4 .

[58]. However, FLAP inhibitors are able to efficiently block LT biosynthesis gaining an interesting drug development field against inflammatory diseases [59].

Activation of 5-LOX and leukotriene formation

Activation of 5-LOX can be mediated by cell stress or various external stimuli. Cell stress as a Ca^{2+} -independent mechanism is caused by heat shock, osmotic stress, oxidative, or genotoxic agents [60]. These factors initiate activation of mitogen-activated protein kinases (MAPK) followed by phosphorylation of 5-LOX on several serine residues with divergent impacts [61]. External stimuli like N-formyl-methionyl-leucyl-phenylalanine in combination with lipopolysaccharide (fMLP/LPS), ionophores [62], platelet activating factor (PAF), thapsigargin [63], C5a , LTB_4 , and cytokines increase the intracellular Ca^{2+} concentration, and thus, 5-LOX and cPLA_2 are activated [46]. cPLA_2 translocates together with 5-LOX to the nuclear membrane and liberates, among other things, AA from arachidonyl-phosphatidylcholine. Accordingly, FLAP transfers AA to the membrane-associated 5-LOX for LT biosynthesis [64]. 5-LOX generates pro-inflammatory LT in a two-step reaction: (I) oxygenation of AA to 5(S)-hydroperoxy-6-*trans*-8,11,14-*cis*-eicosatetraenoic acid (5-HpETE), and (II) dehydration to the instable epoxide 5(S)-*trans*-5,6-oxido-7,9-*trans*-11,14-*cis*-eicosatetraenoic acid (LTA_4) [37, 65]. Alternatively, 5-HpETE can be reduced by glutathione peroxidases to 5(S)-hydroxy-6-*trans*-8,11,14-*cis*-eicosatetraenoic (5-HETE) [66]. The instable LTA_4 can be stereospecific hydrolyzed by LTA_4 hydrolase (LTA_4H) to the important chemoattractant 5(S),12(R)-dihydroxy-6,14-*cis*-8,10-*trans*-eicosatetraenoid acid (LTB_4). Additional, LTA_4 degrades non-enzymatically into two inactive isomers (6-*trans*- LTB_4 , and 6-*trans*-12-*epi*- LTB_4) [67]. Alternatively, LTA_4 is transformed by LTC_4 synthase (LTC_4S) conjugating a glutathione (GSH) residue at the epoxide moiety to 5(S)-hydroxy-6(R)-S-glutathionyl-7,9-*trans*-11,14-*cis*-eicosatetraenoic acid (LTC_4) in monocytes, macrophages, dendritic cells, and mast cells [68, 69]. Several enzymes can metabolize LTC_4 to 5(S)-hydroxy-6(R)-S-cysteinylglycyl-7,9-*trans*-11,14-*cis*-eicosatetraenoic acid (LTD_4) and 5(S)-hydroxy-6(R)-cysteinyl-7,9-*trans*-11,14-*cis*-eicosatetraenoic acid (LTE_4), which can be summarized together with LTC_4 to cysteinyl-LT (cysLT).

5-LOX inhibitors

LT play an important role in acute and chronic inflammatory diseases and promote also the development and progression of cancer [37, 41, 65]. Different strategies are conceivable to interfere with LT: direct inhibition of enzymes involved in the AA pathway like cPLA_2 , 5-LOX, FLAP, LTA_4H , LTC_4S or antagonists of LT receptors like the compound montelukast [70]. Besides cPLA_2 , direct inhibition of 5-LOX is a common strategy to suppress a diversity of eicosanoids especially AA-derived LM. Direct 5-LOX inhibitors can be subdivided, based on their therapeutic mode of action, in four different inhibitor types: (I) redox active compounds

(e.g., natural compounds like coumarins, or flavonoids [71]) influencing mainly the 5-LOX redox cycle by reducing the active site iron (Fe^{3+}) to its inactive ferrous (Fe^{2+}) state, thereby, interrupting the catalytic reaction of 5-LOX [40, 41], (II) iron-chelating compounds characterized by hydroxamic acid (e.g., BWA4C [72]), or N-hydroxyurea residues (e.g., zileuton [6]) that cause reduced 5-LOX activity by chelating the active site iron, (III) non-redox active agents (e.g., embelin, and its derivatives [73, 74], ZD2138 [75], L-739,010 [76]), which are independent of redox characteristics competing with AA or lipid hydroxyperoxides for the binding to 5-LOX [40, 41], and (IV) novel inhibitors with unknown modes of action. These inhibitors of the latter group show interactions with different binding sites of the C2-like domain like hyperforin with the PC binding site [77, 78], or indirubin derivatives with the ATP binding site [79]. Furthermore, Michael acceptor-containing agents (e.g., thymoquinone, nitro fatty acids, U73122) are considered as additional new class of 5-LOX inhibitors by interacting with surface cysteines (C^{159} , C^{300} , C^{416} , C^{418}) at the dimerization interface of the catalytic center of 5-LOX [16].

1.1.1.2 Leukotriene A₄ hydrolase and leukotrienes

LTA₄H, a soluble 69 kDa protein, is widely expressed in mammalian cells preferable in neutrophils but negligibly in eosinophils. The enzyme is localized in the cytosol or in the extracellular space [47, 80], but nuclear distribution has also been observed [81]. Additionally, LTA₄H is a monomeric Zn^{2+} metalloenzyme that exhibits two distinct enzymatic activities: (I) an epoxide hydrolase activity that metabolizes LTA₄ to the pro-inflammatory chemoattractant LTB₄ predominantly in the cytosol, and (II) during the resolution state of inflammation an aminopeptidase activity that hydrolyzes and thus inactivates the pro-inflammatory tripeptide proline-glycine-proline (PGP) mainly in the extracellular space [12, 13, 82]. The aminopeptidase and epoxide hydrolase activities are exerted via distinct but overlapping active sites [82]. Interestingly, LTA₄H can be inhibited by its own substrate LTA₄ through a suicide inactivation mechanism interacting with Tyr³⁷⁸ within the active site [80, 83]. The crystal structure discloses three different domains: (I) an N-terminal domain (residues 1-207), (II) a Zn^{2+} containing catalytic domain (residues 461-450), and (III) an α -helical C-terminal domain (residues 461-610). The active site is situated between all three domains, and the catalytic Zn^{2+} ion is coordinated by two histidines (His²⁹⁵, His²⁹⁹), and Glu³¹⁸ [84]. Close to the Zn^{2+} , the residue Glu²⁷¹ is shared between the two catalytic pockets and is responsible for both enzyme activities [85]. The binding site for LTA₄ appears to be localized in the L-shaped hydrophobic pocket and contains the catalytic Zn^{2+} and Arg⁵⁶³ playing important roles for the epoxide hydrolase as well as the aminopeptidase activity [13, 86]. A mutation of Asp³⁷⁵ supported a crucial role of this residue for hydrolyzing LTA₄ into LTB₄ [87], and in contrast, mutations of the residues Glu²⁹⁶ and Tyr³⁸³ show a selective elimination of the aminopeptidase activity [88]. Besides LTA₄, the tripeptide PGP is a physiological substrate of LTA₄H [89] and exhibits similar

to LTB₄ chemoattractant properties for neutrophils [90, 91]. PGP belongs to the family of matrikines and is generated from extracellular matrix collagen by metalloproteinases and prolylenpeptidases [92]. Normally, PGP is degraded by the aminopeptidase activity of LTA₄H. If LTA₄H is blocked, the enzyme fails to decompose PGP, and thus, PGP accumulates and induces neutrophil infiltration especially in the lung [12, 93]. For this reason, PGP plays an important role in pathology and development of chronic lung diseases and is used as biomarker for chronic obstructive pulmonary disease (COPD) [94].

LTA₄H inhibitors

LTA₄H constitutes an attractive therapeutic target for the treatment of chronic inflammatory diseases, e.g., respiratory disease [89], inflammatory bowel diseases [95], or cancer [96], due to its high importance in the biosynthesis of inflammatory mediators. Until now, a variety of LTA₄H inhibitors were discovered and developed, but most potent selective inhibitors failed in clinical trials due to their minimal efficacy [97]. Furthermore, the problem of most identified inhibitors is to block also the aminopeptidase activity, which plays a crucial role in the resolution of inflammation by degradation of the tripeptide PGP, beside hampering the epoxide hydrolase activity [98], e.g., JNJ-40929837 [99], SC-57461A [7, 8, 100], or SC-22716 [101]. Interestingly, inhibitors of other Zn²⁺ metalloproteinases, for example, bestatin [102], captopril [103], or kelatorphan [11], affect additionally both LTA₄H activities by chelating the central Zn²⁺ ion. According to the importance of the PGP-degrading activity of LTA₄H [12, 89], the novel route in drug design is to create new LTA₄H inhibitors with a selective blockade of epoxide hydrolase activity without affecting the aminopeptidase activity [104, 105]. Recently, two selective epoxide hydrolase inhibitors were developed, 4-methoxydipehnylmethane (4-MDM) [106], and 4-(4-benzylphenyl)thiazol-2-amine (ARM-1) [107]. These two compound classes are used to design analogues with an improved potency for clinical trials and an unaffected selectivity for inhibition of LTB₄ biosynthesis [104, 105].

Leukotrienes

LT are bioactive LM involved in the innate and adaptive immune response and play physiological and pathological roles in inflammation and in several diseases like asthma bronchiale, psoriasis, rheumatoid arthritis, cardiovascular diseases, allergy, and cancer. They are produced by pro-inflammatory cells, mainly by leukocytes, through the AA/5-LOX pathway, released from the cells by ATP-dependent efflux pumps and deliver their biological activity via specific G-protein coupled receptors (GPCR). LT can be divided into two classes: (I) the chemoattractant LTB₄, and (II) the multi-functional cysLT.

LTB₄ is one of the most potent chemoattractants for neutrophils [4, 5] and plays an important role for the immune defense. LTB₄ triggers the recruitment of immune cells like granulocytes, monocytes, macrophages, and T-cells into inflammatory tissue, their adherence

to the endothelium, and their activation [108]. Additional, LTB_4 promotes the activation of phagocytosis of neutrophils and macrophages and triggers the generation of cytokines (IL1, IL2, IL6), and chemokines (MCP-1) in macrophages [108, 109]. These effects confirm the relevance of LTB_4 in host defense against infections and pathologies of acute and chronic diseases like atherosclerosis [110], rheumatoid arthritis [111, 112], and cancer [4, 113]. LTB_4 mediates its effects by two GPCRs: (I) BLT_1 , and (II) BLT_2 . The expression of BLT_1 is confined to leukocytes and represents a high affinity receptor. In contrast, the BLT_2 receptor is ubiquitously expressed with low affinity for LTB_4 . A participation of BLT_2 for host defense was reported, but the physiological role is poorly understood [114, 115].

Biological effects of cysLT were first discovered in the year 1938 without any knowledge about chemical features and their mode of action [116]. As described before, cysLT are GSH-conjugated LT including LTC_4 , LTD_4 , and LTE_4 known as slow acting substances of anaphylaxis but also as powerful smooth muscle contracting agents [116, 117] primarily in eosinophils, basophiles, mast cells, monocytes, and macrophages [68]. CysLT exhibit pro-inflammatory, bronchoconstrictive, and vasoconstrictive properties and increase the recruitment of eosinophils by the release of chemokines (MCP-1), mucus secretion from bronchial epithelial cells, and the pulmonary vascular permeability [118, 119]. Besides their effects on asthma bronchiale, they play also a role in allergic rhinitis, atopic dermatitis, and chronic diseases, e.g., cardiovascular diseases [119-121]. CysLT can bind to three GPCR – $CysLT_1$, $CysLT_2$, and $CysLT_3$. All cysLT bind to $CysLT_1$ conveying most of their pro-inflammatory effects but with different levels of affinity ($LTD_4 > LTC_4 > LTE_4$) [122]. Potent selective LTD_4 antagonists like montelukast, zafirlukast (withdrew from the pharmaceutical market since 2019) , and pranlukast (with primary usage in Japan) are used for the treatment of asthma bronchiale [123]. In contrast, LTC_4 and LTD_4 bind with equal affinity to $CysLT_2$, and again LTE_4 shows a reduced binding affinity ($LTC_4 = LTD_4 > LTE_4$) [119, 124]. Recently discovered, the third cysLT receptor ($CysLT_3$) exhibited a selective binding of LTE_4 [125], but its role in inflammation has to be clarified.

1.2 Cell death

Cell death belongs to essential basic processes in mammalian cells mediating development and regulation of tissue homeostasis. On the basis of morphological and biochemical characteristics, cell death can be classified into three subgroups: (I) apoptosis (section 1.2.1), (II) autophagic cell death (section 1.2.2), and (III) necrosis (section 1.2.3) [126-128], whereby in many cases no clear distinction exists between individual forms, and composited processes occur.

1.2.1 Apoptosis

Fig. 2 Apoptosis pathway. I) intrinsic pathway; II) extrinsic pathway.

Apoptosis is the classical programmed cell death without induction of inflammation and is characterized by several morphological alterations to protect cells from an undesirable immune response [129, 130]. Typical morphological changes are chromatin condensation, and nuclear fragmentation, cell shrinkage, mitochondrial outer membrane permeabilization, and formation of apoptotic bodies [128-130]. These apoptotic bodies are small intact plasma membrane vesicles of disintegrated cells, containing cellular components and organelles, and can be eliminated by phagocytosis via neighboring cells [129]. Beside morphological features, apoptosis exhibits also biochemical characteristics. One major role plays the contribution of caspases, which are cysteine aspartyl proteases [131]. Under non-apoptotic conditions, caspases are inactive enzymes, called zymogens, and these pro-caspases can be activated by cleavage or dimerization [132, 133]. Caspase-mediated apoptosis can occur through two predominant pathways: (I) the extrinsic pathway, and (II) the intrinsic pathway. The extrinsic pathway is induced by extracellular signals, e.g., Fas ligands, TNF α , and TNF-related apoptosis-inducing ligands (TRAIL) binding to trans-membrane death receptors. Activated receptors form together with pro-caspase 8 a multi-protein death initiation signaling complex (DISC), which cleaves pro-caspase 8 in its active form. Subsequently, caspase 8 activates itself by autocleavage and triggers the cleavage of caspase 3 or induces the intrinsic mitochondrial pathway [134, 135]. Additionally, in response to stressing conditions, e.g., DNA damage, oxidative stress, growth factor withdrawal, cytotoxic compounds, or toxic insults, the mitochondrial outer membrane permeabilization increases by oligomerization of Bax/Bak [136], and the mitochondrial membrane potential dissipates resulting in an elimination of ATP

production [129, 137]. Consequently, mitochondria release several proteins like Cytochrome c, and these trigger together with ATP and the apoptotic protease-activating factor-1 (Apaf-1) the assembly of an apoptosome [138]. This complex initiates the recruitment and activation of caspase 9, which is able to cleave and therefore to activate caspase 3. Both pathways result in an activation of caspase 3 provoking the subsequent cleavage of poly-(ADP-ribose) polymerase-1 (PARP-1), which is essential for DNA repair and thus for cell survival. Furthermore, a caspase-independent PARP cleavage is also possible [139, 140].

1.2.2 Autophagy and autophagic cell death

Autophagy is a lysosomal degradation pathway, which is a pro-survival mechanism with spatial restriction. In short, cytoplasmic components are degraded and recycled in double-membraned vacuoles with the help of lysosomal hydrolases [141, 142]. Autophagic digestion is essential for survival, development, differentiation, and homeostasis, and it protects organisms from pathologies, e.g., cancer and infections [141]. In general, autophagy can be classified in (I) chaperone-mediated autophagy, (II) microautophagy, and (III) macroautophagy, whereby the latter is the major degradation process, which is primarily used by cells to generate energy in the form of ATP for their cell survival [143]. The basic macroautophagy process begins with isolated membrane residues, so-called phagophores. These membrane residues can originate from plasma membrane, endoplasmic reticulum (ER), Golgi, or mitochondria. Expansion of phagophores generates a double membrane-layered vesicle, the autophagosome. This autophagosome, containing cell organelles, protein aggregates, and endosomes, merges with lysosomes, holding lysosomal hydrolases, to the autolysosome. Within the autolysosome, captured material is degraded by hydrolases, and component parts are released to the cytosol for biosynthetic processes or for energy generation [142-144]. Autophagy can be regulated by many different factors which are specific for the respective organism, e.g., the up- and downstream pathway of the mechanistic target of rapamycin (mTOR), protein kinase A (PKA), proteins of the Bcl-2 family, and AMP-activated protein kinase (AMPK) as possible regulators for the mammalian macroautophagy [143-145]. The autophagic process is upregulated for generation of intracellular nutrients and energy or during oxidative stress, infection, and protein aggregate accumulation to remove intracellular pathogens [141, 145]. Furthermore, autophagy can also be activated by caspases [146]. Hyperactive autophagy provokes a breakdown of cellular organelles and proteins to generate energy comparable with a self-cannibalism that finally leads to cell death [141]. Cell death is mediated through autophagy, and on the other hand, cell death occurs with autophagy. In fact, the complete mechanism of autophagic cell death have not yet been fully clarified, but it is known that an increased autophagy activates the c-Jun N-terminal kinase (JNK) generating death signals [147]. Furthermore, autophagic cell death is mediated through the Bcl-2 family proteins Bax/Bak, located at the lysosomal

monomeric membrane, which cause an enhanced lysosomal membrane permeability resulting in an increased acidity [148].

1.2.3 Necrosis

In contrast to the previous types of cell death, necrosis is an uncontrolled process lacking the characteristics of apoptosis and autophagic cell death [128, 149] and can be elicited by direct chemical or radiologic insult [150]. Necrosis is originally characterized by a rapid rupture of plasma membrane caused by cytoplasmic swelling, dismantling of swollen organelles, and the involvement of the immune system leading to the release of pro-inflammatory intracellular factors [128, 149, 151]. Furthermore, necrosis exhibits several highly regulated mechanisms. These include early signs of mitochondrial dysfunction, e.g., ATP depletion, failed Ca^{2+} homeostasis, swelling, and enhanced ROS production, lysosomal rupture, and activation of proteases like calpains and cathepsins [149, 152, 153]. In fact, necrosis plays also a relevant role in many biological and immunological processes like microbial infections, adaptive immune responses, septic shock, cell homeostasis, and cancer [151, 153]. Three different types of necrosis are described: (I) pyroptosis, (II) necroptosis, and (III) lysosome-mediated necrosis (LMN) [151]. The best characterized form is pyroptosis, mediated through caspase 1 activation and inflammasome signaling [154]. Also known as back up cell death pathway, necroptosis combines apoptotic and necrotic features. In the presence of caspase inhibitors, necrosis is initiated by death receptor ligands ($\text{TNF}\alpha$, TRAIL, or Fas) and is regulated by receptor-interacting kinase 1 and 3 (RIP1/RIP3), and mixed lineage kinase domain-like (MLKL) [155]. Both necrotic forms are linked to inflammation. In contrast, LMN is linked to the adaptive immunity [156] and is induced by alum, silicea crystals, cholesterol crystals, amyloid proteins, and the dipeptide methyl ester Leu-Leu-OMe (LLOMe). One major characteristic feature is an early lysosome rupture followed by irreversible plasma membrane damage and proteolysis of proteins with low-molecular weight [151, 157, 158]. These effects are regulated by cathepsins [157].

1.3 Natural products

Fig. 3 Structures of investigated natural compounds.

1.3.1 Gliotoxin from *Aspergillus fumigatus*

The fungal secondary metabolite gliotoxin is an epidithiodioxopiperazine mycotoxin, and it is characterized by an intramolecular sulfur bridge and a dipiperazine core [159-161]. This intramolecular disulfide bond is responsible for the majority of biological activities [162] by triggering ROS production and interaction with cysteines within proteins [160], due to an intracellular redox cycle of gliotoxin. Gliotoxin is produced by various fungal species like *Eurotium chevalieri* and *Trichoderma vireus* but most commonly produced in *Aspergillus fumigatus* [160, 163]. The mycotoxin shows a variety of biological activities including antiviral effects by decreasing of multiplication of RNA through inhibition of RNA-dependent RNA polymerase [164, 165], inhibition of angiogenesis [166], and immunosuppressive impact [167, 168]. These immunosuppressive effects are conferred by effects on the cytoskeleton of immune cells, features as potent virulence factor, and also by its cytotoxicity [160]. Gliotoxin abrogates phagocytosis of polymorphonuclear leukocytes (PMNL) and affects the actin cytoskeleton organization resulting in alterations of cell morphology and cell adhesion [169-171]. In RAW264.7 macrophages, gliotoxin interferes with the inositol triphosphate metabolism impeding integrin activation, dysfunction in the actin cytoskeleton remodeling, and finally reduced phagocytosis [172]. Furthermore, gliotoxin shows inhibitory effects on farnesyltransferase and geranylgeranyltransferase [160], and it interferes with nicotinamide adenine dinucleotide phosphate oxidase complex formation leading to reduced ROS formation in phagocytes [173, 174]. Moreover, gliotoxin induces apoptosis in various cell types, except PMNL [175], through different pathways. Gliotoxin is able to stabilize I κ B α preventing its degradation by proteasome [176], and thus, the transcription factor NF κ B cannot be activated [177], causing a diminished pro-inflammatory cytokine release *in vivo* and *in vitro* [178]. Additional, gliotoxin increases the cellular concentration of cyclic adenosine monophosphate (AMP) by phosphorylation of histone H3 leading to an activation of PKA in thymocytes [179]. Another pathway of gliotoxin to trigger apoptosis is the interference with the Bcl-2 family member Bak resulting in a stimulation of the mitochondrial apoptosis pathway. As result, ROS production is increased and mediates the release of proapoptotic proteins like cytochrome C and leads eventually to apoptosis [180]. Finally, gliotoxin is a significant virulence factor in the pathology of *A. fumigatus* [1] eliciting IA [2]. IA affects primarily immunocompromised patients as well as immunocompetent patients with a high mortality rate varying between 30 to 90% [181]. During the infection process, *A. fumigatus* produces various mycotoxins with gliotoxin as most abundant and best characterized compound [163]. Indeed, gliotoxin is detectable in lung and sera of mice and human patients [182], and it is able to evoke aspergillosis in mice [2]. Due to its immunosuppressive characteristics, gliotoxin is used as diagnostic marker for IA [160].

1.3.2 Melleolides from *Armillaria mellea*

Melleolides are fungal secondary metabolites of the basidiomycete genus *Armillaria mellea*, a global widespread and edible genus with particular saprotrophic and parasitic characteristics [183, 184]. Constituents are sesquiterpene aryl esters with orsellinic acid from the polyketide pathway [185] as basic structure esterified with a protoilludene type secondary alcohol derived from the sesquiterpene pathway [184]. These combined structural elements are unique for the genus *Armillaria* [186]. The cultured mycelium of *A. mellea* is used as “Tienma” in traditional Chinese medicine to treat dizziness, headache, neurothenia, and insomnia [187, 188]. Melleolides show, besides antioxidative properties [189], also antimicrobial and antifungal activities [184, 188, 190, 191]. The modes of action for antimicrobial and antifungal effects are still unclear. Moreover, melleolides increase the maturation of dendritic cells [192] and enhance concanavalin A- or LPS-mediated lymphocyte proliferation [193]. Additionally, melleolides exhibit cytotoxic properties towards various cancer cells [194] with several modes of action. Armillarikin induces apoptosis in human leukemia cells and hepatocellular carcinoma cells by caspase activation and increased ROS production followed by collapse of mitochondrial transmembrane potential [187]. In contrast, armillaridin causes autophagy-mediated cell death in human leukemia cells by reduction of the mitochondrial transmembrane potential and effects on autophagic flux and on autophagosome-lysosome fusion resulting in an induction of autophagosome formation [195, 196]. Also arnamial possesses cytotoxic features [197] with a still unclear mechanism. Additionally, some melleolides cause decreased DNA biosynthesis in human cancer cells hypothesizing this effect as reason for their cytotoxicity [194]. During the last years, several structure-activity relationship studies were performed and some structural properties disclosed, whether melleolides exhibit antifungal or cytotoxic effects. Of interest, structural elements causing antifungal or cytotoxic activity are dissimilar. While the position of the double bond within the sesquiterpene moiety causes antifungal activity [186], the degree of hydroxylation within the sesquiterpene moiety and a low number of alcohol functionalities are responsible for cytotoxicity [194].

1.3.3 Myxochelin A from *Pyxidicoccus fallax*

Pyxidicoccus fallax belongs to the family of Gram negative bacteria - these so-called predatory myxobacteria contain diverse macrolide antibiotics, e.g., gulfmirecins [198], disciformycins [199], and anti-cancer agents, e.g., myxochelin A [200-202]. Myxochelins are assumed to mediate their biological activity as siderophores and thus securing the iron supply of the producing bacterium as iron chelating agents [203]. Besides their antiproliferative effects in leukemic cancer cell lines [200], myxochelins exert also antimetastatic effects [204, 205]. The catechol residues seem to be responsible for the biological activity, whereas methylation of the catechol hydroxyl residues diminishes their effects [200, 206].

2. AIM OF THE THESIS

Acute inflammation is a physiological process to protect the host organism against infection and to restore homeostasis upon injury by an immune response. This response is mediated by various internal signals, e.g., eicosanoids, cytokines, and chemokines, or external signals, e.g., diverse microbes, leading to chronic inflammation and cancer in some cases. As member of the Excellence Graduate School “Jena School for microbial communication” (JSMC), which addresses microbial communication between microorganisms, their metabolic products and host organisms, this thesis aimed to investigate several natural secondary metabolites with potential anti-inflammatory and/or cytotoxic effects in primary immune cells and cancer cells for their immunomodulatory actions and to resolve the underlying molecular mechanisms. In view of the growing link between inflammation and cancer and the role of primary immune cells in tumorigenesis, the identification of crucial effectors is key for understanding their connection and may offer potential targets for therapeutic approaches.

First, the effect of these secondary metabolites on LT biosynthesis have been investigated with the aim to clarify and to characterize the mechanisms for the underlying inhibition of LT formation. LT are bioactive LM, which are formed by 5-LOX and LTA₄H, or LTC₄S from the polyunsaturated fatty acid AA, playing a pivotal role in the innate and adaptive immune response, inflammation, and several diseases due to the recruitment of leukocytes to the site of infection or injury. In the last decades, a variety of 5-LOX, LTA₄H, and LTC₄S inhibitors were designed, investigated, and tested in clinical trials, but only a few compounds reached the pharmaceutical market, e.g., the 5-LOX inhibitor zileuton [6]. Main focus of this thesis was placed on an abrogation of LT biosynthesis by inhibition of 5-LOX or LTA₄H. Therefore, inhibitory effects in cell-free assays were compared with the efficacy in various leukocytes including the influence of different stimuli or redox active agents. Furthermore, selectivity of inhibition was confirmed by the exclusion of effects on other enzymes involved in the AA metabolic pathway. In the case of 5-LOX inhibition, interaction with the 5-LOX helper protein was analyzed by immunofluorescence, and the detailed impact of concerned compounds was investigated. Moreover, physiological data for LTA₄H inhibition were collected by distinct animal models of inflammation and infection.

Second, the effects of natural compounds on human cell viability have been investigated to elucidate their mode of action as new approach for the development of anti-cancer drugs. Hence, the cytotoxic properties of melleolides were studied in human primary monocytes and cancer cells including the characterization of apoptotic and necrotic features by flow cytometry experiments. Additionally, modifications in cell morphology were analyzed by light microscopy followed by a new established UPLC-MS/MS method to detect phospholipid-compound interactions, and subcellular fractionation was performed to address a specific accumulation in various cell organelles including cell membranes.

3. MANUSCRIPTS

Manuscript I (M-I)

Melleolides from honey mushroom inhibit 5-lipoxygenase via C159

Stefanie König, Erik Romp, Verena Krauth, Michael Rühl, Maximilian Dörfer, Stefanie Liening, Bettina Hofmann, Ann-Kathrin Häfner, Dieter Steinhilber, Michael Karas, Ulrike Garscha, Dirk Hoffmeister, Oliver Werz, Cell Chemical Biology **2019** 26(1), 60-70

Manuscript II (M-II)

Gliotoxin from *Aspergillus fumigatus* abrogates leukotriene B₄ formation through inhibition of leukotriene A₄ hydrolase

Cell Chemical Biology 2019 26(1), 60-70

In the present work, we characterized four melleolides isolated from *Armillaria mellea* and their effects on LT biosynthesis in human primary neutrophils. Melleolides abrogated the formation of LTB₄ due to a selective inhibition of 5-LOX. In more detail, melleolides prevented the interaction between 5-LOX and its helper protein FLAP at the nuclear membrane by covalent binding of their α,β -unsaturated aldehyde moiety to cysteines located around the entrance to the catalytic center. Moreover, experiments with 5-LOX mutants, where selected cysteines have been substituted by serine, revealed two possible modes of actions caused by melleolides. First, the direct interaction with more than two of the cysteines C¹⁵⁹, C³⁰⁰, C⁴¹⁶, and C⁴¹⁸ leading to a reduced 5-LOX activity, and second, the selective influence on C¹⁵⁹, which prevented the 5-LOX/FLAP complex assembly at the nuclear envelope. Taken together, melleolides harboring a Michael acceptor functionality mediated the 5-LOX inhibition by targeting C¹⁵⁹.

Own contribution: Experimental design and performance of 5-LOX assays, immunofluorescence analysis, proximity ligation assays; assistance to HEK cell transfection; measurement of 5-LOX expression, FLAP expression, and phosphorylation of cPLA₂, ERK-1/2, p38 MAPK by Western Blot; maintenance of cell culture and performance of blood cell isolation; data analysis; writing the manuscript. **Total contribution: 80%.**

oliver.werz@uni-jena.de

In Brief

König et al. revealed human 5-lipoxygenase as a functional target of melleolides from honey mushroom, where cysteines at the substrate entrance of 5-lipoxygenase mediate enzyme inhibition. Exploiting melleolides as a tool they identified Cys159 as a determinant for interaction of 5-lipoxygenase with its helper protein.

Highlights

- Human 5-lipoxygenase (5-LO) was identified as a molecular target of melleolides
- Melleolides inhibit 5-LO via two or more of the cysteines 159, 300, 416, and 418
- Melleolides prevent interaction of 5-LO with its helper protein via Cys159 in 5-LO
- Cys159 in 5-LO determines interaction with its helper protein and 5-LO activity

Gliotoxin from *Aspergillus fumigatus* abrogates leukotriene B₄ formation through inhibition of leukotriene A₄ hydrolase

Stefanie König, Simona Pace, Helmut Pein, Thorsten Heinekamp, Jan Kramer, Erik Romp, Maria Straßburger, Fabiana Troisi, Anna Proschak, Jan Dworschak, Kirstin Scherlach, Antonietta Rossi, Lidia Sautebin, Jesper Z. Haeggström, Christian Hertweck, Axel A. Brakhage, Jana Gerstmeier, Ewgenij Proschak, Oliver Werz

Cell Chemical Biology 2019 26(4), 524-534

This publication presents the effects of gliotoxin isolated from *Aspergillus fumigatus* on LTB₄ biosynthesis caused by inhibition of LTA₄H in human primary immune cells. The potent neutrophil chemoattractant LTB₄ is involved in several inflammatory diseases, e.g., IA caused by *A. fumigatus* leading to high mortality rates, especially for immunocompromised patients. The major virulence factor of *A. fumigatus*, gliotoxin, inhibited selectively the biosynthesis of LTB₄ *in vivo* in two distinct animal models: (I) murine peritonitis, and (II) pleurisy in rats. Furthermore, we confirmed selective LTB₄ inhibition *in vitro* in human primary immune cells. Intracellular GSH was crucial to cleave the disulfide bond of gliotoxin in order to chelate the zinc ion in the active center of the epoxide hydrolase pocket of LTA₄H without affecting the aminopeptidase function and thus preventing neutrophil recruitment to the site of inflammation. Conclusively, we identified the target and a potential mode of action of gliotoxin in *A. fumigatus* pathology.

Own contribution: Experimental design and performance of 5-LOX assays with several cell types, purified enzyme, agents, and stimuli, LM extraction for UPLC-MS/MS analysis; extraction of LM from animal samples and their analysis by UPLC-MS/MS and ELISA; experimental design, optimization, and performance of epoxide hydrolase and aminopeptidase activity assays of LTA₄H; maintenance of cell culture and performance of blood cell isolation; data analysis; writing the manuscript. **Total contribution: 75%.**

In Brief

König et al. identified leukotriene A₄ hydrolase (LTA₄H) in human leukocytes as a molecular target of gliotoxin from *Aspergillus fumigatus*. Under reducing conditions, gliotoxin inhibits leukotriene A₄ hydrolase activity leading to suppression of chemotactic leukotriene B₄ biosynthesis and neutrophil infiltration, which may underlie the neutrophil-compromising properties of this fungal toxin.

Highlights

- Gliotoxin suppresses neutrophil influx and LTB₄ formation in mice and rats
- Gliotoxin selectively inhibits LTB₄ biosynthesis via inhibition of LTA₄H
- Gliotoxin blocks epoxide hydrolase but not aminopeptidase activity of LTA₄H
- Reducing conditions confer gliotoxin LTA₄H inhibitory activity

3.3 Manuscript III (M-III)

Myxochelins target human 5-lipoxygenase

Sebastian Schieferdecker, Stefanie König, Andreas Koeberle, Hans-Martin Dahse, Oliver Werz, Markus Nett

Journal of Natural Products 2015 78(2), 335-338

Here, we described the isolation and characterization of biological activity of three myxochelins isolated from *Pyxidicoccus fallax*. While myxochelin A was already known, we identified myxochelin C and D as new structural representatives with isotopic incorporation. Besides the clarification of the structure, we performed various biological assay to clarify the mode of action of these myxochelins. We found that myxochelin A exhibits potent antiproliferative effects towards the leukemic K-562 cells, but fails to affect adherent HeLa cells. A methylation of the catechol residues reduced these antiproliferative effects. Furthermore, we identified 5-LOX as molecular target of myxochelins in cell-free assays ($IC_{50}=1.9\ \mu M$) correlating to suppression of proliferation of K-562 cells. As described before, myxochelins act as siderophores thus hypothesizing 5-LOX inhibition by iron chelation. Taken together, myxochelins may targeted 5-LOX as iron-ligand agents leading to inhibition of proliferation in leukemic cells harboring 5-LOX.

Own contribution: Experimental design and performance of 5-LOX assays with purified enzyme, purification of human recombinant 5-LOX from *E. coli*; coordination of mPGES-1 activity assay; data analysis; partially writing the manuscript. **Total contribution: 30%.**

Bioorganic & Medicinal Chemistry 2014 22(15), 3856-61

In this manuscript, we analyzed several melleolides, isolated from the basidiomycete genus *Armillaria mellea*, for their cytotoxic potential in human primary monocytes and in various cancer cell lines. Structure-activity relationship analysis revealed the importance of the α,β -unsaturated double bond for potent cytotoxicity. Interestingly, DAO displayed comparable results for monocytes and HeLa cells in contrast to other antiproliferative compounds, which were less active against primary monocytes, e.g., staurosporine, or pretubulysin. Furthermore, DAO induced an unusual rapid onset of cell death (within < 1 hr), which contrasts cell death induction for other cytotoxic compounds (> 5 hrs). Based on morphological analysis and flow cytometry experiments, we hypothesized an untypical mechanism of rapid cell death induction for melleolides with an unknown target, combining necrotic as well as apoptotic features.

Own contribution: Experimental design and performance of MTT assays with DAO and staurosporine in human primary monocytes and HeLa cells; isolation of monocytes and cell culture; data analysis; partially writing the manuscript. **Total contribution: 20%.**

manuscript in preparation, **planned submission: 3rd quarter 2019** in *Cell Chemical Biology*

This work presents the clarification of the mode of action for the cytotoxicity of the melleolide DAO in human primary monocytes and cancer cells. DAO rapidly induced cell death within 15 min analyzed by a reduced mitochondrial reductase activity and an increased PARP cleavage. We found that these effects were caused by an interaction of the α,β -unsaturated aldehyde of DAO with the head groups of phospholipids of cell membranes, which might be the reason for the rapid loss of plasma membrane integrity and cellular viability. As result, DAO reacted covalently via an 1,4-addition with ethanolamine and PE. In addition, subcellular fractionation was used to determine a predominant accumulation of DAO within a specific cell organelle fraction. Conclusively, DAO causes cell death by membrane damage, seemingly due to covalent modification of PE with detrimental consequences for cell integrity and viability.

Own contribution: Experimental design and performance of MTT and LDH assay, Western Blot analysis of phospho-p38 MAPK, phospho-Akt, BiP, CHOP, and ATF-4 in monocytes; experimental design and performance of measurement of non-cellular and cellular DAO-PE adducts for UPLC-MS/MS analysis after treatment with phospholipase D; extraction of cellular DAO-PE adducts and their analysis by UPLC-MS/MS; experimental design, optimization, and performance of subcellular fractionation, Western Blot analysis of each fraction, extraction of cellular DAO-PE adducts and phospholipids in separated fractions and their analysis by UPLC-MS/MS; maintenance of cell culture and performance of blood cell isolation; data analysis; writing the manuscript. **Total contribution: 70%.**

4. DISCUSSION

In the last decades, several studies have described diverse biological functions of natural products in mammals biosynthesized by fungi, bacteria, or plants. Natural products are also known to interfere with the host defense as potent virulent factors, can cause cell death or possess anti-inflammatory features, but the underlying modes of action and molecular targets are still elusive. Considering the growing connection between inflammation and cancer, the present work focuses on the target identification of natural secondary metabolites to clarify interference with inflammation and their importance for pathogenicity. Here, we investigated DAO, gliotoxin, and myxochelins for their effects and underlying mechanisms in inflammatory processes and cell death induction in human cells.

We identified 5-LOX as molecular target of the myxobacterial compound myxochelin A biosynthesized by *Pyxidicoccus fallax* and of the melleolide DAO from honey mushroom *Armillaria mellea*. While myxochelin A and various derivatives chelated the ferrous iron in the enzyme's active site by its catechol residues (**manuscript III**), DAO interfered with surface cysteines located at the substrate entrance of 5-LOX (**manuscript I**) resulting in abrogated LT formation. Besides DAO, we tested several melleolides for structure-activity relationships and identified that the α,β -unsaturated aldehyde group serves as Michael acceptor mediating 5-LOX inhibition. Michael acceptor containing compounds interact, inter alia, with cysteines located at the entrance to the catalytic center of 5-LOX and hence influencing 5-LOX activity and LT biosynthesis [15, 16]. In the case of DAO, this α,β -unsaturated aldehyde group interacts with C¹⁵⁹ preventing 5-LOX/FLAP interaction without prejudicing nuclear 5-LOX translocation in intact neutrophils but failed to selectively target C¹⁵⁹ in cell homogenates. Instead, DAO affected two or more cysteines (C¹⁵⁹, C³⁰⁰, C⁴¹⁶, C⁴¹⁸) in lysed cells that results in an equally abrogated LT formation, indicating two distinct mode of actions in neutrophils (**manuscript I**) with minimal impairment of cell viability (unpublished data). Furthermore, DAO exhibited potent and similar cytotoxic properties in human monocytes as well as in various cancer cells with an untypical rapid onset of cell death compared to various antiproliferative and cytotoxic compounds. However, we revealed apoptotic as well as necrotic cell death characteristics of DAO by flow cytometry and light microscopy analysis including an abrogated metabolic activity of mitochondria (**manuscript IV**). Subsequently, we identified a covalent binding of the reactive α,β -unsaturated aldehyde group to the ethanolamine head group of the membrane phospholipid PE. Hence, we confirmed our previous hypothesis of a composed cell death process by showing simultaneously PARP cleavage and membrane rupture, measured by LDH release, correlating with increased DAO-ethanolamine adducts. Moreover, DAO manipulated mitochondrial functions and caused impaired autophagic processes with enhanced lysosomal rupture and decreased intracellular pH value leading to the assumption that DAO-induced cell death linked several dysfunctional cellular processes (**manuscript V**).

Another fungal toxin, gliotoxin, plays an important role in several inflammatory processes, e.g., inducing cell death in primary immune cells [175, 207] or inducing IA as potent virulence factor of *Aspergillus fumigatus* [1, 2]. Various theories exist for cell death induction and triggering IA with its indications [160], whereby only target identification of gliotoxin for IA plays a central role in this thesis. Our data show that gliotoxin abrogates the biosynthesis of the important neutrophil chemoattractant LTB₄ by covalent binding to LTA₄H. Furthermore, we found that gliotoxin chelates the zinc ion in the epoxide hydrolase center by its reduced free thiol groups but failed to inhibit LTA₄H under non-cellular conditions. An inhibition of the aminopeptidase activity and an abrogation of other epoxide hydrolases could be excluded. Moreover, we confirmed our results *in vivo* and verified gliotoxin as virulence factor of *A. fumigatus* responsible for neutropenia and the resulting host resistance to *A. fumigatus* (**manuscript II**).

4.1 Natural compounds and their effect on inflammatory key processes

During the early phase of inflammation, pro-inflammatory signaling molecules, e.g., cytokines, chemokines, and several eicosanoids are produced by tissue resident macrophages or mast cells. These inflammatory mediators initiate the recruitment of leukocytes, mainly neutrophils, to the site of infection or injury for host protection. In the case of dysregulation, inflammation becomes persistent, which ultimately can even lead to cancer [21, 29, 208]. We tested the secondary metabolites DAO, myxochelin A, and gliotoxin in human primary immune cells to clarify their role in inflammatory processes and to reveal their modes of action.

The metabolism of AA is one important pathway mediating initiation and resolution of inflammation depending on particular enzyme activity and LM formation. 5-LOX is part of the AA pathway and responsible for the biosynthesis of pro-inflammatory LT. The melleolide DAO abrogated 5-LOX activity in a direct and selective manner by interacting with C¹⁵⁹ located at the catalytic entry and prevented thereby an interaction between 5-LOX and its helper protein FLAP (**manuscript I**). Indeed, the myxobacterial compound myxochelin A reduced also directly 5-LOX activity but instead of interacting with essential amino acids, myxochelin A seemingly chelated the central iron in 5-LOX by its catechol basic structure belonging to the family of iron ligand inhibitors (**manuscript III**).

In the last years, the number of investigated naturally occurring 5-LOX inhibitors increased [40, 41], harboring various modes of action to impede LT biosynthesis. While embelin acted as non-redox inhibitor for hampering 5-LOX activity [74] or the indirubin derivative 6-BIO interacted with the ATP binding site of 5-LOX [79], compounds containing a catechol residue, e.g., rosmarinic acid [209], caffeic acid, and its derivatives [210, 211] were typical natural representatives for the iron-complexing inhibitor type. Also the siderophore myxochelin A [203] contained a catechol basic structure. We analyzed myxochelin A and various derivatives for structure-activity relationships for 5-LOX inhibition (**manuscript III**, [206,

212]). In line with results from previous investigations [203], we showed that the catechol basic structure was essential for abrogated LT biosynthesis and methylation of the aromatic hydroxyl residues resulted in a completely reversed 5-LOX inhibition. We observed increased inhibition of 5-LOX activity if the second hydroxyl moiety was located in meta position [206, 212], whereas the second hydroxyl residue in para position impaired the bioactivity [206]. Interestingly, derivatives harboring the second hydroxyl group in meta position did not lose their biological activity, although the chrome azurol S assay, measuring iron affinities, was negative [212]. This supports different modes of action for 5-LOX inhibition depending on the myxochelin structure. Furthermore, a single methoxy substituent at the catechol residue is sufficient for reducing 5-LOX inhibition. However, structural modifications at the lysinol partial structure were negligible for 5-LOX inhibition [206]. Myxochelins failed to inhibit 5-LOX activity in cellular systems or exhibited only a weak activity, assuming that the high polarity of the structure was responsible for limited cellular uptake. Of interest, the myxochelins showed a structural resemblance to another natural product, that is, curcumin which is biosynthesized by the plant *Curcuma longa*. Curcumin was previously identified as potent 5-LOX and mPGES-1 inhibitor [213, 214], hypothesizing that myxochelins could also interfere with mPGES-1. However, myxochelins failed to inhibit mPGES-1 activity in cell-free assays supporting selective 5-LOX inhibition. Conceivably, myxochelins could possess antioxidant activities similar to caffeic acid and derivatives [210], which requires further investigations. In conclusion, myxochelins impeded primarily 5-LOX activity by iron-chelating effects of the catechol residue in the active center of the enzyme and represent an interesting substance class for investigation of new natural 5-LOX inhibitors.

We examined four different melleolides for structure activity relationship for 5-LOX inhibition under cellular and non-cellular conditions (**manuscript I**). The structure of melleolides can be divided in a sesquiterpene moiety and an orsellinic acid residue. Melleolides harboring an α,β -unsaturated aldehyde group at position 1 with a $\Delta^{2,3}$ or $\Delta^{2,4}$ double bond exhibited potent 5-LOX inhibition, whereby compounds with a $\Delta^{2,3}$ double bond were less active or failed to diminish LT biosynthesis, when the α,β -unsaturated aldehyde group was replaced by a hydroxyl moiety. Interestingly, the Michael acceptor functionality might be responsible for further biological activities of melleolides like antifungal activity, antimicrobial activity, and cytotoxic properties published in previous studies [186, 194]. However, structural modifications at the orsellinic residue like a hydroxyl group at position 5' instead of methylation or a 6'-chlorine and hydroxylation at position 4 of the sesquiterpene moiety caused only a minor loss of 5-LOX inhibitory potency. We identified DAO and arnamial as most potent compounds for 5-LOX inhibition, whereby arnamial was more potent under cell-free conditions, and DAO exhibited more reducing activity in cells with 10-fold lower IC_{50} . Both structures were characterized by the α,β -unsaturated aldehyde group at position 1 with a $\Delta^{2,4}$ double bond but

arnamial contained a more lipophilic orsellinic acid residue (5'-methylation, 6'-chlorine). In fact, compounds with high lipophilicity correlated with more potent 5-LOX inhibition than less lipophilic structures [215], but this correlation explains not a 10-fold less inhibition under cell free conditions in case of DAO. All experiments were compared to the well-known 5-LOX inhibitor zileuton suppressing 5-LOX activity in comparable manner in different experimental settings (this study and others [6]). Furthermore, external supplementation of AA to intact cells reduced the inhibitory effect of DAO similarly to the potency under cell-free conditions, suggesting an additional effect of DAO on proteins/enzymes involved in the 5-LOX pathway. Indeed, several enzymes and enzyme activities participate in LT biosynthesis: (I) AA release by cPLA₂ from membrane phospholipids, (II) AA transfer by FLAP to 5-LOX and 5-LOX/FLAP complex assembly, (III) nuclear 5-LOX translocation, and (IV) preceding activating 5-LOX signaling pathways such as phosphorylation by MAPK and cellular Ca²⁺ mobilization [10]. By means of our data, we excluded direct cPLA₂ inhibition by determination of unaffected released [³H]-labeled AA. Instead we observed hampered 5-LOX/FLAP complex assembly leading to impeded AA transport by FLAP or a competition between DAO and AA for the 5-LOX binding pocket without affecting the 5-LOX translocation to the nuclear membrane. In general, 5-LOX inhibition can be mediated by iron-chelating agents, redox active compounds, or AA mimetics, which compete with AA for binding at the active or allosteric site of 5-LOX [40, 41]. Based on the chemical structure, DAO possesses no fatty acid-like features excluding competition with AA. Also, redox activities and iron-chelating effects were not reported for DAO. Interestingly, compounds containing a Michael acceptor functionality like thymoquinone (TQ), U73122 or nitro fatty acids showed a high reactivity with SH-groups and exhibited LT abrogation by building covalent adducts with surface cysteines located at the catalytic entrance to the 5-LOX activity center [15, 16, 216]. The 5-LOX structure contained nine different cysteines, whereby C⁹⁹ and C⁴⁴⁹ were present in 12-LOX as well as in 15-LOX [15, 19]. As DAO inhibited neither 12-LOX nor 15-LOX activity, we excluded an interaction with these two cysteines. The four cysteine residues C¹⁵⁹, C³⁰⁰, C⁴¹⁶, and C⁴¹⁸ were located closed to the substrate entry [19, 51], and as published before, they are responsible for 5-LOX dimerization [51], 5-LOX/FLAP co-localization at the nuclear envelope, and finally for influencing 5-LOX product formation without hampering 5-LOX translocation [50, 51]. We incubated stable transfected HEK cells containing cysteine mutants in which respective cysteines were replaced by serine (5-LOX_4C mutant). Interestingly, DAO failed to inhibit 5-LOX activity in intact cells as well as in cell homogenates supporting our presumption that DAO affected one or more cysteines by building a covalent bonding between the Michael acceptor group and the thiol group of cysteines. In contrast, zileuton, which is an iron-chelating agent [6], was still able to abrogate LT biosynthesis of the 5-LOX_4C mutant, as expected. We replaced the four individual cysteines by serine and the melleolide was tested in cell-free and cell-based assays. Under cell-free conditions, DAO failed

to inhibit LT formation for single cysteine mutations implying that two or more cysteines were necessary for inhibition by DAO hypothesizing that DAO might affect a 5-LOX dimerization [51] via two or more cysteines with lacking 5-LOX/FLAP interaction, since FLAP has been active only in intact cells [53]. In contrast, interaction with C¹⁵⁹ played a crucial role for diminished 5-LOX activity in cells. Thus, our results indicated that DAO caused abrogated 5-LOX/FLAP complex assembly essentially via C¹⁵⁹, except a participation of C³⁰⁰, C⁴¹⁶, and C⁴¹⁸ in intact cells.

The nuclear membrane protein FLAP is essential for the LT biosynthesis as 5-LOX helper protein for AA transfer [64, 217] but exhibits no own enzymatic activity [52, 55]. Typical FLAP inhibitors showed comparable inhibitory characteristics as melleolides: active in cellular systems and reduced active or rather inactive under cell-free conditions. These compounds triggered reduced LT biosynthesis by preventing 5-LOX/FLAP assemblies without affecting 5-LOX translocation being important for LT biosynthesis [217-220]. Furthermore, FLAP belongs to the MAPEG family and possesses sequence and structure homology to LTC₄S and mPGES-1 [221, 222]. Indeed, our data revealed no interference of MAPEG family members, e.g., LTC₄S, mPGES-1, thus excluding a class effect against these proteins. In addition, cysteines (C¹⁵⁹, C³⁰⁰, C⁴¹⁶, C⁴¹⁸) played an important role for 5-LOX/FLAP co-localization at the nuclear membrane as described before [50] and interaction with C⁴¹⁶ and C⁴¹⁸ by Michael acceptors impeded the entry of AA to the catalytic center of 5-LOX along with impaired LT biosynthesis [15, 216]. Along these lines, all cysteine mutants caused a strikingly lower LT formation, and interestingly the 5-LOX_4C mutant as well as the 5-LOX_C¹⁵⁹S mutant failed to form complex assemblies with FLAP indicating the importance of C¹⁵⁹ in AA metabolism. Interestingly, DAO required C¹⁵⁹ for direct inhibition of 5-LOX activity leading to abrogated LT formation in intact cells. In contrast to zileuton, whose 5-LOX inhibition was independent of cysteine mutants, DAO failed to inhibit 5-LOX activity, when C¹⁵⁹ was replaced by serine, suggesting a direct hampered 5-LOX/FLAP interaction, or the interaction between DAO and C¹⁵⁹ evoked strong conformational modifications preventing 5-LOX/FLAP interaction and/or avoiding the substrate entry to the catalytic center. Moreover, melleolides and other Michael acceptors failed to inhibit 5-LOX translocation, which is essential for LT formation [220, 223]. Hence, Michael acceptor-containing compounds evinced commonalities to classical FLAP inhibitors, e.g., MK886 [217, 219], but they differed clearly from other novel direct 5-LOX inhibitors like hyperforin [77] or indirubin [79].

Taken together, melleolides especially DAO targets 5-LOX through a covalent binding via their α,β -unsaturated aldehyde group with the thiol group of C¹⁵⁹ located at the catalytic entry of 5-LOX. DAO reduces LT biosynthesis by preventing 5-LOX/FLAP interaction via C¹⁵⁹ in cells, while on the enzymatic level DAO interferes with two or more cysteines leading to less

potent inhibition of 5-LOX activity. Finally, C¹⁵⁹ is crucial for the 5-LOX/FLAP complex assembly at the nuclear envelope and the formation of LT.

Besides 5-LOX inhibition, suppression of LT can be also mediated by LTA₄H inhibition preventing LTB₄ biosynthesis or through hampered LTC₄S activity leading to abrogation of cysLT. LTB₄ is known as potent chemoattractant for immune cells and plays an important role in host protection against infection through the recruitment of primary immune cells, especially neutrophils to the site of infection [4, 5]. We found that the mycotoxin gliotoxin abrogated LT formation by LTA₄H inhibition *in vitro* and *in vivo* and hence causing neutrophil-mediated host resistance to IA (**manuscript II**).

We used two distinct inflammatory animal models: (I) a murine zymosan-induced peritonitis model [224], and a (II) carrageenan-induced pleurisy model in rats [225] to investigate the effects of gliotoxin on inflammation and immune cells. In comparison to the well-known 5-LOX inhibitor zileuton [6], gliotoxin reduced LTB₄ formation in murine and rat plasma and suppressed neutrophil infiltration into peritoneal and thoracic exudates at low doses. Furthermore, gliotoxin abrogated selective LTB₄ formation without inhibiting 5-LOX, 12-/15-LOX, and COX. Interestingly, tr-LTB₄ isomers and LTC₄ were increased after gliotoxin treatment, indicating further utilization of LTA₄ and thus an intact upstream LTA₄ biosynthetic pathway. These data suggest that LTA₄ was used as substrate by LTC₄S to generate LTC₄ and was non-enzymatically converted to tr-LTB₄ derivatives. Such substrate shunting was previously reported and is a typical behavior of LTA₄H inhibitors like captopril [226], SC-57461A [8], and others [99], suggesting that gliotoxin targets LTA₄H.

Gliotoxin exhibited comparable results *in vitro* in human primary neutrophils and monocytes in comparison to the 5-LOX inhibitor zileuton [6] and the LTA₄H inhibitor SC-57461A [7], while zileuton suppressed all 5-LOX products and SC-57461A showed similar results to gliotoxin implying that gliotoxin acted as a selective LTA₄H inhibitor. LTA₄H is a bifunctional metalloenzyme harboring two distinct enzyme activities: (I) an epoxide hydrolase activity hydrolyzing LTA₄ to the potent chemoattractant LTB₄ during initiation of inflammation, and (II) an aminopeptidase activity inactivating the pro-inflammatory tripeptide PGP during resolution of inflammation [13, 82, 89]. Hence, development of LTA₄H inhibitors with selective inhibition of the epoxide hydrolase activity is essential for therapeutic application interfering with the inflammatory response during a chronic inflammation [104]. Until now, only one selective epoxide hydrolase inhibitor was identified, that is, ARM-1 [107], whereas several other LTA₄H inhibitors affect both enzyme activities including chemically synthesized compounds, e.g., SC-57461A [7], bestatin [102], captopril [103] as well as natural occurring ingredients, e.g., 6-gingerol [227], resveratrol [228], or α -lipoic acid [229]. Our data revealed gliotoxin as first natural compound targeting selective epoxide hydrolase activity. Furthermore, several other enzymes involved in the AA pathway harbor an epoxide hydrolase activity like

sEH or other hepxilin hydrolases. Apart from its N-terminal phosphatase activity, sEH contains also a C-terminal epoxide hydrolase activity [230] converting anti-inflammatory epoxy fatty acids to their corresponding diol metabolites and playing hence an important role in inflammatory diseases, e.g., cardiovascular, neuro-inflammatory, and metabolic diseases [14, 231, 232]. However, gliotoxin failed to inhibit sEH in two different cell lines A549 and HepG2 [218] as wells as under cell-free conditions (unpublished data).

Gliotoxin failed to suppress LTA₄H activity under cell-free conditions. Structurally, epidthiodioxopiperazines contain an intramolecular disulfide bridge, which is mandatory for their biological activity and can be cleaved, inter alia, by glutathione (GSH) or dithiothreitol (DTT) to its reduced dithiol form [164]. Our data revealed that the reduced dithiol form of gliotoxin is required for suppression of LTA₄H activity. Indeed, we provided exogenous GSH in cell-free experimental settings, whereas in intact cells GSH is abundant in the cytosol. Cellular treatment with the oxidizing diamide impaired the inhibitory effect of gliotoxin on LTA₄H. As expected, redox active agents, e.g., GSH or diamide, did not influence the activity of SC-57461A. Moreover, gliotoxin suppressed LTA₄H activity, when it was first incubated in intact cells followed by a cell lysis prior stimulation, which indicates irreversible LTA₄H inhibition comparable to SC-57461A. We assumed that reduced gliotoxin interacted with LTA₄H, where the free thiol moieties reacted with the active site of LTA₄H coordinating the epoxide hydrolase activity [82]. As described before, LTA₄H is a monomeric zinc metalloenzyme in which zinc connects both enzymatic binding pockets [84]. Conceivably, gliotoxin reacted with the active site Zn²⁺ forming chelate complexes by its reduced free thiol groups supported by the results that supplementation of external Zn²⁺ ions impaired the inhibitory activity of gliotoxin without affecting the potency of SC-57461A. Our data were confirmed by a recently published paper, where reduced gliotoxin inhibited the Zn²⁺-dependent alkaline phosphatase by chelation of Zn²⁺ [233]. Along these lines, other thiodioxopiperazines exhibited similar modes of action like sporidesmin playing an important role in agriculture and veterinary medicine [234, 235] due to its interaction with thiol-disulfide oxidoreductases [236], or chaetocin being a substrate for thioredoxin reductase [237] as well as the antibiotic thiolutin harboring a dithiopyrrolone structure and inactivating JAB1/MPN/Mov34 (JAMM) metalloproteases [238]. All compounds are natural ingredients of fungi species containing an intramolecular disulfide bond and acted mostly under reducing conditions with metalloproteases harboring an active site Zn²⁺ ion. Furthermore, the inhibitory effects were avoided by external supplementation of Zn²⁺ ions [238, 239] indicating further targets of gliotoxin and a possible substance class effect for Zn²⁺-containing metalloproteases, where previously described structures could also interact with LTA₄H except of chaetocin, which we have already tested (unpublished data).

In the last decades, the influence of mycotoxins especially ingredients of the mold *A. fumigatus* increased the triggering of allergic and respiratory diseases for humans due to the

enhanced contact with molds [240, 241]. Humans continuously inhale conidia of *A. fumigatus* that trigger the host defense leading to a recruitment of neutrophils to the site of infection [242]. Immunocompromised patients lack the efficient innate immune response and hence exhibit an increased risk for diseases [243]. One major virulence factor of *A. fumigatus* is gliotoxin [244] causing IA with high mortality rates (30-95%) of immunocompromised patients [181] particularly with neutropenic conditions [1, 170, 245]. Of interest, neutrophils were resistant to gliotoxin-mediated apoptosis [175], and neutrophil functions were not affected by gliotoxin except phagocytosis [170]. Recently, it was shown that host-derived LTB₄ played an important role in innate immunity to IA, and LTB₄ was crucial for the host resistance to *A. fumigatus* mediating the recruitment of neutrophils [246]. Furthermore, LTB₄-treated neutrophils exhibited an increased antifungal activity against *A. fumigatus* [247], and reduced LTB₄ levels led to enhanced mortality of *A. fumigatus* infected mice and raised fungal germination in lung tissue [246]. These facts and the knowledge that gliotoxin was produced during the infection process [3] supported our hypothesis that reduced LTB₄ formation by gliotoxin is the underlying mechanism for neutropenic conditions in the infected host. Furthermore, infection of mice with an *A. fumigatus* strain with an eliminated *gliP* gene (involved in the first biosynthesis step of gliotoxin ($\Delta gliP$) [248]) exhibited a reduced virulence of *A. fumigatus* confirming gliotoxin as significant inducer of aspergillosis [1]. As expected, $\Delta gliP$ -infected mice showed an abrogated neutrophil infiltration and a lower degree of destructed neutrophils in lung tissue in comparison to lung tissue of mice infected with wild type *A. fumigatus*. Together, $\Delta gliP$ and thus, the reduced gliotoxin biosynthesis failed to compromise neutrophils and their functions, indicating that gliotoxin caused neutropenia by hampered LTB₄ formation due to LTA₄H inhibition in *A. fumigatus*-infected hosts and clarifying thereby the underlying virulence mechanism of *A. fumigatus*-triggered IA.

In conclusion, we identified LTA₄H as a target of gliotoxin hampering the biosynthesis of the major chemoattractant for neutrophils, namely LTB₄, which plays an important role in the innate immune response. The clarification of the mode of action of gliotoxin is of biological relevance for the pathology of *A. fumigatus* and the neutrophil-mediated host resistance against IA for the generation of clinical pictures and the development of new therapeutic approaches.

4.2 Natural compounds and their influence on cell viability in human cells

As previously described, gliotoxin and DAO play also an important role as potent fungal toxins in human cancer cells as well as in primary immune cells [186, 194, 207, 249] with partially enlightened modes of action, whereby the cytotoxicity of myxochelins have not been yet analyzed in human cells (**additional data**).

In contrast to DAO, several targets of gliotoxin are known to mediate cell death. In general, cell death can be distinguished by three main types: (I) apoptosis, (II) autophagy, and

(III) necrosis, mediated by various signaling pathways [126]. In fact, gliotoxin induced apoptosis by caspase 3 activation [207] and increased ROS formation during its redox cycle eliciting oxidative stress [250, 251]. Additionally, gliotoxin caused activation of JNK leading to Bim activation and facilitation of the pro-apoptotic Bak oligomerization resulting in cytochrome c and ROS release by mitochondria followed by caspase 9 activation [180, 252]. Furthermore, DNA was fragmented by gliotoxin after enhanced cAMP levels, which activated PKA and triggered the phosphorylation of histone 3 [179], and gliotoxin prevented NF κ B activation by I κ B α stabilization [177]. However, neutrophils were not affected by gliotoxin regarding apoptosis [175]. Conventionally, cytotoxic agents exhibit a higher potency to induce cell death in cancer cells than in non-transformed cells (**manuscript IV**, [253]) mediated by intensified metabolic processes with high energy turnover and stronger proliferation of cancer cells. Also myxochelins reduced the viability only of cancer cells without affecting primary immune cells (**additional data**). Interestingly, these myxobacterial compounds exhibited cytotoxic effects primarily in leukemic cells hypothesizing a correlation to 5-LOX inhibition, since 5-LOX is one key enzyme in myeloid leukemia cells [254-256], and myxochelins failed to cause cytotoxicity in 5-LOX deficient HeLa cells (**additional data**, **manuscript III**). Nevertheless, existence of further targets related to their cytotoxicity should be considered. In the case of melleolides, DAO showed similar apoptotic patterns in primary monocytes as compared to several cancer cells with an untypical rapid onset of cell death (**manuscript IV**) linking apoptosis, autophagic cell death, and necrosis by targeting the phospholipid PE of various cellular membranes, leading to a loss of several pivotal cell functions (**manuscript V**).

As described before, melleolides caused cytotoxic effects in human cells by ROS-mediated caspase activation [187], decreased DNA synthesis [194], or due to autophagy-associated cell death [195], but a specific target is still elusive. In general, most compounds mediating cell death evinced more potent cytotoxicity towards cancer cells due to their enhanced proliferation and increased metabolic processes as non-transformed cells [253, 257, 258]. It was shown that melleolides from *Armillaria mellea* reduced potently cell viability of various human cancer cell lines [186, 194] lacking the analysis of cytotoxicity of melleolides in human primary cells. Our results exhibited similar cytotoxic effects of the sesquiterpene aryl ester DAO in human primary monocytes (IC₅₀=2.3 μ M) and in various cancer cells including the leukemic cell lines THP-1 (IC₅₀=3.0 μ M), MM6 (IC₅₀=4.2 μ M), K-562 (IC₅₀=5.0 μ M), and the immortal cervix carcinoma cell line HeLa cells (IC₅₀=1.6 μ M) (**manuscript IV**). Subsequently, we analyzed the structure-activity relationship of six different melleolides (including arnamial, 6'-dechloroarnamial, DAO, armillarin, armillaridin, melleolide D) to get information about the structural residues, which are actively participated in cell death induction. As a result, compounds harboring a $\Delta^{2,4}$ double bond, e.g., arnamial, 6'-dechloroarnamial, and DAO, caused a potent loss of cell viability for all tested cell types, comparable to their antifungal

activity [186]. Armillarin and armillaridin, which possess a $\Delta^{2,3}$ double bond, induced similar cytotoxic effects in monocytic THP-1 and MM6 cell lines but showed a reduced cytotoxic potency in primary monocytes, K-562, and HeLa cells. Of interest, THP-1 and MM6 cells are acute monocytic leukemia cells, whereas K-562 cells are chronic myelogenous leukemia cells, which might be the reason for the different cytotoxic impact of DAO between the leukemia cell lines. In contrast, melleolide D possesses a $\Delta^{2,3}$ double bond and a hydroxyl residue instead of the free aldehyde moiety at position 1, resulting in negligible cytotoxic properties. In fact, compounds containing a $\Delta^{2,4}$ or a $\Delta^{2,3}$ unsaturated aldehyde caused potent cytotoxicity, whereas the $\Delta^{2,3}$ unsaturated aldehyde exerted reduced effects suggesting that only an unsaturated aldehyde residue at the sesquiterpene moiety caused reduced cell viability. Contrarily to the melleolides, the well-known apoptotic pan-kinase inhibitor staurosporine [259] and the cytotoxic myxobacterial compound pretubulysin, acting as microtubule disrupting agent [258, 260], caused efficient cytotoxicity in cancer cells but not so in monocytes. Hence, we hypothesize a general target for cytotoxicity of melleolides, which might be independent from proliferation and metabolic processes. Other sesquiterpenes like acylfulvenes and their natural precursor illudin S harboring also a $\Delta^{2,4}$ unsaturated aldehyde moiety [261], which show a high reactivity with thiol residues and cysteine-containing proteins [262], exhibited a comparable cytotoxicity for non-transformed cells and cancer cells, presumably due to an interaction with DNA after a reductive activation by prostaglandin reductase 1 [261]. Acylfulvenes and melleolides harbor similar structural elements, which may result in similar mechanisms for cell death induction like impaired DNA biosynthesis [194, 261, 262].

Melleolides, especially DAO, caused rapid cytotoxic effects after about 1 hr measured by MTT assay, whereas the pan-kinase inhibitor staurosporine [259], the protein biosynthesis inhibitor cycloheximide and the DNA transcription inhibitor actinomycin [263] required more than 5 hrs to impair cell viability. We speculated that melleolides could interact with the plasma membrane to induce cell lysis. Opposed to this, morphological analysis of cells treated with DAO, staurosporine, or triton X-100 by light microscopy excluded cell lysis as possible mechanism. Thus, the detergent triton X-100 was used as positive control for cell permeabilization exhibiting contrarily modifications of cell morphology. Within the analyzed time, DAO caused typical features of necrosis such as plasma membrane rupture of the monocytes after 3 hrs exposure to DAO, whereas staurosporine induced fragmentation of the nucleus and triggered the formation of apoptotic bodies, which are characteristics of apoptosis [126, 128]. Interestingly, further investigations by flow cytometry disclosed also apoptotic signals without statistical significance in contrast to staurosporine, which clearly provoked significantly apoptosis without any necrotic patterns, as expected. Moreover, metabolic activity of mitochondria was decreased by DAO, which is also a sign of apoptosis, leading to the

hypothesis, that DAO may influence the mitochondrial membrane potential and DAO may induce various forms of cell death (**manuscript IV**).

In general, the classical apoptosis pathway is dependent on caspase activation initiated by an extrinsic or intrinsic pathway leading to the cleavage of PARP [130]. In our study, DAO affected PARP cleavage already after 15 min, while staurosporine required 5 hrs for the cleavage. Of interest, caspases were only slightly affected by DAO indicating a caspase-independent apoptosis [139], but pre-incubation with the pan-caspase inhibitor QVD prevented at least PARP cleavage [264], nevertheless reduced cell viability was available caused by DAO as well as staurosporine. Seemingly, slightly caspase 8 activation by DAO was sufficient for triggering apoptosis signaling (**manuscript V**). Furthermore, we showed by the decrease of the phosphorylation of the survival factor Akt and an increased phosphorylation of the stress factor p38 MAPK that cellular processes became disordered. However, activation of p38 MAPK was independent on ER stress and on the activation of the unfolded protein response. Of interest, besides an abrogated metabolic activity, DAO disrupted also the cell membrane within 15 min measured by LDH assay supporting initiation of necrosis with the loss of membrane integrity. As described before, DAO harbors a reactive α,β -unsaturated aldehyde residue mediating the majority of its biological activities [186, 265]. Other natural products containing a Michael acceptor residue, especially an α,β -unsaturated aldehyde, modulated membrane functions like the sesquiterpene dialdehyde polygodial triggering a membrane rupture of *Saccharomyces cerevisiae* by building covalent adducts with phospholipids of the plasma membrane [266-269]. Similar effects were reported for ophiobolin A isolated from the *Bipolaris* genus that mediated cell death by forming pyrrole-containing adducts with PE of the cellular membrane [270]. However, ophiobolin A did not affect exclusively plasma membrane phospholipids, but also mitochondrial functionality provoked by depolarized mitochondrial membrane potential, increased ROS production, and mitochondrial network fragmentation [271, 272] linking apoptosis, autophagy, and necrosis. In the case of DAO, we detected a comparable mode of action to polygodial and ophiobolin A. By pre-incubations with the phospholipids PE, PS, and PC, we demonstrated that DAO interacted with the ethanolamine head group of PE measured by UPLC-MS/MS. Furthermore, the time course of DAO-ethanolamine (DAO-EA) product formation correlated to LDH release, supporting our hypothesis that DAO-EA product formation was responsible for the early loss of membrane fluidity and functionality. Usually, PE is located at the inner leaflet of plasma membranes [273], but during the early stage of apoptosis PE as well as PS are translocated from the inner leaflet to the cell membrane surface [274], which may explain the early cytotoxic effects of DAO. Additional, PE is not only available in plasma membranes but also in other cell organelle membranes like nuclei, mitochondria, ER, or lysosomes, where a greater portion of PE is located within the outer leaflet of mitochondria in comparison to other organelles [273]. This

can be explained by the synthesis and trafficking of PE between ER and mitochondria [273]. As described before, other melleolides like armillarikin or armillaridin made a negative impact on mitochondrial transmembrane potential [187, 195], which plays an important role for ATP generation, and inducing thereby apoptosis. Consequently, mitochondrial dysfunction leads to an increased permeability of the mitochondrial membrane and a subsequent release of the proapoptotic stimulus cytochrome c into the cytosol, which initialize downstream events in the apoptotic cascade [275]. Of interest, exposure to DAO for 3 hrs enhanced strongly the release of cytochrome c into the cytosol with a simultaneously decrease of non-cytosolic cytochrome c. These results were comparable to staurosporine increasing also the release of cytochrome c from mitochondria, but less pronounced as compared to DAO. Moreover, transmission electron microscopy (TEM) of monocytes after DAO treatment revealed us defects of the nuclear membrane and in particular, a disappearance of mitochondria, leading to the hypothesis that DAO induced rapid cell death by interacting with membranous PE of several cell organelles. Additional, we supported our thesis with liposome leakage assays, where DAO caused leakage of PE-composed liposomes in cell-free system, but liposomes made from PC were not affected by DAO indicating a covalent binding to the EA moiety in PE. Otherwise PE acts as anchor for autophagosomes [276] thus supporting recycling of cytoplasmic structures by autophagy leading to ATP generation [141]. Our data revealed that DAO interacted primarily with PE of the membrane fraction containing plasma membrane, lysosomes, and Golgi vesicles, and equally with mitochondria and nuclei after 15 min incubations analyzed by a subcellular fractionation. Interestingly, after 3 hrs, plasma membrane interaction of DAO was increased, whereas the accumulation in mitochondria remained unchanged and in nuclei decreased. As expected, exposure to DAO induced a reorganization of PE species, especially the most common PE species PE(18:0/18:1) and PE(18:1/18:1), in the plasma membrane fraction, which could be explained as protecting metabolic processes. Furthermore, an interaction of DAO with lysosomal PE could cause reduced PE amounts in lysosomal membranes and abrogated autophagic processes leading to apoptosis due to impaired ATP formation [276]. An enhanced amount of autophagosomes was detectable in apoptotic cells supporting autophagy as cytoprotective mechanism for elimination of toxic molecules [277, 278]. As a consequence of intensified autophagic processes, formation of lysosomes increased resulting in a strengthened intake of DAO leading to a lysosomal rupture with intracellular acidification caused by released lysosomal hydrolases and finally triggering necrosis. Additional, lysosome formation could become hyperactive to support cell functions by energy generation resulting in a breakdown of cellular organelles and proteins provoking eventually self-cannibalism [147]. This hypothesis is supported by an increased lysosomal rupture and decreased intracellular pH value caused by DAO. However, autophagy correlated also with caspase 8 activation involving autophagy protein 5 (Atg5) and LC3-PE that are

responsible for the extension of autophagosomal membrane and autophagosome formation [279-282]. Our results demonstrate that DAO influenced only slightly caspase 8 activity without affecting other apoptotic caspases. Together with the intracellular PE interaction, the decreased PE amount and the decreased intracellular pH value, we speculate that DAO additionally prevented the autophagosomal membrane formation hypothesizing that affected cells might execute appropriate countermeasures to gain energy which could result in a hyperactive autophagy leading to a loss of organized metabolic processes and finally fast cell death.

In conclusion, we studied the cytotoxic mode of action of DAO causing cell death by a covalent interaction of its α,β -unsaturated aldehyde moiety with the ethanolamine head group of PE of several cell organelles acting as non-ionic surfactant. Due to these effects, DAO linked various forms of cytotoxicity and thus leading to a destruction of metabolic processes.

4.3 Conclusion

We here characterized and clarified several biological activities and mode of actions of natural compounds from fungi and bacteria, namely DAO from *Armillaria mellea*, gliotoxin from *Aspergillus fumigatus*, and myxochelin A from *Pyxidicoccus fallax*, respectively, in human primary immune cells. The 5-LOX pathway plays a considerable role in inflammation by mediating the biosynthesis of important pro-inflammatory LM. DAO as well as myxochelins inhibited 5-LOX activity and thus prevented the formation of LT. In brief, we identified 5-LOX as a molecular target of melleolides from *A. mellea* and myxochelins from *P. fallax*. We propose that melleolides containing an α,β -unsaturated aldehyde moiety function as Michael acceptors leading to an interference of critical surface cysteines of 5-LOX. On the enzymatic level, two or more of these cysteines trigger the inhibitory effect of melleolides, whereas only C¹⁵⁹ mediates the suppression of cellular 5-LOX product formation by melleolides due to the prevention of 5-LOX/FLAP complex assembly. Conclusively, our data emphasize the importance of C¹⁵⁹ for 5-LOX/FLAP interaction, which is a requirement for cellular LT biosynthesis. While melleolides appear unsuitable for the therapeutic usage due to their potent cytotoxicity towards primary immune cells representing a new way for cell death induction, myxochelins constitute an interesting substance class for new 5-LOX inhibitors. However, further investigations are crucial to fulfil the characterization of 5-LOX inhibition *in vitro* and to analyze the compounds *in vivo*. Furthermore, myxochelins could be used in the therapy of acute and chronic leukemia due to their anti-proliferative effects in leukemic cells without affecting primary cells requiring further investigations to clarify the mode of action. In contrast, DAO targets the membrane PE by a covalent reaction of its α,β -unsaturated aldehyde moiety with the EA head group of the phospholipid leading to a perturbation of cellular membrane structure. Consequently, membrane integrity is impaired, which might be the reason for the unusual rapid onset of cell death in various cell types. The knowledge about the cytotoxic

mechanism of DAO can be used as tool for the analysis of cellular processes and the generation of new anti-cancer drugs. Last but not least, we reveal LTA₄H as molecular target of the mycotoxin gliotoxin from *A. fumigatus*, and thus, we suggest inhibition of the biosynthesis of the pivotal chemoattractant LTB₄ as biological relevant mode of action of gliotoxin. On the basis of these immunomodulatory effects by gliotoxin in human neutrophils, new therapeutic approaches can be developed to successfully treat IA of immunocompromised patients and thus reducing the high mortality rate. Furthermore, gliotoxin can be used as structural starting basis for the design of new LTA₄H inhibitors which affect only the pro-inflammatory epoxide hydrolase activity without influencing the aminopeptidase activity.

APPENDIX 1: ADDITIONAL DATA

A.1 Effects of natural products on cancer cell proliferation

The prevalence of cancer increases dictated due to our lifestyle, thus initiating 90% to 95% of cancer by lifestyle factors, for instance, tobacco smoke, obesity, stress, UV, or environmental pollutants [32]. Hence, it is of prime interest to search for additional compounds enabling new therapeutic approaches and to improve cancer therapy with reduced side effects. Several natural products exhibit, besides their anti-inflammatory potential, also antiproliferative effects on human cancer cells without affecting human primary immune cells suggesting a beneficial therapy option, e.g., pretubulysin [265], or myxochelin A.

A.1.1 Myxochelin A reduces primarily cell viability of leukemic cancer cells

Fig. A1 Effect by myxochelin A on cell viability of human cells. Various epithelial and leukemic cancer cells were treated with myxochelin A at indicated concentrations for (A) 24 hrs or (B) 48 hrs in comparison to human primary monocytes. Cell viability was analyzed by MTT assay after 24 hrs. Data are given as mean + S.E, $n = 3$.

As published before, predatory myxobacteria generate a variety of antibiotics and anti-cancer agents [201, 202], e.g., myxochelin A. Moreover, myxochelin A and its derivatives were also described as antimetastatic agents analyzed in murine colon 26L-5 cells [204, 205], supporting their use as anti-cancer drugs. We analyzed the cytotoxic effect of myxochelin A in various cancer cells: (I) epithelial cancer cells including A549, HeLa, and MDAMB-231 cells, (II) leukemic cells consisting of HL-60, MM6, and THP-1 cells in comparison to freshly isolated human monocytes. Cells were treated with myxochelin A for 24 hrs or 48 hrs followed by addition of MTT (5 mg/mL PBS, as described in **manuscript IV, V**). As control, we used the well-known pan-kinase inhibitor staurosporine (1 μ M) [259]. After 24 h (**Fig. A1 A**), myxochelin A reduced the cell viability of leukemic cells much more potent than the viability of endothelial

cancer cells except the breast cancer cells MDAMB-231. Interestingly, MDAMB-231 cells are derived from metastatic site hypothesizing comparable characteristics to systemic cancer cells like HL-60, MM6, or THP-1 cells. As expected, after 48 hrs (**Fig. A1 B**), cytotoxic effects towards cancer cells increased, and again, leukemic cells were more affected by myxochelin A than epithelial cells. In contrast, cell viability of human primary monocytes was not impaired after 24 hrs neither 48 hrs.

SUMMARY

5-Lipoxygenase (5-LO) initiates the biosynthesis of pro-inflammatory leukotrienes from arachidonic acid, which requires the nuclear membrane-bound 5-LO-activating protein (FLAP) for substrate transfer. Here, we identified human 5-LO as a molecular target of melleolides from honey mushroom (*Armillaria mellea*). Melleolides inhibit 5-LO via an α,β -unsaturated aldehyde serving as Michael acceptor for surface cysteines at the substrate entrance that are revealed as molecular determinants for 5-LO activity. Experiments with 5-LO mutants, where select cysteines had been replaced by serine, indicated that the investigated melleolides suppress 5-LO product formation via two distinct modes of action: (1) by direct interference with 5-LO activity involving two or more of the cysteines 159, 300, 416, and 418, and (2) by preventing 5-LO/FLAP assemblies involving selectively Cys159 in 5-LO. Interestingly, replacement of Cys159 by serine prevented 5-LO/FLAP assemblies as well, implying Cys159 as determinant for 5-LO/FLAP complex formation at the nuclear membrane required for leukotriene biosynthesis.

INTRODUCTION

Natural products are discovered at a rapid rate, and bioactivities are extensively screened for in routine assays. However, the knowledge on the modes of action and molecular targets of these bioactive compounds is severely lagging behind. In the arena of mushroom toxins, the mode of action is understood only for very few compounds, among them the amanitins, psilocybin, muscarine, coprine, and ibotenic acid. The melleolides (Figure 1A) are natural products of the basidiomycete *Armillaria mellea* (honey mushroom), a globally distributed mushroom that also represents an important plant pathogen (Baumgartner et al., 2011). Bioactivities include antimicrobial and antifungal effects, as well as cytotoxicity against human monocytes and cancer cells (Bohnert et al., 2011, 2014b; Misiek et al., 2009; Momose et al., 2000). Intriguingly, these ac-

tivities follow dissimilar structure-activity relationships (SARs) (Bohnert et al., 2014a). With more than 60 published members, melleolides rank among the largest and most diverse classes of fungal natural products. Structurally, they are composed of an orsellinic acid moiety esterified to a protoilludene-type sesquiterpene secondary alcohol. Many melleolides feature an α,β -unsaturated aldehyde moiety that may act as Michael acceptor, but molecular targets of the melleolides are thus far unknown. We previously showed that Michael acceptor-containing drugs such as thymoquinone (TQ) (Maucher et al., 2017) or nitro fatty acids (Awwad et al., 2014) are direct covalent inhibitors of human 5-lipoxygenase (5-LO) by targeting Cys416 and Cys418.

5-LO is the key enzyme in the biosynthesis of pro-inflammatory leukotrienes (LTs) from arachidonic acid (AA) that play important roles in disorders such as asthma, rheumatoid arthritis, allergic rhinitis, neurodegenerative and cardiovascular diseases, and cancer (Radmark et al., 2015). LT biosynthesis is mainly restricted to leukocytes where the cytosolic phospholipase A₂ (cPLA₂) and 5-LO translocate to the nuclear envelope upon cell activation. cPLA₂ releases AA from membrane phospholipids (Leslie, 2015), and AA is then transferred by the nuclear membrane-bound 5-LO-activating protein (FLAP) to 5-LO, which assembles a complex with FLAP. 5-LO oxygenates AA to yield the intermediate 5(S)-hydroperoxyicosatetraenoic acid (5-HPETE) and then dehydrates 5-HPETE to LTA₄, again aided by FLAP (Radmark et al., 2015). LTA₄ can be enzymatically converted to the chemoattractant LTB₄ or to cysteinyl-LTs (LTC₄, D₄, or E₄) that contract smooth muscles in the airways and microcirculation (Haeggstrom and Funk, 2011). FLAP binds AA and is essential for 5-LO activity in intact cells, seemingly by accomplishing appropriate substrate access for 5-LO (Evans et al., 2008). The 5-LO/FLAP complex assembly at the nuclear membrane requires AA, and FLAP inhibitors prevent 5-LO/FLAP interactions and 5-LO product formation in an AA-competitive fashion (Bair et al., 2012; Gerstmeier et al., 2014, 2016b). Recently, we showed that the cysteines 159, 300, 416, and 418, located on the 5-LO protein surface close to the AA entry site, are important for co-localization with FLAP (Häfner et al., 2015).

The poor knowledge on the pharmacology behind mushroom toxins, and the fact that honey mushrooms are considered edible and collected in many regions prompted us to investigate the mode of action of the melleolides. To explore their molecular

(A) Chemical structures of melleolides 1-4.

(B) Effect of 1-4 on 5-LO product formation in a cell-free assay. Purified human recombinant 5-LO (0.5 μg/mL) was pre-incubated with compounds or vehicle (0.1% DMSO) at 4°C for 10 min. Samples were pre-warmed for 30 s at 37°C and incubated with 2 mM CaCl₂ and 20 μM AA for another 10 min. The reaction was terminated and 5-LO products were then analyzed by reverse-phase high-performance liquid chromatography (RP-HPLC).

(C) Effect of 1-4 on 5-LO product formation in a cell-based system. Neutrophils (5 × 10⁶/mL) were pre-incubated with compounds or 0.1% DMSO (vehicle) for 10 min at 37°C prior to stimulation with 2.5 μM A23187 for 10 min at 37°C, and 5-LO product formation was determined. Data are expressed as percentage of vehicle control (100%), means ± SEM, n = 3.

targets in mammalian cells, we investigated four structurally different representatives (Figure 1A) for interference with human 5-LO. We identified 5-LO as a molecular target for those melleolides that possess an α,β -unsaturated aldehyde with thiol-reactive Michael acceptor functionality. These melleolides mediate their 5-LO-inhibitory effects via surface cysteines of 5-LO. Our data suggest that melleolides interact with Cys159 at the entrance of the catalytic center of 5-LO, which prevents the complex assembly with FLAP and thus abrogates 5-LO activity. We conclude that Cys159 of 5-LO is critical for the assembly of the 5-LO/FLAP complex, whereas cysteines 300, 416, and 418 do not contribute.

RESULTS

Melleolides Inhibit 5-LO Activity in Cell-Free and Cell-Based Systems

We investigated the effects of four structurally related melleolides isolated from *Armillaria mellea* (Figure 1A) on the activity of 5-LO in a cell-based model using Ca²⁺-ionophore A23187-stimulated human neutrophils, and in a cell-free assay using purified human recombinant 5-LO as enzyme source. The investigated compounds included dehydroarmillilorsellinate (DAO) (1), amamial (2), armillarin (3), and melleolide D (4). Concentration-response experiments with these melleolides in the cell-free assay revealed 2 as most potent derivative with a half maximal inhibitory concentration (IC₅₀) of 0.3 ± 0.02 μM, followed by 3 (IC₅₀ = 2.5 ± 0.4 μM) and 1 (IC₅₀ = 2.8 ± 0.9 μM, Figure 1B). Compound 4 was much less efficient (IC₅₀ > 10 μM). Of interest, in neutrophils, 1 was the most efficient derivative against 5-LO (IC₅₀ = 0.3 ± 0.1 μM, Figure 1C), with 10-fold higher potency versus cell-free assay conditions. Melleolides 2 (IC₅₀ = 1.0 ± 0.2 μM) and 3 (IC₅₀ = 5.2 ± 1.4 μM) showed comparable efficiency as in the cell-free test system. Again, 4 caused only moderate inhibition of 5-LO activity in neutrophils (IC₅₀ > 10 μM). Cell viability analysis (trypan blue and light microscopy) exclude detrimental effects of 1-4 during the 10 min pre-incubation period of neutrophils (data not shown).

DAO (1) Potently Inhibits 5-LO Activity in Intact Neutrophils and Monocytes

To explore 5-LO inhibition by melleolides, we focused on 1, which was the most potent derivative in neutrophils. First, we analyzed the effect of 1 against 5-LO in neutrophil homogenates, another cell-free test system for assessment of 5-LO activity (Werz and Steinhilber, 2005). Compared with its high potency in neutrophils, 1 was less active against 5-LO in corresponding homogenates (IC₅₀ = 1.1 ± 0.2 μM), similar as for isolated 5-LO (Figure 2A). In contrast, the 5-LO inhibitor zileuton was equally effective for isolated 5-LO and cellular 5-LO activity (IC₅₀ ~ 0.8 μM, Figure 2B). This suggested that 1 may interact with other enzyme(s) or factors involved in cellular 5-LO product formation such as cPLA₂ or FLAP. Analysis of AA release using [³H]AA-labeled neutrophils indicated weak suppression of AA liberation by 1 (at 1 μM), which was much less pronounced as compared with RSC-3388, a specific cPLA₂ inhibitor (Table S1). We next supplemented neutrophils with exogenous AA (20 μM), to overcome potential deficiencies in endogenous AA supply due to potential cPLA₂ or FLAP inhibition (Werz and Steinhilber, 2005). The strong potency of 1 in absence of exogenous AA (i.e., IC₅₀ = 0.3 μM) was about 7-fold decreased upon AA supplementation (IC₅₀ = 2.1 μM, Figure 2C), suggesting that 1 may interfere with AA-related action(s). We also tested whether 1 may interfere with signaling processes important for 5-LO activation, such as its activation by mitogen-activated protein kinases (MAPKs) (Radmark et al., 2015). However, up to 10 μM, 1 failed to suppress the phosphorylation of p38 MAPK and extracellular signal-regulated kinase-1/2, and thus of cPLA₂ in neutrophils (Figure S1). Moreover, 1 did not cause strong inhibition of other enzymes in LT or eicosanoid biosynthesis such as LTC₄ synthase, cyclooxygenase-1/2, or microsomal prostaglandin E2 synthase-1 (Table S1), indicating a certain selectivity against 5-LO.

Besides neutrophils, also monocytes have high capacities to biosynthesize 5-LO products (Surette et al., 1993). Melleolide 1 inhibited 5-LO activity also in human monocytes stimulated with A23187, with comparable efficiency (IC₅₀ = 0.8 μM), as in neutrophils (Figure 2D). A more detailed analysis showed that 1

Figure 2. DAO (1) Potently Inhibits 5-LO Activity in Intact Neutrophils and Monocytes

(A) Purified human recombinant 5-LO, intact human neutrophils (5×10^6 /mL), or neutrophil homogenates (corresponding to 5×10^6 cells/mL) were incubated with 1 or vehicle (0.1% DMSO) for 10 min at 37°C (neutrophils) or 4°C (5-LO, homogenates) prior to addition of 2.5 μM A23187 (neutrophils) or 2 mM CaCl₂ and 20 μM AA (5-LO, homogenates).

(B) Neutrophils or purified human recombinant 5-LO were pre-incubated for 10 min with zileuton or vehicle (0.1% DMSO) prior to addition of 2.5 μM A23187 (neutrophils) or 2 mM CaCl₂ and 20 μM AA (5-LO).

(C) Neutrophils were pre-incubated for 10 min with 1 or vehicle (0.1% DMSO) prior to addition of 2.5 μM A23187 with or without 20 μM AA.

(D) Effect of 1 on 5-LO product formation in neutrophils and monocytes. Cells (5×10^6 /mL) were pre-treated with 1 or vehicle (0.1% DMSO) for 10 min. 5-LO product formation was started by 2.5 μM A23187.

(E) Effect of 1 (1 μM) on eicosanoid biosynthesis in intact monocytes stimulated with 2.5 μM A23187 in the presence or absence of 20 μM AA. All incubations (A–E) were performed for 10 min at 37°C, and then 5-LO product formation was determined by RP-HPLC and eicosanoids in (E) were analyzed by ultra-performance liquid chromatography-MS/MS. Data are expressed as percentage of uninhibited control (100%), means \pm SEM, $n = 3$, + $p < 0.05$ versus vehicle control, paired t test.

See also Figure S1 and Table S1.

(at 1 μM) decreased all lipid mediators formed by 5-LO (i.e., *tr*-LTB₄ isomers, LTB₄, and 5-hydroxyeicosatetraenoic acid [HETE]) to a similar degree, which again was less pronounced when exogenous AA was supplemented (Figure 2E). Formation of 12- and 15-HETE was less affected by 1, and, in the presence of exogenous AA (20 μM), 1 lost its inhibitory potency to suppress the biosynthesis of these lipid mediators.

Characterization of 5-LO Inhibition by Melleolides and Interaction with Cysteine

We characterized 5-LO inhibition by 1 in more detail. Washout experiments with isolated 5-LO revealed that 1 acts in a partially irreversible manner (Figure 3A), since the suppressive effect of 1 against 5-LO was hardly reversed upon 10-fold dilution. 5-LO activity studies with increasing AA concentrations (3–60 μM) in the cell-free assay revealed that the inhibitory potency of 1 is

markedly improved at higher AA concentrations ($IC_{50} = 7 \mu M$ at 3 μM AA versus $IC_{50} = 0.3 \mu M$ at 60 μM AA, Figure 3B, left panel), even though the absolute activities of 5-LO strongly differ at the various AA concentrations (Figure 3B, right panel). Note that in intact neutrophils, exogenous supplementation of 20 μM AA gave the opposite effect and decreased the potency of 1 to inhibit 5-LO product formation, suggesting that the molecular mechanisms for suppression of 5-LO activity differ between intact cells and cell-free assays.

Compounds featuring a Michael acceptor, such as TQ or nitro fatty acids, were shown to act as direct covalent enzyme inhibitors that target the catalytically relevant Cys416 and Cys418 in 5-LO (Awwad et al., 2014; Maucher et al., 2017). It appeared reasonable that the α,β -unsaturated aldehyde in 1, 2, and 3 may function as Michael acceptors and react with these cysteines. Incubation of melleolides with glutathione (GSH) for

**Figure 3. Characterization of 5-LO Inhibition by Melleolides and Interaction with Cysteine**

(A) Reversibility of 5-LO inhibition by **1**. Purified 5-LO (0.5 $\mu\text{g/mL}$) was pre-incubated with **1** (1 or 10 μM) or vehicle (0.1% DMSO) at 4°C for 10 min, pre-warmed at 37°C for 30 s, and 2 mM CaCl_2 and 20 μM AA were added. "Wash out" samples had been diluted 10-fold with assay buffer prior to addition of 2 mM CaCl_2 and 20 μM AA. After 10 min at 37°C, 5-LO products were analyzed by RP-HPLC. Data are expressed as percentage of control (100%), means \pm SEM, $n = 3$, * $p < 0.05$ versus control, paired t test.

(B) Effect of various AA concentrations on 5-LO inhibition by **1**. Purified 5-LO (0.5 $\mu\text{g/mL}$) was pre-incubated with **1** or vehicle (0.1% DMSO) at 4°C for 10 min. Samples were pre-warmed at 37°C for 30 s, and 2 mM CaCl_2 and the indicated concentrations of AA were added and then incubated for 10 min at 37°C. Data are expressed as percentage of control (100%, left panel) or as ng/mL 5-LO products formed (right panel) and are given as means \pm SEM, $n = 3$.

60 min at 37°C and subsequent analysis of the reaction mixture by tandem mass spectrometry (MS/MS) showed that **1** (Figures 3C and 3D) and **2** (Figure S2) reacted with the thiol group of GSH.

The spectra revealed the expected signals for the resulting GSH-melleolide adducts (708.5 Da for **1**, Figure 3C, and 756.7 Da for **2**, Figure S2).

(legend on next page)

We next performed an amino acid residue specificity analysis (Figure 3E) to study binding of the melleolides to cysteine, histidine, serine, or lysine residues. These residues react in a Michael-like reaction but can also yield a semi-thioacetal or a semi-aminal. High-resolution MS spectra display the predicted masses of the reaction products that show the modification of cysteine, histidine, and lysine by **1** and **2**. MS/MS spectra displayed one main peak, which indicated the loss of chloroorsellinic acid or orsellenic acid, depending on the used melleolide. MS³-spectra then showed the expected peptide fragment ion spectra and pointed out the binding side of the reactive sesquiterpene (Figure S3). The reaction of the melleolides with 5-LO displayed the mass of the modified peptide of **2** containing Cys159. MS/MS spectra yielded poor fragment ion abundance, so the exact modification site could not be confirmed.

Modulation of 5-LO Translocation and 5-LO/FLAP Interaction by Melleolides

5-LO translocation to the nuclear envelope and interaction with FLAP is a determinant for cellular 5-LO product formation (Gerstmeier et al., 2016a; Mandal et al., 2008). The superior potency of **1** against 5-LO activity in intact cells versus isolated enzyme led us to investigate if melleolides could block 5-LO translocation and/or interaction with FLAP. A convenient model based on HEK293 cells, stably transfected with 5-LO and FLAP, as well as human primary monocytes, were used. Immunofluorescence (IF) microscopy was performed to visualize the localization of the target proteins in the cell (Gerstmeier et al., 2014, 2016a). In agreement with previous data, 5-LO in resting HEK cells or human monocytes was mainly nucleosolic but co-localized with FLAP at the nuclear envelope upon A23187 stimulation (Figures 4A and 4C). However, neither **1** or **2** nor the Michael acceptor TQ or the FLAP inhibitor MK886 blocked A23187-induced 5-LO translocation (Figures 4A and 4C). Of interest, **1** and **2** (3 μ M, each) as well as TQ (10 μ M) impeded A23187-induced 5-LO/FLAP complex assembly in HEK cells (Figure 4B) and in monocytes (Figure 4D) that was monitored by *in situ* proximity ligation assay (PLA). The FLAP inhibitor MK886 (0.3 μ M, used as control) blocked 5-LO/FLAP complex formation (Figures 4B and 4D), while the 5-LO inhibitor zileuton failed in this respect (not shown), as reported previously (Gerstmeier et al., 2016b). Taken together, the melleolides **1** and **2** as well as TQ impeded the assembly of the LT-biosynthetic 5-LO/FLAP complex at the nuclear membrane, yet without blocking 5-LO translocation. This effect may be causative for superior inhibition of 5-LO product formation in intact cells.

Mutation of 5-LO Cysteines Affects Product Formation and Susceptibility for Melleolides

Previous studies suggested a role of the four surface cysteines 159, 300, 416, and 418 in 5-LO for cellular product formation

(Hafner et al., 2015). Michael acceptors can act at either at Cys416 or Cys418 causing inhibition of 5-LO (Maucher et al., 2017). Thus, we studied if melleolides require these critical cysteines (Figure 5A) for inhibition of 5-LO. HEK cells were co-transfected with FLAP and with wild-type 5-LO (5-LO_WT) or with 5-LO mutants in which all four cysteines (5-LO_4C) or single cysteines had been replaced by serine. The mutated 5-LO proteins were expressed in HEK cells to a similar (5-LO_4C) or somewhat minor degree (5-LO_C159S, 5-LO_C300S, 5-LO_C416S, and 5-LO_C418S) versus 5-LO_WT (Figure 5B). Along these lines, the enzymatic capacities of corresponding HEK cell homogenates containing these 5-LO mutants were about 2- to 4-fold lower versus 5-LO_WT (Table 1). In HEK cell homogenates, **1** (Figure 5C, Table 1) and **2** (Figure S4) blocked 5-LO_WT activity, whereas 5-LO_4C was not affected at all. As for 5-LO_WT, the enzymatic activities of the mutants 5-LO_C159S, 5-LO_C300S, 5-LO_C416S, or 5-LO_C418S were also inhibited by **1** (Figure 5C, Table 1) and **2** (Figure S4). In contrast, zileuton inhibited 5-LO_WT and all mutated 5-LOs about equally well (Figure 5D).

Next, we analyzed cellular 5-LO product formation in intact HEK cells. Since previous data showed that 5-LO/FLAP-expressing HEK cells require exogenous AA for significant 5-LO product formation (Gerstmeier et al., 2014, 2016a), the cells were stimulated with A23187 plus 3 μ M AA. In contrast to 5-LO activity in homogenates, all mutated 5-LOs formed much less amounts of products versus 5-LO_WT in intact cells (approximately 5- to 10-fold lower), in particular 5-LO_C159S (Table 1). Of interest, while product formation of 5-LO_WT was efficiently inhibited by **1** (10 μ M), in HEK cells expressing 5-LO_4C but also 5-LO_C159S, melleolide **1** (or **2**, Figure S4) failed to markedly inhibit 5-LO product formation (Figure 5E, Table 1). Note that in cells expressing either 5-LO_C300S, 5-LO_C416S, or 5-LO_C418S, treatment with **1** (or **2**, Figure S4) caused efficient and concentration-dependent inhibition of 5-LO product formation comparable with cells expressing 5-LO_WT (Figure 5E). In contrast, zileuton consistently inhibited 5-LO activity in HEK cells regardless of the 5-LO mutations (Figure 5F). Hence, **1** and **2** may inhibit 5-LO product formation in intact cells via Cys159.

Role of Cysteines in 5-LO for Translocation and 5-LO/FLAP Interaction

In agreement with previous data (Hafner et al., 2015), the strikingly reduced capacities of the cysteine-mutated 5-LOs in intact HEK cells versus the moderately decreased activity of the 5-LO mutants in homogenates implied that cysteine mutations could affect 5-LO translocation and/or interaction with FLAP. Analysis of 5-LO translocation and co-localization with FLAP by IF microscopy revealed no impact of the cysteine mutations. That is, the subcellular localization of 5-LO_WT and all 5-LO mutants in resting HEK cells was comparable, and, upon A23187

Figure 4. Modulation of 5-LO Translocation and 5-LO/FLAP Interaction by Melleolides

Stably transfected HEK293 cells expressing 5-LO and FLAP (A and B) or human monocytes (C and D) were pre-incubated with compounds or vehicle (0.1% DMSO) for 10 min at 37°C, and subsequently incubated with 2.5 μ M A23187 for 10 min. Images show single staining for FLAP (green), 5-LO (red), and overlay of 5-LO and FLAP (bottom lane). Results are representative for 100 individual cells of three independent experiments. (B) Western blot analysis of 5-LO protein expression in stably transfected HEK293 cells expressing FLAP and various 5-LO proteins (5-LO_WT and the mutants 5-LO_4C, 5-LO_C159S, 5-LO_C300S, 5-LO_C416S, and 5-LO_C418S). Results are representative for three independent experiments. Densitometric protein analysis: correlation of 5-LO density to β -actin density, means \pm SEM, $n = 3$.

(C and D) Inhibition of 5-LO product formation in homogenates of HEK cells expressing FLAP and 5-LO (WT or mutants) by **1** at the indicated concentrations (C) and by 3 μ M zileuton (D). HEK cells were sonicated on ice and pre-incubated with compounds or vehicle (0.1% DMSO) at 4°C for 10 min. Samples were pre-warmed for 30 s at 37°C and incubated with 2 mM CaCl_2 and 20 μ M AA for another 10 min.

(E and F) Inhibition of 5-LO product formation in intact HEK cells expressing FLAP and 5-LO (WT or mutants) by **1** at the indicated concentrations (E) and by 3 μ M zileuton (F). HEK cells ($1 \times 10^5/\text{mL}$) were pre-incubated with **1**, zileuton, or vehicle (0.1% DMSO) for 10 min at 37°C and then stimulated with 2.5 μ M A23187 and 3 μ M AA for 10 min. Data are expressed as percentage of vehicle control (100%), means \pm SEM, $n = 4$.

See also Figure S4.

stimulation, they all translocated to FLAP at the nuclear envelope (Figure 6A). Of interest, Cys159 seems to be instrumental for the 5-LO/FLAP interaction which was visualized by *in situ* PLA (Figure 6B). Thus, in HEK cells expressing 5-LO_WT, 5-LO_C300S, 5-LO_C416S, or 5-LO_C418S, stimulation with A23187 led to 5-LO/FLAP complex assembly. However, in HEK cells expressing 5-LO_4C or 5-LO_C159S, challenge with A23187 failed in

this respect, implying a critical role of Cys159 in 5-LO/FLAP interaction.

DISCUSSION

Here, we identified human 5-LO as a molecular target of melleolides from honey mushroom. Exploiting **1** and **2** as the most

5-LO_C418S	465.3 ± 22.8	124.9 ± 5.2 (73.2%)	66.6 ± 23.1	23.0 ± 9.5 (66.7%)

For analysis of 5-LO product formation in intact cells, HEK cells (1×10^6 /mL) stably expressing FLAP and 5-LO enzymes (wild-type or mutants) were pre-incubated with 10 μ M of **1** or vehicle (0.1% DMSO), and then stimulated with 2.5 μ M A23187 and 3 μ M AA for 10 min at 37°C. For analysis of 5-LO product formation in homogenates, the HEK cells (1×10^6 /mL) were sonicated, the resulting homogenates were pre-incubated with 10 μ M of **1** or vehicle (0.1% DMSO) and then incubated with 20 μ M AA for 10 min at 37°C. Data are expressed as ng 5-LO products formed per 10⁶ cells; means ± SEM, n = 4. w/o, without.

potent melleolide representatives revealed Cys159 in 5-LO as a crucial moiety for functional interaction of 5-LO with FLAP in LT biosynthesis. Our data suggest that melleolides suppress 5-LO product formation by two distinct modes of action: (1) by direct interference with the 5-LO enzyme activity involving two or more of the cysteines 159, 300, 416, and 418, and (2) by a more efficient mechanism that selectively involves Cys159 and prevents cellular 5-LO/FLAP complex assembly without affecting 5-LO translocation. Thus, our results shed light on the catalytic and regulatory role of cysteines at the substrate entrance of the 5-LO active site for the cellular capacity to biosynthesize LTs.

Melleolides were shown to exhibit antimicrobial activity and cytotoxic properties for cancer cells and primary human monocytes (Bohnert et al., 2011, 2014b), but interference with LT biosynthesis is thus far unexplored. With 5-LO, we identified a molecular target for these bioactive natural products. The efficient 5-LO-inhibitory melleolides possess a reactive aldehyde group at position 1 and a $\Delta^{2,4}$ (i.e., **1** and **2**) or $\Delta^{2,3}$ (i.e., **3**) double bond in the sesquiterpene moiety. Our SAR analysis indicates that the Michael acceptor functionality impacts 5-LO inhibitory activity, but also minor structural arrangements in the sesquiterpene moiety (α,β double bond at $\Delta^{2,4}$ versus $\Delta^{2,3}$ position, and the 4-OH moiety) and in the orsellinic acid residue (5'-OH methylation, 6'-chlorine). Strong potencies of 5-LO inhibitors often correlate with high lipophilicity (Werz, 2002), which may explain the superior effect of **2** with 5'-methoxy and 6'-chlorine residues over **1** in the cell-free assay.

Unexpectedly, the SARs for 5-LO inhibition by melleolides in intact neutrophils differ and reveal **1** as the most potent compound with a 10-fold lower IC₅₀ value compared with interference with 5-LO in cell-free assays. Such superior potency in intact cells was not observed for the 5-LO inhibitor zileuton (this study and others [Carter et al., 1991]) and implies that additional factors that govern cellular 5-LO activity might be affected by melleolides. In fact, cellular regulation of 5-LO is complex, and several points of attack are conceivable that eventually cause or potentiate suppression of 5-LO product formation including interference with (1) AA release, (2) AA transfer via FLAP, (3) 5-LO translocation, and (4) upstream 5-LO signaling pathways

such as MAPK and Ca²⁺, and other 5-LO-activating processes (Radmark et al., 2015; Werz and Steinhilber, 2005). Our data show that melleolides, in addition to directly inhibiting 5-LO activity, prevent the 5-LO/FLAP complex assembly and, thus, could interfere with the AA transfer from FLAP to 5-LO. This may explain why excess of AA (20 μ M) in intact cells diminishes the 5-LO-inhibitory potency of melleolides, although inhibition of 5-LO activity in cell-free assays is favored by high AA concentrations.

Most direct 5-LO inhibitors comprise lipophilic redox-active and/or iron-chelating compounds as well as AA mimetics that reversibly block AA conversion at the active or allosteric sites of 5-LO (Werz, 2002; Werz and Steinhilber, 2005). Based on the chemical structures of melleolides, fatty acid-like features are not readily apparent, and iron-chelating or redox properties have not been reported. Of interest, structurally different compounds containing SH-reactive groups such as the Michael acceptors TQ (Maucher et al., 2017), nitro fatty acids (Awwad et al., 2014), unsubstituted aminophenols (Kretschmer et al., 2017), or the maleimide-featured inhibitor U73122 (Feisst et al., 2005; Hornig et al., 2012) were shown to form covalent adducts with the surface cysteines 159, 416, and/or 418 and thereby potently and irreversibly inhibit 5-LO activity. The 5-LO structure exposes nine cysteine residues on the surface (Gilbert et al., 2011). We previously identified four cysteines (cysteines 159, 300, 416, and 418) located on the 5-LO surface in the region around the substrate entrance of the catalytic center that mediate dimerization of 5-LO (Hafner et al., 2011) and are important for the co-localization of 5-LO with FLAP at the nuclear membrane (Hafner et al., 2015). In our present study, melleolides failed to inhibit the activity of the 5-LO_4C mutant in cell-free and cell-based assays, suggesting that one or more of these cysteines are necessary to confer the 5-LO suppressive effect. In contrast, zileuton, which chelates the active site iron in 5-LO (Carter et al., 1991), suppressed the activity of this mutant, as expected. Note that 5-LO single mutants, with only one of the cysteines 159, 300, 416, or 418 being replaced by serine, were still effectively inhibited by melleolides in cell-free assays, implying that at least two of these cysteines are involved. This contrasts the suppressive effect of melleolides on 5-LO activity in intact

Figure 6. Role of Cysteines in 5-LO for Translocation and 5-LO/FLAP Interaction

(A) Immunofluorescence microscopy analysis of 5-LO translocation and co-localization with FLAP. Images show overlay of 5-LO (red) and FLAP (green).

(B) PLA for analysis of cellular *in situ* 5-LO/FLAP complex assembly. DAPI (blue) was used to stain the nucleus and *in situ* PLA signals (magenta dots) visualize 5-LO/FLAP complexes. Scale bars, 25 μm (insets) and 100 μm (overview). For both (A) and (B), stably transfected HEK cells expressing FLAP and 5-LO (WT or mutants) were incubated with 2.5 μM A23187 or vehicle (0.1% DMSO) for 10 min at 37°C. Results are representative for 100 individual cells of three independent experiments.

5-LO (Kulkarni et al., 2002), and is essential for product biosynthesis (Gerstmeier et al., 2016b; Mandal et al., 2008; Radmark et al., 2015). The prenylated acylphloroglucinol hyperforin binds to the 5-LO C2-like domain and blocks 5-LO translocation and activity (Feisst et al., 2009), while FLAP inhibitors primarily prevent 5-LO/FLAP interaction without definite blockade of 5-LO movement (Garscha et al., 2016; Gerstmeier et al., 2016b). In analogy to MK886, **1** and **2** as well as TQ failed to block 5-LO translocation but they clearly inhibited the 5-LO/FLAP interaction.

cells, where Cys159 emerged as a crucial residue required to mediate inhibition of 5-LO product formation. Thus, our results suggest that melleolides act via Cys159 to prevent the 5-LO/FLAP complex assembly while cysteines 300, 416, and 418 do not contribute.

FLAP, a nuclear membrane protein without any known enzymatic activity, is essential for 5-LO product formation in intact cells (Miller et al., 1990) by enabling AA substrate transfer to 5-LO for conversion to LTA₄ (Ferguson et al., 2007). Accordingly, FLAP inhibitors efficiently inhibit cellular LT biosynthesis by preventing 5-LO/FLAP assemblies (Garscha et al., 2016; Gerstmeier et al., 2016b) but they fail to inhibit 5-LO activity in cell-free assays where FLAP is dispensable for 5-LO to convert AA (Evans et al., 2008). Along these lines, mutation of cysteines 159, 300, 416, or 418, which were postulated to be important for 5-LO/FLAP co-localization (Hafner et al., 2015), hardly affected 5-LO activity in cell-free homogenates, but strikingly in intact cells. Moreover, 5-LO_{C159S} or 5-LO_{4C} failed to form complex assemblies with FLAP, in contrast to 5-LOs possessing Cys159. Interestingly, **1** and **2** (but not zileuton) required Cys159 to inhibit 5-LO product formation in intact cells. However, when this cysteine was replaced by serine, these mutants were not susceptible to the tested melleolides. Therefore, Cys159 is of major importance for 5-LO to interact with FLAP and as such mediates suppression of cellular 5-LO product formation by melleolides.

5-LO translocation to the nuclear envelope is mediated by elevated intracellular Ca²⁺ that binds to the C2-like domain of

Taken together, we identified human 5-LO as a molecular target of melleolides from the honey mushroom. We propose that melleolides containing an α,β -unsaturated aldehyde function as Michael acceptors that interfere with critical surface cysteines of 5-LO. While two or more of these cysteines mediate the direct inhibitory effects of melleolides on the enzymatic level, Cys159 confers suppression of cellular 5-LO product formation by melleolides via preventing the 5-LO/FLAP complex assembly. Finally, our data highlight the importance of Cys159 for 5-LO to interact with FLAP, a prerequisite for the biosynthesis of LTs in the cellular context.

SIGNIFICANCE

Only for very few mushroom toxins is the pharmacological mode of action understood and the molecular targets known. Melleolides are a family of sesquiterpene aryl esters of the globally distributed plant pathogenic and edible honey mushroom (*Armillaria mellea*). This family of natural products comprises >60 published members and represents one of the largest family of fungal small bioactive molecules. We discovered human 5-lipoxygenase (5-LO), the key enzyme in leukotriene biosynthesis, as a molecular target for those melleolides that possess an α,β -unsaturated aldehyde with thiol-reactive Michael acceptor functionality. Since leukotrienes are potent bioactive mediators with pivotal functions in inflammation and in the immune

response, their formation needs to be tightly controlled, for example, by temporal assembly of the biosynthetic protein complex of 5-LO with its helper protein FLAP. We provide evidence that melleolides mediate 5-LO inhibition via critical surface cysteines of the enzyme by two distinct modes of action: (1) by direct interference with the 5-LO catalytic activity involving two or more of the cysteines 159, 300, 416, and 418, and (2) by a more efficient cellular mechanism involving selectively Cys159, which prevents assembly of the 5-LO/FLAP complex in leukotriene biosynthesis. In conclusion, identification of 5-LO as a target for melleolides represents a basis for further investigations that will help evaluate the bioactions of this mushroom and its ingredients in view of the use for culinary purposes. By exploiting these melleolides as chemical tools we shed light on the catalytic and regulatory role of cysteines of 5-LO at the substrate entrance of the active site for the cellular capacity to generate bioactive mediators. Therefore, our study also unravels Cys159 in 5-LO as a crucial residue for accomplishing the functional interaction of 5-LO with FLAP in leukotriene biosynthesis, which offers a potential site for novel small-molecule inhibitors to intervene with 5-LO-related disorders.

STAR★METHODS

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- CONTACT FOR REAGENT AND RESOURCE SHARING
- EXPERIMENTAL MODEL AND SUBJECT DETAILS
 - Human Cells
- METHODS DETAILS
 - Expression and Purification of Human Recombinant 5-LO
 - Determination of 5-LO Product Formation in Intact Cells and Homogenates
 - Determination of Release of [³H]-Labeled Arachidonic Acid
 - LTC₄ Synthase Activity Assay
 - Determination of Isolated COX-1 and -2 Activity
 - Determination of PGE₂ Synthase Activity in a Cell-Free Assay
 - SDS PAGE and Western Blot
 - GSH Incubation
 - Standard Peptide Incubation
 - MALDI-MS Measurement and Data Analysis
 - Analysis of Subcellular Localization of 5-LO by Immunofluorescence Microscopy
 - In Situ Analysis of 5-LO/FLAP Interaction by Proximity Ligation Assay
- QUANTIFICATION AND STATISTICAL ANALYSIS

SUPPLEMENTAL INFORMATION

Supplemental Information includes four figures and one table and can be found with this article online at <https://doi.org/10.1016/j.chembiol.2018.10.010>.

EXPERIMENTAL MODEL AND SUBJECT DETAILS**Human Cells**

Neutrophils and monocytes were isolated from peripheral human blood of adult healthy male and female volunteers (18–65 years) as described (Pace et al., 2017; Scherer et al., 2014) and with consent obtained from the Institute of Transfusion Medicine, University Hospital Jena. Individual blood samples provided and used for leukocyte isolation were blinded and thus, the exact age and the sex of the donor was unknown. The protocols for experiments with human neutrophils and monocytes were approved by the ethical commission of the Friedrich-Schiller-University Jena (approval no. 4025-02/14). All methods were performed in accordance with the relevant guidelines and regulations. Leukocyte concentrates were prepared by centrifugation (4000×g, 20 min, 20°C) and erythrocytes were removed by dextran sedimentation, followed by centrifugation on lymphocyte separation medium (Histopaque®-1077, Sigma-Aldrich) to obtain peripheral blood mononuclear cells (PBMC) and neutrophils. Resulting neutrophils were finally resuspended in PBS pH 7.4 containing 1 mg/mL glucose and 1 mM CaCl₂ (PGC buffer). PBMC were seeded in RPMI 1640 (Sigma-Aldrich) containing 10% (v/v) heat inactivated fetal calf serum (FCS), 100 U/mL penicillin, and 100 µg/mL streptomycin in cell culture flasks (Greiner Bio-one, Frickenhausen, Germany) for 1.5 h at 37°C and 5% CO₂. Adherent monocytes were washed twice with PBS and were resuspended in PGC buffer. HEK (human embryonic kidney, female fetus) 293 cells stably transfected with FLAP and 5-LO or 5-LO mutants (Hornig et al., 2012; Hafner et al., 2015) were cultured in monolayers in DMEM High Glucose (4.5 g/L) medium supplemented with heat-inactivated FCS (10%, v/v), 100 U/mL penicillin, and 100 µg/mL streptomycin at 37°C in a 5% CO₂ incubator.

METHODS DETAILS**Expression and Purification of Human Recombinant 5-LO**

Escherichia coli (BL21) cells were transformed with plasmid pT3-5-LO, and human recombinant 5-LO protein was expressed overnight at 30°C as previously described (Fischer et al., 2003). Cells were lysed in 50 mM triethanolamine/HCl pH 8.0, 5 mM EDTA, 1 mM phenylmethanesulfonyl fluoride (PMSF), soybean trypsin inhibitor (STI, 60 µg/mL), and lysozyme (1 mg/mL), homogenized by sonication (3 × 20 s), and centrifuged at 40,000×g for 20 min at 4°C. For purification of 5-LO, ATP affinity chromatography was used and the 40,000×g supernatant (S40) was applied to an ATP agarose column (Sigma-Aldrich). Aliquots of semi-purified 5-LO were diluted with ice-cold PBS containing 1 mM EDTA. Samples were pre-incubated with the test compounds or vehicle (0.1% DMSO). After 10 min at 4°C, samples were stimulated with 2 mM CaCl₂ plus the indicated concentrations of AA to start 5-LO product formation. The reaction was stopped after 10 min by addition of one volume of ice-cold methanol, and the formed metabolites were analyzed by RP-HPLC as described (Pergola et al., 2014; Steinhilber et al., 1989). 5-LO products include the all-trans isomers of LTB₄ as well as 5-HPETE and its corresponding alcohol 5-HETE.

Determination of 5-LO Product Formation in Intact Cells and Homogenates

For activity assays with intact cells, 5 × 10⁶ freshly isolated neutrophils or monocytes, or 1 × 10⁶ HEK293 cells stably producing the indicated recombinant proteins, were resuspended in 1 mL PGC buffer. After pre-incubation with compounds 1–4 (10 min, 37°C), 5-LO product formation was started by addition of 2.5 µM A23187 with or without 20 µM AA (neutrophils, monocytes) or 3 µM AA (HEK cells). After 10 min at 37°C, the reaction was stopped with 1 mL of ice-cold methanol. Formed 5-LO metabolites were extracted

and analyzed by RP-HPLC using a C18 RP Radial PAK column (Waters, Eschborn, Germany) (Pergola et al., 2014; Steinhilber et al., 1989) or optionally by UPLC-MS/MS as described (Pace et al., 2017).

To determine 5-LO product formation in homogenates, neutrophils (5×10^6) or HEK293 cells (1×10^6) were resuspended in 1 mL PBS containing 1 mM EDTA. Cells were lysed on ice by sonication (3×20 s) and resulting cell homogenates were pre-incubated with compounds or vehicle (0.1% DMSO) for 10 min on ice. 5-LO product formation was started by addition of 2 mM CaCl_2 and 20 μM AA (neutrophils) or 10 μM AA (HEK cells). After 10 min at 37°C , reaction was stopped by 1 mL ice-cold methanol. 5-LO product formation was analyzed as described above for intact cells.

Determination of Release of [^3H]-Labeled Arachidonic Acid

Release of [^3H]-labeled AA from human neutrophils was analyzed as described (Fischer et al., 2005). In brief, freshly isolated neutrophils were immediately resuspended at 10^7 cells/mL RPMI 1640 medium containing 5 nM [^3H]AA (corresponding to 0.5 $\mu\text{Ci/mL}$, specific activity 200 Ci/mmol) and incubated for 120 min at 37°C in 5% CO_2 atmosphere. Cells were then washed twice with PBS containing 1 mg/mL glucose and 2 mg/mL fatty acid-free bovine albumin, to remove unincorporated [^3H]AA. Labeled neutrophils (2×10^7) were resuspended in 1 mL PGC containing 2 mg/mL fatty acid-free bovine albumin and pre-incubated with 0.1% DMSO or test compounds (15 min, 37°C) and then stimulated with 2.5 μM A23187 for 10 min. The samples were then placed on ice, centrifuged and aliquots (300 μL) of the supernatants were assayed for radioactivity by scintillation counting (Micro Beta Trilux, Perkin Elmer, Waltham, MA, USA).

LTC₄ Synthase Activity Assay

Preparation of HEK293 cells stably expressing LTC₄ synthase and generation of microsomes were performed as described (Liening et al., 2016). Microsomes were pre-incubated with compounds or vehicle (0.1% DMSO) for 10 min at 4°C prior stimulation with 1 μM LTC₄ methyl ester (Cayman, Ann Harbor, MI) for 10 min. The reaction was stopped by 1 vol ice-cold methanol and acidified PBS, and the internal standard LTC₄ methyl ester-*d*₅ was added prior to solid phase extraction. LTC₄ methyl ester formation was analyzed by UPLC-MS/MS as described previously (Liening et al., 2016).

Determination of Isolated COX-1 and -2 Activity

Purified COX-1 (ovine, 50 units) or COX-2 (human recombinant, 20 units) were pre-incubated with compounds or vehicle (0.1% DMSO) for 5 min at 4°C in 1 mL reaction buffer containing 100 mM Tris buffer pH 8, 5 mM GSH, 5 μM hemoglobin, and 100 μM EDTA prior 1 min at 37°C to prewarm samples. COX product formation was started by adding AA (COX-1: 5 μM , COX-2: 2 μM) which resulted in generation of 12-HHT (12(S)-hydroxy-5-*cis*-8,10-*trans*-heptadecatrienoic acid) non-enzymatically formed from COX-derived PGH₂. 12-HHT was measured by RP-HPLC as previously reported (Albert et al., 2002).

Determination of PGE₂ Synthase Activity in a Cell-Free Assay

Preparation of A549 cells, induction of mPGES-1 by IL-1 β , generation of microsomes, and analysis of mPGES-1 activity was performed exactly as described previously (Koeberle et al., 2008, 2009).

SDS PAGE and Western Blot

Neutrophils ($1 \times 10^7/100 \mu\text{L}$ ice-cold PGC buffer) were pre-incubated for 10 min at 37°C with test compounds at 37°C , stimulated with 1 μM *N*-formyl-methionyl-leucyl-phenylalanine (fMLP) for 1.5 min at 37°C . The reaction was stopped by addition of 100 μL ice-cold 2 \times SDS loading buffer (20 mM Tris-HCl pH 8, 2 mM EDTA, 5% (m/v) SDS, 10% (v/v) β -mercaptoethanol, 10 $\mu\text{g/mL}$ leupeptin, 60 $\mu\text{g/mL}$ STI, 1 mM PMSF, 40 μL glycerol and 0.1% bromophenol blue (1:1, v/v). Samples were boiled for 5 min at 96°C , sonicated (3×10 sec, 4°C) and proteins were separated and analyzed by SDS-PAGE and Western Blotting.

To control stable expression of transfected enzymes, HEK cells ($1 \times 10^6/100 \mu\text{L}$) were washed and lysed with Triton X-100 lysis buffer (20 mM Tris-HCl pH 7.4, 150 mM NaCl, 2 mM EDTA, 1% (v/v) Triton X-100, 0.5% (v/v) NP-40, 10 $\mu\text{g/mL}$ leupeptin, 60 $\mu\text{g/mL}$ STI, 1 mM PMSF) for 15 min on ice with occasional vortexing. Lysates were centrifuged (21,000 \times g, 10 min, 4°C) and the supernatant was mixed with 4 \times Laemmli buffer (50 mM Tris-HCl pH 6.8, 12.5 mM EDTA, 2% (m/v) SDS, 10% (v/v) glycerol, 1% (v/v) β -mercaptoethanol, 0.02% (m/v) bromophenol blue) and samples were boiled for 5 min at 96°C .

Correct protein loading on the gels and transfer of proteins to nitrocellulose membrane (Amersham PROTRAN® supported 0.45 NC, GE Healthcare, Freiburg, Germany) were confirmed by Ponceau staining. Antibodies recognizing phosphorylated ERK1/2 (Thr202/Tyr204), ERK1/2, p-cPLA₂ (Ser505), p-p38 (Thr180/Tyr182) or β -actin were from Cell Signaling Technology (Boston, MA) and used at 1:1000 dilution. The antibody against GAPDH (1:1000) was purchased from Santa Cruz (Dallas, TX) and the rabbit FLAP (1:1000) antibody was obtained from Abcam (Cambridge, UK). The rabbit 5-LO antiserum (1551, AK7, 1:8 dilution) was kindly provided by Dr. Olof Rådmark, Karolinska Institutet, Stockholm, Sweden. Infrared-labeled secondary antibody IRDye 800CW goat anti-mouse was from LI-COR Biosciences (Lincoln, NE). For detection, the Odyssey Infrared Imaging System (LI-COR Bioscience, Lincoln, NE) and for analysis the Odyssey application software (version 3.0.25) were used.

GSH Incubation

Glutathione (GSH) adduct formation tests were carried out directly on the MALDI-target in a total volume of 2 μL . 1 μL of 2 mM GSH in PBS pH 7.4 and 1 μL of 20 μM compound or vehicle in PBS pH 7.4 were mixed on the target to obtain a final concentration of 1 mM

Please cite this article in press as: König et al., Melleolides from Honey Mushroom Inhibit 5-Lipoxygenase via Cys159, Cell Chemical Biology (2018), <https://doi.org/10.1016/j.chembiol.2018.10.010>

CellPress

GSH and 10 μ M compound. The reaction mixture was kept humid for 30 min at 37°C using a SunDigest digestion chamber (SunChrom, Friedrichsdorf, Germany). The reaction was stopped after 30 min of incubation with 1 μ L CHCA-solution (3 mg/mL CHCA (α -cyano-4-hydroxy-cinnamic acid) in 70/30/0.1 acetonitrile/water/trifluoroacetic acid (TFA)). After matrix crystallization, we used chilled 5%-formic acid to remove salt contaminations from the matrix crystals and recrystallized the sample with acetonitrile/water (80/20, v/v) mixture containing 0.1% TFA to obtain a homogeneous crystallization.

Standard Peptide Incubation

Binding assays using the standard peptides AAAACAAAAR, AAAAHAAAAR, AAAAKAAAAR, AAAASAAAAR (JPT Peptide technology, Berlin, Germany) were also directly carried out on the MALDI-target. Peptides were diluted in PBS pH 7.4 to a concentration of 20 μ M and mixed separately with each compound at a concentration of 20 μ M in a total volume of 2 μ L to obtain a final concentration of 10 μ M peptide and 10 μ M compound. Incubation was performed using the SunDigest system for 1 h at 37°C. The reaction was stopped using the same matrix solution as described above. Washing and recrystallization of the formed spots were performed as previously described (Kretschmer et al., 2017).

MALDI-MS Measurement and Data Analysis

MALDI-MS measurements were carried out using a MALDI-Duo ion source coupled to an Orbitrap LTQ XL mass spectrometer (Thermo Fisher Scientific, Bremen, Germany). MS measurements were carried out on an Orbitrap mass analyzer. For GSH adducts, the mass was recorded from m/z 200.00 to 800.00 and for standard peptide assay, the mass range was between m/z 800.00 and 2000.00. 50 subspectra were accumulated for data analysis. Mass resolution was set to 30,000 (FWHM at m/z: 400), laser energy was adjusted to optimize MS spectra quality. MS/MS spectra of reaction products and peptides were recorded using the ion trap mass analyzer. 100 subspectra were accumulated for data analysis. Normalized collision energy was set to 50. Isolation of the particular reaction product was performed using an isolation width of 1 Da. MS spectra were analyzed using the Qual Browser software version 2.0.7 (Thermo Fisher Scientific). This software was also used to compare the theoretical masses. Theoretical masses of peptides, reaction products, and MS/MS ion masses were calculated using mMass version 5.5.0.

Analysis of Subcellular Localization of 5-LO by Immunofluorescence Microscopy

For analysis of 5-LO and FLAP subcellular localization in monocytes, PBMC were seeded in RPMI medium containing 2 mM L-glutamine, 100 U/ml penicillin, and 100 μ g/ml streptomycin onto glass coverslips in a 12-well plate and cultured for 1.5 h. The 5-LO/FLAP subcellular localization was also analyzed using HEK293 cells stably transfected with 5-LO enzymes and FLAP. Cells (0.45×10^6 /mL) were seeded on poly-D-lysine-coated coverslips and cultured at 37°C, 5% CO₂ until 60% confluence. Cells were washed with PGC buffer and pre-incubated with test compounds or vehicle (0.1% DMSO) 10 min at 37°C in PGC buffer prior to activation. Cells were then stimulated for 10 min with 2.5 μ M A23187 and stopped by fixation with 4% paraformaldehyde solution. Ice-cold acetone (5 min, 4°C) was used for permeabilization prior to blocking with non-immune goat serum. Samples were incubated with mouse monoclonal anti-5-LO antibody (1:300; made in-house, Goethe University Frankfurt, Germany) (Gerstmeier et al., 2014; Pergola et al., 2014) and rabbit polyclonal anti-FLAP antibody (1:500; Abcam, Cambridge, UK) at 4°C overnight. 5-LO and FLAP were stained with the fluorophore-labeled secondary antibodies; Alexa Fluor 488 goat anti-rabbit (1:1000) and Alexa Fluor 555 goat anti-mouse (1:1000, Invitrogen, Darmstadt, Germany). Nuclear DNA was stained with DAPI (Invitrogen). Samples were analyzed with a Zeiss Axiovert 200 M microscope, and a Plan Neofluar $\times 100/1.30$ Oil (DIC III) objective (Zeiss, Jena, Germany). A Zeiss AxioCam MR camera was used for image acquisition.

In Situ Analysis of 5-LO/FLAP Interaction by Proximity Ligation Assay

To analyze the *in situ* interaction of 5-LO with FLAP in monocytes and HEK293 cells, an *in situ* proximity ligation assay (PLA) was performed, according to the manufacturers' protocol (Soderberg et al., 2006) and as described (Gerstmeier et al., 2016b). Samples were treated, fixed and incubated with primary antibody as described for IF microscopy above. Cells were then incubated with species specific secondary antibodies conjugated with oligonucleotides (PLA probe anti-mouse MINUS and anti-rabbit PLUS) for 1 h at 37°C. By addition of two other circleforming DNA oligonucleotides and a ligase (30 min at 37°C) the antibody-bound oligonucleotides form a DNA circle when the target proteins are less than 40 nm distant from each other. The newly generated DNA circle was amplified by rolling circle amplification and visualized by hybridization with fluorescently labeled oligonucleotides. Nuclear DNA was stained with DAPI. The PLA interaction signal appears as a fluorescent spot and was analyzed using the above described microscope and equipment.

QUANTIFICATION AND STATISTICAL ANALYSIS

Results are presented as means \pm standard error of the mean (SEM) of n independent observations, where n represents the number of performed experiments at different days or with different donors. Statistical analysis of the data was performed by one-way ANOVA using GraphPad InStat (Graphpad Software Inc., San Diego, CA) followed by a Bonferroni post-hoc test for multiple or student t-test for single comparisons, respectively. P-values < 0.05 were considered as significant.

SUMMARY

The epidithiodioxopiperazine gliotoxin is a virulence factor of *Aspergillus fumigatus*, the most important airborne fungal pathogen of humans. Gliotoxin suppresses innate immunity in invasive aspergillosis, particularly by compromising neutrophils, but the underlying molecular mechanisms remain elusive. Neutrophils are the first responders among innate immune cells recruited to sites of infection by the chemoattractant leukotriene (LT)B₄ that is biosynthesized by 5-lipoxygenase and LTA₄ hydrolase (LTA₄H). Here, we identified gliotoxin as inhibitor of LTA₄H that selectively abrogates LTB₄ formation in human leukocytes and in distinct animal models. Gliotoxin failed to inhibit the formation of other eicosanoids and the aminopeptidase activity of the bifunctional LTA₄H. Suppression of LTB₄ formation by gliotoxin required the cellular environment and/or reducing conditions, and only the reduced form of gliotoxin inhibited LTA₄H activity. Conclusively, gliotoxin suppresses the biosynthesis of the potent neutrophil chemoattractant LTB₄ by direct interference with LTA₄H thereby impairing neutrophil functions in invasive aspergillosis.

INTRODUCTION

Aspergillus fumigatus is a ubiquitous fungus and the most common cause of invasive aspergillosis (IA), which affects primarily

immunocompromised patients with a mortality rate of 30%–95% (Segal, 2009). During IA, *A. fumigatus* produces toxic secondary metabolites with gliotoxin as an important mycotoxin (Scharf et al., 2016). Gliotoxin is considered as a virulence factor contributing to IA due to its immunosuppressive properties (Park and Mehrad, 2009; Sutton et al., 1996), particularly in neutrophils (Comera et al., 2007; Spikes et al., 2008; Sugui et al., 2007). A variety of bioactivities were demonstrated for gliotoxin, such as induction of apoptosis, inhibition of nuclear factor κ B (NF- κ B) by preventing proteasome-mediated degradation of I κ B α , inhibition of reactive oxygen species generation by phagocytes, and inhibition of angiogenesis (Scharf et al., 2016; Waring and Beaver, 1996), as well as changes in cell morphology and cell adhesion of neutrophils (Comera et al., 2007). So far, the underlying mechanism of how gliotoxin contributes to IA and compromises neutrophils is incompletely understood.

Leukotrienes are bioactive lipid mediators (LMs) involved in innate and adaptive immune responses, inflammation, and in several diseases such as asthma and atherosclerosis (Haeggstrom and Funk, 2011; Radmark et al., 2015). LTB₄ is one of the most potent chemoattractants for neutrophils (Afonso et al., 2012; Lammermann et al., 2013), with crucial roles in host defense against infections and inflammation by triggering the recruitment and activation of innate immune cells (Brandt and Serezani, 2017; Haeggstrom and Funk, 2011; Radmark et al., 2015). Neutrophils and monocytes possess high capacities to generate LTB₄ and are considered as major sources for LTB₄ in the blood and at sites of inflammation (Lammermann et al., 2013; Surette et al., 1993). In LT biosynthesis (Figure 1A), arachidonic acid (AA) is released by cytosolic phospholipase A₂ (cPLA₂) and then converted by 5-lipoxygenase (5-LO) in a two-step reaction: first dioxygenation to 5-hydroperoxyeicosatetraenoic acid (5-HPETE) and then dehydration to the instable

epoxide leukotriene A₄ (LTA₄) (Radmark et al., 2015). LTA₄ can be hydrolyzed by LTA₄ hydrolase (LTA₄H) to LTB₄ or conjugated with glutathione (GSH) by LTC₄ synthase (LTC₄S) to LTC₄ (Figure 1A). Moreover, LTA₄ may degrade non-enzymatically to *trans* (tr)-LTB₄ isomers, and the intermediate 5-HPETE can be reduced to 5-HETE (Haeggstrom and Funk, 2011; Radmark et al., 2015). LTA₄H is a ubiquitously expressed, soluble Zn²⁺ metalloenzyme that harbors two distinct enzymatic activities with overlapping active sites: (1) an epoxide hydrolase activity that converts LTA₄ to the pro-inflammatory chemoattractant LTB₄ and (2) an aminopeptidase activity that, for instance, hydrolyses the pro-inflammatory tripeptide Pro-Gly-Pro (PGP)

(Haeggstrom et al., 2007; Snelgrove et al., 2010; Stsiapanava et al., 2017).

Recently, host-derived LTB₄ was shown to be critical for neutrophil recruitment and resistance to pulmonary *A. fumigatus* challenge in mice (Caffrey-Carr et al., 2017). Here, we identified gliotoxin as a potent and selective inhibitor of the epoxide hydrolase activity of LTA₄H. We show that pre-treatment of mice and rats with gliotoxin effectively blocked agonist-induced neutrophil recruitment along with reduced levels of circulating LTB₄, while other LMs were not suppressed. Our data propose that abrogating chemotactic LTB₄ formation through inhibition of LTA₄H might be one crucial mode of action of how gliotoxin

exerts its neutrophil-compromising properties during establishment of IA.

RESULTS

Gliotoxin Selectively Suppresses LTB₄ Biosynthesis and Blocks Neutrophil Recruitment *In Vivo*

Since 5-LO and LTB₄ are critical for neutrophil recruitment and defense against *A. fumigatus* (Caffrey-Carr et al., 2017), we hypothesized that the neutrophil-compromising properties of gliotoxin could be due to interference with LTB₄ biosynthesis. To study the effects of gliotoxin on LT formation and on neutrophil recruitment *in vivo*, we used two distinct (agonist, species, organ) LT/neutrophil-driven models of acute inflammation, i.e., (1) zymosan-induced mouse peritonitis (Rao et al., 1994) and (2) carrageenan-induced rat pleurisy (Cuzzocrea et al., 2003). Since in *A. fumigatus*-infected murine lungs, gliotoxin was locally found at ~4 mg/kg of lung tissue (Lewis et al., 2005), we here used a dose of 5 mg/kg gliotoxin. The clinically used LT biosynthesis blocker zileuton (a 5-LO inhibitor) was applied as reference drug (10 mg/kg). In zymosan-induced peritonitis, a well-established experimental *in vivo* model for evaluation of inhibitors of LT biosynthesis and LTB₄-mediated neutrophil chemotaxis, intraperitoneal (i.p.) pre-treatment of mice with gliotoxin (5 mg/kg, 30 min) suppressed circulating LTB₄ plasma levels at 4 h after zymosan injection to 36.6% ± 13.4% versus vehicle control (=100%) with similar efficacy as zileuton (10 mg/kg; 35.4% ± 20.3%) (Figure 1B). In parallel, gliotoxin blocked neutrophil infiltration into the peritoneal cavity, comparable with zileuton (Figure 1C). However, zileuton also caused significant suppression of all other 5-LO-derived products (i.e., tr-LTB₄ isomers, 5-HETE, and LTC₄), and to a minor extent also reduced 12-LO- and cyclooxygenase-derived eicosanoids. In contrast, gliotoxin exclusively suppressed LTB₄ formation but enhanced the levels of tr-LTB₄ isomers (194.9% ± 12.7% versus vehicle control), probably by redirection to non-enzymatic LTA₄ hydrolysis (Figure 1D).

Comparable results were obtained with rats using carrageenan-induced pleurisy, which represents a model of lung inflammation. Thus, pre-treatment with gliotoxin (5 mg/kg, i.p., 30 min) as well as zileuton (10 mg/kg, i.p., 30 min) efficiently reduced circulating LTB₄ plasma levels 2 h after intrathoracic carrageenan injection (Figure 1E), and neutrophil recruitment in the thoracic cavity was markedly reduced (Figure 1F). Similar effects of gliotoxin were evident at the lower dose of only 1.5 mg/kg (Figures 1E and 1F). Again, tr-LTB₄ isomer levels were elevated and other 5-LO-derived LMs or detectable eicosanoids were not impaired by gliotoxin (Figure S1). Together, gliotoxin selectively impaired the levels of chemotactic LTB₄ among various LMs, accompanied by potent suppression of neutrophil infiltration, suggesting LTA₄H as potential point of attack.

Gliotoxin Potently and Selectively Inhibits LTB₄ Biosynthesis in Human Neutrophils and Monocytes

Next, we studied the LTB₄-suppressive effects of gliotoxin in isolated human primary leukocytes side-by-side with the structurally distinct but selective LTA₄H inhibitor SC-57461A (Askonas et al., 2002). Pre-incubation of neutrophils with gliotoxin

and subsequent stimulation with Ca²⁺-ionophore A23187 inhibited LTB₄ formation (half maximal inhibitory concentration [IC₅₀] = 1.5 ± 0.5 μM) with concomitant increase of the tr-LTB₄ isomers, but without alteration of 5-HETE production (Figure 2A). Short-term incubations of neutrophils for 0.5–2 h with gliotoxin (0.3–10 μM) revealed no cytotoxic effects (MTT assay, not shown). In sharp contrast, zileuton inhibited the formation of all 5-LO products, as expected, while the LTA₄H inhibitor SC-57461A modulated 5-LO product biosynthesis in the same way as gliotoxin, that is, inhibition of LTB₄ formation with moderate impairment of 5-HETE but strong elevation of tr-LTB₄ isomers (Figure 2A).

Besides neutrophils, monocytes possess high capacities to generate LTB₄ and in addition also express LTC₄S and, thus, substantially produce LTC₄ from LTA₄ (Lam and Austen, 2002; Surette et al., 1993). Like in neutrophils, gliotoxin potently suppressed A23187-induced LTB₄ formation in human monocytes (IC₅₀ = 0.8 ± 0.1 μM) with concomitant increase of LTC₄ (Figure 2B). In contrast, zileuton blocked the formation of all 5-LO products, while SC-57461A, in analogy to gliotoxin, inhibited only LTB₄ formation but not the formation of other 5-LO-derived products (Figure 2B). Finally, we analyzed the eicosanoid profiles in neutrophils and monocytes more comprehensively to learn about modulation of other biosynthetic enzymes and redirection of substrates for LM formation. Gliotoxin caused only moderate or non-significant suppression of 5-, 12-, and 15-HETE formation in both cell types, but, interestingly, increased (besides tr-LTB₄ isomers and LTC₄) also lipoxin (LX) A₄ formation (Figures 2C and 2D), which is another LTA₄ hydrolysis product that requires 5-LO and 15-LO activity for its biosynthesis but not LTA₄H (Serhan and Samuelsson, 1988). Increased LXA₄ formation was also evident with SC-57461A but not with zileuton, which blocked LXA₄ formation as expected. Collectively, gliotoxin potently and selectively inhibited LTB₄ formation with concomitant increase of other LTA₄ hydrolysis products, thus sharing pharmacodynamic profiles with the LTA₄H inhibitor SC-57461A.

Gliotoxin Represents the Virulence Factor of *A. fumigatus* that Inhibits LTB₄ Formation

We aimed to investigate if products secreted by *A. fumigatus* would mimic the LTB₄-suppressive effects of gliotoxin. In analogy to gliotoxin, supernatants from *A. fumigatus* cultures suppressed LTB₄ biosynthesis in neutrophils along with elevated levels of tr-LTB₄ isomers (Figure 3A). To trace this effect back to gliotoxin, we made use of an *A. fumigatus* strain unable to produce gliotoxin due to a mutation of the nonribosomal peptide synthetase GliP involved in gliotoxin biosynthesis (Δ gliP strain) (Hillmann et al., 2015). Supernatants from the Δ gliP strain failed to suppress LTB₄ formation and to elevate tr-LTB₄ isomers. Of interest, neutrophils in the lesions of lungs infected with gliotoxin-producing *A. fumigatus* (wild-type) displayed extensive nuclear fragmentation as a sign for apoptosis and/or necrosis (Figure 3B), suggesting direct neutrophil killing by gliotoxin (in agreement with Comera et al., 2007 and Spikes et al., 2008), whereas neutrophils infiltrated around Δ gliP hyphae appeared intact (Figure 3C). These data indicate that gliotoxin as part of the secretome of *A. fumigatus* is causative for inhibition of LTB₄ biosynthesis in neutrophils and support this

(A and B) Inhibition of 5-LO product formation in intact human neutrophils (A) and in human monocytes (B). Cells were pre-incubated with gliotoxin, SC-57461A, zileuton, or 0.1% (v/v) DMSO (vehicle) for 10 min at 37°C prior stimulation with 2.5 μ M A23187. Formation of tr-LTB₄ isomers, LTB₄, and 5-HETE was analyzed after 10 min by reversed-phase high-performance liquid chromatography (RP-HPLC). LTC₄ formation in monocytes was evaluated by ELISA. Data are means \pm SEM; n = 4, ***p < 0.001; **p < 0.01; *p < 0.05; inhibitor versus vehicle control (100%), one-way ANOVA plus Bonferroni *post hoc* test. (C and D) Effect of gliotoxin on eicosanoid formation in human neutrophils (C) and in human monocytes (D). Cells were pre-incubated with 1 μ M gliotoxin, 3 μ M zileuton, 0.1 μ M SC-57461A, or 0.1% (v/v) DMSO (vehicle) for 10 min at 37°C prior stimulation with 2.5 μ M A23187 for another 10 min. Formed eicosanoids were analyzed by UPLC-MS/MS. Data are means \pm SEM; n = 4, duplicates. ***p < 0.001; **p < 0.01; *p < 0.05; inhibitor versus vehicle control, Student's t test.

Figure 3. Gliotoxin Represents the Virulence Factor of *A. fumigatus* that Inhibits LTB₄ Formation

(A) Effect of crude extracts obtained from supernatants of *A. fumigatus* wild-type or *A. fumigatus* $\Delta gliP$ mutant cultures on LT formation in intact human neutrophils. After pre-incubation of neutrophils with the extracts for 15 min at 37°C, cells were stimulated with 2.5 μ M A23187 for 10 min. Formed LT were analyzed by RP-HPLC. Data are means \pm SEM; n = 3, **p < 0.01; inhibitor versus vehicle control, Student's t test.

(B) Histopathology of lungs of corticosteroid-treated mice 4 days after infection with *A. fumigatus* wild-type or $\Delta gliP$ conidia showing representative areas of bronchopneumonia; similar results were obtained in three additional mice, each. Non-neutropenic female CD-1 mice were infected intranasally with 2×10^5 conidia. For histopathology, 4- μ m sections of lungs were stained with periodic acid-Schiff (hyphae stain pink, neutrophils stain blue). Hyphae are surrounded by inflammatory tissue; details are presented in the lower panels; white arrows indicate filamentous hyphae and black arrows point to neutrophils. As control, a lung section of a PBS-treated mouse is shown.

trienoic acids (EETs) into di-hydroxy-eicosatrienoic acids (di-HETEs) (Morisseau and Hammock, 2013). A549 and HepG2 cells express sEH, which converts exogenously added 14,15-EET to the corresponding 14,15-diHETE (Garscha et al., 2017). Gliotoxin (and SC-57461A) failed to inhibit 14,15-diHETE formation in either cell type up to 10 μ M, whereas the sEH inhibitor 12-

(3-adamantan-1-yl-ureido) dodecanoic acid (AUDA, 5 μ M) inhibited this reaction (Figure 4B), as expected.

action as potential virulence mechanism of *A. fumigatus* triggering IA.

Gliotoxin Selectively Inhibits the Epoxide Hydrolase Activity of the Bifunctional LTA₄H

Next, we investigated whether gliotoxin, apart from the epoxide hydrolase function, also inhibits the aminopeptidase activity of LTA₄H. SC-57461A (Askonas et al., 2002) and captopril (Orning et al., 1991) inhibit both enzyme activities, while ARM1 is a selective epoxide hydrolase inhibitor and does not affect the aminopeptidase activity (Stsiapanava et al., 2014). The target peptide PGP was added to human neutrophils, and its enzymatic degradation was recorded by liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis. Pre-treatment with gliotoxin efficiently reduced LTB₄ formation but failed to inhibit the aminopeptidase activity up to 10 μ M (Figure 4A). Captopril and SC-57461A suppressed both LTA₄H activities, whereas ARM1 inhibited LTB₄ formation but not PGP degradation (Figure 4A), as expected (Stsiapanava et al., 2014). We then investigated if gliotoxin could affect also other relevant epoxide hydrolases involved in eicosanoid biosynthesis, such as the soluble epoxide hydrolase (sEH), which converts epoxy-eicosa-

The Cellular Environment Confers Gliotoxin LTA₄H-Inhibitory Activity

To demonstrate direct interference with LTA₄H activity in a cell-free assay, we analyzed gliotoxin (and SC-57461A as control) against crude LTA₄H in neutrophil homogenates. To these homogenates, gliotoxin, SC-57461A, or vehicle were added, and after 10 min, 20 μ M AA was provided for 5-LO to generate LTA₄ as substrate for LTA₄H *in situ*. Interestingly, in contrast to intact neutrophils, LTB₄ formation under these cell-free conditions was only moderately inhibited by gliotoxin and tr-LTB₄ isomers were not elevated, while SC-57461A efficiently blocked LTB₄ formation and elevated tr-LTB₄ isomers as expected (Figure 5A). We then first pre-incubated intact neutrophils for 10 min with gliotoxin and subsequently prepared homogenates to assay LTA₄H activity as described above. Under these conditions, gliotoxin efficiently inhibited LTB₄ biosynthesis in homogenates with IC₅₀ = 0.6 \pm 0.1 μ M and elevated tr-LTB₄ isomers (Figure 5B). These data imply that gliotoxin may (1) require the cellular environment for bioactivation to enable interference

Figure 4. Gliotoxin Selectively Inhibits the Epoxide Hydrolase Activity of the Bifunctional LTA₄H

(A) Effect of gliotoxin and other LTA₄H inhibitors on the epoxide hydrolase activity (LTB₄ formation) and on the aminopeptidase activity (PGP degradation) of LTA₄H in intact human neutrophils. Neutrophils were pre-incubated with test compounds or 0.1% DMSO (vehicle) for 10 min at 37°C. For analysis of epoxide hydrolase activity, cells were stimulated with 2.5 μ M A23187 for 10 min at 37°C and formed LTB₄ was analyzed by RP-HPLC. For analysis of aminopeptidase activity, 1 μ M PGP plus 1 μ M N-acetyl-PGP was added, and after 2 h PGP degradation was assessed by UPLC-MS/MS. Data are provided as means \pm SEM; n = 3–4, ***p < 0.001; **p < 0.01; *p < 0.05; inhibitor versus vehicle control, ANOVA plus Bonferroni test.

(B) A549 or HepG2 cells were pre-incubated with gliotoxin, 0.3 μ M SC-57461A, 5 μ M AUDA, or 0.1% DMSO (vehicle) for 15 min at 37°C. Then, cells were incubated with 1.5 μ M 14,15-EET for 30 min at 37°C. Formed 14,15-DiHETE was measured by UPLC-MS/MS. Data are provided as means \pm SEM; n = 3, *p < 0.05; inhibitor versus vehicle control, ANOVA plus Bonferroni test.

with LTA₄H and (2) may act in an irreversible fashion with the enzyme. In fact, pre-incubation of neutrophils with gliotoxin and subsequent wash-out retained the ability to inhibit LTB₄ formation in homogenates without any loss of potency (Figure 5C), supporting persistent/irreversible interaction.

Reducing Conditions Activate Gliotoxin for Inhibition of LTA₄H

Based on the proposed redox-cycling mechanism of gliotoxin (Scharf et al., 2016), we assumed that reduction of the disulfide of gliotoxin to the dithiol form inside the cell (e.g., by GSH) is a prerequisite for inhibition of LTA₄H. In fact, when the oxidative status of neutrophils was elevated by diamide (Jakobsson et al., 1992), the strong LTA₄-inhibitory potency of gliotoxin (but not of SC-57461A) was lost (Figure 6A). In a cell-free assay, gliotoxin only moderately inhibited LTB₄ formation by isolated LTA₄H from *in-situ*-generated LTA₄ (by isolated 5-LO from exogenous AA), while SC-57461A was fully active in this respect, and zileuton blocked formation of all 5-LO products (Figure 6B). Similarly, gliotoxin hardly inhibited the hydrolysis of L-arginine-7-amido-4-methylcoumarine, a suitable substrate for both the aminopeptidase and the epoxide hydrolase activity (Wittmann et al., 2016), by isolated human recombinant LTA₄H (Figure 6C). However, pre-treatment of gliotoxin with 5 mM

GSH restored LTA₄H inhibition in the cell-free assay, while in the presence of oxidized glutathione (GSSG) gliotoxin failed in this respect (Figure 6C). Analysis of gliotoxin from these incubations by ultra-performance liquid chromatography (UPLC)-MS confirmed that in the presence of GSH the disulfide was cleaved to the dithiol, while with GSSG or in absence of GSH gliotoxin was in the disulfide form (Figure 6D). LTA₄H is a Zn²⁺ metalloenzyme and it appeared possible that gliotoxin may act by complexing the catalytic Zn²⁺ ion in the active site of LTA₄H. Interestingly, inclusion of 100 μ M ZnCl₂ in the cell-free assay (in the presence of GSH) abolished the inhibitory effect of gliotoxin on isolated LTA₄H (Figure 6C), suggesting that gliotoxin could interact with Zn²⁺. Similarly, when neutrophils were pre-incubated with gliotoxin prior to sonication and subsequent incubation of the homogenates in the presence of 200 μ M ZnCl₂, inhibition of LTB₄ formation by gliotoxin was strongly impaired (Figure 6E). Notably, LTA₄H inhibition by SC-57461A was not affected by ZnCl₂ addition (Figure 6E). These data support the hypothesis that the disulfide of gliotoxin becomes cleaved within the reducing milieu (\approx 5 mM GSH) in intact cells and that the dithiol form then acts in the active site of the epoxide hydrolase center of LTA₄H. In this respect, among various gliotoxin derivatives isolated from *A. fumigatus*, only compound 1, a biosynthetic intermediate with an intramolecular

Figure 5. The Cellular Environment Confers Gliotoxin LTA₄H-Inhibitory Activity

(A) Effects of gliotoxin and SC-57461A on LT formation in cell-free neutrophil homogenates. Neutrophil homogenates were pre-incubated with test compounds or vehicle (0.1% DMSO) for 10 min on ice, pre-warmed for 30 s at 37°C, and then 20 μ M AA plus 2 mM CaCl₂ was added. After 10 min, formation of tr-LTB₄ isomers, LTB₄, and 5-H(p)ETE was analyzed by RP-HPLC.

(B) Intact human neutrophils were first pre-incubated with test compounds or vehicle (0.1% DMSO) for 10 min at 37°C, placed on ice and sonicated. Then, the resulting homogenates were pre-warmed for 30 s at 37°C, 20 μ M AA plus

disulfide bond, inhibited LTB₄ formation and tr-LTB₄ isomers as gliotoxin did (Figure S2).

DISCUSSION

We show here that gliotoxin causes specific suppression of LTB₄ biosynthesis without inhibiting the formation of additional products from the same substrate (i.e., LTA₄) or related LMs generated by other enzymatic eicosanoid pathways. These LTB₄-suppressing properties of gliotoxin are directly related to selective inhibition of the epoxide hydrolase activity of LTA₄H, which either requires the cellular environment and/or reducing conditions. Our data suggest that the inactive disulfide form of gliotoxin is reduced into the bioactive dithiol, which may then target the Zn²⁺ within the active site in LTA₄H. Because LTB₄ is one of the most potent and relevant chemoattractants for neutrophils (Afonso et al., 2012; Lammernann et al., 2013) and critical for neutrophil-mediated host resistance against IA (Caffrey-Carr et al., 2017), suppression of neutrophil infiltration by gliotoxin could be the consequence of abrogated LTB₄ generation. Therefore, our data provide a molecular basis for the neutrophil-compromising properties of *A. fumigatus* during infections.

To assess LTB₄ formation and related neutrophil recruitment we used two different LT-driven *in vivo* models, i.e., zymosan-induced peritonitis in mice (Rao et al., 1994) and carrageenan-induced pleurisy in rats (Cuzzocrea et al., 2003). Both, gliotoxin and the 5-LO inhibitor zileuton strongly suppressed LTB₄ formation in these models, along with marked inhibition of neutrophil infiltration at sites of injury. Suppression of LTB₄ levels in intact cells or *in vivo* may generally be achieved via diverse modes of actions, such as direct inhibition of cPLA₂, 5-LO, FLAP, or LTA₄H, by interference with upstream signaling pathways of these enzymes, or by promoting LTB₄ metabolism (Werz et al., 2017). While zileuton reduced the levels of all 5-LO-derived products to a comparable degree, as expected, gliotoxin selectively suppressed LTB₄ formation without lowering any other LMs. Of interest, gliotoxin increased the amounts of tr-LTB₄ isomers and LTC₄ at the expense of LTB₄, seemingly due to redirection of LTA₄ as substrate, excluding cPLA₂, 5-LO, or FLAP as targets, but instead favoring LTA₄H as point of attack. Such substrate shunting from LTB₄ toward tr-LTB₄ isomers or LTC₄ due to LTA₄H blockade was observed for other LTA₄H inhibitors as well (Kachur et al., 2002; Rao et al., 2007; Shindo et al., 1994). Inhibition of LTB₄ formation by gliotoxin, accompanied by an increase of alternative LTA₄ hydrolysis products (e.g., tr-LTB₄ isomers, LTC₄, and LXA₄), was also observed in A23187-stimulated neutrophils or monocytes, effects that were shared with the LTA₄H inhibitor SC-57461A but not with zileuton, which inhibited the formation of all 5-LO-derived products. Elevated levels of the

2 mM CaCl₂ was added, and after 10 min formation of tr-LTB₄ isomers, LTB₄, and 5-H(p)ETE was analyzed by RP-HPLC.

(C) Intact human neutrophils were pre-incubated with test compounds or vehicle (0.1% DMSO) for 10 min at 37°C, centrifuged, resuspended in fresh PG buffer, sonicated, and the resulting homogenates were pre-warmed for 30 s at 37°C. Then, 20 μ M AA plus 2 mM CaCl₂ was added, and after 10 min formation of tr-LTB₄ isomers, LTB₄, and 5-HETE was analyzed by RP-HPLC.

(A) Intact human neutrophils were pre-incubated with 50 μM diamide or vehicle (PBS) for 3 min at room temperature. Then, neutrophils were incubated with test compounds or vehicle (0.1% DMSO) for 10 min and stimulated with 2.5 μM A23187 plus 20 μM AA for 10 min at 37°C. LTB₄ formation was analyzed by RP-HPLC. (B) Inhibition of 5-LO/LTA₄H-coupled LTB₄ formation from *in-situ*-generated LTA₄ by gliotoxin (10 μM), zileuton (3 μM), SC-57461A (0.1 μM), or vehicle (0.1% DMSO) in a cell-free assay. Purified 5-LO and LTA₄H were pre-incubated with test compounds or 0.1% DMSO (vehicle) for 10 min on ice, pre-warmed for 30 s at 37°C, and 20 μM AA plus 2 mM CaCl₂ was added. After 10 min at 37°C, formation of tr-LTB₄ isomers, LTB₄, and 5-H(p)ETE was analyzed by RP-HPLC.

(C and D) Glutathione confers inhibition of LTA₄H activity by gliotoxin in a cell-free assay; effects of Zn²⁺ ions. Gliotoxin was pre-incubated with GSH or GSSG (5 mM, each), in the presence or absence of ZnCl₂ (100 μM) at 37°C for 2 h. (C) Purified LTA₄H and substrate were added. Reaction was monitored for 60 min to determine LTA₄H activity. (D) In parallel, aliquots of these incubations were analyzed by UPLC-MS/MS for gliotoxin in reduced (dithiol) or oxidized (disulfide, blue) form.

(E) Neutrophils were pre-incubated with test compounds for 10 min at 37°C, placed on ice, and sonicated. The resulting homogenates were supplemented with 200 μM ZnCl₂ or vehicle (water), pre-incubated for 30 s at 37°C, and then incubated with 20 μM AA plus 2 mM CaCl₂ for 10 min at 37°C. LTB₄ formation was analyzed by RP-HPLC.

Data are means ± SEM; n = 3–4; ***p < 0.001; **p < 0.01 inhibitor versus vehicle control (100%), one-way ANOVA plus Bonferroni. See also Figure S2.

anti-inflammatory LXA₄ may counter-regulate the inflammatory response and sustain chemotaxis and migration of neutrophils (Serhan and Samuelsson, 1988).

A remarkable characteristic of gliotoxin as an LTA₄H inhibitor is its apparent selectivity against epoxide hydrolase function without affecting aminopeptidase activity, a feature that was shared with ARM1 (Stsiapanava et al., 2014). Most of the known LTA₄H inhibitors including SC-57461A and captopril block both activities (Caliskan and Banoglu, 2013). As aminopeptidase ac-

tivity degrades the chemoattractant peptide PGP, implying anti-inflammatory properties of LTA₄H, inhibition of the aminopeptidase activity might be detrimental, and selective interference with epoxide hydrolase function is favored (Caliskan and Banoglu, 2013; Stsiapanava et al., 2014). Since the epoxide hydrolase activity of sEH, which hydrolyses structurally related eicosanoid epoxides (Wagner et al., 2017), was not affected by gliotoxin, promiscuous interference with epoxide hydrolases in eicosanoid metabolism in general is unlikely.

CellPress

Several molecular targets of gliotoxin have been proposed before, including I κ B α /NF- κ B (Pahl et al., 1996), alcohol dehydrogenase (Waring et al., 1995), creatine kinase (Hurne et al., 2000), farnesyl transferase (Van der Pyl et al., 1992), chymotrypsin-like activities of the 20S proteasome (Kroll et al., 1999), the flavocytochrome b558 of NAPH oxidase (Nishida et al., 2005), and X-linked neuroigin 4 (Scafuri et al., 2017). Gliotoxin contains an internal disulfide bridge, and, interestingly, either the oxidized disulfide form or the reduced dithiol form was shown to be the active moiety depending on the target enzyme studied (Scharf et al., 2012). For inhibition of LTA₄H, the reduced dithiol form of gliotoxin was required. Cleavage of the disulfide can be achieved by treatment with excess of thiols such as GSH or dithiothreitol (Trown and Bielelo, 1972). Indeed, gliotoxin inhibited LTA₄H activity in the cell-free assays only when exogenous GSH was provided, and gliotoxin blocked LTA₄H activity in intact leukocytes where abundant cytosolic GSH is present. On the other hand, intracellular GSH depletion in neutrophils by diamide impaired the potency of gliotoxin but not that of SC-57461A. We propose that the free thiol moieties of reduced gliotoxin interferes with the active site in LTA₄H that coordinates the epoxide moiety of LTA₄ (Stsiapanava et al., 2017). Possibly, gliotoxin chelates the active site Zn²⁺, supported by the finding that excess of Zn²⁺ ions abolished the inhibitory activities of gliotoxin but not of SC-57461A, probably by capturing gliotoxin's thiol groups. Along these lines, the disulfide-containing antibiotic thiolactin acts as a Zn²⁺ chelator under reducing conditions (presence of dithiothreitol) thereby inhibiting JAMM metalloproteases, an effect that was abrogated by exogenous addition of Zn²⁺ ions as well (Lauinger et al., 2017). Attempts to demonstrate binding of gliotoxin to LTA₄H using MS-based proteomics failed to yield experimental support for covalent modification of the enzyme (data not shown).

Humans are continuously exposed to inhaled *A. fumigatus* conidia and healthy hosts can clear the organism without antibody- or cell-mediated acquired immunity (Park and Mehrad, 2009). Thus, innate immunity appears to be sufficient to resist against *A. fumigatus* for healthy humans, while for immunocompromised patients who lack efficient innate immune responses, *A. fumigatus* infections cause severe pulmonary diseases along with substantial mortality (Park and Mehrad, 2009; Segal, 2009). Neutrophils are key effector cells required for resistance against *A. fumigatus* infection (Comera et al., 2007; Heinekamp et al., 2015; Spikes et al., 2008; Sugui et al., 2007), and neutropenia is a key risk factor for patients who develop IA (Park and Mehrad, 2009; Sugui et al., 2007). Recent data demonstrate a crucial role of host-derived LTB₄ for neutrophil recruitment and innate immunity against *A. fumigatus* infection in murine lungs (Caffrey-Carr et al., 2017). These facts further support the hypothesis that suppression of LTB₄ formation by gliotoxin is a crucial mechanism underlying its neutrophil-compromising properties in the infected host. In this respect, gliotoxin is a virulence factor of *A. fumigatus* that mediates immunocompromising properties by primarily targeting neutrophils (Comera et al., 2007; Spikes et al., 2008; Sugui et al., 2007; Sutton et al., 1996). Thus, abrogation of gliotoxin production in *A. fumigatus* by deletion of *gliP* impaired the virulence in mice immunosuppressed with cortisone that still have residual neutrophil activity (Spikes et al., 2008), but not in neutropenic mice basically lacking neutrophils

(Kupfahl et al., 2006; Spikes et al., 2008). This finding confirms the requirement of neutrophils for gliotoxin's immunosuppressive actions. Our present data showing that the Δ *gliP* strain failed to suppress LTB₄ formation and to compromise neutrophils, indicate that gliotoxin as part of the secretome of *A. fumigatus* is the primary mycotoxin that is causative for inhibition of LTB₄ formation, and support this action as a potential virulence mechanism of gliotoxin in IA. Apparently, reduced chemotaxis and direct neutrophil killing are causative for gliotoxin's detrimental effects on neutrophils during *A. fumigatus* infection.

Together, we reveal LTA₄H as molecular target of gliotoxin and, thus, propose inhibition of LTB₄ biosynthesis as biological relevant mode of action of this mycotoxin from *A. fumigatus*. Because LTB₄ is a major chemoattractant for neutrophils with crucial roles in neutrophil-mediated host resistance against IA, suppression of LTB₄ formation by gliotoxin may underlie its neutrophil-compromising properties.

SIGNIFICANCE

The fungal pathogen *Aspergillus fumigatus* is the most common cause of invasive aspergillosis which affects primarily immunocompromised patients with a mortality rate of 30%–95%. Humans are continuously exposed to inhaled *A. fumigatus* conidia, and healthy hosts can clear the organism without antibody- or cell-mediated acquired immunity. The epidithiodioxopiperazine gliotoxin is well recognized as one of the virulence factors of *A. fumigatus* that suppresses innate immunity in humans, particularly by compromising neutrophils. A variety of bioactivities were reported for gliotoxin, such as induction of apoptosis and angiogenesis, inhibition of NF- κ B, suppression of reactive oxygen species generation by phagocytes, and induction of changes in cell morphology and cell adhesion of neutrophils. However, the molecular mechanisms underlying the immunosuppressing properties of gliotoxin remain elusive. Recently, the host-derived chemoattractant leukotriene (LT) B₄ was shown to be critical for neutrophil recruitment and resistance to pulmonary *A. fumigatus* challenge in mice. Here, we show that gliotoxin specifically abrogates the biosynthesis of LTB₄, an arachidonic acid-derived lipid mediator that is among the most potent and relevant chemoattractants for neutrophils. Thus, pre-treatment of mice and rats with gliotoxin effectively blocked agonist-induced neutrophil recruitment along with reduced levels of circulating LTB₄, while other lipid mediators were not suppressed. These LTB₄-suppressing properties of gliotoxin are mediated through selective inhibition of leukotriene A₄ hydrolase (LTA₄H), the key enzyme in LTB₄ biosynthesis. Since LTB₄ is critical for neutrophil-mediated host resistance against invasive aspergillosis, we suggest that the immunosuppressive properties of gliotoxin are directly related to abrogated LTB₄ generation. Based on the unmet medical need for efficient therapeutics to intervene with *A. fumigatus* immunopathology, understanding of the mechanisms underlying its virulence factors is of utmost importance. Therefore, our data provide a molecular basis for the neutrophil-compromising properties of *A. fumigatus* during infections, and reveal LTA₄H as a functional, molecular target of gliotoxin.

EXPERIMENTAL MODEL AND SUBJECT DETAILS**Animals**

For the murine infection model, specific-pathogen-free female outbred CD-1 mice (18-20 g) were supplied by Charles River (Sulzfeld, Germany). Animals were housed under standard conditions in individually ventilated cages and fed with normal mouse chow and water ad libitum. All animals were cared for in accordance with the European animal welfare regulation and approved by the responsible federal/state authority and ethics committee in accordance with the German animal welfare act (permit no. 03-001/12).

Male adult CD-1 mice (6-8 weeks, Charles River Laboratories, Calco, Italy) for the peritonitis model and Male Wistar Han rats (200-240 g, Harlan, San Pietro al Natisone, Italy) for the pleurisy model, were housed in a controlled environment and provided with standard rodent chow and water. The experimental procedures were approved by the Italian Ministry according to the guidelines of Italian (N. 26/2014) and European Council law (N.63/2010/UE) for animal care.

Human Cells

Monocytes and neutrophils were isolated from peripheral blood of human adult healthy male and female volunteers (18-65 years) as described (Pace et al., 2017b) and with consent obtained from the Institute of Transfusion Medicine, University Hospital Jena. Individual blood samples provided and used for isolation of the leukocytes were blinded and the exact age and the sex of the donor was unknown. The protocols for experiments with human neutrophils and monocytes were approved by the ethical commission of the Friedrich-Schiller-University Jena (approval no. 4025-02/14). All methods were performed in accordance with the relevant guidelines and regulations. Leukocyte concentrates were prepared by centrifugation (4000×g, 20 min, 20°C). Venous blood was collected in heparinized tubes (16 I.E. heparin/mL blood). Peripheral blood mononuclear cells (PBMCs) and neutrophils were freshly isolated by dextran sedimentation and centrifugation on lymphocyte separation medium (Histopaque®-1077, Sigma Aldrich). Remaining erythrocytes were removed by hypotonic lysis using water, and resulting neutrophils were resuspended in PBS containing 0.1% (w/v) glucose (PG buffer) or PBS containing 0.1% (w/v) glucose plus 1 mM CaCl₂ (PGC buffer) as indicated. PBMCs were seeded in RPMI 1640 (Sigma Aldrich) supplemented with 10% heat inactivated fetal calf serum (FCS), 100 U/mL penicillin and 100 µg/mL streptomycin in cell culture flasks (Greiner Bio-one, Frickenhausen, Germany) for 1.5 hrs at 37°C, 5% CO₂. Adherent monocytes were washed twice with PBS, and finally resuspended in PG or PGC buffer as indicated.

A549 cells (ATCC CCL-185, obtained from a 58 years male human donor) were cultured in monolayers at 37°C and 5% CO₂ in DMEM supplemented with 10% (v/v) FCS, 100 U/mL penicillin and 100 µg/mL streptomycin. HepG2 cells (ATCC HB-8065, obtained from a 15 years male human donor) were cultured at 37°C and 5% CO₂ in RPMI 1640 containing 10% (v/v) FCS, 100 U/mL penicillin and 100 µg/mL streptomycin.

METHODS DETAILS**Murine Infection Model**

CD-1 mice were immunosuppressed with two single doses of 25 mg cortisone acetate (Sigma-Aldrich, Taufkirchen, Germany), which were injected intraperitoneally (i.p.) three days before and immediately prior to infection (day 0). Mice were anesthetized by an i.p. anesthetic combination of midazolam, fentanyl, and medetomidine. Conidia (2×10^5 in 20 µL PBS) were applied to the nares of the mice. Deep anesthesia ensured inhalation of the conidia. Anesthesia was terminated by subcutaneous injection of flumazenil, naloxon and atipamezol. Infected animals were monitored at least twice daily and humanely sacrificed if moribund (defined by severe lethargy, severe dyspnea, hypothermia, or substantial weight loss). For histopathological analyses lungs from sacrificed animals

were removed, fixed in formalin and paraffin-embedded according to standard protocols. 4 μ m sections were stained with Periodic Acid-Schiff (PAS) using standard protocols. Sections were analyzed with a Zeiss Axio Imager.M2 microscope (Carl Zeiss, Jena, Germany). Images were taken with an AxioCam 105 color and analyzed by AxioVision SE64 Rel. 4.9.1 Imaging-Software (Carl Zeiss).

Murine Peritonitis Model

CD-1 mice were treated with i.p. injections of gliotoxin (5 mg/kg), zileuton (10 mg/kg) or vehicle (0.9% saline solution containing 2% (v/v) DMSO) 30 min prior induction of peritonitis by zymosan i.p. injection (0.5 mL, 2 mg/mL in 0.9% saline solution). Four hrs after zymosan injection, mice were euthanized by CO₂ inhalation. For analysis of infiltrated cells, 2 mL peritoneal exudates were collected by lavage of the peritoneal cavity with PBS. Infiltrated cells were stained with trypan blue and counted using a Burkner chamber under a light microscope.

For the analysis of lipid mediators in the plasma, blood (approximately 0.7–0.9 mL) was collected by intracardiac puncture using citrate as anticoagulant. Plasma was obtained by centrifugation of the blood at 800 \times g at 4°C for 10 min and immediately frozen at –80°C. Plasma samples were used to analyze LTB₄ levels by ELISA (ENZO life sciences, Lörrach, Germany), and other lipid mediators by UPLC-MS-MS. For preparation of samples for UPLC-MS-MS analysis, plasma samples were centrifuged (400 \times g, 10 min, 4°C), and 400 μ L supernatant were mixed with 1 mL methanol containing 200 ng of PGB₁. After 1 hr at –20°C, precipitated proteins were removed by centrifugation (1200 \times g, 10 min, 4°C) and lipid mediators were purified by C18 RP solid phase extraction prior to measurement by UPLC-MS-MS as reported before (Pace et al., 2017a).

Carrageenan-Induced Pleurisy in Rats

Rats were treated i.p. with gliotoxin (1.5 mg/kg and 5 mg/kg), zileuton (10 mg/kg) or vehicle (4% DMSO) 30 min before intrathoracic injection of λ -carrageenan type IV (1%, w/v, 0.2 mL). For injection of carrageenan, rats were narcotized with 4% (v/v) enfluran mixed with 0.5 L/min O₂, 0.5 L/min N₂ and applied to a skin incision at the level of the left skin intercostal space. The skin incision was closed and rats were allowed to recover. After 2 hrs of pleurisy induction, rats were sacrificed by CO₂ inhalation prior to obtaining 2 mL thoracic exudate by lavage of the cavity with 2 mL PBS. The number of infiltrated neutrophils was determined by light microscopy using a Burkner chamber and vital trypan blue staining (Pace et al., 2017a). Collected plasma was used to determine circulating LTB₄ by ELISA (Enzo life sciences) and lipid mediators by UPLC-MS-MS as described for murine peritonitis above.

Cultivation of *A. fumigatus*, Preparation of Culture Supernatants

A. fumigatus strain CEA17 Δ akuB derives from the sequenced clinical isolate A1163 and was used to generate the Δ gliP mutant by targeted gene deletion as previously described (Hillmann et al., 2015). Fungal strains were cultivated from frozen conidia stock solutions for 5 days at 37°C on malt-extract agar plates. Conidia were harvested in PBS and filtrated through a 30 μ m MACS SmartStrainer (Miltenyi Biotec, Bergisch Gladbach, Germany) to remove mycelial debris. Conidia were counted with a CASY cell counter. 6×10^7 conidia of the Δ gliP mutant or the wild type were cultivated in 30 mL Czapek Dox medium (BD Biosciences, Heidelberg, Germany) for six days at 28°C and shaking at 220 rpm. The supernatant was filtrated using miracloth gaze and sterilized by passing through a 0.2 μ m filter. The filtrate was vacuum dried for 36 hrs and the precipitate was resuspended in sterile PBS.

5-LO Product Formation in Neutrophils or Monocytes and in Corresponding Homogenates

Human neutrophils or monocytes (5×10^6 /mL) were resuspended in PGC buffer and pre-incubated with test compounds, precipitates from *A. fumigatus* cultures, or 0.1% (v/v) vehicle for 10 min at 37°C prior stimulation with 2.5 μ M A23187. In some set of experiments, neutrophils were first pre-incubated with or without 50 μ M diamide for 3 min prior to addition of test compounds or vehicle. After 10 min at 37°C, 5-LO product formation was stopped on ice. An aliquot (100 μ L) of the monocyte suspension was removed and used for measuring cysLT by ELISA. To the remaining monocyte suspension and the entire neutrophil suspension, one volume of ice-cold methanol was added. Then, 530 μ L acidified PBS and 200 ng of PGB₁ as internal standard were added and samples were purified by RP18 solid phase extraction. 5-LO products were eluted with methanol and subsequently measured with RP-HPLC using a C18 RP Radial PAK column (Waters, Eschborn, Germany) or optionally by UPLC-MS-MS as described (Pace et al., 2017a).

To determine 5-LO product formation in cell homogenates, neutrophils were resuspended in PBS containing 1 mM EDTA (5×10^6 cells/mL). Cells were lysed on ice by sonication (3 \times 20 sec). Cell homogenates were pre-incubated with compounds or 0.1% (v/v) vehicle for 10 min on ice, pre-warmed for 30 sec at 37°C, and 20 μ M AA and 2 mM CaCl₂ was added. After 10 min at 37°C, the reaction was stopped by addition of 1 mL ice-cold methanol and 5-LO products were analyzed as described above for intact cells. In some experiments, neutrophils were first pre-incubated with the test compounds or 0.1% (v/v) vehicle for 10 min at 37°C, the samples were placed on ice, homogenates were prepared by sonication (3 \times 20 sec), and then 5-LO activity in the cell homogenates was determined as described above. For wash out experiments, neutrophils were first pre-incubated with compounds or 0.1% (v/v) vehicle for 10 min at 37°C, then spun down at 1200 rpm, resuspended in PBS containing 1 mM EDTA, and homogenates were prepared.

Expression and Purification of Human Recombinant 5-LO and LTA₄H

Human recombinant 5-LO was expressed overnight in *Escherichia coli* BL21 cells transformed with the pT3-5-LO vector as described previously (Fischer et al., 2003), followed by sonication (3 \times 20 sec) on ice. For purification of 5-LO, ATP affinity chromatography was used. Homogenates were centrifuged at 40,000 \times g (20 min, 4°C) and the supernatant was loaded on an ATP-agarose

CellPress

(Sigma-Aldrich) column, washed with 50 mM phosphate buffer (PB) containing 1 mM EDTA and eluted with PB supplemented with 1 mM EDTA and 20 mM ATP. Isolated 5-LO was immediately used for activity assays together with isolated LTA₄H.

Human recombinant LTA₄H was expressed and purified according to Moser et al. (2015). In brief, LTA₄H was expressed in *E. coli* BL21(DE3)RPL-Codon Plus cells (Invitrogen, Darmstadt, Germany) transformed with pET24(+)-LTA₄H expression-plasmid. Cells were lysed and recombinant LTA₄H was purified by immobilized metal ion affinity chromatography (5 mL HisTrap HP column, GE Healthcare Life Science, Freiburg, Germany). LTA₄H was subsequently purified by size exclusion chromatography (Superdex200 column, GE Healthcare Life Science) with running buffer containing 50 mM Tris-HCl, 50 mM NaCl at pH 8. Pure protein was stored as glycerol stocks (20% (v/v) glycerol) at -80°C.

Determination of the Epoxide Hydrolase Activity of LTA₄H Activity from *In-Situ* Generated LTA₄

To assay the epoxide hydrolase activity of LTA₄H with *in situ* generated LTA₄, 0.5 µg purified 5-LO and 5 µg human recombinant LTA₄H were incubated with compounds or 0.1% (v/v) vehicle in 1 mL PBS containing 1 mM EDTA on ice. Samples were pre-warmed at 37°C for 30 sec, and 20 µM AA plus 2 mM CaCl₂ were added to start the reaction. After 10 min at 37°C, 1 mL ice-cold methanol was added and the formed lipid mediators were analyzed by RP-HPLC as described above.

Determination of the Epoxide Hydrolase Activity of LTA₄H in a Cell-free Fluorescence-Based Assay

The epoxide hydrolase activity of recombinant LTA₄H using L-arginine-7-amido-4-methylcoumarine as substrate for both functionalities, the aminopeptidase and the epoxide hydrolase activity, was determined as described before (Wittmann et al., 2016) with some minor modifications. 10 µL of the premixes of assay buffer (50 mM Tris-HCl, 50 mM NaCl, pH 8) with or without ZnCl₂ (100 µM), GSH (5 mM) or GSSG (5 mM) were incubated with gliotoxin or vehicle (1%, v/v, DMSO) at 37°C for 2 hrs in a sealed black polystyrol 96 well plate (Greiner Bio-one, Frickenhausen, Germany). Then, isolated LTA₄H (145 nM) in assay buffer with Triton X-100 (0.01%, v/v) were added, and the plate was incubated at room temperature (RT) for 30 min. The reaction was started by the addition of 300 µM of non-fluorescent L-arginine-7-amido-4-methylcoumarine hydrochloride (Merck, Darmstadt, Germany) solution to a total volume of 100 µL. The change of the fluorescence intensity was measured (excitation at 370 nm and emission at 460 nm) for 60 min (one point per minute) at RT in a Tecan fluorescence plate reader (Infinite F200 pro). For the evaluation of the reaction, the slope in the linear phase was determined.

Analysis of Gliotoxin by UPLC-MS-MS

Samples from the cell-free LTA₄H assay were mixed with 79 µL acetonitrile instead of adding master mix. Analysis of gliotoxin was carried out on an Acquity UPLC with TUV detector (Waters, Eschborn, Germany) coupled to a single quadrupole mass detector (QDa, Waters). 2 µL of the sample were injected. Separation was achieved on a UPLC BEH C18 (1.7 µm, 2.1 × 50 mm) RP column (Waters) with a column temperature of 45°C. Acetonitrile and H₂O with 0.1% (v/v) formic acid were used as eluents following the gradient range from 5 to 95% in 5 min at a flow rate of 0.5 mL/min. Gliotoxin (*m/z* = 327.2) as well as its reduced dithiol form (*m/z* = 329.2) were analyzed in positive single ion mode [M+H]⁺ using the Selected Ion Monitoring (SIM) approach. The obtained ion chromatograms were analyzed with Empower 3 software (Waters).

Determination of the Aminopeptidase Activity of LTA₄H

Neutrophils (5 × 10⁶/mL in PG buffer) were pre-incubated with compounds or 0.1% (v/v) vehicle for 10 min at 37°C prior incubation with 1 µM Pro-Gly-Pro (PGP) and 0.1 µM N-acetyl-PGP (Cayman, Biomol, Hamburg, Germany) for 2 hrs at 37°C. The reaction was stopped on ice with 1.5 mL methanol and PGP was extracted in 60% (v/v) methanol after 1 hr at -20°C. N-acetyl-PGP (12 pmol) was used as internal standard. The extracted tripeptides were centrifuged at 2,000 rpm, 4°C for 10 min and applied to UPLC-MS-MS.

UPLC-MS-MS analysis of PGP was carried out on an Acquity UPLC BEH C₁₈ column (1.7 µm, 2.1 × 100 mm) using an Acquity UPLC system (Waters). A linear gradient was used at a flow rate of 0.8 mL/min at 45°C from 100% mobile phase A (water, 0.07% (v/v) formic acid)/0% mobile phase B (acetonitrile, 0.07% (v/v) formic acid) to 60% mobile phase A/40% mobile phase B within 5 min. Quantification was performed by multiple reaction monitoring (MRM) in the positive ion mode using a QTRAP 5500 Mass Spectrometer (Sciex, Darmstadt, Germany). The ion spray voltage was set to 4500 V, the heated capillary temperature to 550°C, the curtain gas pressure to 35 psi, the sheath gas pressure to 50 psi, the auxiliary gas pressure to 80 psi, the declustering potential to 52 V, the entrance potential to 9 V, and the collision energy to 21 (PGP) and 27 V (acPGP). Under optimized ESI conditions, PGP [M + H]⁺ ion, *m/z* 270.1, generated ions at *m/z* 173.1 and acPGP [M + H]⁺ ion, *m/z* 312.3, generated ions at *m/z* 112 as its major product ions which were selected for quantification. Analyst software 1.6 was used for the processing of analytical data.

Determination of Cellular sEH Activity

To assay the activity of sEH in a cell-based assay, HepG2 or A549 cells were harvested and resuspended in PGC buffer (1.5 × 10⁶ cells/mL). Cells were pre-incubated with test compounds or 0.1% (v/v) DMSO at 37°C for 15 min, and incubated with 1.5 µM 14,15-EET (Cayman Chemical/Biomol, Hamburg, Germany) for 30 min at 37°C. The reactions were stopped with one volume of ice-cold methanol, 1.31 ng d₈-5(S)-HETE and 1.36 ng d₄-LTB₄ (Cayman Chemical/Biomol) were added as internal standards, and samples were subjected to solid phase extraction on Waters Sep-Pak® Vac 6cc columns (Waters, Milford, MA, USA), washed once with water and *n*-hexane, and eluted with methylformiate (Werz et al., 2018). The nitrogen-dried samples were dissolved in 50% (v/v) methanol, and 14,15-DiHETE formation was measured by UPLC-MS-MS using an Acquity UPLC system (Waters, Milford,

Please cite this article in press as: König et al., Gliotoxin from *Aspergillus fumigatus* Abrogates Leukotriene B₄ Formation through Inhibition of Leukotriene A₄ Hydrolase, *Cell Chemical Biology* (2019), <https://doi.org/10.1016/j.chembiol.2019.01.001>

MA, USA) and a QTRAP 5500 Mass Spectrometer (Sciex) equipped with a Turbo V™ Source and electrospray ionization (ESI) as reported previously (Garscha et al., 2017).

QUANTIFICATION AND STATISTICAL ANALYSIS

Results are presented as means ± SEM of n independent observations, where n represents the number of performed experiments at different days or with different donors/animals. Analyses of data were conducted using GraphPad Prism software (Graphpad Software Inc., San Diego, CA). IC₅₀ values were determined by linear interpolation and validated with the GraphPad InStat program. Data fit was obtained using the sigmoidal concentration-response equation (variable slope) or the linear regression (GraphPad Prism software). Statistical evaluations were performed by one-way ANOVA followed by a Bonferroni post-hoc test for multiple or student t-test for single comparisons, respectively. P-values < 0.05 were considered as significant.

S Supporting Information

ABSTRACT: Extracts of the predatory myxobacterium *Pyxidicoccus fallax* HKI 727 showed antiproliferative effects on leukemic K-562 cells. Bioactivity-guided fractionation led to the isolation of the bis-catechol myxochelin A and two new congeners. The biosynthetic origin of myxochelins C and D was confirmed by feeding studies with isotopically labeled precursors. Pharmacological testing revealed human 5-lipoxygenase (5-LO) as a molecular target of the myxochelins. In particular, myxochelin A efficiently inhibited 5-LO activity with an IC_{50} of 1.9 μ M and reduced the proliferation of K-562 cells at similar concentrations.

The myxobacteria are Gram-negative bacteria, which thrive in soil and in marine environments. They have been recognized as a rich source of antibiotics and anticancer agents.^{1–3} Similar to other microbial producers of secondary metabolites, a single myxobacterium harbors the potential for the biosynthesis of multiple natural products.^{4,5} The bioactive molecules that can be produced by a myxobacterium may foster its predatory lifestyle, facilitating the lysis of different prey organisms.^{6,7} An illustrative example is *Pyxidicoccus fallax*, which secretes diverse macrolide antibiotics, including the gulumirecins and the disciformycins.^{8,9} Although the activity spectrum of these molecules correlates quite well with the bacterial prey spectrum of *P. fallax*, it does not explain the observed predation of eukaryotic microorganisms. In consideration of the metabolic versatility of myxobacteria, we hence decided to expand the bioactivity testing of the gulumirecin-producing *P. fallax* strain HKI 727 and to search for compounds with antiproliferative or cytotoxic effects. This approach led to the isolation of three metabolites belonging to the myxochelin family (Figure 1).^{10,11} The biosynthetic origin of the two new representatives myxochelin C (2) and myxochelin D (3) was verified in feeding studies with isotopically labeled L-methionine. Structural resemblance to the plant-derived natural product curcumin (4), which had previously been identified as an inhibitor of 5-lipoxygenase (5-LO),^{12–14} suggested that the myxochelins might exert similar pharmacological effects. Here, we provide experimental evidence for this assumption.

Extracts of screening cultures from *P. fallax* HKI 727 grown in MD1 medium inhibited cell proliferation of K-562 cells. Since the activity could not be traced to the previously described gulumirecins,⁸ the fermentation was repeated on a larger scale (30 L) in order to isolate and identify the active compound(s). The resulting culture broth was exhaustively

Figure 1. Structures of myxochelin A (1), myxochelin C (2), myxochelin D (3), and curcumin (4).

extracted with ethyl acetate after the cell biomass had been removed by filtration. A preliminary fractionation was accomplished by ODS flash chromatography using increasing concentrations of methanol in water as eluant. All fractions were tested for their antiproliferative properties on K-562 cells, and the active ones were combined and subjected to HPLC separation. Final purification was achieved on a reversed-phase HPLC column, yielding 4.2 mg of 1, 2.7 mg of 2, and 2.1 mg of 3.

The isolated compound 1 was identified as the known natural product myxochelin A by comparison of its spectroscopic data with literature values.¹⁵ Compound 2, which eluted after 1 from the reversed-phase HPLC column, possessed almost identical NMR spectra. A unique singlet at 3.86 ppm in the ¹H NMR spectrum together with an additional carbon signal at 56.7 ppm suggested that an aromatic hydroxy

Published: February 16, 2015

Figure 2. Inhibitory effects of 1 and 2 on K-562 (A) and HeLa cells (B).

of myxochelin A is replaced by a methoxy group in 2. Consistent with this assumption, a molecular formula of $C_{21}H_{26}N_2O_7$ was deduced for 2 by HRESIMS. The exact position of the methoxy group could be assigned by HMBC measurement, thereby establishing the planar structure of myxochelin C. The remaining compound 3 was retained even longer on the reversed-phase HPLC column than 2. Its pseudomolecular ion peak at m/z 433.1968 $[M + H]^+$ indicated a mass increase by 28 Da in comparison to myxochelin A. Interpretation of the NMR data led to the identification of two methoxy groups, which were allocated on the basis of heteronuclear long-range correlations to give the gross structure of myxochelin D. The configuration of the single chiral centers in 2 and 3 was determined as *S* by comparison of their optical rotation with that of myxochelin A.¹⁵

The myxochelins are assumed to act as siderophores, securing the iron supply of the producing bacterium.¹⁰ Since methoxylation of the catechol residues in myxochelin A was anticipated to interfere with the coordination properties, the isolated compounds were tested in the chrome azurol S assay.¹⁶ The poor or absent color changes confirmed that 2 and 3 are much weaker ligands than myxochelin A (Figure S1), challenging a siderophore function for the former two molecules. To exclude an abiotic origin (e.g., from methanol as a result of the chromatographic workup conditions),¹⁷ [*methyl*-¹³C]-L-methionine was fed to a culture of *P. fallax* HKI 727 grown in MD1 medium. Subsequently, myxochelin C was isolated and the incorporation of label was analyzed by NMR spectroscopy. While a strong enrichment of the methoxy carbon was detected, the signals of the other carbons in 2 provided no indication of specific labeling (Figure S2). This result strongly supported a biosynthetic origin for the methoxy groups in myxochelins C and D.

All isolated myxochelins were evaluated against K-562 and HeLa cells for their inhibitory effects. While myxochelin A and 2 reduced the proliferation of K-562 cells in the micromolar range in a concentration-dependent manner, 3 exerted only negligible effects on the human leukemic cell line (data not shown). In contrast, the effects on HeLa cells, which are epithelial cells from a human cervical carcinoma, were relatively weak (Figure 2). In the case of myxochelin A, the activity was significantly lower, with IC_{50} values of 305.2 μ M compared to 3.9 μ M for K-562 cells (Table 1). Although myxochelin A had previously been described as an antimetastatic agent and a series of synthetic analogues had been prepared for SAR studies,^{15,18} the basis for its preferential activity against leukemic cells was not clear. Intrigued by the structural relatedness to curcumin (4), it appeared possible that curcumin

Table 1. IC_{50} Values of Myxochelins for the Inhibitory Effects on K-562 and HeLa Cells

	HeLa IC_{50} [μ M]	K-562 IC_{50} [μ M]
myxochelin A (1)	305.2 (\pm 19.5)	3.9 (\pm 0.1)
myxochelin C (2)	424.0 (\pm 51.9)	53.5 (\pm 5.8)
myxochelin D (3)	>500	>500

and myxochelin A share the same molecular targets. The anticarcinogenic properties of curcumin are due to an inhibition of 5-LO and microsomal prostaglandin E_2 synthase (mPGES)-1,^{13,19} which not only are key enzymes for the progression of inflammatory processes but have also been associated with tumorigenesis.²⁰ The enzyme 5-LO was shown to be critically involved in chronic myeloid leukemia and was proposed to be a candidate target for therapeutic management of stem-cell-like cells in acute myeloid leukemia.^{21,22} Similarly, mPGES-1 inhibitors were proposed to be promising candidates for leukemia treatment.²³ Therefore, inhibition of 5-LO and/or mPGES-1 could provide a plausible explanation for the marked antiproliferative effects of myxochelin A in K-562 cells, in particular since various 5-LO inhibitors were found to induce cell death of K-562 cells.²⁴ Subsequent testing in a cell-free assay confirmed that 5-LO is inhibited by myxochelin A. The natural product blocked 5-LO activity at 10 μ M, comparable to the reference inhibitor zileuton at 3 μ M (Figure 3A). More detailed analysis revealed concentration-dependent inhibition of 5-LO activity by myxochelin A with an IC_{50} of 1.9 μ M (Figure 3B). For comparison, curcumin suppressed 5-LO activity in this cell-free assay with only slightly better efficiency, with an IC_{50} value of 0.5 μ M.¹³ The new myxochelins 2 and 3 were less active (IC_{50} > 10 μ M) and reduced 5-LO activity at 10 μ M by only $41 \pm 4.1\%$ and $33 \pm 5.2\%$, respectively. Since 5-LO is a nonheme iron-dependent enzyme,²⁵ it is possible that the varying iron-binding capabilities of 1–3 account for the differences in 5-LO inhibition. As a matter of fact, many known 5-LO inhibitors act by chelation of ferrous iron in the enzyme's active site.²⁶ In contrast to curcumin and the synthetic reference inhibitor MK-886, compounds 1–3 failed to inhibit mPGES-1 activity up to 100 μ M in a routine cell-free assay (data not shown).

In summary, myxochelin A was identified as a potent inhibitor of 5-LO. The bis-catechol natural product efficiently suppresses the proliferation of leukemic K-562 cells, whereas it has much less activity against HeLa cells. Increasing evidence suggests 5-LO is a key enzyme in myeloid leukemia.^{21,22} Actually, several 5-LO inhibitors were found to induce cell death of K-562 cells but not of 5-LO-deficient HeLa cells.^{24,27}

Figure 3. Effects of myxochelin A (1), myxochelin C (2), and myxochelin D (3) on 5-LO activity. (A) Myxochelins inhibit 5-LO. (B) Concentration–response curves of myxochelin A (1) for inhibition of 5-LO. Purified 5-LO (0.5 μg/mL) was incubated with the indicated test compounds at the indicated concentrations or with vehicle (DMSO, 0.1%; “veh”) at 4 °C for 15 min. Samples were prewarmed for 30 s at 37 °C, 2 mM CaCl₂ and 20 μM arachidonic acid were added, and 5-LO product formation was determined after 10 min. Data are expressed as percentage of control (100%), means ± SE, $n = 3–6$, *** $p < 0.001$; ANOVA + Tukey HSD *post-hoc* tests.

Our findings support the assumed correlation between 5-LO inhibition and antileukemic activity, even though additional leukemia-associated targets cannot be excluded for myxochelin A. The two methylated derivatives 2 and 3 are much weaker 5-LO inhibitors than myxochelin A. At 10 μM neither compound showed significant 5-LO inhibition or antiproliferative effects against K-562 cells. At higher concentrations 2 reduced the growth of the leukemic cells, while 3 remained inactive. Therefore, the weak 5-LO inhibition of 2 or 3 seems to be irrelevant to their effect on K-562 cells. Unlike curcumin, the myxochelins do not target mPGES-1. This finding indicates discrete structural requirements for 5-LO and mPGES-1 inhibition and is consistent with previous investigations, in which a 1,3-diketone motif was proposed to be essential for affinity to mPGES-1.¹³

EXPERIMENTAL SECTION

General Experimental Procedures. Optical rotation was measured using a 0.5 dm cuvette with a JASCO P-1020 polarimeter at 25 °C. UV spectra were recorded on a Varian UV–visible Cary spectrophotometer. IR spectra were recorded on a Bruker FT-IR (IFS 55) spectrometer. High-resolution mass determination was carried out using an Exactive mass spectrometer (Thermo-Scientific). NMR spectra were measured at 300 K on a Bruker Avance III 500 MHz spectrometer with methanol-*d*₄ as solvent and internal standard. Preparative HPLC was conducted on a Shimadzu HPLC system (LC-20AT, SPD-M20A).

Production and Isolation of Myxochelins. Fermentation of *P. fallax* strain HKI 727 was carried out at 30 °C in 5 L Erlenmeyer flasks containing 3 L of MD1 medium, as previously described.⁸ After 7 days of shaking at 130 rpm, the culture broth was exhaustively extracted with ethyl acetate. The organic layers were combined, and residual water was removed through the addition of anhydrous sodium sulfate (30 g/L) and filtration. Subsequently, the organic extract was concentrated to dryness under reduced pressure. The residue was suspended in a small amount of methanol and subjected to flash column chromatography using Polygoprep 60-50 C₁₈ (Macherey-Nagel) as a stationary phase. Elution started with 20% methanol. The concentration of the organic solvent in the eluent was gradually increased up to 100%. All fractions that were obtained from this initial chromatographic separation were tested for their antiproliferative effects on K-562 cells. Active fractions were combined and further purified on a Nucleodur PFP column (250 × 10 mm, 5 μm; Macherey-Nagel) using a linear gradient of methanol in water (+0.1% trifluoroacetic acid). After a second round of bioactivity testing, the isolation of myxochelins was achieved on a Nucleodur C₁₈ HTec column (250 × 10 mm, 5 μm; Macherey-Nagel) under isocratic

conditions (70% methanol in water + 0.1% TFA) with a flow rate of 2 mL/min. The elution of compounds was detected by wavelength monitoring at 210 and 280 nm.

Myxochelin C (2): [α]_D²⁵ −17.6 (*c* 0.75, MeOH); UV (MeOH) λ_{\max} (log ϵ) 210 (4.70), 245 (4.30), 310 (3.70) nm; IR (film) ν_{\max} 3360, 2935, 1637, 1586, 1543, 1458, 1343, 1250, 1075, 740 cm^{−1}; ¹H NMR (MeOD, 500 MHz) δ 7.32 (1H, dd, *J* = 8.2, 1.4 Hz, H-6''), 7.26 (1H, dd, *J* = 8.1, 1.4 Hz, H-6'), 7.06 (1H, dd, *J* = 8.0, 1.4 Hz, H-4''), 6.91 (1H, dd, *J* = 7.8, 1.4 Hz, H-4'), 6.81 (1H, t, *J* = 8.2, 8.0 Hz, H-5''), 6.69 (1H, t, *J* = 8.1, 7.8 Hz, H-5'), 4.16 (2H, m, H-2), 3.86 (3H, s, H-8''), 3.64 (1H, dd, *J* = 11.2, 5.3 Hz, H-1a), 3.61 (1H, dd, *J* = 11.2, 5.3 Hz, H-1b), 3.40 (2H, t, *J* = 7.0 Hz, H-6), 1.74 (1H, m, H-3a), 1.68 (2H, m, H-5), 1.63 (1H, m, H-3b), 1.49 (2H, m, H-4); ¹³C NMR (MeOD, 125 MHz) δ 171.4 (C, C-7'), 170.6 (C, C-7''), 150.5 (C, C-2''), 150.0 (C, C-2'), 149.8 (C, C-3''), 147.2 (C, C-3'), 120.5 (CH, C-6''), 119.7 (CH, C-5''), 119.6 (CH, C-5'), 119.5 (CH, C-4'), 119.0 (CH, C-6'), 117.6 (C, C-1''), 117.1 (C, C-1'), 116.0 (CH, C-4''), 65.0 (CH₂, C-1), 56.7 (CH₃, C-8''), 52.6 (CH, C-2), 40.3 (CH₂, C-6), 31.6 (CH₂, C-3), 30.3 (CH₂, C-5), 24.6 (CH₂, C-4); HRESIMS *m/z* 441.1632 (calcd for C₂₁H₂₆O₇N₂, 441.1638).

Myxochelin D (3): [α]_D²⁵ −15.8 (*c* 0.82, MeOH); UV (MeOH) λ_{\max} (log ϵ) 210 (4.71), 248 (4.20), 309 (3.80) nm; IR (film) ν_{\max} 2930, 1636, 1586, 1541, 1461, 1361, 1248, 1056, 740 cm^{−1}; ¹H NMR (MeOD, 500 MHz) δ 7.41 (1H, dd, *J* = 8.1, 1.4 Hz, H-6''), 7.32 (1H, dd, *J* = 8.1, 1.4 Hz, H-6'), 7.07 (1H, dd, *J* = 8.1, 1.4 Hz, H-4''), 7.06 (1H, dd, *J* = 8.1, 1.4 Hz, H-4'), 6.83 (1H, t, *J* = 8.1 Hz, H-5''), 6.81 (1H, t, *J* = 8.1 Hz, H-5'), 4.15 (2H, m, H-2), 3.87 (3H, s, H-8''), 3.86 (3H, s, H-8'), 3.65 (1H, dd, *J* = 11.2, 5.2 Hz, H-1a), 3.62 (1H, dd, *J* = 11.2, 5.1 Hz, H-1b), 3.40 (2H, t, *J* = 7.0 Hz, H-6), 1.75 (1H, m, H-3a), 1.68 (2H, m, H-5), 1.64 (1H, m, H-3b), 1.50 (2H, m, H-4); ¹³C NMR (MeOD, 125 MHz) δ 170.6 (C, C-7''), 170.2 (C, C-7'), 150.6 (C, C-2''), 150.1 (C, C-2'), 149.8 (C, C-3''), 149.7 (C, C-3'), 121.1 (CH, C-6''), 120.5 (CH, C-6'), 119.7 (CH, C-5''), 119.7 (CH, C-5'), 118.1 (C, C-1''), 117.6 (C, C-1'), 116.0 (CH, C-4''), 116.0 (CH, C-4'), 64.9 (CH₂, C-1), 56.7 (CH₃, C-8''), 56.7 (CH₃, C-8'), 52.7 (CH, C-2), 40.4 (CH₂, C-6), 31.7 (CH₂, C-3), 30.3 (CH₂, C-5), 24.5 (CH₂, C-4); HRESIMS *m/z* 433.1968 (calcd for C₂₂H₂₉O₇N₂, 433.1975).

Isotope Incorporation into Myxochelin C. For the labeling study, *P. fallax* HKI 727 was grown in MD1 medium. The production culture (5 × 3 L of medium dispensed in 5 L Erlenmeyer flasks) was amended with a filter-sterilized aqueous solution of [*methyl*-¹³C]-L-methionine to give a final concentration of 0.44 mM. Subsequently, the culture was shaken at 130 rpm and 30 °C for 7 days. Extraction and isolation of 2 were carried out as previously described. ¹³C NMR spectra were recorded using the inverse-gated decoupling pulse sequence.

Biological Assays. Inhibitory effects were evaluated against K-562 (DSM ACC 10) and HeLa cells (DSM ACC 57), which had been grown in RPMI 1640 medium. The adherent cells were harvested

during the logarithmic growth phase after soft trypsinization using 0.25% trypsin in phosphate-buffered saline (PBS) containing 0.02% EDTA. For each experiment, approximately 10 000 cells were seeded with 0.1 mL of culture medium per well of the 96-well microplates. Test substances and fractions were dissolved in methanol before being diluted in RPMI 1640. Incubation was then conducted in a humidified atmosphere at 37 °C and 5% CO₂ for 72 h. In the case of K-562 cells, the number of viable cells in every well was determined using the CellTiter-Blue assay.²⁸ The adherent HeLa cells were fixed by glutaraldehyde and stained with a 0.05% solution of methylene blue for 5 min. After gently washing, the stain was eluted with 0.2 mL of 0.33 N HCl in the wells. The optical densities were measured at 660 nm in a Sunrise microplate reader (TECAN).

Expression, Purification, and Activity Assay of Human Recombinant 5-LO. Human recombinant 5-LO was expressed in *E. coli* BL21 (DE3), which were transformed with pT3-SLO plasmid as reported.²⁹ Cells were lysed in 50 mM triethanolamine/HCl pH 8.0, 5 mM EDTA, soybean trypsin inhibitor (60 µg/mL), 1 mM phenylmethanesulfonyl fluoride, dithiothreitol (1 mM), and lysozyme (1 mg/mL) and then sonified (3 × 15 s). The homogenate was centrifuged at 10000g for 15 min, and the remaining supernatant at 40000g for 70 min at 4 °C. 5-LO in the supernatant was partially purified by affinity chromatography on an ATP-agarose column. Semipurified 5-LO was diluted in PBS containing EDTA (1 mM) plus freshly added ATP (1 mM). Samples were preincubated with the test compounds for 10 min at 4 °C and prewarmed for 30 s at 37 °C. 5-LO product formation was initiated by addition of 2 mM CaCl₂ and 20 µM arachidonic acid. After 10 min at 37 °C, the reaction was terminated by addition of 1 mL of ice-cold methanol. Formed 5-LO metabolites including all-*trans* isomers of LTB₄ and 5S-hydro(pero)xy-6-*trans*-8,11,14-*cis*-eicosate-traenoic acid (5-HETE) were analyzed by RP-HPLC as previously described.³⁰

Cell-Free mPGES-1 Activity Assay. Preparations of A549 cells, induction of mPGES-1, and determination of mPGES-1 activity was performed exactly as described previously.¹⁹

ABSTRACT

The melleolides are structurally unique and bioactive natural products of the basidiomycete genus *Armillaria*. Here, we report on cytotoxic effects of melleolides from *Armillaria mellea* towards non-transformed human primary monocytes and human cancer cell lines, respectively. In contrast to staurosporine or pretubulysin that are less cytotoxic for monocytes, the cytotoxic potency of the active melleolides in primary monocytes is comparable to that in cancer cells. The onset of the cytotoxic effects of melleolides was rapid (within <1 h), as compared to the apoptosis inducer staurosporine, the protein biosynthesis inhibitor cycloheximide, and the DNA transcription inhibitor actinomycin D (>5 h, each). Side-by-side comparison with the detergent triton X-100 and staurosporine in microscopic and flow cytometric analysis studies as well as analysis of the viability of mitochondria exclude cell lysis and apoptosis as relevant or primary mechanisms. Our results rather point to necrotic features of cell death mediated by an as yet elusive but rapid mechanism.

1. Introduction

The melleolides, made by the basidiomycete genus *Armillaria* (honey mushrooms), are a structurally unique family of natural products as they combine orsellinic acid, or a derivative thereof, with a protoilludene-type secondary alcohol.^{1,2} The melleolide backbone represents a metabolic hybrid, as both a sesquiterpene cyclase³ and a polyketide synthase mediate biosynthesis, with the latter cross-linking the building blocks through esterification.⁴ Some, but not all melleolides are regioselectively chlorinated at C-6', as exemplified by arnamial **1** and its 6'-dechloro derivative **2**.

Initially, the melleolides were recognized as antimicrobially active compounds.^{5,6} Subsequently, cytotoxic activity against human cancer cell lines was described for **1**⁷ which showed an IC₅₀ of 3.9 μM for Jurkat cells. First insight into the structure–activity relationship came from a subsequent study which included Jurkat, K-562, HeLa, and MCF-7 cancer cells.⁸ The more hydrophilic compounds did not affect cell viability implying that primarily terpene hydroxylation at positions 10, 13, and 14 is critical for

cytotoxicity. Consequently, dehydroarmillylorsellinate (**3**) which does not carry an alcohol functionality at any of these positions, was found to be active against K-562 cells (IC₅₀ = 5.0 μM).

For antifungal activity, the double bond position (Δ^{2,4}) of the sesquiterpene moiety of melleolides was shown to be critical for antifungal activity. An absent or shifted double bond (Δ^{2,3}), like in armillarin (**4**), armillaridin (**5**), and melleolide D (**6**), leads to a loss of antifungal activity but does not impact cytotoxicity against human cells.⁹

In our present study we compared the cytotoxic activity of melleolides towards proliferating cancer cells and non-transformed primary monocytes. We hypothesized that monocytes would be less susceptible, due to their non-proliferating character and the fact that they are generally less sensitive to most cytotoxic/anti-proliferative agents, as compared to cancer cells. In fact, primary monocytes or peripheral blood mononuclear cells (i.e., monocytes and lymphocytes) are often utilized as models in order to demonstrate cancer cell selectivity of proposed anti-cancer agents. For example, we previously showed that induction of cell death of primary human monocytes by the microtubule-disrupting agent pretubulysin and the apoptosis inducer myrtoicommulone required 20- to >100-fold higher concentrations, respectively, as compared to various cancer cell lines.^{10,11} Conversely, agents that target specific cell receptors of leukocytes such as leukotoxin from

Figure 1. Structures of the melleolides 1–6 from *A. mellea*.

Aggregatibacter actinomycetemcomitans may cause selective cytotoxicity against leukocytes without affecting cancer cells.^{12–14}

In the present study we screened a set of six melleolides (Fig. 1) with (1–3) or without (4–6) antifungal activity for their cytotoxic effects on primary monocytes from human whole blood. Consistent with our previous results for cancer cell lines,⁸ we found that the α,β -unsaturated aldehyde and absence of hydroxy groups at the cyclopentene primarily correlated with potent cytotoxic properties towards various cancer cells, but also against primary monocytes.

Intriguingly, we observed an unusually rapid onset of cell death (<1–2 h) for the cytotoxic melleolides, which has not been reported for other well-recognized cytotoxic agents such as staurosporine, cycloheximide, or actinomycin D. Our data suggest a unique mode of action of melleolides regarding their cytotoxicity that warrants further attempts to identify the respective molecular target(s) in future studies.

2. Results and discussion

2.1. Structure–activity relationship of melleolides for induction of cell death

A set of six previously described melleolides (1–6, Fig. 1)^{8,9} was analyzed for cytotoxicity properties against freshly isolated human primary monocytes and a set of cancer cells (i.e., THP-1, Mono Mac 6 (MM6), K-562 and HeLa cells). Employing the MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay, we determined the lowest EC₅₀ of 2.3 μ M for 3 regarding the loss of monocyte viability, which is comparable or even lower than the EC₅₀ values (1.6–5.0 μ M) analyzed for transformed cancer cell lines in this respect (Table 1). Similar results were obtained for 1 and 2, which share the important structural feature for anti-fungal

activity, that is, the $\Delta^{2,4}$ -double bond. Melleolides 4 and 5, which are characterized by a $\Delta^{2,3}$ double bond, were equally active against THP-1 and MM6 cells (EC₅₀ values between 4.5 and 6.6 μ M), but exerted lower cytotoxic effects against monocytes, HeLa, and K-562 cells (8.9–43.2 μ M). Melleolide D (6), which features a hydroxy group at C-1, instead of the aldehyde, is essentially inactive (Table 1, Fig. 2A).

The high cytotoxic potential of selected melleolides observed in primary monocytes was also evident in the human leukemia cell lines THP-1 and MM6, implying the presence of a common cellular target in primary monocytes and cancer cells as being responsible for the cytotoxic effects.

Next, we verified the induction of monocytic cell death by measuring LDH levels as marker for loss of membrane integrity in melleolide-treated supernatants. As shown in Figure 2B, marked cytotoxic effects of 3 with the $\Delta^{2,4}$ -double bond, but not for the antifungally inactive 6 with its tetrahydroxylated sesquiterpene moiety were evident; staurosporine and triton X-100 were used as reference controls that caused LDH release, as expected.

Figure 2. Reduction of monocyte viability by melleolides. (A) Monocytes were incubated with melleolides 1–6 at the indicated concentrations (μ M) or staurosporine (stsp, 3 μ M). Cell viability was analyzed by the MTT assay after 24 h. (B) Monocytes were treated with melleolides 3 and 6 at the indicated concentrations (μ M), staurosporine (stsp, 3 μ M), and triton X-100 (0.2%), respectively. After 4 h the release of LDH was analyzed. Data are given as mean \pm SE, $n = 3$. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ versus vehicle control; ANOVA + Bonferroni.

Table 1
Cytotoxic effects of melleolides

Compd	THP-1 EC ₅₀ (μ M)	MM6 EC ₅₀ (μ M)	monoc. EC ₅₀ (μ M)	K-562 EC ₅₀ (μ M)	HeLa EC ₅₀ (μ M)	
1	2.9 (± 0.4)	3.2 (± 0.4)	3.8 (± 0.5)	2.3 (± 0.3)	4.9 (± 0.2)	$\Delta^{2,4}$ -Double bond
2	2.4 (± 0.7)	2.9 (± 0.7)	3.1 (± 0.7)	4.1 (± 0.1)	12.3 (± 0.3)	
3	3.0 (± 0.5)	4.2 (± 1.9)	2.3 (± 0.4)	5.0 (± 0.3)	1.6 (± 0.1)	
4	4.8 (± 0.5)	6.6 (± 0.7)	43.2 (± 2.4)	23.7 (± 1.5)	16.7 (± 2.1)	$\Delta^{2,3}$ -Double bond
5	4.5 (± 0.1)	5.6 (± 0.3)	12.3 (± 2.2)	8.9 (± 1.3)	9.2 (± 1.7)	
6	>100	48.6 (± 1.0)	60.7 (± 0.7)	>100	>100	

EC₅₀ values for induction of cell death of THP-1, Mono Mac 6 (MM6), monocytes (monoc.), K-562, and HeLa cells within 24 h. Data are given as mean \pm SE, $n = 3$.

In contrast to the melleolide **3** that was about equally potent against monocytes and HeLa cells, the multiple protein kinase inhibitor staurosporine was much more potent in cancer cells (HeLa) as compared to primary monocytes (Fig. 3). Similarly, the microtubule disrupting agent pretubulysin, a highly cytotoxic myxobacterial compound against cancer cells¹⁵ also failed to reduce the viability of primary monocytes up to 1 μM but clearly caused cell death of transformed MM6 cells ($\text{EC}_{50} = 0.03 \mu\text{M}$, Fig. 3). As outlined above, such reduced susceptibility of primary monocytes towards cell death induction is usually the case with (potential) anti-cancer agents, for example, myrtilcommulone, hyperforin, boswellic acids, and others.

2.2. Rapid onset of cytotoxicity by melleolides

We performed time-course experiments in order to investigate the timing of the cell death. In parallel to the melleolide **3** we

Figure 3. Effects of staurosporine (A), melleolide **3** (B), and pretubulysin (C) on primary monocytes and transformed HeLa or MM6 cells. Monocytes, HeLa or MM6 cells were treated with staurosporine, compound **3** or pretubulysin at the indicated concentrations. Cell viability was analyzed by the MTT assay after 24 h. Data are given as mean \pm SE, $n = 3$, $^{**}p < 0.01$, $^{***}p < 0.001$ versus vehicle control; ANOVA + Bonferroni.

Figure 4. Time course of cell death induction in (A) primary monocytes and (B) HeLa cells. Cells were treated with compounds **3** and **5** (5 μM each), staurosporine (3 μM), cycloheximide (CHX, 25 μM), actinomycin D (Act D, 1 μM) or vehicle (0.3% DMSO) for the indicated times and cell viability was analyzed by the inverse MTT assay. Data are means \pm SE, $n = 3$, $^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$ versus vehicle control; ANOVA + Bonferroni.

analyzed (I) staurosporine, a well-recognized inducer of the mitochondrial pathway of apoptosis,¹⁶ (II) cycloheximide, an inhibitor of protein biosynthesis, and (III) actinomycin D, an inhibitor of DNA transcription, which all are known to be cytotoxic for cancer cells.¹⁷

To assess the rapid onset of cell death by **3** (<5 h) more accurately, the MTT assay was modified. In fact, the first significant reduction of cell viability (approx. 40%) was observed 2 h after exposure to compound **3** in monocytes and HeLa cells (Fig. 4). None of the other agents caused a comparably rapid onset of cell

Figure 5. (A) Morphological analysis of monocytes. Cells were treated with the given agents (5 μM compound **3**, 3 μM staurosporine, 0.2% triton X-100) for the indicated periods of time, and analyzed by light microscopy. Pictures shown are representatives out of three independent experiments. (B) Flow cytometric analysis of PE Annexin V and 7-amino-actinomycin staining for apoptotic and necrotic cells, respectively. Data are means \pm SE, $n = 3-4$, $^{*}p < 0.05$, versus vehicle control; ANOVA + Bonferroni.

Figure 6. Effects of melleolide **3** on the viability of mitochondria. Mitochondria, isolated from MM6 cells, were treated with compound **3**, carbonyl cyanide 3-chlorophenyl-hydrazone (CCCP 10 μM), or 0.3% DMSO (vehicle control) for 3 h at 4 °C. MTT solution was added and after blue staining of the vehicle control, formazan formation was stopped and were analyzed. Data are given as means ± SE; $n = 3$; * $p < 0.05$, *** $p < 0.001$ versus vehicle control, ANOVA + Bonferroni.

death. A significant effect of staurosporine (3 μM) was observed after about 18 h. Similarly, CHX (25 μM) and actinomycin reduced cell viability only after 18, but not after 5 h of monocyte exposure (Fig. 4A).

2.3. Effects of melleolide on cell morphology and mitochondrial functionality

The rapid onset of cell death induction by **3** suggested that the melleolides may cause cell lysis. Within 1–3 h, morphological analysis of primary monocytes by light microscopy revealed typical features of necrosis after treatment with **3**. Thus, after 15 min cells started to form blebs devoid of organelles. Marked effects were observed after 1 h. After 3 h the plasma membrane was ruptured (Fig. 5). In contrast, after 3 h staurosporine caused signs of apoptosis, i.e., fragmentation of the nucleus and formation of apoptotic bodies. Also, a different pattern was evident for monocytes treated with the detergent triton X-100 that rapidly permeabilized the cells with subsequent structural collapse (Fig. 5).

Based on the comparative morphological analysis, our data suggest that **3**, unlike triton X-100, does not permeabilize monocytes, and unlike staurosporine, does not induce apoptosis, but instead may eventually cause necrosis. Attempts to study induction of necrosis and apoptosis of monocytes by **3** using flow cytometric analysis and PE Annexin V and 7-amino-actinomycin (7-AAD) staining revealed a tendency towards necrosis (i.e., 7-AAD positive) but also some apoptotic features (i.e., PE Annexin V positive) were evident, without reaching statistical significances, whereas staurosporine clearly caused apoptosis without any significant increased necrosis pattern (Fig. 5B).

Finally, we also investigated whether mitochondria are affected by the melleolide **3** by analysis of their metabolic activity using the MTT assay. Incubation of isolated mitochondria with **3** (up to 10 μM) caused about 50% reduction of metabolic activity, while carbonyl cyanide 3-chlorophenyl-hydrazone (CCCP), used as a control that abolishes mitochondrial membrane potential, completely reduced mitochondrial activity, as expected (Fig. 6).

3. Conclusion

We showed that cytotoxic melleolides rapidly induce cell death in human primary monocytes and transformed cells by a yet undefined destructive mechanism. Intriguingly, in contrast to other cytotoxic agents such as staurosporine, pretubulysin or myrtoxinomulone,^{10,11,16} the melleolides seemingly affect non-transformed cells equally well as hyperproliferative cancer cells. Therefore, our findings may be relevant in view of the function of melleolides

as molecular probes for yet unknown target(s), rather than as potential drug leads. Moreover, in contrast to other cytotoxic agents, induction of cell death by **3** is rapid, and our data do not support apoptotic or lytic effects by **3** as primary mode of cell death. Some indications (morphological pattern and 7-AAD staining) point to necrotic features. Therefore, and as isolated mitochondria were hardly affected by **3** in the MTT assay, we suggest that modulation of a specific target protein on the plasma membrane might be responsible for cell death induction by bioactive melleolides. Notably, the vicinally unsaturated aldehyde function could readily react with the SH-group of cysteines within active sites of proteins. Thus, multiple targets might be addressed by the reactive aldehydes. Contrasting the melleolides' potent bioactivity, the fruiting bodies of *Armillaria* species are considered edible mushrooms which are traditionally used for nutrition. This is consistent with our own observations that fruiting bodies contain melleolides only in traces, if at all, whereas all published work describes that melleolides were isolated from cultures of undifferentiated asexual mycelium.

4. Experimental section

4.1. General and microbiological procedures

Seed cultures of *Armillaria mellea* FR-P 75⁷ were routinely grown in potato dextrose broth shaken at 24 °C and 120 rpm in the dark, for 18–20 days. The mycelium was homogenized using an Ultraturrax disperser prior to inoculation of the production culture. For melleolide production glucose minimal medium¹⁸ was used. The total culture volume was 12 L, dispensed into 2 L Erlenmeyer flasks. The fungus was incubated for about four weeks, at 25 °C and 120 rpm. Chemicals, solvents, and media components were purchased from Roth, Sigma-Aldrich, and VWR.

4.2. Isolation of melleolides

To procure melleolides from liquid fungal cultures, the biomass was separated from the broth and extracted three times with an equal volume of a cyclohexane ethyl acetate (3:1, v/v) mixture. The extract was dried over Na₂SO₄ and then successively concentrated under reduced pressure using a rotary evaporator. Subsequent lyophilization yielded a greyish amorphous powder. Small aliquots were dissolved in methanol for initial preparative HPLC (method I, below) which resulted in nine fractions. Fractions six and seven were identified as pure compounds **4** and **5**, respectively. Three fractions were rechromatographed using methods II, III and IV which resulted in pure melleolides **1**, **2** and **3**, respectively. To analyze extracts and purification steps by HPLC and LC-MS, analytical methods V and VI were applied. Melleolide D (**6**) was isolated as described previously.⁸ The isolation yields were: **1**, 6 mg/L; **2**, 0.6 mg/L; **3**, 5 mg/L; **4** and **5**, 1 mg/L; **6**, 2 mg/L.

For preparative HPLC an Agilent 1260 series instrument equipped with a Phenomenex Luna C18 column (250 × 21.2 mm, 10 μm particle size) was used. Analytical HPLC was run on an Agilent 1200 instrument with a Zorbax Eclipse XDB C-18 column 150 × 4.6 mm, 3.5 μm particle size. For LC-MS runs an Agilent 1100 instrument with a Zorbax Eclipse XDB C-8 column (150 × 4.6 mm, 5 μm particle size) fitted to a 1100 MSD Trap was used. All chromatograms were recorded at λ = 254 nm, the respective diode array detectors covered the wavelength range from λ = 190–700 nm. The preparative methods (I–IV) used water (A) and 83% acetonitrile in water (B) as solvents, the flow rate was 21.0 mL/min.

Method I (gradient): 50% B, held for 1 min, then linear increase to 85% within 2 min and within 10.5 min to 100% B.

Method II (gradient): 80% B, held for 1 min, then increased to 100% B within 19 min.

Method III (gradient): solvent B increased from 85% to 100% B within 10 min.

Method IV (gradient): 45% B, held for 1 min, followed by a linear increase to 83% within 4 min. Then, B was increased to 95% within 8 min.

Method V: Solvents were water (A) and acetonitrile (B). The gradient was 2 min held at 15% B, then linear increase to 95% B within 31 min, at a flow of 0.6 mL/min.

Method VI: Solvents were 0.1% (v/v) formic acid in water (A) and 0.1% (v/v) formic acid in MeOH (B). The gradient was 10% B, held for 30 s, followed by a linear increase to 90% B within 14.5 min, and held at 90% B for 2 min, at a flow of 1 mL/min.

4.3. Isolation of primary monocytes and cell lines

Leukocyte concentrates were obtained from the Institute of Transfusion Medicine at the University Hospital Jena, Germany. The concentrates were prepared from the blood of healthy adult human donors who had not taken any anti-inflammatory medication for the 10 days prior to blood donation, as described.¹⁹ In brief, freshly withdrawn peripheral blood was pretreated with citrate-phosphate-dextrose solution as anticoagulant and processed with the 2C+ protocol of the Atrius Whole Blood Processing System (Terum BCT, Lakewood, CO). Peripheral blood mononuclear cells (PBMC) were isolated by dextran sedimentation and centrifugation on LSM 1077 lymphocyte separation medium (PAA Laboratories, Pasching, Austria). For isolation of monocytes, the PBMC were washed twice with ice-cold phosphate-buffered saline (PBS) and plated (density 2×10^7 cells/mL) in culture flasks (Greiner Bio-One, Frickenhausen, Germany) containing PBMC medium (RPMI 1640 medium supplemented with 100 U/mL penicillin, 100 µg/mL streptomycin and 2 mM L-glutamine) for 1.5 h at 37 °C, 5% CO₂. Non-adherent cells were removed; adherent monocytes were scraped, washed with ice-cold PBS and resuspended in ice-cold PBS with a purity of >85%, defined by forward- and side-light scatter properties and detection of the CD14 surface molecule by flow cytometry (BD FACS Calibur, Heidelberg, Germany). Monocytes were cultured in monocyte medium (RPMI 1640 supplemented with 2% human serum, L-glutamine (2 mM), penicillin (100 U/mL), and streptomycin (100 µg/mL)).

The human monocytic cell line MM6 (kindly provided by Dr. Thorsten Maier, University of Frankfurt, Germany) was cultured in RPMI 1640 medium supplemented with heat-inactivated fetal calf serum (FCS, 10%, v/v), penicillin (100 U/mL), streptomycin (100 µg/mL), insulin (10 µg/mL), oxaloacetic acid (1 mM), sodium pyruvate (1 mM), and 1 × non-essential amino acids at 37 °C and 5% CO₂. HeLa cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM) supplemented with heat-inactivated FCS (10%, v/v), penicillin (100 U/mL), and streptomycin (100 µg/mL) at 37 °C and 5% CO₂. THP-1 and K-562 cells were cultured in RPMI 1640 medium supplemented with heat-inactivated FCS (10%, v/v), 2 mM L-glutamine, penicillin (100 U/mL), and streptomycin (100 µg/mL) at 37 °C and 5% CO₂.

4.4. MTT assay

Cells (3×10^4 MM6, THP-1, and K-562, 1×10^4 HeLa, or 2×10^5 monocytes per well) were seeded in a 96-well plate in the respective medium (100 µL/well). Monocytes were allowed to adhere for 1.5 h (37 °C, 5% CO₂) prior to treatment. Test compounds (0.3% DMSO as vehicle) were added to each well and samples were incubated for the indicated time. Then, 20 µL of thiazolyl blue tetrazolium bromide (MTT, 5 mg/mL PBS) were added, and the incubation

was continued at 37 °C, 5% CO₂ until blue staining of the vehicle control. Formazan formation was stopped by adding 100 µL of lysis buffer (SDS, 10%, w/v in 20 mM HCl) and samples were shaken overnight. Absorbance of each well was measured at 570 nm in a Multiskan™ microplate spectrophotometer (Thermo Scientific, Ulm, Germany).

4.5. Inverse MTT assay

Cells were seeded in a 96-well plate (10^4 (HeLa) or 2×10^5 cells (monocytes) per well) in the respective medium (100 µL/well). HeLa cells were allowed to adhere for 24 h, monocytes for 1.5 h (37 °C, 5% CO₂). 20 µL of MTT (5 mg/mL PBS) were added 2 h prior to cell lysis. In contrast to the conventional MTT assay, test compounds (0.3% DMSO as vehicle) were added at the indicated time points prior to cell lysis to avoid a prolonged exposure time during incubation with MTT. Termination of formazan formation, as well as sample analysis, was performed as described in 4.4.

4.6. LDH release assay

Monocytes (1.5×10^6 /mL) were resuspended in monocyte medium and seeded into 96-well plates (duplicates). Cells were incubated for 1.5 h, 37 °C and 5% CO₂ for adhesion. Subsequently, compounds, vehicle (DMSO) or 0.2% triton X-100 as lysis control were added. After 4 h at 37 °C and 5% CO₂, cells were removed by centrifugation (600g, 4 °C) and the resulting supernatant was pipetted into a 96-well plate. Reaction buffer (containing, 0.3 mM NADH and 1.5 mM sodium pyruvate in 75 mM Tris/HCl, pH 7.4) was added and absorbance of NADH was immediately measured at 340 nm, 25 °C.

4.7. Life cell imaging

Monocytes (2.5×10^5 /mL) were plated into glass bottom dishes (MatTek Corporation, MA) containing RPMI 1640 supplemented with FCS (10%, v/v), 100 U/mL penicillin, 100 µg/mL streptomycin and 2 mM L-glutamine. Cells were allowed to adhere for 1.5 h at 37 °C and 5% CO₂. Then, cells were washed with pre-warmed PBS and PBS plus 0.1% (w/v) glucose, 1 mM CaCl₂, and 1 mM MgCl₂ was added. Compounds were added and images of the monocytes were taken after indicated times using an AxioCam MR3 camera (Zeiss, Jena, Germany) and were acquired, cut, linearly adjusted in the overall brightness and contrast, and exported to TIF by the AxioVision 4.8 software. The microscope incubator (Axio Observer Z1 inverted microscope, LCI Plan-Neofluar 63x/1.3 Imm Corr DIC M27 objective, Carl Zeiss, Jena, Germany) was kept at 37 °C and 5% CO₂.

4.8. Determination of mitochondrial MTT reduction capacity

MM6 cells were washed in PBS (450 × g, 10 min, 4 °C), resuspended in ice-cold isolation buffer¹⁹ and homogenized on ice with 4 × 10 strokes in a dounce homogenizer. Disrupted cells were centrifuged (750g, 20 min, 4 °C) and the resulting supernatant containing mitochondria was spun down (10,000 × g, 15 min, 4 °C). Pelleted mitochondria were washed in ice-cold isolation buffer (10,000 × g, 15 min, 4 °C) and resuspended in ice-cold respiratory buffer.²⁰ Mitochondrial protein concentration was determined using the DC Protein Assay (Bio-Rad, Munich, Germany). Mitochondria (2.5 µg/µL, 100 µL/sample) were exposed to the test compounds (0.3% DMSO as vehicle) for 1 h at 4 °C. Then, 20 µL of MTT (5 mg/mL PBS) were added and mitochondria were incubated at 30 °C until blue staining of the vehicle control. Further steps were performed as described in 4.4.

4.9. Flow cytometric analysis of PE Annexin V and 7-amino-actinomycin staining

Monocytes ($1.0 \times 10^6/\text{ml}$) were isolated and cultured in monocyte medium overnight. Then, cells were incubated with the test compounds for 1 or 5 h, respectively. After detachment with Accutase I (PAA Laboratories, Pasching, Austria), monocytes were stained with phycoerythrin (PE)-conjugated Annexin V and the intercalator 7-amino-actinomycin (7-AAD). For staining, the Annexin V PE apoptosis detection Kit I (BD Biosciences) was used according to manufacturer instructions. Flow cytometric analysis was performed on Attune Acoustic Focusing Cytometer (Life Technologies).

Summary

Melleolides form a group of fungal mycotoxins of the basidiomycete genus *Armillaria mellea* that induce rapid cell death in various mammalian cells with yet unknown mode of action. Here, we show that the melleolide dehydroarmillylorsellinate (DAO) covalently binds to phosphatidylethanolamine (PE) contained in cell membranes, accompanied by rapid loss of plasma membrane integrity and cellular viability. DAO caused a remarkable rapid onset of cell death of human cancer cells and primary human monocytes (i.e. within 15 min), which was temporally accompanied by PARP cleavage and loss of membrane integrity. DAO possesses a reactive α,β -unsaturated aldehyde group as Michael acceptor and covalently reacted via 1,4-addition with ethanolamine (EA) and with PE but not with other phospholipids containing serine or choline head groups. DAO-PE adduct formation coincided with membrane damage, and excess of exogenous EA prevented DAO-induced cell death. Moreover, DAO caused leakage of artificial PE-composed liposomes in a cell-free system. Subcellular fractionation studies indicate that DAO-PE adducts accumulate in cellular membranes along with decreased PE contents. Conclusively, DAO causes cell death by membrane damage seemingly due to covalent modification of PE with detrimental consequences for cell integrity and viability.

Introduction

The honey mushroom *Armillaria mellea* produces antimicrobial and cytotoxic natural products belonging to the large group of melleolides with more than 60 elucidated members [1-5]. These secondary metabolites combine sesquiterpene arylesters with orsellinic acid residues and exhibit mainly secondary alcohols. Up to now only a few targets and mode of actions are investigated for these mushroom toxins [6, 7]. Several melleolides show antitumor and cytotoxic effects in various human cells [1, 3, 8-10]. For example, armillarikin induces ROS-mediated and caspase-dependent apoptosis by downregulation of the mitochondrial transmembrane potential in leukemia cells [9, 11], and armillaridin induces autophagy-associated apoptosis in human leukemia cells and negatively influences the mitochondrial transmembrane potential [8, 12, 13]. Furthermore, decreased DNA synthesis was observed in different human cancer cell lines for some melleolides [1].

Cell death can be classified in three major subgroups – apoptosis, autophagic cell death and necrosis [14-16]. Typical characteristics for apoptosis are caspase activation, mitochondrial outer membrane permeabilization, cell rounding, nuclear condensation, and cell fragmentation to apoptotic bodies [17]. Autophagy is also a programmed physiological process in organism required to recycle macromolecules, cytoplasmic material, and cell organelles [18] but also for ATP production [19] via a lysosomal degradation pathway. In contrast, necrosis is an uncontrolled process and is constituted by signaling- and damage-induced lesions like mitochondrial dysfunction, ATP depletion, increased reactive oxygen species (ROS) formation or early plasma membrane ruptures [20, 21].

Membrane phospholipids (PL) constitute of a phosphate-bound head group (sn-3 position) and a glycerol residue connected with two ester-linked fatty acid chains (sn-1/sn-2 position). PL are classified by the functional head group, encompassing PE, phosphatidylcholine (PC), phosphatidylserine (PS), phosphatidylinositol (PI), phosphatidylglycerol (PG), phosphatidic

acid (PA), sphingomyelins (SP), and cardiolipins (CL). Typical cellular membranes consists of 45-55% PC, 15-25% PE, 10-15% PI, and 5-10% PS, where PE and PS are mainly found in the inner membrane leaflet [22]. During the early stage of apoptosis, PE and PS are exposed to the outer leaflet of the plasma membrane [23]. PE is participating in a wide range of cellular processes like the formation of hexagonal phases within the membrane because of its cone shape [24], protein arrangement inside the membrane [25], enhancing membrane fusion [24, 26], oxidative phosphorylation [27], mitochondrial stability [28] and autophagy [29, 30] and plays a substantial role in lipid synthesis as precursor of other lipids [31].

Here we show that the melleolide dehydroarmillylorsellinate (DAO, **Fig. 1A**) interferes with PE in cellular membranes by covalent binding to the EA head group. DAO possesses an α,β -unsaturated aldehyde that functions as Michael acceptor to react with nucleophilic residues such as thiol moieties of cysteine residue in 5-lipoxygenase (5-LO) [7]. Previous data showed that in contrast to other cytotoxic cell death-inducing agents, DAO causes remarkably rapid cell death with equal effectiveness in primary human monocytes and various cancer cell lines [3]. Our data suggest that covalent binding of DAO to membranous PE is the cause for the rapid perturbation of membrane integrity and consequent induction of cell death with characteristics of apoptosis and necrosis.

Results

DAO causes rapid cell death in human cells with unique characteristics

As reported before [3], the effectiveness of DAO and of the pan kinase inhibitor staurosporine (Stsp) for induction of cell death (assessed by MTT assay) in HeLa cells and primary monocytes was strikingly different. Thus, while Stsp-induced cell death is mainly mediated by apoptosis [32], DAO might confer its cytotoxicity primarily via necrotic features [3]. Moreover, DAO was about equipotent in monocytes and HeLa cells ($EC_{50} = 1.6$ and $2.3 \mu\text{M}$, respectively), while Stsp was much more (40-fold) effective in HeLa cells ($EC_{50} = 0.01 \mu\text{M}$) as compared to monocytes ($EC_{50} = 0.4 \mu\text{M}$). The onset in cell death induction by DAO was remarkably rapid. Thus, exposure to DAO for only 15 min caused significant loss of viability of monocytes which was hardly different from 1 hr or 24 hrs treatment (**Fig. 1B**). In contrast, for Stsp, exposure for more than 5 hrs was needed to cause cytotoxicity in monocytes (not shown, see [3]). Release of lactate dehydrogenase (LDH) from cells to the external space reflects the loss of plasma membrane integrity. In agreement with the loss of cell viability assessed by MTT assay, LDH release from monocytes and HeLa cells was rapidly induced by DAO with almost maximal effects after about 30 min of exposure (**Fig. 1C**).

We next studied the effects of DAO and Stsp on cell morphology using light microscopy and transmission electron microscopy (TEM). DAO (even at low concentrations such as $0.1 \mu\text{M}$) caused morphological signs of cells death within 3 hrs, reflected by wrinkling and shriveling of the plasma membrane (PM, **Fig. 1D**), which is actually a typical feature of necrosis. In contrast, Stsp caused classical signs of apoptosis in HeLa cells such as cellular fragmentation and formation of apoptotic bodies, along with shrinkage of the cells (**Fig. 1D**). Analysis by TEM revealed typical morphological features of monocytes with bean-shaped nucleus as well as intact organelles and plasma membrane (**Fig. 1E**). Upon Stsp-treatment (3 hrs), the nucleus lost its bean shape and rendered to a round structure with seemingly intact nuclear membrane and

also intact mitochondria. In contrast, 3 hrs treatment of monocytes with DAO caused defects of the nuclear membrane and in particular, mitochondria appeared to be lost (**Fig. 1E**). Together, DAO induces a remarkable rapid onset of cell death of primary cells and cancer cells accompanied by apparent membrane damages, which are characteristics that differ from those of classical apoptotic cell death inducers like Stsp.

Contribution of apoptotic pathways in mediating cell death by DAO

In order to explore the contribution of apoptotic pathways in mediating cell death by DAO, we analyzed hallmarks of apoptosis and stress signaling on a molecular level in monocytes. In fact, the rapid cell death induction by DAO (5 μ M) within 15 min coincided with cleavage of PARP to a 89 kDa fragment as marker for apoptosis in monocytes; in contrast Stsp failed to induce PARP cleavage during short term treatment (within 1 hr, **Fig. 2A**) but instead required at least 5 hrs (**Supplemental Fig. 1**). The intrinsic pathway of apoptosis is initialized by a loss of mitochondrial membrane potential ($\Delta\psi_m$) and the release of cytochrome c from mitochondria [33]. We found that in contrast to vehicle-treated monocytes exposure to 10 μ M DAO for 3 hrs caused substantial release of cytochrome c into the cytosol, while in parallel the cytochrome c levels in organelles was minute (**Fig. 2B**). Also Stsp (3 μ M) induced cytochrome c release from mitochondria within 3 hrs, albeit much less pronounced as compared to DAO.

Protein kinase signaling critically regulates the initiation of apoptosis, where the survival kinase Akt counteracts apoptosis [34] while p38 MAPK rather promotes it [35]. Exposure of monocytes to DAO (5 μ M) and Stsp (3 μ M) suppressed phosphorylation and thus activation of Akt. In contrast, both compounds elevated phosphorylation/activation of p38 MAPK (**Fig. 2C**). Again, the effects of DAO were more rapidly apparent (15 min) as compared to Stsp (30-60 min, **Fig. 2C**). The activation of p38 MAPK was independent on endoplasmic reticulum (ER)

stress and on the activation of the unfolded protein response (UPR), reflected by the failure of DAO to induce the UPR genes immunoglobulin heavy chain-binding protein (BiP), C/EBP [CCAAT/enhancer-binding protein]-homologous protein (CHOP), and activating transcription factor 4 (ATF4), at the protein level assessed by Western blot (**Fig. 2D**). Finally, we employed the pan-caspase inhibitor QVD to block apoptotic signaling. QVD (10 μ M) inhibited DAO-induced PARP cleavage in monocytes (**Fig. 2E**). In contrast, QVD failed to reverse cell death induction by DAO after 3 and 48 hrs, but also loss of cell viability in response to Stsp was not completely reversed by QVD (**Fig. 2F**), in line with the reported necroptosis induction in monocytic U937 cells [36]. Conclusively, DAO-induced cell death is accompanied by apoptotic features which are seemingly not operative but rather necrotic pathways are responsible.

DAO interacts with the ethanolamine residue of phosphatidylethanolamine

The α,β -unsaturated aldehyde of DAO functions as Michael acceptor to react with nucleophilic residues such as thiol moieties of cysteine residue in 5-lipoxygenase [7]. It appeared reasonable that the rapid induction of cell death by DAO and the associated detrimental membrane alterations could be due to reaction of the α,β -unsaturated aldehyde of DAO with amine moieties of ethanolamine (EA) or serine (Ser) head group of membrane PE and PS thereby perturbing membrane integrity. We incubated different types of phospholipids (i.e., PE, PC, PS) with DAO followed by cleavage of the PL between the phosphate and the EA, Ser or choline moiety, respectively, using exogenously added phospholipase (PL)D and UPLC-MS/MS analysis of potentially formed adducts of DAO with the head group moieties. As shown in **Fig. 3A**, two major signals at 442.4 and 485.3 m/z appeared upon incubation of DAO with PE and subsequent PLD cleavage which may represent adducts of DAO with one or two EA molecules. These DAO-EA adducts are reaction products, where (i) the primary amine of one EA molecule forms an α,β -unsaturated Schiff base with the aldehyde group of DAO (resulting in 442.4 m/z)

and/or (ii) the primary amine moieties of two EA molecules react in 1,4-addition to yield imine structures (485.3 m/z) (**Fig. 3A**). Note that only a weak signal was detectable for DAO itself (399.4 m/z), suggesting that DAO efficiently reacted with PE to form the two adducts. In contrast, when DAO was incubated in parallel with PS or PC, the signal for DAO remained pronounced, whereas peaks with 442.4 or 485.3 m/z were not detectable (**Fig. 3B**), suggesting that DAO does not react with PS or PC.

We then studied if DAO-PE adducts might be formed also from intact monocytes and HeLa cells upon exposure to DAO for 3 hrs, by analysis of DAO-EA after treatment of cell lysates with exogenous PLD. Incubation of these cells with DAO caused concentration-dependent increases in DAO-EA adducts, starting at 0.1 μ M DAO (**Fig. 3C**). The cellular amount of PE was maintained/decreased (**Fig. XY**). Next, we explored if DAO-PE interactions temporally correlate with detrimental effects on membrane integrity and thus with cell death induction. Treatment of monocytes or HeLa cells with 5 μ M DAO resulted in rapid formation of DAO-PE adducts already after 15 min, reaching a plateau after about 1 hr to 3 hrs (**Fig. 3D**), which resembles the kinetics for the loss of membrane integrity (**Fig. 1C**) and decrease in cell viability (**Fig. 1B**). Note that for both the loss of membrane integrity and DAO-PE adduct formation, DAO displays more pronounced effects in monocytes versus HeLa cells (**Fig. 3D** and **Fig. 1C**). Taken together, DAO-EA adduct formation proceeds in parallel to membrane damage, suggesting that the interaction of DAO with PE in the plasma membrane might be eventually causative for cell death induction. In fact, incubation of DAO (10 μ M) or Stsp (3 μ M) with 50 mM EA for 2 hrs prior to addition to monocytes or HeLa cells abrogated the cytotoxic effect of DAO but not of Stsp (**Fig. 3E**), assessed by MTT assay. Note that preincubation of DAO with choline failed in this respect and L-serine could only marginally restore cell viability (**Fig. 3F**). Again, Stsp-induced loss of monocyte viability was not affected by preceeding reaction with EA, serine or choline (**Fig. 3F**). Together, DAO binds to EA in PL and exogenous EA prevents

DAO-induced cell death suggesting that DAO acts by covalent modification of PE in cellular membranes.

Subcellular locales of DAO-PE interactions and consequences for PE contents

In order to explore the interaction between DAO and PE in the cellular context and to locate the subcellular PE binding sites of DAO, we performed subcellular fractionation of HeLa cells to obtain fractions enriched in nuclei, mitochondria, cytosol, and membranes. HeLa cells were preincubated with or without DAO for 15 or 180 min and cells were subjected to hypotonic lysis by passing them through a 25 G needle and subsequent differential centrifugation. Western blot for respective markers proteins confirmed correct cell fractionation and enrichment of related organelles (**Supplemental Fig. 2**). In cells treated with vehicle for 15 min, the cellular PE content was about equally distributed between fractions where nuclei, mitochondria, or membranes are enriched, while no PE was detectable in the cytosol (**Fig. 4A**). DAO did not significantly alter the subcellular distribution of PE (**Fig. 4A**). After 180 min, nuclear PE increased at the expense of membranous PE, and about 5% of the total PE was cytosolic. DAO further promoted this redistribution and increased nuclear PE at the expense of membranous PE (**Fig. 4A**). Importantly, when we analyzed the subcellular fractions for DAO-PE adducts (measured as DAO-EA after treatment of the fractions with PLD to cleave PE), we found that most of the DAO-PE (44% after 15 min and 62% after 180 min) was formed in the membrane fraction, with about equal or somewhat elevated contents in the mitochondrial as compared to the nuclear fraction (**Fig. 4B**).

Next, we analyzed whether DAO affects specific PE species in the subcellular fractions of HeLa cells after 3 hrs incubation using a targeted phospholipidomics approach (UPLC-MS/MS). In general, PE(18:0/18:1) and PE(18:1/18:1) were the most abundant species in the nuclear, mitochondrial and membrane fraction (**Fig. 4C**). However, the contents of PE species were not

markedly affected by DAO in comparison to the vehicle, the amounts of PE(18:0/18:1) and PE(18:1/18:1) were slightly increased in the nuclear fraction upon exposure to DAO after 3 hrs (**Fig. 4C**). Interestingly, after 15 min, PE(18:0/18:1) was the most common PE species in the membrane fraction closely followed by PE(18:1/18:1) (**Fig. 4D**) and after 3 hrs, these two PE species behaved exactly the other way (**Fig. 4C**). If we compared PE levels after 15 min DAO exposure with PE levels after 3 hrs DAO treatment in correlation to the total PE amount, a potent reduction of PE levels in the membrane fraction, especially PE(18:0/18:1) and PE(18:1/18:1) was obvious. Similar effects were observed also for less abundant PE species, such as PE(18:0/20:4), PE(16:0/18:1) or PE(16:1/18:1) (**Fig. 4F**). Together, DAO covalently reacts with the major PE species, preferably with those in membranes, which as a consequence leads to a subcellular rearrangement of single PE species within cell organelles.

In order to confirm that DAO reacts with PE in membranes and thus abrogates membrane integrity, we studied if DAO could cause leakage of artificial PE-composed liposomes in a cell-free system [37]. DAO caused release of the fluorescent dye 8-hydroxypyrene-1,3,6-trisulfonic acid trisodium salt (HPTS) from liposomes composed PE but not of PC indicating that it induces liposome leakage (**Fig. 4G** and **Supplemental Fig. 3**). Moreover, incubation of monocytes with DAO induced rapid (within 15 min) acidification of vesicles, starting at 1 μ M DAO being comparable to the effect of the protonophore carbonyl cyanide m-chlorophenyl hydrazine (CCCP), as demonstrated by fluorescence microscopy using LysoTracker® as pH-sensitive dye for lysosomal staining (**Fig. 4H**).

Discussion

Melleolides belong to one of the largest globally distributed mycotoxin group of mushrooms. Only for a few of these mycotoxins the modes of action and targets are explored like for muscarine, coprine, psilocybin, and ibotenic acid. Since the last century, researchers have followed up with the bioactions of secondary metabolites of the basidiomycete species *Armillaria mellea* in plants and human cells [38-41]. Here, we reveal a mode of action underlying the cytotoxic properties of the melleolide DAO in human cells. We showed before [3] that DAO induces remarkably rapid cell death in human cancer cell lines and in primary immune cells, but the mode of action remained obscure. Here, we provide evidence that DAO covalently binds to PE in cellular membranes. Our data suggest, that DAO covalently reacts with the EA head group of PE thereby perturbing plasma membrane structure and integrity, eventually leading to rapid cell death.

Besides DAO, several other melleolides display cytotoxic properties [1, 2, 4, 8, 9], but the rapid onset of cell death by DAO is unique. Interestingly, in contrast to other well-known cell death-inducing agents such as Stsp or pretubulysin that are more effective in cancer cells versus normal untransformed cells, DAO is equally potent in primary monocytes and cancer cell lines, and loss of cell viability due to DAO is apparent within few minutes as compared to Stsp that needed at least 5 hrs to cause cell death [3]. As described before, DAO displayed apoptotic as well as necrotic features of cell death measured by flow cytometry with an Annexin V/7-amino-actinomycin staining, and marked apoptosis induction was only obvious after 5 hrs [3]. Here, we find that DAO causes cleavage of the classical apoptosis marker PARP in human monocytes to a 89 kDa fragment within 15 min. Furthermore, the increase of phosphorylation of the stress-regulated p38 MAPK and the simultaneous decrease of the phosphorylation of the survival factor Akt due to DAO may contribute to cell death induction. Cells treated with Stsp demonstrated classical apoptotic characteristics like apoptotic bodies and fragmentation of

nuclei [15, 17], DAO-treated cells were crumpled and shrunk along with membrane rupture, particular of mitochondrial membranes. These properties are typical characteristics of necrosis [20, 21] suggesting that both apoptotic and necrotic features of DAO-induced cell death.

Recently, the plant toxin ophiobolin A from the *Bipolaris* genus [42] was shown to react with PE and/or EA [43], accompanied by strong cytotoxic properties in various cancer cells [44-46]. Of interest also ophiobolin A possesses an α,β -unsaturated aldehyde moiety that covalently reacts with the EA moiety in one PE molecule yielding the formation of a pyrrole [43], while DAO forms first an imine (as for ophiobolin A) with PE but then couples via 1,4 addition to a second PE molecule. Our data suggest that via covalent binding to the amine moiety of EA residues DAO interacts with the head group of PE without forming adducts with PC, and seemingly also not with PS, although serine possesses a primary amine function like EA. In fact, substantial excess of exogenously added L-serine partially reverted the cytotoxic effects of DAO (Fig. 3G), while choline failed in this respect.

We suggest that DAO-PE adduct formation causes perturbances of cellular membranes resulting in loss of membrane integrity. Thus, formation of DAO-EA adducts from cells treated with DAO temporally correlated to LDH release as marker for impaired plasma membrane integrity, processes that occurred within 15 min upon cell exposure to DAO, and DAO caused disappearance of mitochondria as visualized by TEM. PE is a cone-shaped lipid and responsible for the formation of hexagonal membrane phases [24]. If DAO covalently binds to the EA moiety in PE, the arranged membrane structure might become perturbed and prone to ruptures with consequent LDH release. In fact, the cytotoxic effects of DAO were abrogated by supplementation of exogenous EA and serine, but not of choline, that may capture the reactive aldehyde moiety of DAO, and DAO cause leakage of liposomes composed of PE but not of liposomes made from PC. Therefore, we hypothesize that the interaction of DAO with membranous PE is the major cause for the rapid cell death induction.

In normal untransformed cells, PE is arranged in the inner leaflet of the plasma membrane and the mitochondrial membrane [22] but during cell death PE and also PS are translocated to the outer plasma membrane [23]. Upon treatment of HeLa cells with DAO, adducts with PE were most abundant in the membrane fraction, supporting the hypothesis that DAO acts on membranous PE. Moreover, treatment of HeLa cells with DAO caused primarily a rearrangement of various PE species (particularly PE (18:0/18:1) and PE (18:1/18:1)) in the plasma membrane fraction leading to the presumption that DAO might affect various metabolic processes.

PE is necessary for autophagosomal membranes and autophagy which is essential to gain ATP by recycling cytoplasmic compounds [19]. During apoptosis, cells increase the autophagic response to support cell functions and to eliminate toxic molecules. These effects were intensified by reduced caspase-8 levels [47, 48]. Cells become hyperactive and lysosomal resorption of DAO is enhanced. Simultaneously, DAO interacts with PE in the inner leaflet of lysosomes followed by a lysosomal membrane rupture and as consequence the pH declines, as shown in monocytes by using the pH-sensitive dye LysoTracker®, eventually inducing necrosis. Taken together, DAO causes apoptosis and necrosis by manipulating several cellular mechanisms initialized by perturbing membrane integrity.

In conclusion, we identified membrane PE as molecular target for the melleolide DAO that via the α,β -unsaturated aldehyde moiety covalently reacts with the EA headgroup of PE. These DAO-PE interactions translate into perturbation of cellular membrane structure with consequent loss of integrity which eventually causes the remarkably rapid onset of cell death in various cell types.

Materials and Methods

Materials

DAO was isolated as described before [3]. Antibodies against Lamin B1, Lamp1, and syntaxin 6, abcam (Cambridge, United Kingdom); DPX, aber GmbH (Karlsruhe, Deutschland); bovine serum albumin (BSA), EDTA, and Tris, AppliChem (Darmstadt, Germany); DOPC, and DOPE, Avanti Polar Lipids (Alabaster, AL); L-glutamine, BioChem GmbH (Karlsruhe, Germany); AA, Cayman Chemical (Biomol, Hamburg, Germany); Antibodies against cleaved PARP (Asp214), phospho-p38 MAPK (Thr180/Tyr182), phospho-Akt (Ser473), ATF-4, CHOP, BiP, calnexin, COX IV, and β -actin were from Cell Signaling Technology (Boston, MA); phospholipase D from *Streptomyces chromofuscus*, ENZO life sciences (Lörrach, Germany); cytochrome c, Epitomics Inc. (Burlingame, CA); acetonitrile, Dulbecco's modified Eagle's high glucose medium with glutamine, penicillin/streptomycin-solution, sepharose and trypsin-EDTA, GE Healthcare Life Science (Freiburg, Germany); goat anti-rabbit IgG Alexa Fluor 488 antibody, and goat anti-mouse IgG Alexa Fluor 555 antibody, Invitrogen (Darmstadt, Germany); DMSO, Merck (Darmstadt, Germany); ATP, Roche (Mannheim, Germany); SDS, Roth GmbH (Karlsruhe, Germany); GAPDH, and β -tubulin, Santa Cruz Biotechnology (Heidelberg, Germany); Dulbecco's Buffer Substance (PBS), staurosporine, and HPLC solvents, VWR (Darmstadt, Germany); dextrane, fetal calf serum (FCS), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), RPMI 1640 Medium, phenylmethanesulfonyl fluoride, soybean trypsin inhibitor, lysozyme, leupeptin, HPTS, ethanolamine, choline, L-serine, triton X-100, chicken egg PE, chicken egg PC, QVD, LysoTracker® as well as other chemicals were from Sigma-Aldrich (Taufkirchen, Germany).

Cells

Monocytes were isolated from peripheral human blood of adult (18-65 years) healthy volunteers with written informed consent, obtained from the Institute of Transfusion Medicine, University

Hospital Jena, as described [49]. The experimental protocol was approved by the ethical committee of the University Hospital Jena. All methods were performed in accordance with the relevant guidelines and regulations. Leukocyte concentrates were prepared by centrifugation ($4000\times g$, 20 min, 20 °C) and erythrocytes were removed by dextran sedimentation followed by centrifugation on lymphocyte separation medium (Histopaque®-1077, Sigma, Taufkirchen, Germany) to obtain peripheral mononuclear blood cells (PBMCs). PBMCs were seeded in RPMI 1640 (Sigma Aldrich, Taufkirchen, Germany) containing 10% (v/v) heat inactivated fetal calf serum (FCS), 100 U/mL penicillin, and 100 µg/mL streptomycin in cell culture flasks (Greiner Bio-one, Frickenhausen, Germany) for 1.5 h at 37 °C and 5% CO₂. Adherent monocytes were washed twice with PBS and were resuspended in PBS containing 1 mg/ml glucose. HeLa cells were cultured in monolayers in DMEM High Glucose (4.5 g/L) medium supplemented with heat-inactivated fetal calf serum (FCS, 10%, v v), 100 U/mL penicillin, and 100 µg/mL streptomycin at 37 °C in a 5% CO₂ incubator.

Analysis of cell viability by MTT assay

Monocytes (2×10^6 /mL in RPMI 1640 containing 5% heat inactivated FCS, 100 U/mL penicillin and 100 µg/mL streptomycin) or 0.1×10^6 /mL HeLa cells in DMEM High Glucose supplemented with 5% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin were seeded in a 96-well plate. Monocytes were allowed to adhere for 1.5 h at 37 °C, 5% CO₂. Cells were incubated at 37 °C and 5% CO₂ with vehicle (0.5% DMSO) or compounds (i.e. DAO or Stsp) for indicated time points. In some experiments, EA, choline, L-serine or QVD were added 15 min prior to DAO or Stsp. After the times indicated, cells were incubated with thiazolyl blue tetrazolium bromide (MTT, 5 mg/mL PBS) until blue staining of the vehicle-containing control cells. Formazan formation was stopped by 100 µL SDS lysis buffer (10%, w/v in 20 mM HCl) and the well plate was shaken overnight. Finally, absorbance was measured at 570 nm with a

Multiskan™ microplate spectrophotometer (Thermo Scientific, Ulm, Germany). The pan protein kinase inhibitor staurosporine (1 μ M) was used as cytotoxic control inhibitor.

LDH release assay

For analysis of extracellular LDH as marker for loss of plasma membrane integrity, we used the CytoTox96® Non-Radioactive Cytotoxicity assay kit (Promega, Madison, WI, USA). Freshly prepared monocytes (0.5×10^6 /mL RPMI 1640 containing 5% heat inactivated FCS, 100 U/mL penicillin and 100 μ g/mL streptomycin) or 0.1×10^6 /mL HeLa cells in DMEM High Glucose supplemented with 5% FCS, 100 U/mL penicillin and 100 μ g/mL streptomycin were seeded in a 96-well plate. Monocytes were allowed to adhere for 1.5 h at 37 °C, 5% CO₂ prior treatment with vehicle (0.5% DMSO), triton X-100 (lysis control) or 5 μ M DAO for indicated time points. After incubation, the manufactures instructions were followed and the LDH release was measured by recording the absorbance at 490 nm with a Multiskan™ microplate spectrophotometer (Thermo Scientific, Ulm, Germany).

Microscopic morphology analysis

HeLa cells (0.25×10^6 /mL DMEM High Glucose supplemented with 5% FCS, 100 U/mL penicillin and 100 μ g/mL streptomycin) were incubated for 3 hrs with vehicle (0.1% DMSO, v/v), DAO or Stsp. Then, cells were placed on ice, washed with PBS, and analyzed by light microscopy using an AxioCam MR3 camera (Zeiss, Jena, Germany). Images were acquired, cut, linearly adjusted in the overall brightness and contrast, and exported to TIF by the AxioVision 4.8 software. The microscope incubator (Axio Observer Z1 inverted microscope, LCI Plan-Neofluar 63x/1.3 Imm Corr DIC M27 objective, Carl Zeiss, Jena, Germany) was kept at 37 °C and 5% CO₂.

Lysotracker® analysis

For acidification analysis of monocytes by fluorescence microscopy, freshly isolated monocytes (2.5×10^5 /mL RPMI 1640 containing 5% heat inactivated FCS, 100 U/mL penicillin and 100 µg/mL streptomycin) were seeded in Glass Bottom Microwell Dishes (MatTek Corporation, MA). After 1.5 hr adhesion time at 37 °C and 5% CO₂, cells were treated for 1 hr with vehicle (0.1% (v/v) DMSO), 10 µM CCCP or 0.1 µM, 1 µM, 10 µM DAO at 37 °C and 5% CO₂ followed by washing with pre-warmed PBS. Cells were resuspended in PBS containing 1 mM CaCl₂, 1 mM MgCl₂ and 0.1% glucose. For the staining, 50 nM LysoTracker® Red-DND-99 (Sigma, Taufkirchen, Germany) was added to the cells and after 5 min, red fluorescence of the accumulated probe in acidic cell organelles was imaged using an Axio Observer Z1 microscope (Carl Zeiss, Jena, Germany).

For analysis by a fluorescence microplate reader (NOVOstar®, BMG Labtechnologies, Offenburg, Germany), freshly isolated monocytes (1.5×10^6 /mL RPMI 1640 containing 5% heat inactivated FCS, 100 U/mL penicillin and 100 µg/mL streptomycin) were seeded into a black 96-well plate with glass bottom. Monocytes were allowed to adhere for 1.5 hr at 37 °C, 5% CO₂ prior treatment with vehicle (0.1% (v/v) DMSO), 10 µM CCCP as control, and DAO as indicated concentrations for 1 hr. After washing and resuspension in PBS (0.1% glucose, 1 mM CaCl₂, 1 mM MgCl₂), cells were stained with 50 nM LysoTracker® and 0.5% (v/v) Hoechst for 5 min at 37 °C, 5% CO₂. After washing, fluorescence was excited at 577 nm (LysoTracker®) and 350 nm (Hoechst staining) and the emission was recorded at 590 nm (LysoTracker®) and 480 nm (Hoechst staining). Acidification was calculated from ratio of fluorescence intensities of LysoTracker® in relation to the fluorescence of Hoechst staining.

TEM

Monocytes, resuspended in RPMI 1640 containing 5% heat-inactivated FCS, 5 ml L-glutamine, 100 U/mL penicillin and 100 µg/mL streptomycin, were incubated with DAO, Stsp or vehicle for 3 hrs at 37 °C and 5% CO₂. Cells were washed in PBS pH 7.4, centrifuged (800×g, 5 min,

20 °C) and resuspended in 2.5% glutaraldehyde (v/v, in water) for fixation. After 20 min at RT, cells were washed by centrifugation (5000 rpm, 5 min, 4 °C) and resuspended in PBS. For the embedding process, cells were washed 3 times with PBS pH 7.4 for 5 min. After each washing step, the sample was centrifuged at 2000 rpm for 2 min. Post-fixation was performed by osmium tetroxide (1% OsO₄ in PBS pH 7.4) for 1 hr. Samples were washed again with PBS pH 7.4 and the monocytes were gradually dehydrated by a series of increasing ethanol:water mixtures (50%, 70%, 90% and 100% ethanol, 10 min for each step and centrifugation at 2000 rpm for 2 min). Resin infiltration was performed in 2 steps (Embed812: EtOH 2:1 with 18 µL per mL resin DMP-30 (for 1 hr at RT), Science Services). Samples were centrifuged at 2000 rpm for 8 min. The second infiltration step was performed in undiluted Embed812 resin (overnight at RT). After an additional centrifugation step the resin was exchanged and infiltrated for 2 hrs. Samples were subsequently transferred to BEEM capsules (Plano), centrifuged once (2000 rpm, 8 min) and cured at 60° C for 24 hrs. The embedded samples were sectioned in 80 to 100 nm thick slices utilizing an ultramicrotome (PowerTome PC, RMC Products) equipped with a diamond knife (Diatome). The slices were placed on a carbon coated TEM grid (Quantifoil) and imaged with a 200 kV FEI Tecnai G²20 (FEI Company).

Detection of DAO-PE adducts *in vitro*

For analysis of DAO-PE adduct formation, 5.2 µL solution of DAO (5 mM) and 2 µL transphosphorylated chicken egg PE (13 mM, Sigma Aldrich, Taufkirchen, Germany) were added to 44.8 µL reaction buffer containing 1 M triethylammonium acetate, CHCl₃ and MeOH (1:1:3, v/v/v). Vehicle and chicken egg PC (13 mM, instead of PE) were used as controls. After 3 hrs incubation at 37 °C, samples were diluted with MeOH to 500 µL, internal standard was added and 50 µL were dried under a nitrogen stream. The pellet was resuspended with 25 µL MeOH and diluted to 250 µL with PBS, following incubation with 275 U phospholipase D from *Streptomyces chromofuscus* (ENZO life sciences, Lörrach, Germany) for 16 hrs at 37 °C. DAO

adducts were extracted with 1 mL CHCl₃/MeOH (2:1, v/v). The lower organic phase was dried by a nitrogen stream and the pellet was resuspended with 1 mL MeOH before measuring by UPLC-MS/MS.

Isolation of cellular DAO-PE adducts

Monocytes (5×10^6 cells/mL) in RPMI 1640 containing 5% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin or HeLa cells (0.25×10^6 cells/mL) in DMEM High Glucose supplemented with 5% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin were incubated with vehicle (0.1% DMSO, v/v) or DAO for the indicated time points at 37 °C and 5% CO₂. Cells were placed on ice and washed twice with ice-cold PBS. The cell pellet was resuspended with ice-cold 200 µL CHCl₃/MeOH (2:1, v/v) supplemented with 50 mM pentyl-pyridoxamine. The cell suspension was allowed to homogenize for 20 min at RT followed by addition of internal standard and extraction with 40 µL 0.9% NaCl solution. The suspension was vortexed for 30 sec and centrifuged (4000 rpm, 5 min, 4 °C). The lower phase was dried under a stream of nitrogen and the pellet was resuspended with 50 µL MeOH by sonication. An aliquot of the solution (50 µL) was diluted with 200 µL PBS and sonicated for 2 min in an ultrasonic bath, followed by incubation of extracted phospholipids with 875 U phospholipase D from *S. chromofuscus* for 16 hrs at 37 °C. The solution was extracted with 1 mL ice-cold CHCl₃/MeOH mixture (2:1, v/v). The lower organic phase was dried, and the pellet was resuspended with 0.5 mL CHCl₃/MeOH mixture (2:1, v/v) followed by addition of 125 µL 0.9% NaCl solution and another extraction. The dried lower phase was resuspended with 100 µL MeOH and DAO-EA adducts were measured by UPLC-MS/MS.

Reversed phase liquid chromatography and mass spectrometry

Chromatography was carried out on an Acquity UPLC BEH C8 column (1.7 µm, 1 × 100 mm) using an Acquity™ Ultra Performance liquid chromatography system from Waters (Milford, MA, USA). DAO, PL's, and DAO-PE conjugates were separated at 0.75 ml/min and 45°C using

19

a gradient of 30% mobile phase A (acetonitrile/water, 10/90, 10 mM ammoniumacetate)/70% mobile phase B (acetonitrile/water, 95/5, 10 mM ammonium acetate) to 20% mobile phase A/80% mobile phase B within 5 min and to 100% mobile phase B within 2 min followed by isocratic elution for another 2 min. The chromatography system, controlled by Acquity UPLC Software 1.40 (Waters), was coupled to a QTRAP 5500 Mass Spectrometer (Sciex, Darmstadt, Germany) equipped with an electrospray ionization source.

For identification of DAO, the precursor-to-product ion transitions in multiple reaction monitoring were m/z 399.2 \rightarrow 104.9 (collision energy: -50 eV; collision cell exit potential: -13 V), and 399.2 \rightarrow 148.9 (collision energy: -24 eV; collision cell exit potential: -16 V). Quantification of DAO was based on the transition 399.2 \rightarrow 148.9 using an external calibration curve, quantification of phospholipids and PL-conjugates was based on the internal standard DMPC (collision energy: -38 eV; collision cell exit potential: -12 V). Analytes with varying collision energies (CE) and collision cell exit potentials are listed below in table 1. The ion spray voltage was set to -4000 V, the heated capillary temperature to 650°C, the curtain gas pressure to 30 psi, the declustering potential to -50 V, collisionally activated dissociation (CAD) to medium, nebulizer gas (GS1) to 50, heater gas (GS2) to 60, and the entrance potential -10 V. Analyst software 1.6 (Sciex, Darmstadt, Germany) was used for the processing of analytical data.

analyt	precursor-to-product ion transition (m/z)	Collision energy (CE)	Collision cell exit potential (CXP)
DAO 1xEA T1	442.4 \rightarrow 149.0	-20 \rightarrow 50	-17 \rightarrow 64
DAO 1xEA T2	442.4 \rightarrow 105.0	-56 \rightarrow 36	-7 \rightarrow 2
DAO 2xEA T1	484.8 \rightarrow 149.0	-41 \rightarrow 46	-52
DAO 2xEA T2	484.4 \rightarrow 105.0	-66 \rightarrow 44	-52 \rightarrow 90

DAO-PE(16:0/18:1)	1098.7 → 948.5	-52 → 35	-42 → 7
DAO-PE(16:0/18:11)	1098.7 → 281.2	-76 → 80	-42 → 7

Liposomal leakage assay

Solutions containing either 5 μmol dioleoyl-PC (DOPC) or 2.5 μmol dioleoyl-PE (DOPE) plus 2.5 μmol DOPC (Avanti Polar Lipids, Inc.) were prepared in CHCl_3 . The solvent was removed using a nitrogen stream and subsequent evaporation under vacuum. Lipid films were rehydrated by vortexing in a water bath (30 °C) with 1 mL of a solution of 35 mM 8-hydroxypyrene-1,3,6-trisulfonic acid trisodium salt (HPTS, fluorophore) and 50 mM 1,1'-[1,4-phenylenebis(methylene)]-bis pyridinium dibromide (DPX, collisional quencher) in 20 mM HEPES, 150 mM NaCl, and 1 mM EDTA forming essentially heterogenous multilamellar vesicles (MLV). Then, large unilamellar vesicles (LUV) were formed by six freeze-thaw cycles. Liposome suspensions were extruded 20 times through 100 nm polycarbonate filters (LiposoFast-Basic, Avestin Inc.) to generate LUVs with HPTS/DPX encapsulated [50]. LUVs were separated from free HPTS/DPX by size exclusion chromatography using a Sepharose column and 20 mM HEPES, 150 mM NaCl, 1 mM EDTA as buffer.

A 100 μL sample of HPTS/DPX-containing liposomes diluted (1:20) in 20 mM HEPES, 150 mM NaCl, 1 mM EDTA was dispensed in 96-well-plates. Then, 10 μM DAO was added and the fluorescence of HPTS was monitored each 14 s on a NOVOstar (BMG LABTECH GmbH)

using excitation at 450 nm and emission at 520 nm over 15 min and at RT. A negative control using DMSO was used as the 0% leakage reference, and 0.2% Triton X-100 was used as positive control yielding 100% leakage. For each time point, the fluorescence data were normalized to these two reference samples.

Cytochrome c release

Cells were seeded in RPMI 1640 containing 5% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin (4×10^6 /ml) and incubated with the test compounds or vehicle (DMSO). After 3 hrs, cells were washed once in PBS and 10^7 cells were resuspended in 200 µl PBS. For permeabilization of the plasma membrane, 20.3 µM digitonin was added and immediately vortexed (10 sec), incubated for another 30 seconds at room temperature and centrifuged at 20,000g at 4°C for 1 min. The supernatant (cytosolic fraction) and pellet (non-cytosolic fraction) were transferred to a new tube, respectively, and mixed 1:1 (vol/vol) with 5% trichloroacetic acid. Precipitation of cytosolic proteins was performed at 4°C overnight. Proteins were pelleted by centrifugation at 20,000g at 4°C for 30 min and resuspended in 25 µl PBS. Aliquots of 5 µl were used for determination of protein concentration using Roti-Nanoquant (Roth, Karlsruhe, Germany). Equal amounts of protein were mixed 1:1 (vol/vol) with $2 \times$ SDS/PAGE sample loading buffer and analyzed for cytochrome c by SDS-PAGE and Western Blot using an anti-cytochrome c-antibody (Epitomics Inc., Burlingame, CA).

Subcellular fractionation

HeLa cells (0.25×10^6 cells/mL, in DMEM High Glucose supplemented with 5% FCS, 100 U/mL penicillin and 100 µg/mL streptomycin) were pre-incubated with vehicle (0.1% DMSO, v/v) or DAO (5 µM) for the indicated time points at 37 °C and 5% CO₂. Cells were placed on ice and the cell pellet was washed with 500 µL PBS followed by 5 min centrifugation (4600 rpm) at 4 °C. The cell pellet was resuspended with hypotonic lysis buffer pH 7.4 (10 mM HEPES, 2 mM MgCl₂, 0.1 mM EDTA, 0.1 mM EGTA, 10 mM KCl, 1 mM DTT) and cells

were passed through a 25 G needle (sterican 0.5 × 40 mm, Gr 17/42, B. Braun Melsungen AG) 10 times using a 10 mL syringe. The cell suspension was kept on ice for 20 min before adding kinase inhibitor cocktail. To get nuclei, the cell suspension was centrifuged for 10 min at 550 g and 4 °C. Supernatant was used for continuing subcellular fractionation and pellet was again washed with hypotonic lysis buffer, centrifuged (550 g, 10 min, 4 °C) and frozen at -20 °C. The supernatant was centrifuged at 10,000 g and 4 °C for 10 min. The resulting mitochondrial pellet was again washed as described for the nuclear pellet and subsequently frozen at -20 °C. The supernatant was used to obtain the cytosolic and microsomal fraction by ultracentrifugation at 100,000 g and 4 °C for 1 h. The cytosolic fraction corresponds to the supernatant and was evaporated until dryness with Eppendorf® concentrator at 30 °C. The pellet corresponds to the microsomal fraction and was frozen at -20 °C.

For preparation of Western Blot samples, pellets were resuspended in 100 µL Western Blot lysis buffer and homogenized by sonification on ice. On the other hand, pellets were used for mass spectroscopy analysis. Lipids were extracted as described before by Bligh and Dyer method [51] and cellular DAO-PE adducts were analyzed as specified above.

SDS PAGE and Western Blot

Subcellular fractions (see above) or isolated monocytes were resuspended in 100 µL ice-cold 2 × SDS loading buffer (20 mM Tris-HCl pH 8, 2 mM EDTA, 5% (m/v) SDS, 10% (v/v) β-mercaptoethanol, 10 µg/mL leupeptin, 60 µg/mL soybean trypsin (STI), 1 mM PMSF, 40 µL glycerol and 0.1% bromophenol blue (1:1, v/v)). Samples were heated for 5 min at 96 °C and proteins were separated by SDS-PAGE on a 10% acrylamide gel. Correct protein loading on the gels and transfer of proteins to the nitrocellulose membrane (Amersham PROTRAN® supported 0.45 NC, GE Healthcare, Freiburg; Germany) was confirmed by Ponceau staining. Antibody recognizing cleaved PARP (Asp214), phospho-p38 MAPK (Thr180/Tyr182), phospho-Akt (Ser473), ATF-4, CHOP, BiP, calnexin, syntaxin 6, COX IV and β-actin were from

Cell Signaling Technology (Boston, MA) and used at 1:1000 dilution. Antibodies against GAPDH and β -tubulin were purchased from SantaCruz (Dallas, TX) and also used at 1:1000 dilution. Antibodies against Lamin B1 (1:200), syntaxin 6 (1:1000) and Lamp1 (1:1000) were purchased from abcam (Cambridge, United Kingdom). Infrared labeled secondary antibody IRDye 800CW goat anti-mouse was from LI-COR Biosciences (Lincoln, NE). For detection, the Odyssey Infrared Imaging System (LI-COR Bioscience, Lincoln, NE) and for analysis the Odyssey application software (version 3.0.25) were used.

Statistics

Results are presented as means \pm standard error of the mean (SEM) of n independent observations, where n represents the number of performed experiments at different days or with different donors. Statistical analysis of the data was performed by one-way ANOVA using GraphPad InStat (Graphpad Software Inc., San Diego, CA) followed by a Bonferroni post-hoc test for multiple or student t-test for single comparisons, respectively. P-values < 0.05 were considered as significant.

Legends for the figures**Figure 1: DAO causes rapid cell death in human cells with unique characteristics.**

(A) Chemical structure of DAO. (B) Monocytes were incubated with DAO at indicated concentrations for 15 min, 60 min, and 24 hrs. Cell viability was analyzed by MTT assay. Means \pm SEM, $n = 3$. (C) Monocytes or HeLa cells were incubated with DAO (5 μ M) for the indicated time points. Plasma membrane integrity was analyzed by LDH assay. Means \pm SEM, $n = 3$. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ vs vehicle control; ANOVA plus Bonferroni post hoc test. (D) Morphological analysis of HeLa cells by light microscopy. Cells were treated with the compounds at indicated concentrations for 3 hrs and were then analyzed by light microscopy. Pictures shown are representatives out of three independent experiments. (E) TEM analysis of monocytes. Freshly isolated human monocytes were pretreated with 10 μ M DAO, 3 μ M Stsp or vehicle (0.1% DMSO) for 3 hrs. Cells were prepared for TEM analysis which was performed as described in the Method section. Arrows indicate the presence of mitochondria.

Figure 2: Contribution of apoptotic pathways in mediating cell death by DAO.

(A) Monocytes were treated with DAO (5 μ M) or staurosporine (Stsp, 3 μ M) for the indicated time points. Then, PARP cleavage to an 89 kDa fragment was assessed by Western Blotting (left panel) and densitometric analysis (right panel) was performed in correlation to GAPDH. Means \pm SEM, $n = 3$. (B) Cytochrome C release from human monocytes. Intact monocytes were pretreated with 10 μ M DAO, 3 μ M Stsp or vehicle (0.1% DMSO) for 3 hrs. Then, cells were fractionated by mild detergent lysis and the cytosolic and the non-cytosolic fractions were analyzed by Western blot for cytochrome (Cyt) c. β -Actin and calnexin were used as marker proteins for respective fractions. (C) Monocytes were incubated with 5 μ M DAO, 3 μ M Stsp or vehicle. Total cell lysates were prepared after the indicated times and analyzed for phospho-p38 MAPK and phospho-Akt by Western blot (left panel). Densitometric analysis (right panel) was performed in correlation to β -actin. Means \pm SEM, $n = 3$. (D) Protein expression of BiP, ATF-4 and CHOP in monocytes. Cells were incubated with DAO (5 μ M) or vehicle (0.1% DMSO) for the indicated time points and then analyzed by Western blot (left panel). Densitometric analysis (right panel) was performed in correlation to β -actin. Means \pm SEM, $n = 3$. (E) Monocytes were pre-incubated with the pan-caspase inhibitor QVD (10 μ M) 30 min prior incubation with 5 μ M DAO, 3 μ M Stsp or vehicle for 3 hrs. Protein levels were analyzed by Western Blot (lower panel) and densitometric analysis (upper panel) were performed in correlation to GAPDH. (F) Monocytes were pre-incubated with the pan-caspase inhibitor QVD (10 μ M) 30 min prior incubation with 10 μ M DAO, 3 μ M Stsp or vehicle for 3 hrs (left panel) or 48 hrs (right panel). Then, cell viability was assessed by MTT assay. Means \pm SEM, $n = 3$. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ vs vehicle control; ANOVA plus Bonferroni post hoc test.

Figure S1: Effect of staurosporine on PARP cleavage after 5 hrs incubation.

Monocytes were treated with DAO (5 μ M) or staurosporine (Stsp, 3 μ M) for 5 hrs. Then, PARP cleavage to a 89 kDa fragment was assessed by Western Blotting (left panel) and densitometric analysis (right panel) was performed in correlation to GAPDH. Means \pm SEM, $n = 3$. $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ vs vehicle control; students t-test.

Figure 3: DAO interacts with the ethanolamine (EA) residue of phosphatidylethanolamine.

(A, B) DAO (0.5 mM) was incubated with chicken egg PE (13 mM in CHCl₃), chicken PC (13 mM in CHCl₃) and bovine brain PS in reaction buffer for 3 hrs at 37 °C. Then, phospholipids were cleaved by exogenously added phospholipase D for 16 hrs at 37 °C (insert panel A). DAO-EA, -choline or -serine adducts were analyzed by UPLC-MS/MS. (C) Monocytes and HeLa cells were incubated with DAO at the indicated concentrations for 3 hrs. DAO-PE adducts were extracted with CHCl₃/MeOH (3:1) and cleaved by phospholipase D treatment for analysis of DAO-EA adducts by UPLC-MS/MS. Means ± SEM, n = 3. (D) Monocytes and HeLa cells were incubated with 5 μM DAO for the indicated periods. DAO-PE adducts were extracted and analyzed by UPLC-MS/MS. Means ± SEM, n = 3. (E) DAO (5 μM), Stsp (1 μM) or vehicle (0.1% DMSO) were incubated with 50 mM EA for 2 hrs at 37 °C and subsequently extracted using MeOH/CHCl₃ (1:2, vol:vol) as described in the Method section. Extracts containing EA-adducts or unreacted DAO or Stsp were resolved in ethanol (vehicle) and added to monocytes (left panel) or HeLa cells (right panel) for 3 hrs, and cell viability was assessed by MTT assay. (F) DAO (10 μM), Stsp (3 μM) or vehicle (0.1% DMSO) were incubated with EA, choline (Chol) or L-serine (L-Ser) (50 mM, each) for 2 hrs at 37 °C and subsequently extracted as described above. Extracts containing adducts or unreacted agents (in ethanol as vehicle) were added to monocytes for 3 hrs (left panel) or 48 hrs (right panel), and cell viability was assessed by MTT assay. Data are means ± S.E, n = 3. *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001 vs vehicle control; ANOVA plus Bonferroni post hoc test.

Figure S2: Markers subcellular fractionation.

HeLa cells were incubated with DAO (5 μM) or vehicle (0.1% DMSO) 15 min. Subcellular fractions were generated by hypotonic cell lysis and differential centrifugation. Respective fractions were analyzed by Western blot for specific fraction proteins. Western blots are representative for three independent experiments.

Figure 4: Subcellular locales of DAO-PE interactions and consequences for PE contents and membrane stability.

HeLa cells were incubated with DAO (5 μM) or vehicle (0.1% DMSO) for the indicated time points. Subcellular fractions were generated by hypotonic cell lysis and differential centrifugation. (A) Subcellular distribution of PE in HeLa cells after 15 min (left panel) and 3 hrs (right panel). (B) Subcellular distribution of DAO-PE adducts. The DAO-PE adducts formed within 15 min (left panel) or after 3 hrs (right panel) were extracted with CHCl₃/MeOH (3:1), cleaved by phospholipase D from PE, and then analyzed with UPLC-MS/MS. (C, D, E) HeLa cells were pre-incubated with 5 μM DAO for 3 hrs (C) or 15 min only (D). PE species were extracted by the Bligh and Dyer method and were analyzed by UPLC-MS/MS. (E) Correlation of PE species obtained after 15 min and after 3 hrs to total PE. (F) Correlation of PE species obtained after 15 min and after 3 hrs to vehicle control, shown as heat map. Data are given as mean + S.E, n = 3. *p < 0.05, **p < 0.01, ***p < 0.001 vs vehicle control; ANOVA plus Bonferroni post hoc test. (G) Liposomal leakage test. Liposomes (LUVs) composed of DOPC or DOPC/DOPE (1:1) containing HPTS/DPX were incubated with DAO (10 μM) and the fluorescence was measured. Liposomal leakage is expressed as % of the positive control

incubated with Triton X-100 (=100%). (H) Monocytes were incubated with DAO at the indicated concentrations or vehicle (0.1% DMSO) for 15 min or 60 min, acidic vesicles (red) were stained with the LysoTracker probe for 5 min. Fluorescence microscopy pictures (left panel) are representative of four independent experiments. Acidification of vesicles (right panel) was assessed by fluorescence measured by NOVOstar®. Acidification is expressed in correlation to Hoechst staining of each cell per sample with vehicle = 100%. Data are given as mean + S.E, n = 3. *p < 0.05, **p < 0.01, ***p < 0.001 vs vehicle control; ANOVA plus Bonferroni post hoc test.

Figure S3: Liposomal leakage test.

Liposomes (LUVs) composed of DOPC or DOPC/DOPE (1:1) containing HPTS/DPX were incubated with vehicle (DMSO, negative control) or DAO (10 µM) and the fluorescence was measured. Results are representative for n=3 independent experiments.

APPENDIX 3: AUTHORS' CONTRIBUTIONS TO THE MANUSCRIPTS**Manuscript I**

Author	Contribution
Stefanie König	Experimental design and performance of 5-LOX assays, immunofluorescence analysis, proximity ligation assays; assistance to HEK cell transfection; measurement of 5-LOX expression, FLAP expression, and phosphorylation of cPLA ₂ , ERK-1/2, p38 MAPK by Western Blot; maintenance of cell culture and performance of blood cell isolation; data analysis; writing the manuscript. Total contribution: 80%.
Erik Romp	HEK cell transfection with cysteine mutants; performance of [³ H]-labeled arachidonic acid release; support with immunofluorescence and PLA interpretation; maintenance of cell culture.
Verena Krauth	Performance of COX-1/COX-2 assays and mPGES ₁ activity assay; assistance to 5-LOX assays; performance of blood cell isolation.
Michael Rühl	Performance of GSH incubation, standard peptide incubation, MALDI-MS measurement and data analysis.
Maximilian Dörfer	Isolation of DAO from <i>Armillaria mellea</i> .
Stefanie Liening	Performance of LTC ₄ S activity assay.
Bettina Hofmann	Supply of 5-LOX cysteine mutants; helped with interpretation of MALDI-MS data; experimental design.
Ann-Kathrin Häfner	Supply of 5-LOX cysteine mutants.
Dieter Steinhilber	Supply of 5-LOX cysteine mutants; experimental design.
Michael Karas	Performance of GSH incubation, standard peptide incubation, MALDI-MS measurement and data analysis; experimental design.
Dirk Hoffmeister	Isolation of DAO from <i>Armillaria mellea</i> ; experimental design.
Ulrike Garscha	HEK cell transfection with cysteine mutants; support with immunofluorescence and PLA interpretation; experimental design.
Oliver Werz	Conceiving the project; experimental design, writing the manuscript.

Manuscript II

Author	Contribution
Stefanie König	Experimental design and performance of 5-LOX assays with several cell types, purified enzyme, agents, and stimuli, LM extraction for UPLC-MS/MS analysis; extraction of LM from animal samples and their analysis by UPLC-MS/MS and ELISA; experimental design, optimization and performance of epoxide hydrolase and aminopeptidase activity assays of LTA ₄ H; maintenance of cell culture and performance of blood cell isolation; data analysis; writing the manuscript. Total contribution: 75%..
Simona Pace	Experimental design and performance of animal models: peritonitis, pleurisy.
Helmut Pein	Experimental design, optimization and performance of aminopeptidase activity assay by UPLC-MS/MS.
Thorsten Heinekamp	Experimental design and performance of murine infection model with <i>A. fumigatus</i> conidia; cultivation of <i>A. fumigatus</i> and preparation of supernatants; histopathological investigations of murine lung tissue.
Jan Kramer	Performance of epoxide hydrolase activity by fluorescence-based assay; expression and purification of human recombinant LTA ₄ H; analysis of gliotoxin by UPLC-MS/MS after GSH incubation.
Erik Romp	Performance of sEH activity assay; maintenance of cell culture and performance of blood cell isolation.
Maria Straßburger	Assistance to performance of <i>A. fumigatus</i> experiments; histopathological investigations of murine lung tissue.
Fabiane Troisi	Assistance to performance of animal models: peritonitis, pleurisy.
Anna Proschak	Analysis of gliotoxin by UPLC-MS/MS.
Jan Dscherwak	Isolation of gliotoxin and derivatives from <i>A. fumigatus</i> .
Kirstin Scherlach	Isolation of gliotoxin and derivatives from <i>A. fumigatus</i> .
Antonieta Rossi	Experimental design and performance of animal models: peritonitis, pleurisy.
Lidia Sautebin	Experimental design and performance of animal models: peritonitis, pleurisy.

Jesper Z. Haeggström	Support with interpretation of LTA ₄ H data; experimental design.
Christian Hertweck	Isolation of gliotoxin and derivatives from <i>A. fumigatus</i> .
Axel Brakhage	Conceiving the project; experimental design.
Jana Gerstmeier	experimental design; helped with the interpretation of gliotoxin data.
Ewgenij Proschak	Performance of epoxide hydrolase activity by fluorescence-based assay; supply of human recombinant LTA ₄ H; analysis of gliotoxin by UPLC-MS/MS; experimental design.
Oliver Werz	Conceiving the project; experimental design, writing the manuscript.

Manuscript III

Author	Contribution
Sebastian Schieferdecker	Experimental design and performance of production and isolation of myxochelins; performance and design of isotope incorporation; performance of chrome azurol assay; cultivation of <i>Pyxidicoccus fallax</i> ; data analysis; partially writing the manuscript.
Stefanie König	Experimental design and performance of 5-LOX assays with purified enzyme, purification of human recombinant 5-LOX from <i>E. coli</i> ; coordination of mPGES-1 activity assay; data analysis; partially writing the manuscript. Total contribution: 30%.
Andreas Koeberle	Experimental design; coordination of mPGES-1 activity assay; support with the analysis of data from 5-LOX and mPGES-1 activity assays.
Hans-Martin Dahse	Performance of MTT assay with HeLa and K-562 cells.
Oliver Werz	Conceiving the project; experimental design, partially writing the manuscript.
Markus Nett	Conceiving the project; experimental design, partially writing the manuscript.

Manuscript IV

Author	Contribution
Markus Bohnert	Experimental design and performance of isolation of melleolides; partially writing the manuscript.
Olga Scherer	Experimental design and performance of MTT assays, inverse MTT and LDH assay; evaluation and performance of life cell imaging and flow cytometry experiments; data analysis; partially writing the manuscript.
Katja Wiechmann	Experimental design and performance of mitochondrial analysis; partially writing the manuscript.
Stefanie König	Experimental design and performance of MTT assays with DAO and staurosporine in human primary monocytes and HeLa cells; isolation of monocytes and cell culture; data analysis; partially writing the manuscript. Total contribution: 20%.
Hans-Martin Dahse	Performance of MTT assay with K-562 cells
Dirk Hoffmeister	Conceiving the project; experimental design, partially writing the manuscript.
Oliver Werz	Conceiving the project; experimental design, partially writing the manuscript.

Manuscript V

Author	Contribution
Stefanie König	Experimental design and performance of MTT and LDH assay, Western Blot analysis of phospho-p38 MAPK, phospho-Akt, BiP, CHOP, and ATF-4 in monocytes; experimental design and performance of measurement of non-cellular and cellular DAO-PE adducts for UPLC-MS/MS analysis after treatment with phospholipase D; extraction of cellular DAO-PE adducts and their analysis by UPLC-MS/MS; experimental design, optimization and performance of subcellular fractionation, Western Blot analysis of each fraction, extraction of cellular DAO-PE adducts and phospholipids in separated fractions and their analysis by UPLC-MS/MS; maintenance of cell culture

	and performance of blood cell isolation; data analysis; writing the manuscript. Total contribution: 70%.
Konstantin Löser	Experimental design, optimization and performance of subcellular fractionation, optimization and performance of measurements of DAO fragments with UPLC-MS/MS; partially writing the manuscript.
Helmut Pein	Experimental design, optimization and performance of DAO-PE binding assay with UPLC-MS/MS and measurements of DAO fragments with UPLC-MS/MS; partially writing the manuscript.
Konstantin Neukirch	Performance and analysis of MTT assay in monocytes with QVD pre-incubation and with ethanolamine, serine, and choline; performance and analysis of liposomal leakage test.
Anna Czapka	Western blot analysis of Cytochrome c levels in monocytes after fractionation in cytosolic and non-cytosolic fraction, performance of transmission electron microscopy (TEM).
Stephanie Hoepfener	Experimental design, optimization and performance of TEM
Maximilian Dörfer	Isolation of DAO from <i>Armillaria mellea</i> .
Dirk Hoffmeister	Conceiving the project; experimental design, partially writing the manuscript.
Oliver Werz	Conceiving the project; experimental design, partially writing the manuscript.

APPENDIX 3: ACKNOWLEDGMENTS

Ich möchte mich ganz besonders bei meinem Doktorvater Prof. Dr. Oliver Werz für das Vertrauen und die Möglichkeit bedanken dieses äußerst spannende Projekt im Rahmen der Förderung der Exzellenz Graduiertenschule Jena School for Microbial Communication in seinem Arbeitskreis bearbeiten zu dürfen. Ganz besonders bedanke ich mich für seine exzellente Betreuung, den regen wissenschaftlichen Austausch, seine Unterstützung, sein jederzeit offenes Ohr und die stetige Motivation für die Bearbeitung kniffliger Fragestellungen.

Des Weiteren danke ich Prof. Dr. Dirk Hoffmeister für die Möglichkeit am DAO Projekt teilzuhaben. Außerdem möchte ich mich bei Ihm und Maximilian Dörfer bedanken für die Bereitstellung der Melleolide, die erfolgreiche wissenschaftliche Zusammenarbeit und die interessanten Anregungen für das DAO Projekt.

Allen Gutachtern danke ich für die Bereitschaft, die Gutachten zu übernehmen und anzufertigen.

Ich bedanke mich bei Prof. Dr. Axel Brakhage und Dr. Thorsten Heinekamp für die hervorragende Zusammenarbeit bei der Erforschung des Wirkmechanismus von Gliotoxin, die Durchführung des *Aspergillus fumigatus*-Infektions-Tiermodells, die Bereitstellung der $\Delta gliP A. fumigatus$ Mutante, die Hilfe bei der Interpretation der Gliotoxin Daten und der Erstellung des Gliotoxin Manuskriptes.

Außerdem möchte ich mich herzlich bedanken bei Prof. Dr. Ewgenij Proschak und Jan Kramer für die Hilfe und Unterstützung bei der Erstellung des Gliotoxin Manuskriptes, für die Durchführung der Experimente mit reduziertem Gliotoxin, der MS-Analytik für das Manuskript und die Bereitstellung von Gliotoxin und rekombinanter LTA₄H.

Weiterhin danke ich den Frankfurter Arbeitskreisen von Prof. Dr. Dieter Steinhilber und Prof. Dr. Michael Karas mit Dr. Bettina Hofmann und Michael Rühl für die tatkräftige Unterstützung und die regen wissenschaftlichen Diskussionen bei der Analyse der Interaktion von DAO und Cysteinin innerhalb der 5-Lipoxygenase, der Bereitstellung der Plasmide der 5-LOX Cystein-Mutanten, der Peptid-Analytik und die MALDI-MS Messungen.

Herrn Prof. Dr. Markus Nett, Dr. Sebastian Schieferdecker und Juliane Korp danke ich für die Synthese und Bereitstellung vielfältiger Myxocheline und für die erfolgreiche und hervorragende Zusammenarbeit hinsichtlich gemeinsamer Publikationen.

Bedanken möchte ich mich außerdem bei Prof. Dr. Christian Hertweck und Dr. Kirstin Scherlach für die Bereitstellung von Gliotoxin und die Hilfe bei chemischen Fragen zu Gliotoxin.

Ich danke Prof. Dr. Lidia Sautebin, Dr. Antonietta Rossi und dem Arbeitskreis in Neapel für die Durchführung der Tiermodelle.

Allen Koautoren danke ich für die ausgezeichnete wissenschaftliche Zusammenarbeit!

Vielen Dank an die Transfusionsmedizin des Universitätsklinikums Jena für die Bereitstellung von Blutspenden.

Weiterhin danke ich der Jena School for Microbial Communication für die Finanzierung meines Projektes.

Von Herzen danke ich meinen ehemaligen Kollegen des Philosophenweg 14! Ohne sie wäre diese erfolgreiche Arbeit nicht möglich gewesen und die gemeinsame Zeit nicht so intensiv und unvergesslich geworden! Vielen Dank für jedes offene Ohr, für jede Motivation, für jede Unterstützung und die vielen wunderbaren, gemeinsamen und geselligen Abende! Vielen Dank an:

Herrn PD Dr. Andreas Koeberle für die geduldige Beantwortung und hilfreichen Ratschläge aller aufkommenden wissenschaftlichen Fragen!

Frau Dr. Ulrike Garscha für ihre große Hilfe in Fragen der Molekularbiologie, ihr offenes Ohr für Probleme jeglicher Art und die kritische Diskussion wissenschaftlicher Ergebnisse.

Frau Dr. Simona Pace für die erfolgreiche Zusammenarbeit bei Kadsurenin F- und Gliotoxin-Projekt und für die durchgeführten *in vivo* Experimente.

Katrin Fischer und Petra Wiecha möchte ich von Herzen danken für die großartige Unterstützung im alltäglichen Laborgeschehen, die Hilfe bei der Testung vielzähliger Substanzen, die Einführung im Umgang mit der HPLC und der Liebe zum ELISA, dem Messen von MS-Proben und der geordneten Koordination vieler Laborvorgänge! Weiterhin danke ich Nadja Gerlitz für das ausgezeichnete Laborbestellmanagement, die witzigen Unterhaltungen und jede Aufmunterung! Uwe Beck danke ich für seine Hilfsbereitschaft, sein handwerkliches Geschick und den ein oder anderen Tipp für manch kreative Idee! Ich bedanke mich bei Shanice Liebeskind und Theresa Hildebrandt für die Hilfestellung bei allen administrativen Fragestellungen. Bei Monika Listing, Bärbel Schmalwasser und Heidi Traber möchte ich mich für die Unterstützung bei der Testung von Natursubstanzen bedanken.

Von ganzem Herzen möchte ich mich bei Euch, meinen beiden Jungs, Konstantin Löser und Helmut Pein, für diese unvergessliche und intensive Zeit bedanken. Danke Euch für Eure Hilfe, Eure Unterstützung, Eure offenen Ohren, Eure Kritik, Eure verrückten Ideen und die gemeinsam verbrachte Zeit. Verena Krauth, danke Dir für die vielen schönen und geselligen Abende, Deine aufbauenden Worte, Deine Zeit und Deine Hilfsbereitschaft im Labor als auch im wahren Leben. Zusammen mit Stefanie Liening, Markus Werner, Erik Romp, Jana Fischer,

Petra Wiecha, Katrin Fischer, Ulrike Garscha, Nadja Gerlitz, Olga Sailer und Katrin Schubert habt ihr meine Promotionszeit zu etwas Besonderem gemacht und ohne euch wäre die Zeit nur halb so schön gewesen! Den beiden Computer-Spezialisten Helmut Pein und Markus Werner danke ich für die exzellente Behebung jegliches IT- und Computerproblems. Herzlichen Dank auch an Olga Sailer für die Einführung in das DAO Thema und die Übergabe vielfältiger Tipps und Tricks der jeweiligen Methoden. Außerdem bedanke ich mich bei allen anderen Mitarbeitern, Doktoranden, Diplomanden und Masteranden, die mich auf meinem Weg begleitet haben, für diese schöne Zeit!

Ein ganz besonderer Dank gebührt meiner Oma Erna, meinen Eltern und meinem Bruder, die mir diesen Weg ermöglicht haben und an mich bedingungslos glauben. Ohne meine langjährigen Freunde Judith und Martin mit Ferdi, Doreen und Martin mit Jakob, Claudia und Peter, Christina, Martin, Conny und Helmut mit Emil und Junus, Franzi und Konstantin mit Magda, Maria und Markus mit Willi, Anne und Markus mit Emil und Theo wäre ich heute nicht da, wo ich jetzt bin! Danke Euch für Eure Kraft, Eure Unterstützung, Euer Vertrauen und Eure Freundschaft! Ihr seid unendlich wertvoll für mich!

„Wer gar zu viel bedenkt, wird wenig leisten.“ – Friedrich Schiller

A3.2 Conference contributions

A3.2.1 Oral presentations

Stefanie König, Maximilian Dörfer, Dirk Hoffmeister, Oliver Werz (October 2017). “Exploiting a melleolide from honey mushroom as tool for deciphering Cys159 in 5-lipoxygenase as determinant for regulation of leukotriene biosynthesis.” JSMC Symposium, Jena, Germany

Stefanie König, Jana Gerstmeier, Kirstin Scherlach, Thorsten Heinekamp, Axel Brakhage, Christian Hertweck, Oliver Werz (November 2015). “Gliotoxin inhibits leukotriene A₄ hydrolase, the enzyme that synthesizes chemotactic leukotriene B₄.” JSMC Retreat, Bad Sulza, Germany

A3.2.2 Poster presentations

Stefanie König, Maximilian Dörfer, Dirk Hoffmeister, Oliver Werz (September 2016). “The melleolide dehydroarmillylorsellinate (DAO) from honey mushroom inhibits 5-lipoxygenase and decreases eicosanoid biosynthesis in leukocytes.” 6th European Workshop on Lipid Mediators (6EWLM 2016), Frankfurt, Germany

Stefanie König, Maximilian Dörfer, Dirk Hoffmeister, Oliver Werz (September 2016). “The melleolide dehydroarmillylorsellinate (DAO) inhibits 5-lipoxygenase and decreases eicosanoid biosynthesis in human leukocytes.” 3rd EFMC Young Medicinal Chemist Symposium, Manchester, United Kingdom

Stefanie König, Jana Gerstmeier, Kirstin Scherlach, Thorsten Heinekamp, Axel Brakhage, Christian Hertweck, Oliver Werz (November 2015). “Gliotoxin inhibits leukotriene A₄ hydrolase, the enzyme that synthesizes chemotactic leukotriene B₄.” JSMC Retreat, Bad Sulza, Germany

Stefanie König, Maximilian Dörfer, Dirk Hoffmeister, Oliver Werz (July 2015). “Dehydroarmillylorsellinate (DAO) from honey mushroom inhibits 5-lipoxygenase and suppresses eicosanoid biosynthesis in leukocytes.” 14th International Conference of Bioactive Lipids in Cancer, Inflammation and Diseases, Budapest, Hungary

Stefanie König, Olga Scherer, Markus Bohnert, Dirk Hoffmeister, Oliver Werz (September 2014). “The melleolide DAO induces rapid cell death in human primary monocytes and cancer cells.” JSMC Symposium, Jena, Germany

APPENDIX 5: CURRICULUM VITAE

PERSÖNLICHE DATEN

Name Stefanie König

APPENDIX 6: EIGENSTÄNDIGKEITSERKLÄRUNG

Hiermit erkläre ich, dass mir die Promotionsordnung der Fakultät für Biowissenschaften der Friedrich-Schiller-Universität Jena bekannt ist. Die vorliegende Dissertation habe ich selbst angefertigt, keine Textabschnitte eines Dritten oder eigener Prüfungsarbeiten ohne Kennzeichnung übernommen und alle von mir benutzten Hilfsmittel, persönliche Mitteilungen und Quellen wurden als solche kenntlich gemacht.

Ich versichere, dass ich die Hilfe eines Promotionsberaters nicht in Anspruch genommen habe und dass Dritte weder unmittelbar noch mittelbar geldwerte Leistungen von mir für Arbeiten erhalten haben, die im Zusammenhang mit dem Inhalt der vorgelegten Dissertation stehen.

Diese Dissertation wurde für keine staatliche oder andere wissenschaftliche Prüfung als Prüfungsarbeit von mir eingereicht. Weiterhin versichere ich, dass ich die gleiche, eine in wesentlichen Teilen ähnliche oder eine andere Abhandlung nicht bei einer anderen Universität als Dissertation eingereicht habe.

Ort, Datum

Stefanie König
